The differential thermostat availability manager has one output variable.

- HVAC,Average,Availability Manager Differential Thermostat Control Status

#### 1.48.5.2.1 Availability Manager Differential Thermostat Control Status

A value of 1 indicates the manager is signaling *ForceOff*. A value of 2 means the manager is signaling *CycleOn*.

## 1.48.6 AvailabilityManager:HighTemperatureTurnOff

This manager turns the system off if the temperature at the sensor node is above the specified setpoint temperature.

### 1.48.6.1 Inputs

#### 1.48.6.1.1 Field: Name

The name of the object. This is referenced in the [AvailabilityManagerAssignmentList](#).

#### 1.48.6.1.2 Field: Sensor Node Name

The air or plant node where the temperature is monitored.

**1.48.6.1.3 Field: Temperature**

The setpoint temperature [C] at which the system is turned off.

An example of this object in an IDF is:

```
AvailabilityManager:HighTemperatureTurnOff,
  High Temperature Turn Off Availability Manager,    !- Name
  Water Heater Use Outlet Node,    !- Sensor Node Name
  60.0;    !- Temperature {C}
```

---

**1.48.6.2 Outputs**

The high temperature turn off availability manager has one output variable.

- HVAC,Average,Availability Manager High Temperature Turn Off Control Status

**1.48.6.2.1 Availability Manager High Temperature Turn Off Control Status []**

A value of 0 indicates the manager is signaling *NoAction*. A value of 1 means the manager is signaling *ForceOff*.

**1.48.7 AvailabilityManager:HighTemperatureTurnOn**

This manager turns the system on if the temperature at the sensor node is above the specified setpoint temperature.

**1.48.7.1 Inputs****1.48.7.1.1 Field: Name**

The name of the object. This is referenced in the [AvailabilityManagerAssignmentList](#).

**1.48.7.1.2 Field: Sensor Node Name**

The air or plant node where the temperature is monitored.

**1.48.7.1.3 Field: Temperature**

The setpoint temperature [C] at which the system is turned on.

An example of this object in an IDF is:

```
AvailabilityManager:HighTemperatureTurnOn,
  High Temperature Turn On Availability Manager,    !- Name
  Outside Air Inlet Node,    !- Sensor Node
  30.0;    !- Temperature {C}
```

---

**1.48.7.2 Outputs**

The high temperature turn on availability manager has one output variable.

- HVAC,Average,Availability Manager High Temperature Turn On Control Status

**1.48.7.2.1 Availability Manager High Temperature Turn On Control Status []**

A value of 0 indicates the manager is signaling *NoAction*. A value of 2 means the manager is signaling *CycleOn*.

### 1.48.8 AvailabilityManager:LowTemperatureTurnOff

This manager turns the system off if the temperature at the sensor node is below the specified setpoint temperature.

#### 1.48.8.1 Inputs

##### 1.48.8.1.1 Field: Name

The name of the object. This is referenced in the [AvailabilityManagerAssignmentList](#).

##### 1.48.8.1.2 Field: Sensor Node Name

The air or plant node where the temperature is monitored.

##### 1.48.8.1.3 Field: Temperature

The setpoint temperature [C] at which the system is turned off.

##### 1.48.8.1.4 Field: Applicability Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time period this availability manager is to be applied. Schedule values greater than zero (usually 1 is used) indicate the availability manager is to be applied. Schedule values less than or equal to zero (usually 0 is used) denote that the availability manager is not used for this time period. If this field is left blank, this availability manager is always active.

An example of this object in an IDF is:

```
AvailabilityManager:LowTemperatureTurnOff,
  Low Temperature Turn Off Availability Manager,    !- Name
  Outside Air Inlet Node,    !- Sensor Node Name
  0.0,    !- Temperature {C}
  Low Temp Control Schedule;    !- Applicability Schedule Name
```

#### 1.48.8.2 Outputs

The low temperature turn off availability manager has one output variable.

- HVAC,Average,Availability Manager Low Temperature Turn Off Control Status

Availability Manager Low Temperature Turn Off Control Status []

A value of 0 indicates the manager is signaling NoAction. A value of 1 means the manager is signaling ForceOff.

### 1.48.9 AvailabilityManager:LowTemperatureTurnOn

This manager turns the system on if the temperature at the sensor node is below the specified setpoint temperature.

#### 1.48.9.1 Inputs

##### 1.48.9.1.1 Field: Name

The name of the object. This is referenced in the [AvailabilityManagerAssignmentList](#).

**1.48.9.1.2 Field: Sensor Node Name**

The air or plant node where the temperature is monitored.

**1.48.9.1.3 Field: Temperature**

The setpoint temperature [C] at which the system is turned on.

An example of this object in an IDF is:

---

```
AvailabilityManager:LowTemperatureTurnOn,
  Low Temperature Turn On Availability Manager,    !- Name
  Collector Outlet Node,    !- Sensor Node Name
  0.0;    !- Temperature {C}
```

---

**1.48.9.2 Outputs**

The low temperature turn on availability manager has one output variable.

- HVAC,Average,Availability Manager Low Temperature Turn On Control Status []

**1.48.9.2.1 Availability Manager Low Temperature Turn On Control Status []**

A value of 0 indicates the manager is signaling NoAction. A value of 2 means the manager is signaling CycleOn.

**1.48.10 AvailabilityManager:Night Ventilation**

This manager allows the user to implement a strategy for precooling a building at night using outdoor air. This strategy can consist of running the system fans with the outdoor air dampers open when outdoor conditions are favorable for a precooling strategy. The zone terminal unit air dampers may also be held at their fully open position to minimize fan energy consumption while precooling. Fan energy consumption is the critical parameter in deciding whether a precooling strategy will save energy.

The inputs for the night ventilation manager consist of an applicability schedule name (determining when the manager is active), a fan schedule name (for the fan(s) that the manager can switch on), a ventilation temperature schedule name (one zone must be above this temperature for night venting to be active), a ventilation temperature difference (indoor outdoor temperature difference for night venting), a low limit temperature (no conditioned zone may fall below this temperature during night venting), a night venting flow fraction (fraction of the design flow rate at which the fans run during night venting), and the zone name of a control zone.

The night ventilation manager is used in conjunction with another object: **FanPerformance:Night Ventilation**. The performance of the fan during night venting may be very different than during normal operation (a different fan might even be used). The **FanPerformance:Night Ventilation** object allows the user to specify alternate fan performance parameters for use during night ventilation.

**1.48.10.1 Inputs****1.48.10.1.1 Field: Name**

A unique, user-assigned name for an instance of a night ventilation availability manager. Other objects that use this availability manager will reference it by this name.

#### 1.48.10.1.2 Field: Applicability Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time period this availability manager is to be applied. Schedule values greater than zero (usually 1 is used) indicate the availability manager is to be applied. Schedule values less than or equal to zero (usually 0 is used) denote that the availability manager is not used for this time period.

#### 1.48.10.1.3 Field: Fan Schedule Name

The name of the central fan on/off schedule for the air system that this availability manager will affect.

#### 1.48.10.1.4 Field: Ventilation Temperature Schedule Name

The name of a temperature schedule defined elsewhere in the input file. At least one conditioned zone in the forced air system using this availability manager must be above the current temperature specified in this schedule for night ventilation to occur or to continue occurring.

#### 1.48.10.1.5 Field: Ventilation Temperature Difference

This field specifies an indoor / outdoor temperature difference (in degrees C). The control zone temperature minus the outdoor air temperature must be greater than the Ventilation Temperature Difference for night ventilation to occur or to continue occurring. The default is 2 degrees C.

#### 1.48.10.1.6 Field: Ventilation Temperature Low Limit

This field specifies a lower limit (in degrees C) on zone temperatures for night ventilation. If any conditioned zone served by the air system using this availability manager is below the ventilation temperature low limit, night ventilation will not occur or will switch off. The default is 15 degrees C.

#### 1.48.10.1.7 Field: Night Venting Flow Fraction

The fraction (could be greater than 1) of the design flow rate at which the night ventilation will be done. The default is 1.

#### 1.48.10.1.8 Field: Control Zone Name

The name of the control zone used in the ventilation temperature difference check.

An example of this object in an input file:

```
AvailabilityManager:NightVentilation,
  VAV Sys 1 Avail,           !- Name
  NightVentSched,           !- Applicability Schedule Name
  FanAvailSched,             !- Fan Schedule Name
  VentTempSched,             !- Ventilation Temperature Schedule Name
  2.0,                       !- Ventilation Temperature Difference {C}
  15.,                       !- Ventilation Temperature Low Limit
  0.3333,                    !- Night Venting Flow Fraction
  SPACE3-1;                  !- Control Zone Name
```

### 1.48.10.2 Outputs

The night ventilation availability manager has one output variable.

- HVAC,Average,Availability Manager Night Ventilation Control Status []

#### 1.48.10.2.1 Availability Manager Night Ventilation Control Status []

A value of 0 indicates the manager is signaling NoAction. A value of 2 means the manager is signaling CycleOn.

### 1.48.11 AvailabilityManager:HybridVentilation

This availability manager is executed at the start of each HVAC system timestep, before EnergyPlus calculates airflows defined in the objects `ZoneInfiltration:*`, `ZoneVentilation:*`, `ZoneMixing`, and `ZoneCrossMixing`, and before the `AirflowNetwork` model calculates multizone airflows. It serves two purposes: 1) prevents simultaneous natural ventilation and HVAC system operation, and 2) allows users to examine various ventilation strategies to maximize natural ventilation in order to reduce heating/cooling loads. The natural ventilation objects controlled by this availability manager have two groups: simple airflow group and `AirflowNetwork` group. The simple airflow group consists of the `ZoneVentilation:*` and `ZoneMixing` objects. The `AirflowNetwork` group consists of `AirflowNetwork:MultiZone:Component:DetailedOpening` and `AirflowNetwork:MultiZone:Component:SimpleOpening` objects used in the `AirflowNetwork` model. These two groups are not allowed to work simultaneously (see restrictions in the `Airflow Network` model section). Basically, this object overrides the controls for these opening objects or `ZoneVentilation:*` and `ZoneMixing` objects, closing the openings or shutting off ventilation/mixing airflows under certain conditions and allowing the HVAC system (`AirLoopHVAC`) to operate. If the availability manager determines that conditions are favorable for natural ventilation, then the HVAC system (`AirLoopHVAC`) is disabled and the opening objects or ventilation/mixing objects are able to operate based on the controls specified for those objects.

Each `AirLoopHVAC` can have a corresponding hybrid ventilation availability manager. Each hybrid ventilation manager can control natural ventilation in the zones served by the `AirLoopHVAC`. The hybrid ventilation availability manager is triggered by zone air conditions for the controlled zone specified in an object input field. If there is no air loop, hybrid ventilation manager can still be applied to controlled zone specified in the object. To apply hybrid ventilation manager to the controlled zone not served by any air loop, the HVAC air loop name input field must be left blank. Currently, zone component objects such as unit heater, unit ventilator, packaged terminal air conditioner, packaged terminal heat pump, zone water source heat pump, window air conditioner, variable refrigerant flow, energy recovery ventilator, outdoor air unit, fan coil unit, and ventilated slab can individually use hybrid ventilation managers to make a decision regarding whether their fan should be on or off. Also, hybrid ventilation managers can be applied to zones served by ideal load zone components to turn them off when natural ventilation is active. Currently, hybrid ventilation manager is restricted to one per zone. It can either be applied through the air loop or directly to the zone. If hybrid ventilation manager is applied to an air loop and one of the zones served by the air loop also has hybrid ventilation manager, then zone hybrid ventilation manager is disabled. Presently, this availability manager must be used either with the `ZoneVentilation:*` and `ZoneMixing` objects or with the `AirflowNetwork` model.

The inputs for this availability manager consist of the name for the air loop (`AirLoopHVAC`) being controlled, the controlled zone name to determine which zone air conditions are used to determine system availability, a ventilation control mode schedule, maximum wind speed and rain indicator to determine whether natural ventilation is allowed or not, a low limit and high limit for dry-bulb temperature, enthalpy and dewpoint temperature to determine the hybrid ventilation control, and a minimum outdoor air ventilation schedule. The last control allows user to use a wind speed modifier to adjust openness when the `AirflowNetwork` opening objects are selected. The other inputs include how to control simple airflow objects and `AirflowNetwork` opening objects. The operative temperature and zone air CO2 are also allowed to control natural ventilation. The minimum HVAC system operation time and natural ventilation time fields will provide users with more flexibility to force any operation mode to remain the same status within minimum time duration.

The hybrid ventilation availability manager works independently of all other system availability manager objects, so this manager is not a valid system availability manager type in the `AvailabilityManagerAssignmentList` object.

### 1.48.11.1 Inputs

#### 1.48.11.1.1 Field: Name

A unique, user-assigned name for an instance of a hybrid ventilation availability manager. Other objects that use this availability manager will reference it by this name.

#### 1.48.11.1.2 Field: HVAC Air Loop Name

The name of the air loop (**AirLoopHVAC** object) to be controlled by this system availability manager. If this field is left blank, hybrid ventilation manager will be applied to the controlled zone specified in the field below.

#### 1.48.11.1.3 Field: Control Zone Name

The name of a controlled zone served by the air loop defined in the previous field. The air conditions in this zone are used to determine if natural ventilation should be provided.

#### 1.48.11.1.4 Field: Ventilation Control Mode Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time the hybrid ventilation control mode is to be applied. The integer values are required in the schedule and should be varied between 0 and 7. The following bullets show each schedule value and its corresponding control mode:

0 = No ventilation control

Natural ventilation and HVAC system operation are performed based on their own controls.

1 = Temperature control for either cooling or heating

The control mode is determined internally based on thermostat set point and temperature control type and is restricted between the minimum and maximum outdoor temperatures provided in two additional input fields: Minimum Outdoor Temperature and Maximum Outdoor Temperature.

2 = Enthalpy control

The control is restricted between minimum and maximum outdoor enthalpy values given in two additional input fields: Minimum Outdoor Enthalpy and Maximum Outdoor Enthalpy.

3 = Dewpoint control for either dehumidification or humidification

The control is restricted between minimum and maximum outdoor dew point temperatures given in two additional input fields: Minimum Outdoor Dewpoint and Maximum Outdoor Dewpoint.

4 = Outdoor ventilation air control

The outdoor ventilation air control works with **AirflowNetwork** opening objects only, and is not allowed to work with **ZoneVentilation:**\* and **ZoneMixing** objects.

If the zone air change per hour (ACH) level is above the outdoor air setpoint, specified in the Minimum Outdoor Ventilation Air Schedule Name field, the natural ventilation is on and the HVAC system is shut off. Otherwise, the natural ventilation is shut off (i.e., the window or door openings are closed) and the HVAC system may operate if needed.

5 = Operative temperature control using adaptive comfort 80% acceptability limits

If the operative temperature is within the upper and lower 80% acceptability limits specified in ASHRAE Standard 55-2010, the natural ventilation is allowed, and HVAC operation is forced off. If the operative temperature is beyond the upper and lower limits, HVAC system operation is allowed,

and the natural ventilation is shut off. This control model requires the choice = AdaptiveASH55 in one of Thermal Comfort Model Type fields of the **People** object in the same controlled zone.

6 = Operative temperature control using adaptive comfort 90% acceptability limits

If the operative temperature is within the upper and lower 90% acceptability limits specified in ASHRAE Standard 55-2010, the natural ventilation is allowed, and HVAC operation is forced off. If the operative temperature is beyond the upper and lower limits, HVAC system operation is allowed, and the natural ventilation is shut off. This control model requires the choice = AdaptiveASH55 in one of Thermal Comfort Model Type fields of the **People** object in the same controlled zone.

7 = Carbon dioxide (CO2) control

If the zone CO2 level is above the setpoint, the program will check the HVAC system availability first. If available, HVAC operation will be allowed, and natural ventilation is shut off. If the system is not available, the natural ventilation will be allowed. The CO2 setpoint is provided in the **ZoneControl:ContaminantController** object in the same controlled zone.

The detailed control logic is given in the EnergyPlus Engineering Reference.

#### 1.48.11.1.5 Field: Use Weather File Rain Indicators

This logical alpha field indicates whether or not the rain indicator is used to shut off natural ventilation or not. The valid choices for Rain Indicator are Yes and No, with the default being Yes. This can help simulate conditions where one would normally close windows to avoid rain penetration in a space. Any possible rain getting into a space will not be counted as a zone load.

#### 1.48.11.1.6 Field: Maximum Wind Speed

This is the wind speed (m/s) above which hybrid ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid wind problems in a space (papers blowing around, etc).

#### 1.48.11.1.7 Field: Minimum Outdoor Temperature

This is the outdoor temperature (in Celsius) below which hybrid ventilation is shut off when the ventilation control mode = 1 (Temperature). This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

#### 1.48.11.1.8 Field: Maximum Outdoor Temperature

This is the outdoor temperature (in Celsius) above which hybrid ventilation is shut off when the ventilation control mode = 1 (Temperature). This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

#### 1.48.11.1.9 Field: Minimum Outdoor Enthalpy

This is the outdoor enthalpy (in J/kg) below which hybrid ventilation is shut off when the ventilation control mode = 2 (Enthalpy).

#### 1.48.11.1.10 Field: Maximum Outdoor Enthalpy

This is the outdoor enthalpy (in J/kg) above which hybrid ventilation is shut off when the ventilation control mode = 2 (Enthalpy).

**1.48.11.1.11 Field: Minimum Outdoor Dewpoint**

This is the outdoor dewpoint (in Celsius) below which hybrid ventilation is shut off when the ventilation control mode = 3 (Dewpoint). This lower dewpoint temperature limit is intended to avoid dehumidifying a space.

**1.48.11.1.12 Field: Maximum Outdoor Dewpoint**

This is the outdoor dewpoint temperature (in Celsius) above which hybrid ventilation is shut off when the ventilation control mode = 3 (Dewpoint). This upper dewpoint temperature limit is intended to avoid humidifying a space.

**1.48.11.1.13 Field: Minimum Outdoor Ventilation Air Schedule Name**

The name of a schedule defined elsewhere in the input file. This field applies only if Ventilation Control Mode = 4 (Outdoor Ventilation Air Control). This schedule determines the minimum outdoor ventilation air for a given time in the units of air change per hour (ACH). The program calculates the natural (outdoor) ventilation in the controlled zone first and compares the amount of outdoor air introduced by opening windows or doors and other small openings to this minimum value. If the amount of outdoor air from natural ventilation is less than the minimum value, the natural ventilation is shut off (i.e., the window or door openings are closed) and the HVAC system may operate if needed. Otherwise, the natural ventilation is on and the HVAC system is shut off. The amount of outdoor ventilation air entering the controlled zone is determined as air from outdoors and not from other adjacent zones. Therefore, this option is only applied to a zone having a window or door exposed to outdoors.

**1.48.11.1.14 Field: Opening Factor Function of Wind Speed Curve Name**

The name of a linear or quadratic performance curve (ref: Performance Curves) that parameterizes the variation of opening factor as a function of outdoor wind speed. The output of this curve is multiplied by the opening factor of opening objects to give the final openness. This field only works with the AirflowNetwork opening objects.

**1.48.11.1.15 Field: AirflowNetwork Control Type Schedule Name**

The name of a schedule defined elsewhere in the input file. This field works with the AirflowNetwork opening objects only. This schedule determines for a given simulation timestep how the opening objects respond to the hybrid ventilation control when the hybrid ventilation control allows the objects to operate.

Schedule values equal to zero indicate individual ventilation control based on the control requirements specified for each individual AirflowNetwork opening object. Schedule values equal to one denote group control. The opening objects exposed to outdoors in the controlled zone served by the primary air loop (Ref. Field HVAC Air Loop Name ) will be considered as a master to provide group control.

**1.48.11.1.16 Field: Simple Airflow Control Type Schedule Name**

The name of a schedule defined elsewhere in the input file. This field works with ZoneVentilation:\* and ZoneMixing objects only. This schedule determines for a given simulation timestep how the ZoneVentilation:\* and ZoneMixing objects respond to the hybrid ventilation control when the hybrid ventilation control allows the objects to operate.

Schedule values equal to zero indicate the individual ventilation control based on the control requirements from their own objects. Schedule values equal to one denote group control. The ZoneVentilation:\* and ZoneMixing objects in the zones served by the primary air loop defined in a previous input field (Ref. Field HVAC Air Loop Name ) are controlled by a single object, whose name is provided in the following input field.

#### 1.48.11.1.17 Field: ZoneVentilation Object Name

The name of a ZoneVentilation:\* object whose zone name is the controlled zone name defined in a previous input field for this availability manager object (Ref. Field Controlled Zone Name ). The controls defined for this specific ZoneVentilation:\* object to enable ventilation air will be applied to other ZoneVentilation:\* and ZoneMixing objects served by the air loop controlled by this availability manager, regardless of the controls defined for the other ZoneVentilation:\* and ZoneMixing objects. In other words, when ventilation is enabled by this specific ZoneVentilation:\* object, the other ZoneVentilation:\* and ZoneMixing objects in the zones served by the primary air loop are also enabled.

**Note:** A ZoneInfiltration:\* object indicates any one of ZoneInfiltration:DesignFlowRate, ZoneInfiltration:EffectiveLeakageArea, and ZoneInfiltration:FlowCoefficient objects. A object of ZoneVentilation:\* indicates any one of ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects.

#### 1.48.11.1.18 Field: Minimum HVAC Operation Time

The field represents the minimum time that HVAC system operation will be forced on, and the natural ventilation will be off. If accumulated system operation time is less than this value, the system operation status will be forced regardless of other operation conditions, and natural ventilation will shut off.

#### 1.48.11.1.19 Field: Minimum Ventilation Time

The field represents the minimum time that natural ventilation will be forced on regardless of other operation conditions, and the HVAC system will be off. If accumulated ventilation time is less than this value, the natural ventilation will be forced on regardless of other operation conditions unless rain or high wind speed disables natural ventilation.

An example of this object in an input file:

```
AvailabilityManager:HybridVentilation,
  Hybrid ventilation controller 1,  !- Name
  Typical Terminal Reheat 1,  !- HVAC Air Loop Name
  NORTH ZONE,  !- Control Zone Name
  Hybrid Control Mode Schedule,  !- Ventilation Control Mode Schedule Name
  Yes,  !- Use Weather File Rain Indicators
  40.0,  !- Maximum Wind Speed {m/s}
  15.0,  !- Minimum Outdoor Temperature {C}
  35.0,  !- Maximum Outdoor Temperature {C}
  20000.0,  !- Minimum Outdoor Enthalpy {J/kg}
  30000.0,  !- Maximum Outdoor Enthalpy {J/kg}
  15.0,  !- Minimum Outdoor Dewpoint {C}
  30.0,  !- Maximum Outdoor Dewpoint {C}
  Outdoor air Schedule;  !- Minimum Outdoor Ventilation Air Schedule Name
  ,  !- Opening Factor Function of Wind Speed Curve Name
  ,  !- AirflowNetwork Control Type Schedule Name
  ,  !- Simple Airflow Control Type Schedule Name
  ,  !- ZoneVentilation Object Name
  0.0,  !- Minimum HVAC Operation Time
  0.0;  !- Minimum Ventilation Time
```

#### 1.48.11.2 Outputs

The hybrid ventilation availability manager has the following output variables.

HVAC,Average,Availability Manager Hybrid Ventilation Control Mode []  
 HVAC,Average,Availability Manager Hybrid Ventilation Control Status []  
 HVAC,Average,Hybrid Ventilation Control HVAC System Operation Elapsed Time [min]  
 HVAC,Average,Hybrid Ventilation Control Natural Ventilation Elapsed Time [min]  
 HVAC,Average,Hybrid Ventilation Operative Temperature [C]

HVAC,Average,Hybrid Ventilation Lower Limit Operative Temperature [C]  
 HVAC,Average,Hybrid Ventilation Upper Limit Operative Temperature [C]

#### **1.48.11.2.1 Availability Manager Hybrid Ventilation Control Mode []**

This is the hybrid ventilation control mode given in the Ventilation Control Mode Schedule.

#### **1.48.11.2.2 Availability Manager Hybrid Ventilation Control Status []**

This is the hybrid ventilation control status, which can have three integer values: 0, 1, and 2. A zero value indicates no hybrid ventilation control, corresponding to zero value defined in the previous output variable. A value of one indicates that natural ventilation is allowed. A value of two denotes that the natural ventilation is not allowed, so all window/door openings are closed.

#### **1.48.11.2.3 Hybrid Ventilation Control HVAC System Operation Elapsed Time [min]**

This output is the HVAC system operation elapsed time in the units of minutes since the HVAC system starts.

#### **1.48.11.2.4 Hybrid Ventilation Control Natural Ventilation Elapsed Time [min]**

This output is the natural ventilation elapsed time in the units of minutes since the natural ventilation starts.

#### **1.48.11.2.5 Hybrid Ventilation Operative Temperature [C]**

This output is the average of Mean Air Temperature and Mean Radiant Temperature in the hybrid ventilation control zone.

#### **1.48.11.2.6 Hybrid Ventilation Lower Limit Operative Temperature [C]**

This output is the lower acceptability limit in degrees C based on user input selection of either 80% or 90%.

#### **1.48.11.2.7 Hybrid Ventilation Upper Limit Operative Temperature [C]**

This output is the upper acceptability limit in degrees C based on user input selection of either 80% or 90%.

### **1.48.12 AvailabilityManager:OptimumStart**

When night time temperature setback and/or setup are employed, the optimum start availability manager is used to start the HVAC system prior to occupancy to ensure that the space is comfortable when people appear in the building.

#### **1.48.12.1 Inputs**

##### **1.48.12.1.1 Field: Name**

A unique, user-defined name for an instance of this availability manager.

##### **1.48.12.1.2 Field: Applicability Schedule Name**

This schedule decides whether for a given time period this availability manager is to be applied. Schedule value of 1 specifies the availability manager is to be applied. Schedule value of 0 indicates that the availability manager is not used for this time period

#### 1.48.12.1.3 Field: Fan Schedule Name

The name of the central fan schedule for the air system that this availability manager will govern.

#### 1.48.12.1.4 Field: Control Type

The possible inputs are StayOff, MaximumofZoneList, and ControlZone. StayOff means the availability manager will have no effect air handler on/off will be determined by the fan schedule. ControlZone means a specific zone mentioned in the field will govern the start time. The default is ControlZone. MaximumofZoneList means that from all zones mentioned in the zone list field in this availability manager maximum value of start time will be used to start the fan.

#### 1.48.12.1.5 Field: Control Zone Name

For Control type ControlZone the name of zone is added here. Start time for this zone will be used for the air loop.

#### 1.48.12.1.6 Field: Zone List Name

Zones mentioned in this list will be used to determine the start time. Maximum value of start time for the zones mentioned in this list will be used for the air loop.

#### 1.48.12.1.7 Field: Maximum Value for Optimum Start Time

To limit too early start of the system maximum value for the start time can be entered here. Optional input, defaults to 6 hours. This is the maximum number of hours that a system can start before occupancy.

#### 1.48.12.1.8 Field: Control Algorithm

The four possible inputs are **ConstantTemperatureGradient**, **AdaptiveTemperatureGradient**, **AdaptiveASHRAE**, and **ConstantStartTime**. In ConstantTemperatureGradient algorithm the temperature gradient entered by the user will be constant throughout the simulation. The response to heating and cooling operation can be non-linear thus two separate fields for temperature gradients are used. AdaptiveTemperatureGradient algorithm will modify the temperature gradients based on the arithmetic average of the actual temperature gradients calculated for the specified number of previous days. For this algorithm user should enter two initial start values. AdaptiveASHRAE algorithm implements equations suggested in ASHRAE Handbook HVAC Applications (2007). This algorithm will calculate the coefficients of the equation within the code and users need not provide temperature response related inputs. ConstantStartTime method calculates the start time based on specified number of hours before occupancy for each day. **The default control algorithm is AdaptiveASHRAE.**

#### 1.48.12.1.9 Field: Constant Temperature Gradient during Cooling

This input is required if ConstantTemperatureGradient algorithm is selected in the above field. Temperature gradient ( °C/hour) for cooling operation is entered here. Such gradient may be obtained for existing buildings from EMCS or pre-calculated by other programs. This gradient remains constant throughout the simulation.

#### 1.48.12.1.10 Field: Constant Temperature Gradient during Heating

This input is required if ConstantTemperatureGradient algorithm is selected in the Control Algorithm field. Temperature gradient ( °C/hour) for heating operation is entered here. This gradient remains constant throughout the simulation.

#### 1.48.12.1.11 Field: Initial Temperature Gradient during Cooling

This input is required if AdaptiveTemperatureGradient algorithm is selected in Control Algorithm field. Initial value of temperature gradient ( °C/hour) for cooling operation is entered here. This value is used as initial guess value to start the adaptive method. Depending on performance, this value is modified and used in the simulation.

#### 1.48.12.1.12 Field: Initial Temperature Gradient during Heating

This input is required if AdaptiveTemperatureGradient algorithm is selected in Control Algorithm field. Initial value of temperature gradient ( °C/hour) for heating operation is entered here. This value is used as initial guess value to start the adaptive method. Depending on performance, this value is modified and used in the simulation.

#### 1.48.12.1.13 Field: Constant Start Time

This input is required if ConstantStartTime algorithm is selected in the Control Algorithm field. Start time, the number of hours before occupancy occurs for a system, for heating and cooling operation is entered here. Irrespective of thermal response, the heating or cooling operation starts before the occupancy at this fixed time. This start time value remains constant throughout the simulation.

#### 1.48.12.1.14 Field: Number of Previous Days

This input is required if AdaptiveTemperatureGradient algorithm is selected in the Control Algorithm field. The values of optimal start time for number of days entered here will be used to determine the adaptive gradients.

Sample IDFs:

```

### 1.48.12.2 Outputs

The optimum start availability manager has two output variables.

**1.48.12.2.1 Availability Manager Night Ventilation Control Status**

A value of 0 indicates the manager is signaling NoAction. A value of 2 means the manager is signaling CycleOn.

**1.48.12.2.2 Availability Manager Optimum Start Time Before Occupancy**

The current time before occupancy. Occupancy is the first zone timestep after midnight when the Fan Schedule is  $> 0.0$ . The units are hours.

**1.49 Group Setpoint Managers**

Setpoint Managers are one of the high-level control constructs in EnergyPlus. A Setpoint Manager is able to access data from any of the HVAC system nodes and use this data to calculate a setpoint (usually a temperature setpoint) for one or more other HVAC system nodes. Setpoints are then used by Controllers or Plant or Condenser Loops as a goal for their control actions.

Setpoint Managers are executed at the start of each HVAC timestep, and they reside outside the HVAC system iteration loops. Thus, the Setpoint Managers are executed once per HVAC timestep, and they use previous timestep information (except for zone load) to calculate their setpoints.

The following situations require the use of a Setpoint Manager:

- 1) any use of **Controller:WaterCoil**; either in Temperature control only or 2 Setpoint Managers for the "TemperatureAndHumidityRatio" control variable option.
- 2) use of **Controller:OutdoorAir** with *Economizer Control Type* set to anything but *NoEconomizer*;
- 3) use of **Coil:Heating:Fuel** or **Coil: Heating: Electric** with the field *Temperature Setpoint Node Name* set to a node name;
- 4) any use of **CoilSystem:Cooling:DX**;
- 5) any use of **Humidifier:Steam:Electric**.
- 6) Any use of **PlantLoop** or **CondenserLoop** which doesn't use an environment reference such as AIR or GROUND as a set point

Setpoint managers will place a calculated or scheduled setpoint value on the setpoint node and overwrite any previous value. This value may represent one of several control types (e.g., Temperature, HumidityRatio, MassFlowRate, etc.). No two setpoint managers should use the same setpoint node for like control types.

For the case when two setpoint managers place a setpoint on the same setpoint node (e.g., a temperature setpoint placed on the same node by two different setpoint managers), the setpoint value on the node is calculated by the last setpoint manager simulated. Within a specific type of setpoint manager (e.g., Scheduled), the setpoint managers are simulated in the order found in the input data file (idf) when viewed using a text editor. It is also possible for two different types of setpoint managers to place setpoints of like control variable on the same node. In this case, the order of simulation for the type of setpoint manager determines which setpoint manager is the last to write a setpoint value to the node. This conflict in setpoint node data is most likely to cause inaccurate simulation results. For this reason, a conflicting setpoint node name warning message is issued so that the conflict can be resolved. Duplicate setpoint node names found within a specific node list will not typically cause problems with the simulation (the same value is written twice to the same node). In this case a duplicate setpoint node name warning is issued, however, this could be an error in the spelling of the node name and should be corrected.

Simulation order for setpoint managers:

- SetpointManager:Scheduled
- SetpointManager:Scheduled:DualSetpoint
- SetpointManager:OutdoorAirReset
- SetpointManager:SingleZone:Reheat
- SetpointManager:SingleZone:Heating
- SetpointManager:SingleZone:Cooling
- SetpointManager:SingleZone:Humidity:Minimum
- SetpointManager:SingleZone:Humidity:Maximum
- SetpointManager:Warmest
- SetpointManager:Coldest
- SetpointManager:WarmestTemperatureFlow
- SetpointManager:ReturnAirBypassFlow
- SetpointManager:MultiZone:Cooling:Average
- SetpointManager:MultiZone:Heating:Average
- SetpointManager:MultiZone:MinimumHumidity:Average
- SetpointManager:MultiZone:MaximumHumidity:Average
- SetpointManager:MultiZone:Humidity:Minimum
- SetpointManager:MultiZone:Humidity:Maximum
- SetpointManager:FollowOutdoorAirTemperature
- SetpointManager:FollowSystemNodeTemperature
- SetpointManager:FollowGroundTemperature
- SetpointManager:CondenserEnteringReset
- SetpointManager:CondenserEnteringReset:Ideal
- SetpointManager:MixedAir
- SetpointManager:OutdoorAirPretreat
- SetpointManager:ReturnTemperature:ChilledWater,
- SetpointManager:ReturnTemperature:HotWater

### 1.49.1 SetpointManager:Scheduled

The simplest Setpoint Manager simply uses a schedule to determine one or more setpoints. No node data is used as input. The input consists of the Setpoint Manager name, the control variable, the schedule name, and the name of a node list. The node list contains the name of those nodes at which the setpoint is to be applied. Of course, a node list name can always be simply the name of a single node.

Note that although this object provides a very general method of setting the values of many different control variables on nodes, the component models and system solvers may or may not be able to use them. Therefore, it is important to understand that simply setting a control variable using this object will not necessarily always produce the desired behavior.

#### 1.49.1.1 Inputs

##### 1.49.1.1.1 Field: Name

A unique, user-assigned name for an instance of a scheduled setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

##### 1.49.1.1.2 Field: Control Variable

The type of variable that will be controlled. There are several choices for this type of set point manager. The most common control variable is Temperature but other major choices include: HumidityRatio and MassFlowRate. The versatility of control variables available here (probably) exceeds what is actually available in the component and systems models. However, a large number of possible control variables are made available here for maximum flexibility and because some (but not all) component models will be able to use them. The complete list of key words and the units required in the associated schedules follow.

- Temperature Temperture of fluid at node ( °C)
- MaximumTemperature Maximum temperature of fluid at node ( °C)
- MinimumTemperature Minimum temperature of fluid at node ( °C)
- HumidityRatio Humidity ratio of fluid at node (kgWater/kgDryAir)
- MaximumHumidityRatio Maximum humidity ratio of fluid at node (kgWater/kgDryAir)
- MinimumHumidityRatio Minimum humidity ratio of fluid at node (kgWater/kgDryAir)
- MassFlowRate Mass flow rate of fluid at node (kg/s)
- MaximumMassFlowRate Maximum mass flow rate of fluid at node (kg/s)
- MinimumMassFlowRate Minimum mass flow rate of fluid at node (kg/s)

##### 1.49.1.1.3 Field: Schedule Name

The name of a schedule whose values are to be used as setpoints on the node or node list. The schedule value for each time period is the setpoint for this type of setpoint manager. The schedule must have values that are in the appropriate units as defined in the previous field.

#### 1.49.1.1.4 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which setpoints will be established by this setpoint manager.

Following is an example of the input for a Scheduled Setpoint Manager.

```
SetpointManager:Scheduled,
  Supply Air Temp Manager 1,    !- Name
  Temperature,                  !- Control Variable
  Seasonal Reset Supply Air Temp Sch, !- Schedule Name
  VAV Sys 1 Outlet Node;        !- Setpoint Node or NodeList Name
```

---

### 1.49.2 SetpointManager:Scheduled:DualSetpoint

This setpoint manager places a high and low schedule value on one or more nodes. The input consists of the Setpoint Manager name, the control variable, the high and low set point schedule names, and the name of a node list. The node list contains the name of those nodes at which the setpoint is to be applied. Of course, a node list name can simply be the name of a single node. Currently the DualSetpoint Manager will be used with **PlantLoop** when the Plant Loop Demand Calculation Scheme is set to DualSetpointDeadband .

#### 1.49.2.1 Inputs

##### 1.49.2.1.1 Field: Name

A unique, user-assigned name for an instance of this scheduled setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

##### 1.49.2.1.2 Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

##### 1.49.2.1.3 Field: High Setpoint Schedule Name

The name of a schedule that contains the high setpoint values. The schedule value for each time period is the high setpoint for this type of setpoint manager.

##### 1.49.2.1.4 Field: Low Setpoint Schedule Name

The name of a schedule that contains the low setpoint values. The schedule value for each time period is the low setpoint for this type of setpoint manager.

##### 1.49.2.1.5 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Following is an example of the input for a SetpointManager:Scheduled:DualSetpoint object.

```
SetpointManager:Scheduled:DualSetpoint,
  Water Loop Setpoint Manager,    !- Name
  Temperature,                    !- Control Variable
  Plant Loop High Temp Schedule,  !- High Setpoint Schedule Name
  Plant Loop Low Temp Schedule,   !- Low Setpoint Schedule Name
  Plant Supply Outlet Node;       !- Setpoint Node or NodeList Name
```

---

### 1.49.3 SetpointManager:OutdoorAirReset

The Outdoor Air Reset Setpoint Manager is used to place a setpoint temperature on a system node according to the outdoor air temperature using a reset rule. The reset rule is determined by 2 points: the setpoint temperature at the outdoor air high temperature (TSetAtOAHigh) and the setpoint temperature at the outdoor air low temperature (TSetAtOALow). If the outdoor air temperature is above the outdoor air high temperature limit, the setpoint temperature is set to TSetAtOAHigh. If the outdoor air temperature is below the outdoor air low temperature limit, the setpoint temperature is set to TSetAtOALow. If the outdoor air temperature is between the outdoor air high and outdoor air low temperatures limits, the setpoint temperature is linearly interpolated between TSetAtOAHigh and TSetAtOALow. The outdoor air temperature is obtained from the weather information during the simulation. This setpoint manager can be used to place a setpoint temperature on air loop and plant loop system nodes.

The input consists of the setpoint manager name, the type of control variable, a node list name of the nodes affected by the setpoint, and the data for the reset rule: the setpoint temperature at the outdoor air low temperature, the outdoor air low temperature limit, the setpoint temperature at the outdoor air high temperature, and the outdoor air high temperature limit.

There are optional inputs for a second reset rule. First there is the name of a schedule that indicates which rule to use: a schedule value of 1 means use the first rule; a schedule value of 2 means use the second rule. Next, there are the 4 inputs specifying the second reset rule.

#### 1.49.3.1 Inputs

##### 1.49.3.1.1 Field: Name

A unique, user-assigned name for an instance of an outdoor air reset setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

##### 1.49.3.1.2 Field: Control Variable

The type of variable that will be controlled. There are three key choices for this type of set point manager:

- Temperature
- MaximumTemperature
- MinimumTemperature

##### 1.49.3.1.3 Field: Setpoint at Outdoor Low Temperature

The supply air temperature setpoint in °C at the outdoor low temperature for the first reset rule.

##### 1.49.3.1.4 Field: Outdoor Low Temperature

The outdoor air low temperature in °C for the first supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its maximum.

##### 1.49.3.1.5 Field: Setpoint at Outdoor High Temperature

The supply air temperature setpoint in °C at the outdoor high temperature for the first reset rule.

##### 1.49.3.1.6 Field: Outdoor High Temperature

The outdoor air high temperature in °C for the first supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its minimum.

**1.49.3.1.7 Field: Setpoint Node or NodeList Name**

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

**1.49.3.1.8 Field: Schedule Name**

The name of a schedule whose values indicate which reset rule to use. Schedule values of 1 indicate that the first reset rule will be used. Schedule values of 2 select the second reset rule.

**1.49.3.1.9 Field: Setpoint at Outdoor Low Temperature 2**

The supply air temperature setpoint in °C at the outdoor low temperature for the second reset rule.

**1.49.3.1.10 Field: Outdoor Low Temperature 2**

The outdoor air low temperature in °C for the second supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its maximum.

**1.49.3.1.11 Field: Setpoint at Outdoor High Temperature 2**

The supply air temperature setpoint in °C at the outdoor high temperature for the second reset rule.

**1.49.3.1.12 Field: Outdoor High Temperature 2**

The outdoor air high temperature in °C for the second supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its minimum.

Below is an example of the input for an Outdoor Air Reset Setpoint Manager:

```
SetpointManager:OutdoorAirReset,
  Supply Air Temp Manager 1,    !- Name
  Temperature,                  !- Control Variable
  16.7,                          !- Setpoint at Outdoor Low Temperature {C}
  0.0,                          !- Outdoor Low Temperature {C}
  12.8,                         !- Setpoint at Outdoor High Temperature {C}
  32.0,                         !- Outdoor High Temperature {C}
  Supply Air Temp Nodes;        !- Setpoint Node or NodeList Name

NodeList,
  Supply Air Temp Nodes, !- Name
  Air Loop Outlet Node;    !- Node 1 Name
```

**1.49.4 SetpointManager:SingleZone:Reheat**

The Single Zone Reheat Setpoint Manager allows the simulation of a single zone reheat system. This setpoint manager detects the control zone load, zone inlet node flow rate, and zone node temperature and calculates a setpoint temperature for the supply air that will satisfy the zone load for the control zone. This setpoint manager creates a variable temperature system. The input consists of the setpoint manager name, the control variable type, the minimum and maximum supply air temperatures, the name of the control zone, the name of the control zone node, the name of the control zone inlet node, and the name of a node or node list containing the nodes whose setpoint temperatures are to be set by this manager.

**1.49.4.1 Inputs****1.49.4.1.1 Field: Name**

A unique, user-assigned name for an instance of this setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

**1.49.4.1.2 Field: Control Variable**

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

**1.49.4.1.3 Field: Minimum Supply Air Temperature**

The minimum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager).

**1.49.4.1.4 Field: Maximum Supply Air Temperature**

The maximum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager)

**1.49.4.1.5 Field: Control Zone Name**

The name of the control zone for this single zone reheat system. The heating or cooling load for this zone determines the supply air temperature setpoint.

**1.49.4.1.6 Field: Zone Node Name**

The name of the zone node for the control zone.

**1.49.4.1.7 Field: Zone Inlet Node Name**

The name of the zone inlet node that is supplying air to the control zone.

**1.49.4.1.8 Field: Setpoint Node or NodeList Name**

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Below is an example input for a SetpointManager:SingleZone:Reheat object.

```
SetpointManager:SingleZone:Reheat,
  Supply Air Temp Manager,    !- Name
  Temperature,               !- Control Variable
  13.,                       !- Minimum Supply Air Temperature {C}
  45.,                       !- Maximum Supply Air Temperature {C}
  NORTH ZONE,                !- Control Zone Name
  Zone 3 Node,               !- Zone Node Name
  Zone 3 Inlet Node,         !- Zone Inlet Node Name
  Supply Air Temp Nodes;     !- Setpoint Node or NodeList Name

NodeList,
  Supply Air Temp Nodes,    !- Name
  Heating Coil Air Inlet Node, !- Node 1 Name
  Air Loop Outlet Node;    !- Node 2 Name
```

---

**1.49.5 SetpointManager:SingleZone:Heating**

The Single Zone Heating Setpoint Manager allows a component to be controlled based on the load required to meet the zone heating setpoint. This setpoint manager detects the control zone load to meet the current heating setpoint, zone inlet node flow rate, and zone node temperature, and calculates a setpoint temperature for the supply air that will satisfy the zone heating load for the control zone. This setpoint manager creates a variable temperature system. The input consists of the setpoint manager name, the controlled variable type, the minimum and maximum supply air temperatures, the name of the control zone, the name of the control zone node, the name of the control zone inlet node, and the name of a node or node list containing the nodes whose setpoint temperatures are to be set by this manager.

### 1.49.5.1 Inputs

#### 1.49.5.1.1 Field: Name

A unique, user-assigned name for an instance of a single zone heating setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.5.1.2 Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

#### 1.49.5.1.3 Field: Minimum Supply Air Temperature

The minimum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager).

#### 1.49.5.1.4 Field: Maximum Supply Air Temperature

The maximum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager)

#### 1.49.5.1.5 Field: Control Zone Name

The name of the control zone for this setpoint manager. The heating load for this zone (to meet the zone heating setpoint) determines the supply air temperature setpoint.

#### 1.49.5.1.6 Field: Zone Node Name

The name of the zone node for the control zone.

#### 1.49.5.1.7 Field: Zone Inlet Node Name

The name of the zone inlet node that is supplying air to the control zone.

#### 1.49.5.1.8 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Below is an example input for a SetpointManager:SingleZone:Heating object.

```
SetpointManager:SingleZone:Heating,
Zone 1 Heating Supply Air Temp Manager,    !- Name
Temperature,                               !- Control Variable
7.22,                                       !- Minimum Supply Air Temperature {C}
45.,                                       !- Maximum Supply Air Temperature {C}
Zone 1,                                    !- Control Zone Name
Zone 1 Zone Node,                          !- Zone Node Name
Zone 1 Supply Inlet,                      !- Zone Inlet Node Name
Zone 1 Heating Coil Outlet;                !- Setpoint Node or NodeList Name
```

## 1.49.6 SetpointManager:SingleZone:Cooling

The Single Zone Cooling Setpoint Manager allows a component to be controlled based on the load required to meet the zone cooling setpoint. This setpoint manager detects the control zone load to meet the current cooling setpoint, zone inlet node flow rate, and zone node temperature, and calculates a setpoint temperature for the supply air that will satisfy the zone cooling load for the control zone. This setpoint manager creates a variable temperature system. The input consists of the setpoint manager name, the controlled variable type, the minimum and maximum supply air temperatures, the name of the control

zone, the name of the control zone node, the name of the control zone inlet node, and the name of a node or node list containing the nodes whose setpoint temperatures are to be set by this manager.

### 1.49.6.1 Inputs

#### 1.49.6.1.1 Field: Name

A unique, user-assigned name for an instance of a single zone cooling setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.6.1.2 Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

#### 1.49.6.1.3 Field: Minimum Supply Air Temperature

The minimum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager).

#### 1.49.6.1.4 Field: Maximum Supply Air Temperature

The maximum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager)

#### 1.49.6.1.5 Field: Control Zone Name

The name of the control zone for this setpoint manager. The cooling load of this zone (to meet the zone cooling set point) determines the supply air temperature setpoint.

#### 1.49.6.1.6 Field: Zone Node Name

The name of the zone node for the control zone.

#### 1.49.6.1.7 Field: Zone Inlet Node Name

The name of the zone inlet node that is supplying air to the control zone.

#### 1.49.6.1.8 Field: Setpoint Node or NodeList Name

The name of a Node List object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Below is an example input for a SetpointManager:SingleZone:Cooling object.

```
SetpointManager:SingleZone:Cooling,
Zone 1 Cooling Supply Air Temp Manager,    !- Name
Temperature,                               !- Control Variable
7.22,                                     !- Minimum Supply Air Temperature {C}
45.,                                       !- Maximum Supply Air Temperature {C}
Zone 1,                                   !- Control Zone Name
Zone 1 Zone Node,                         !- Zone Node Name
Zone 1 Supply Inlet,                     !- Zone Inlet Node Name
Zone 1 Cooling Coil Outlet;              !- Setpoint Node or NodeList Name
```

---

### 1.49.7 SetpointManager:SingleZone:Humidity:Minimum

The Single Zone Minimum Humidity Setpoint Manager allows the control of a single zone minimum humidity level. This setpoint manager detects the humidity level in a control zone and, using air and moisture mass balance, calculates the supply air humidity ratio needed to maintain the zone relative humidity at or above a given setpoint. The calculated supply air humidity ratio is then used as the setpoint for the designated setpoint node. A humidifier component placed upstream of the setpoint node can then use the humidity ratio setpoint to control its moisture addition rate.

The use of this object requires that a **ZoneControl:Humidistat** object be specified with a humidifying relative humidity schedule for the controlling zone. The humidistat's controlling zone must correspond with the control zone air node name specified in this setpoint manager.

#### 1.49.7.1 Inputs

##### 1.49.7.1.1 Field: Name

A unique, user-assigned name for an instance of a single zone minimum humidity setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

##### 1.49.7.1.2 Field: Setpoint Node or NodeList Name

The name of the HVAC system node where the calculated humidity ratio setpoint is set. If the setpoint is being placed on more than one node, this input should be the name of a **NodeList**.

##### 1.49.7.1.3 Field: Control Zone Air Node Name

The name of the zone node for the humidity control zone (as specified in the object **Zone-HVAC:EquipmentConnections**).

An IDF example for this setpoint manager is shown below with the required humidistat:

```
SetpointManager:SingleZone:Humidity:Minimum,
Zone Min Set Point Manager,    !- Name
Air Loop Outlet Node,         !- Setpoint Node or NodeList Name
Zone 2 Node;                  !- Control Zone Air Node Name

ZoneControl:Humidistat,
Zone 2 Humidistat,            !- Name
ZONE 2,                       !- Zone Name
Min rel Hum Set Sch2;         !- Humidifying Relative Humidity Setpoint Schedule Name
```

### 1.49.8 SetpointManager:SingleZone:Humidity:Maximum

The Single Zone Maximum Humidity Setpoint Manager allows the control of a single zone maximum humidity level. This setpoint manager, used in conjunction with object **ZoneControl:Humidistat**, detects the air humidity level in a single control zone and uses air/moisture mass balances to calculate the supply air humidity ratio needed to maintain the zone relative humidity at or below a given setpoint. The calculated supply air humidity ratio is then used as the setpoint for the designated setpoint node. A dehumidification component placed upstream of this node can then use the humidity ratio setpoint to control its moisture removal rate (e.g., desiccant dehumidifiers).

In the case of a chilled water coil which is used for both temperature and high humidity control, this setpoint manager works in conjunction with a **Controller:WaterCoil** object to determine the minimum supply air temperature required to meet both the temperature (sensible) and humidity (latent) load in the control zone. See object **Controller:WaterCoil** in the EnergyPlus Engineering Reference for a detailed discussion of how this is achieved.

The use of this object requires that a **ZoneControl:Humidistat** object be specified with a relative humidity setpoint schedule for the controlling zone. The humidistat's controlling zone must correspond with the control zone air node name specified in this setpoint manager..

### 1.49.8.1 Inputs

#### 1.49.8.1.1 Field: Name

A unique, user-assigned name for an instance of a single zone maximum humidity setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.8.1.2 Field: Setpoint Node or NodeList Name

The name of the HVAC system node where the calculated humidity ratio setpoint is set. If the setpoint is being placed on more than one node, this input should be the name of a **NodeList**.

#### 1.49.8.1.3 Field: Control Zone Air Node Name

The name of the zone air node for the humidity control zone (as specified in the object **Zone-HVAC:EquipmentConnections**).

An example of this object in an input data file (IDF), along with a temperature set point manager, humidistat, and a simple controller, is shown below:

```
SetpointManager:SingleZone:Humidity:Maximum,
Zone Max Set Point Manager,          !- Name
VAV Sys 1 Outlet Node,                !- Setpoint Node or NodeList Name
Zone 2 Node;                         !-Control Zone Air Node Name

SetpointManager:Scheduled,
Scheduled Set Point Manager 1,        !- Name
Temperature,                          !- Control Variable
Seasonal Reset Supply Air Temp Sch,   !- Schedule Name
VAV Sys 1 Outlet Node;                !- Setpoint Node or NodeList Name

ZoneControl:Humidistat,
Zone 2 Humidistat,                    !-Name
ZONE 2,                               !- Zone Name
Min rel Hum Set Sch2;                 !- Humidifying Relative Humidity Setpoint Schedule Name

Controller:WaterCoil,
Central Cooling Coil Controller 1,    !- Name
TEMPandHUMRAT,                       !- Control Variable
Reverse,                              !- Action
FLOW,                                 !- Actuator Variable
VAV Sys 1 Outlet Node,                !- Sensor Node Name
Main Cooling Coil 1 Water Inlet Node, !- Actuator Node Name
0.002,                                !- Controller Convergence Tolerance {deltaC}
0.025,                                !- Maximum Actuated Flow {m3/s}
0.0;                                  !- Minimum Actuated Flow {m3/s}
```

## 1.49.9 SetpointManager:MixedAir

The Mixed Air Setpoint Manager is meant to be used in conjunction with a **Controller:OutdoorAir** object. This setpoint manager is used to establish a temperature setpoint at the mixed air node. The **Controller:OutdoorAir** then operates the outdoor air damper to attempt to meet this setpoint.

In EnergyPlus the relief and outdoor air dampers, the economizer, and any outdoor air conditioning equipment form a separate subsystem of an air loop system (ref. **AirLoopHVAC**). The outdoor air controller

operates within the subsystem. Consequently the mixed air temperature setpoint must take into account any downstream system fan heat if it is to meet a desired system supply air leaving temperature. The Mixed Air Setpoint Manager accomplishes this by referencing a supply air setpoint set by another setpoint manager (most likely at the **AirLoopHVAC** outlet node). The supply fan inlet and outlet nodes are also inputs to the Mixed Air Setpoint Manager. From this information the Mixed Air Setpoint Manager calculates the supply fan air temperature rise, subtracts it from the reference setpoint temperature, and sets the result as the mixed air node setpoint temperature.

Of course any type of setpoint manager can be used to establish a temperature setpoint at the mixed air node. But the Mixed Air Setpoint Manager is likely to be the most useful.

When optional inputs of Cooling Coil Inlet Node Name, Cooling coil Outlet Node Name, and Minimum Temperature at Cooling Coil Outlet Node are provided, the setpoint temperature at the mixed air node is calculated based on the maximum of both the reference setpoint temperature and minimum cooling coil outlet temperature, minus the cooling coil air temperature reduction and the supply fan air temperature rise if the supply fan placement is blow through. The setpoint temperature at the mixed air node is used to calculate the maximum outdoor air flow fraction in the corresponding **Controller:OutdoorAir** object. The outdoor air flow fraction is capped at the maximum outdoor air flow fraction to prevent the cooling coil from freezing, even though the fraction is below the minimum outdoor air flow fraction.

### 1.49.9.1 Inputs

#### 1.49.9.1.1 Field: Name

A unique, user-assigned name for an instance of a mixed air setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.9.1.2 Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

#### 1.49.9.1.3 Field: Reference Setpoint Node Name

The name of an HVAC system node where the system supply air temperature is set. Normally this would be the **AirLoopHVAC** outlet node. The temperature setpoint at this reference node is set by a different setpoint manager.

#### 1.49.9.1.4 Field: Fan Inlet Node Name

The name of the supply fan inlet node.

#### 1.49.9.1.5 Field: Fan Outlet Node Name

The name of the supply fan outlet node.

#### 1.49.9.1.6 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name where temperature setpoints will be established by this setpoint manager. The node name(s) specified here cannot be the same as the Reference Setpoint Node Name in the previous field.

#### 1.49.9.1.7 Field: Cooling Coil Inlet Node Name

The name of the cooling coil inlet node.

#### 1.49.9.1.8 Field: Cooling Coil Outlet Node Name

The name of the cooling coil outlet node.

### 1.49.9.1.9 Field: Minimum Temperature at Cooling Coil Outlet Node

In order to prevent cooling coil freezing during economizer operation, the minimum temperature at the cooling coil outlet is required based on requirement of ASHRAE Standard 90.1. The default value is 7.2C.

Below is an example input for a Mixed Air Setpoint Manager.

```
SetpointManager:SingleZone:Reheat, ! establishes the setpoint at the system outlet node
Supply Air Temp Manager,      !- Name
Temperature,                  !- Control Variable
13.,                          !- Minimum Supply Air Temperature
45.,                          !- Maximum Supply Air Temperature
NORTH ZONE,                   !- Control Zone Name
Zone 3 Node,                  !- Zone Node Name
Zone 3 Inlet Node,            !- Zone Inlet Node Name
Supply Air Temp Nodes;        !- Setpoint Node or NodeList Name

SetpointManager:MixedAir, ! uses the system outlet setpoint to establish the mixed air setpoint
Mixed Air Temp Manager 1,    !- Name
Temperature,                  !- Control Variable
Air Loop Outlet Node,        !- Reference Setpoint Node Name
Heating Coil Air Outlet Node, !- Fan Inlet Node Name
Air Loop Outlet Node,        !- Fan Outlet Node Name
Mixed Air Nodes;              !- Setpoint Node or NodeList Name

NodeList, Supply Air Temp Nodes,
Air Loop Outlet Node; ! Setpoint Nodes
NodeList, Mixed Air Nodes,
Mixed Air Node; ! Setpoint Nodes
```

---

## 1.49.10 SetpointManager:OutdoorAirPretreat

The OutdoorAir Pretreat Setpoint Manager is meant to be used in conjunction with an **OutdoorAir:Mixer** object. The Outdoor air Pretreat Setpoint Manager is used to establish a temperature or humidity ratio setpoint in the outdoor air stream flowing into the “Outdoor Air Stream Node” of an **OutdoorAir:Mixer** object. This setpoint manager determines the required setpoint in the outdoor air stream to produce the reference setpoint in the mixed air stream after mixing with return air. For example, if the temperature setpoint at the mixed air node is 15 °C, the return air temperature is 20 °C, and the outdoor air flow fraction is 0.5, the Outdoor Air Pretreat setpoint would be set to 10 °C.

Of course any type of setpoint manager can be used to establish setpoints in the outdoor air stream, but this setpoint manager is likely to be the most useful for systems which precondition outdoor air with equipment such as a DX cooling coil or desiccant dehumidifier.

### 1.49.10.1 Inputs

#### 1.49.10.1.1 Field: Name

A unique, user-assigned name for an instance of an outdoor air pretreat setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.10.1.2 Field: Control Variable

The type of variable that will be controlled. The choices are:

- Temperature references and sets the “System Node Setpoint Temperature” property. This single temperature setpoint is set and used by all temperature setpoint managers and equipment controls except dual-setpoint equipment.

- MaximumHumidityRatio references and sets the “System Node Humidity Ratio Max” property. This type of reference setpoint may be set using `SetpointManager:SingleZone:Humidity:Maximum`, `SetpointManager:MultiZone:MaximumHumidity:Average`, or `SetpointManager:MultiZone:Humidity:Maximum` and is used by equipment such as `Controller:WaterCoil` (with control variable `TemperatureAndHumidityRatio`) and `Dehumidifier:Desiccant:NoFans`.
- MinimumHumidityRatio references and sets the “System Node Humidity Ratio Min” property. This type of reference setpoint may be set using `SetpointManager:SingleZone:Humidity:Minimum`, `SetpointManager:MultiZone:MinimumHumidity:Average` or `SetpointManager:MultiZone:Humidity:Minimum` and is used by equipment such as `Humidifier:Steam:Electric`.
- HumidityRatio references and sets the “System Node Setpoint Humidity Ratio” property. This type of reference setpoint may be set using (no applicable setpoint managers at this time) and is used by equipment such as `Controller:WaterCoil` (with control variable `HumidityRatio`).

The system node properties listed above are all available as an `Output:Variable` to facilitate tracking these setpoints both at the reference node and the setpoint nodes.

#### 1.49.10.1.3 Field: Minimum Setpoint Temperature

The minimum temperature (in °C) that is allowed by this setpoint manager. Applicable only if Control variable is Temperature.

#### 1.49.10.1.4 Field: Maximum Setpoint Temperature

The maximum temperature (in °C) that is allowed by this setpoint manager. Applicable only if Control variable is Temperature.

#### 1.49.10.1.5 Field: Minimum Setpoint Humidity Ratio

The minimum humidity ratio (kgWater/kgDryAir) that is allowed by this setpoint manager. Applicable only if Control variable is MaximumHumidityRatio, MinimumHumidityRatio, or HumidityRatio. Note that zero is not allowed as the computed setpoint humidity ratio, because zero is used as a special value to indicate that no humidification or dehumidification is needed. If the reference humidity ratio setpoint value is zero, the zero value will be passed directly to the Set Point Node(s).

#### 1.49.10.1.6 Field: Maximum Setpoint Humidity Ratio

The maximum humidity ratio (kgWater/kgDryAir) that is allowed by this set point manager. Applicable only if Control variable is MaximumHumidityRatio, MinimumHumidityRatio, or HumidityRatio.

#### 1.49.10.1.7 Field: Reference Setpoint Node Name

The name of an HVAC system node where the desired mixed air condition has been set. Normally this would be the mixed air node leaving the `OutdoorAir:Mixer`. The temperature or humidity setpoint at this reference node must be set by a different setpoint manager of the appropriate type (see Control Variable above).

#### 1.49.10.1.8 Field: Mixed Air Stream Node Name

The name of the mixed air node. This node is used to obtain the flow rate of the combined air stream. This node is usually the same node at the Reference Setpoint Node Name, but does not have to be.

#### 1.49.10.1.9 Field: Outdoor Air Stream Node Name

The name of a node in the outdoor air stream. This node is used to obtain the flow rate of the outdoor air stream.

**1.49.10.1.10 Field: Return Air Stream Node Name**

The name of a node in the return air stream. This node is used to obtain the flow rate of the return air stream.

**1.49.10.1.11 Field: Setpoint Node or NodeList Name**

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature or humidity ratio setpoints will be established by this setpoint manager. The node name(s) specified here cannot be the same as the Reference Setpoint Node Name in the previous field.

Below is an example input for an Outdoor Air Pretreat Setpoint Manager.

---

```
SetpointManager:OutdoorAirPretreat,
DXSystem 1 Desiccant Set Point Manager,    !- Name
MaximumHumidityRatio,                      !- Control Variable
-99,                                       !- Minimum Setpoint Temperature {C}
99,                                       !- Maximum Setpoint Temperature {C}
0.00001,                                  !- Minimum Setpoint Humidity Ratio (kgWater/kgDryAir)
1.0,                                       !- Maximum Setpoint Humidity Ratio (kgWater/kgDryAir)
DXSystem 1 Fan Air Inlet Node,             !- Reference Setpoint Node Name
DXSystem 1 Mixed Air Node,                 !- Mixed Air Stream Node Name
Heat Recovery Outlet Node,                 !- Outdoor Air Stream Node Name
DXSystem 1 Air Loop Inlet Node,            !- Return Air Stream Node Name
Desiccant Process Outlet Node;             !- Setpoint Node or NodeList Name
```

---

**1.49.11 SetpointManager:Warmest**

The Warmest Setpoint Manager resets the cooling supply air temperature of a central forced air HVAC system according to the cooling demand of the warmest zone. For each zone in the system at each system timestep, the manager calculates a supply air temperature that will meet the zone cooling load at the maximum zone supply air flow rate. The lowest of the possible supply air temperatures becomes the new supply air temperature setpoint, subject to minimum and maximum supply air temperature constraints. The resulting temperature setpoint is the highest supply air temperature that will meet the cooling requirements of all the zones. When compared to a fixed cooling supply air temperature setpoint, this strategy minimizes zone reheat coil energy (or overcooling) and central chiller energy consumption (if the chilled water temperature is also reset) at the cost of possible increased fan energy.

**1.49.11.1 Inputs****1.49.11.1.1 Field: Name**

A unique, user-assigned name for an instance of a warmest setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

**1.49.11.1.2 Field: Control Variable**

The type of variable that will be controlled. Currently there is only one choice: Temperature.

**1.49.11.1.3 Field: HVAC Air Loop Name**

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its cooling supply air temperature.

**1.49.11.1.4 Field: Minimum Setpoint Temperature**

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum.

#### 1.49.11.1.5 Field: Maximum Setpoint Temperature

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint is greater than this value the setpoint is set to the maximum. This value is also used as the setpoint temperature when none of the zones have a cooling load.

#### 1.49.11.1.6 Field: Strategy

Currently, the only choice for this field is MaximumTemperature.

#### 1.49.11.1.7 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Below is an example input for a Warmest Setpoint Manager.

```
SetpointManager:Warmest,
  Supply Air Temperature Manager 1,    !- Name
  Temperature,    !- Control Variable
  VAV Sys 1,    !- HVAC Air Loop Name
  11.2,    !- Minimum Setpoint Temperature
  16.,    !- Maximum Setpoint Temperature
  MaximumTemperature,    !- Strategy
  Supply Air Temp Nodes 1;    !- Setpoint Node or NodeList Name

SetpointManager:MixedAir,
  Mixed Air Temp Manager 1,    !- Name
  Temperature,    !- Control Variable
  VAV Sys 1 Outlet Node,    !- Reference Setpoint Node Name
  Main Heating Coil 1 Outlet Node,    !- Fan Inlet Node Name
  VAV Sys 1 Outlet Node,    !- Fan Outlet Node Name
  Mixed Air Node 1;    !- Setpoint Node or NodeList Name

NodeList, Supply Air Temp Nodes 1,
  VAV Sys 1 Outlet Node; ! Setpoint Node
```

---

### 1.49.12 SetpointManager:Coldest

The Coldest Setpoint Manager is used in dual duct systems to reset the setpoint temperature of the air in the heating supply duct or in single duct systems to reset the setpoint temperature of the air for central heating coils. Usually it is used in conjunction with a **SetpointManager:Warmest** resetting the temperature of the air in the cooling supply duct. For each zone in the system at each system timestep, the manager calculates a supply air temperature that will meet the zone heating load at the maximum zone supply air flow rate. The highest of the possible supply air temperatures becomes the new supply air temperature setpoint, subject to minimum and maximum supply air temperature constraints. The resulting temperature setpoint is the lowest supply air temperature that will meet the heating requirements of all the zones. When compared to a fixed heating supply air temperature setpoint, this strategy minimizes central boiler energy consumption (if the hot water temperature is also reset or there are variable speed pumps) at the cost of possible increased fan energy (if there is variable volume control in the air system).

#### 1.49.12.1 Inputs

##### 1.49.12.1.1 Field: Name

A unique, user-assigned name for an instance of a coldest setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

**1.49.12.1.2 Field: Control Variable**

The type of variable that will be controlled. Currently there is only one choice: Temperature.

**1.49.12.1.3 Field: HVAC Air Loop Name**

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its heating supply air temperature.

**1.49.12.1.4 Field: Minimum Setpoint Temperature**

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. This value is also used as the setpoint temperature when none of the zones have a heating load.

**1.49.12.1.5 Field: Maximum Setpoint Temperature**

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint is greater than this value the setpoint is set to the maximum.

**1.49.12.1.6 Field: Strategy**

Currently, the only choice for this field is MinimumTemperature.

**1.49.12.1.7 Field: Setpoint Node or NodeList Name**

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Below is an example input for a Coldest Setpoint Manager.

```

Controller:Simple,
  Central Cooling Coil Controller 1,    !- Name
  Temperature,    !- Control Variable
  Reverse,    !- Action
  Flow,    !- Actuator Variable
  VAV Sys 1 Cold Outlet Node,    !- Sensor Node Name
  Main Cooling Coil 1 Water Inlet Node,    !- Actuator Node Name
  0.001,    !- Controller Convergence Tolerance {deltaC}
  autosize, !- Maximum Actuated Flow {m3/s}
  0.0;    !- Minimum Actuated Flow {m3/s}

Controller:WaterCoil,
  Central Heating Coil Controller 1,    !- Name
  Temperature,    !- Control Variable
  Normal,    !- Action
  Flow,    !- Actuator Variable
  VAV Sys 1 Hot Outlet Node,    !- Sensor Node Name
  Main Heating Coil 1 Water Inlet Node,    !- Actuator Node Name
  0.001,    !- Controller Convergence Tolerance {deltaC}
  autosize, !- Maximum Actuated Flow {m3/s}
  0.0;    !- Minimum Actuated Flow {m3/s}

SetpointManager:Warmest,
  Supply Air Temperature Manager 1,    !- Name
  Temperature,    !- Control Variable
  VAV Sys 1,    !- HVAC Air Loop Name
  11.2,    !- Minimum Setpoint Temperature {C}
  16.,    !- Maximum Setpoint Temperature {C}
  MaximumTemperature,    !- Strategy
  Supply Air Temp Nodes 1;    !- Setpoint Node or NodeList Name

NodeList,

```

```

NodeList,
Supply Air Temp Nodes 2,      !- Name
VAV Sys 1 Hot Outlet Node;    !- Node 1 Name

```

---

### 1.49.13 SetpointManager:ReturnAirBypassFlow

This manager is user in conjunction with a return air bypass configuration. This type of air system is basically a standard single duct system with the addition of a bypass duct that bypasses return air around the main system components in particular, the central cooling coil. This allows the central cooling coil to sufficiently dehumidify the mixed air; the bypassed air is then added to the supply air stream to bring the supply air temperature up to the desired temperature set point. This scheme is very useful in situations where an higher than normal supply air temperature is used for instance, in underfloor air distribution systems.

This manager relies on the program to figure out the system configuration and to extract the needed data from the system nodes. All the user needs to input is the name of the air system and a schedule giving the desired supply air temperature setpoint. No node names are required. The manager will establish a bypass air flow rate that upon mixing with the non-bypassed air will yield the temperature given in the schedule.

#### 1.49.13.1 Inputs

##### 1.49.13.1.1 Field: Name

A unique, user-assigned name for an instance of an Return Air Bypass Flow setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

##### 1.49.13.1.2 Field: Control Variable

The type of variable that will be controlled. Currently there is only one choice: Flow.

##### 1.49.13.1.3 Field: HVAC Air Loop Name

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its return air bypass flow rate.

##### 1.49.13.1.4 Field: Temperature Setpoint Schedule Name

The name of a schedule whose values are temperatures in °C. The schedule value for the time period is the setpoint for this type of setpoint manager. The setpoint is assumed to be at the air handler outlet.

The following shows an example input for SetpointManager:ReturnAirBypassFlow.

```

SetpointManager:ReturnAirBypassFlow,
RETURN AIR BYPASS Manager 1,      !- Name
Flow,      !- Control Variable

```

---

```
VAV Sys 1,      !- HVAC Air Loop Name
Seasonal Reset Supply Air Temp Sch;    !- Temperature Setpoint Schedule Name
```

---

### 1.49.14 SetpointManager:WarmestTemperatureFlow

The Warmest Temperature Flow Setpoint Manager resets the cooling supply air temperature of a central forced air HVAC system according to the cooling demand of the warmest zone. The user can select one of two strategies: *TemperatureFirst* or *FlowFirst*.

For *TemperatureFirst* the manager tries to find the highest setpoint temperature that will satisfy all the zone cooling loads at minimum supply air flow rate. If this setpoint temperature is less than the minimum, the setpoint temperature is set to the minimum, and the supply air flow rate is increased to meet the loads.

For *FlowFirst* the manager tries to find the lowest supply air flow rate that will satisfy all the zone cooling loads at the maximum setpoint temperature. If this flow is greater than the maximum, the flow is set to the maximum and the setpoint temperature is reduced to satisfy the cooling loads.

When compared to a fixed cooling supply air temperature setpoint, the *TemperatureFirst* strategy minimizes fan energy at the cost of possible increased zone reheat coil energy (or overcooling) and central chiller energy consumption, whereas the *FlowFirst* strategy minimizes zone reheat coil energy (or overcooling) and central chiller energy consumption at the cost of possible increased fan energy.

#### 1.49.14.1 Inputs

##### 1.49.14.1.1 Field: Name

A unique, user-assigned name for an instance of this setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

##### 1.49.14.1.2 Field: Control Variable

The type of variable that will be controlled. For this setpoint manager, this input should be Temperature.

##### 1.49.14.1.3 Field: HVAC Air Loop Name

he name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its cooling supply air temperature.

##### 1.49.14.1.4 Field: Minimum Setpoint Temperature

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum.

##### 1.49.14.1.5 Field: Maximum Setpoint Temperature

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint is greater than this value the setpoint is set to the maximum. This value is also used as the setpoint temperature when none of the zones have a cooling load.

##### 1.49.14.1.6 Field: Strategy

The choices for this field are *TemperatureFirst* and *FlowFirst*. See discussion above for a description of what each strategy does.

##### 1.49.14.1.7 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

#### 1.49.14.1.8 Field: Minimum Turndown Ratio

The minimum value of the ratio of the actual air flow rate to the maximum air flow rate, either for the supply fan if there are no VAV terminal boxes, or for the VAV boxes if present. If there are VAV boxes, it is assumed that the same value of minimum turndown applies to all boxes.

Below is an example input for a **SetpointManager:Warmest**TemperatureFlow object.

```
SetpointManager:WarmestTemperatureFlow,
  Supply Air Temperature Manager 1,    !- Name
  Temperature,                        !- Control Variable
  VAV Sys 1,                          !- HVAC Air Loop Name
  11.2,                               !- Minimum Setpoint Temperature
  16.,                                !- Maximum Setpoint Temperature
  TemperatureFirst,                   !- Strategy
  Supply Air Temp Nodes 1,            !- Setpoint Node or NodeList Name
  0.3;                                !- Minimum Turndown Ratio

SetpointManager:MixedAir,
  Mixed Air Temp Manager 1,           !- Name
  Temperature,                        !- Control Variable
  VAV Sys 1 Outlet Node,              !- Reference Setpoint Node Name
  Main Heating Coil 1 Outlet Node,    !- Fan Inlet Node Name
  VAV Sys 1 Outlet Node,              !- Fan Outlet Node Name
  Mixed Air Node 1;                   !- Setpoint Node or NodeList Name

NodeList, Supply Air Temp Nodes 1,
  VAV Sys 1 Outlet Node; ! Set Point Node
```

---

### 1.49.14.2 Outputs

#### 1.49.14.2.1 Setpoint Manager Warmest Temperature Critical Zone Number []

This is the number of the zone that was the critical zone for the setpoint manager.

#### 1.49.14.2.2 Setpoint Manager Warmest Temperature Turndown Flow Fraction []

This is the fraction that flow was reduced by the setpoint manager. This is the actual air flow rate divided by the maximum air flow rate.

### 1.49.15 SetpointManager:MultiZone:Cooling:Average

This setpoint manager is used to establish a supply air temperature setpoint for a central forced air HVAC system (air loop) based on the predicted sensible cooling loads and actual supply air mass flow rates for all zones served by the system. For all controlled zones in the air loop (i.e., zones with a thermostat object), the setpoint manager calculates an average supply air temperature that will meet the zone cooling loads based on the actual zone supply air mass flow rates (lagged by one time step). The calculated setpoint temperature is subject to the minimum and maximum setpoint temperature constraints specified by the user. When compared to a fixed cooling supply air temperature setpoint, this strategy may reduce zone reheat coil energy (or overcooling) and central chiller energy consumption (if the chilled water temperature is also reset) at the cost of possible increased fan energy.

#### 1.49.15.1 Inputs

##### 1.49.15.1.1 Field: Name

A unique, user-assigned name for an instance of this multizone average cooling setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

**1.49.15.1.2 Field: HVAC Air Loop Name**

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its cooling supply air temperature.

**1.49.15.1.3 Field: Minimum Setpoint Temperature**

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. The default value is 12C.

**1.49.15.1.4 Field: Maximum Setpoint Temperature**

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is greater than this value, the setpoint is set to this maximum value. The default value is 18C.

**1.49.15.1.5 Field: Setpoint Node or NodeList Name**

The name of a **NodeList** object containing the names of the HVAC system nodes, or the HVAC System Node Name, for which temperature setpoints will be established by this setpoint manager.

Below is an example of this object in an input file.

```
SetpointManager:MultiZone:Cooling:Average,
Cooling Coil Air Sys Branch Set Point,    !- Name
Main Dual Duct Air Loop, !- HVAC Air Loop Name
12.0,                                     !- Minimum Setpoint Temperature {C}
22.0,                                     !- Maximum Setpoint Temperature {C}
Cooling Coil Supply Air Temp Nodes;    !- Setpoint Node or NodeList Name
```

**1.49.16 SetpointManager:MultiZone:Heating:Average**

This setpoint manager is used to establish a supply air temperature setpoint for a central forced air HVAC system (air loop) based on the predicted sensible heating loads and actual supply air mass flow rates for all zones served by the system. For all controlled zones in the air loop (i.e., zones with a thermostat object), the setpoint manager calculates an average supply air temperature that will meet the zone heating loads based on the actual zone supply air mass flow rates (lagged by one time step). The calculated setpoint temperature is subject to the minimum and maximum setpoint temperature constraints specified by the user. When compared to a fixed heating supply air temperature setpoint, this strategy may reduce central boiler energy consumption (if the hot water temperature is also reset or there are variable speed pumps) at the cost of possible increased fan energy (if there is variable volume control for the air system).

**1.49.16.1 Inputs****1.49.16.1.1 Field: Name**

A unique, user-assigned name for an instance of a multizone average heating setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

**1.49.16.1.2 Field: HVAC Air Loop Name**

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its heating supply air temperature.

**1.49.16.1.3 Field: Minimum Setpoint Temperature**

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. The default value is 20C.

#### 1.49.16.1.4 Field: Maximum Setpoint Temperature

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is greater than this value, the setpoint is set to this maximum value. The default value is 50C.

#### 1.49.16.1.5 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes, or the HVAC System Node Name, for which temperature setpoints will be established by this setpoint manager.

Below is an example of this object in an input file.

```
SetpointManager:MultiZone:Heating:Average,
  Heating Coil Air Sys Branch Set Point,    !- Name
  Main Dual Duct Air Loop, !- HVAC Air Loop Name
  24.0,                                     !- Minimum Setpoint Temperature {C}
  41.0,                                     !- Maximum Setpoint Temperature {C}
  Heating Coil Supply Air Temp Nodes;       !- Setpoint Node or NodeList Name
```

### 1.49.17 SetpointManager:MultiZone:MinimumHumidity:Average

This setpoint manager allows for controlling the minimum humidity level in multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, used in conjunction with one or more **ZoneControl:Humidistat** objects, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate an average supply air humidity ratio needed to maintain the zone relative humidity levels near their respective humidifying setpoints. The calculated humidity ratio is then used as the minimum humidity ratio setpoint for the designated setpoint node(s). A humidification component (e.g., **Humidifier:Steam:Electric**) placed upstream of the setpoint node can then use the minimum humidity ratio setpoint to control humidification rate. The use of this object requires that a **ZoneControl:Humidistat** object be specified with a humidifying relative humidity schedule for one or more controlled zones served by the HVAC air loop.

#### 1.49.17.1 Inputs

##### 1.49.17.1.1 Field: Name

A unique, user-assigned name for an instance of an average minimum humidity (humidifying) multizone setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

##### 1.49.17.1.2 Field: HVAC Air Loop Name

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its humidification setpoint (minimum air humidity ratio).

##### 1.49.17.1.3 Field: Minimum Setpoint Humidity Ratio

The minimum humidity ratio (kgWater/kgDryAir) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value. The default value is 0.005 (kgWater/kgDryAir).

##### 1.49.17.1.4 Field: Maximum Setpoint Humidity Ratio

The maximum humidity ratio (kgWater/kgDryAir) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value. The default value is 0.012 (kgWater/kgDryAir).

### 1.49.17.1.5 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes, or the HVAC System Node Name, for which humidity ratio setpoints will be established by this setpoint manager.

An example of this object in an input data file (IDF), along with a humidistat object, is shown below.

```
SetpointManager:MultiZone:MinimumHumidity:Average,
  VAV_1 Humidifier HUMRAT setpoint, !- Name
  VAV_1,                               !- HVAC Air Loop Name
  0.003,                               !- Minimum Setpoint Humidity Ratio (
    kgWater/kgDryAir)
  0.012,                               !- Maximum Setpoint Humidity Ratio (
    kgWater/kgDryAir)
  VAV_1 Humidifier-Outlet Nodes List;    !- Setpoint Node or NodeList Name

ZoneControl:Humidistat,
  ICU_NURSESTN_LOBBY_FLR_2 Humidistat, !- Name
  ICU_NURSESTN_LOBBY_FLR_2,           !- Zone Name
  MinRelHumSetSch,                    !- Humidifying Relative Humidity Setpoint Schedule Name
  MaxRelHumSetSch;                    !- Dehumidifying Relative Humidity Setpoint Schedule Name
```

## 1.49.18 SetpointManager:MultiZone:MaximumHumidity:Average

This setpoint manager allows for controlling the maximum humidity level is multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, used in conjunction with one or more **ZoneControl:Humidistat** objects, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate an average supply air humidity ratio needed to maintain the zone relative humidity levels near their respective dehumidifying setpoints. The calculated humidity ratio is then used as the maximum humidity ratio setpoint for the designated setpoint node(s). A dehumidification component (e.g., desiccant dehumidifiers) placed upstream of the setpoint node can then use the maximum humidity ratio setpoint to control its moisture removal rate. The use of this object requires that a **ZoneControl:Humidistat** object be specified with a dehumidifying relative humidity schedule for one or more controlled zones served by the HVAC air loop.

In the case of a chilled water coil which is used for both temperature and high humidity control, this setpoint manager works in conjunction with a **Controller:WaterCoil** object to determine the supply air temperature required to meet both the temperature (sensible) and humidity (latent) load in the control zone. See object **Controller:WaterCoil** in the EnergyPlus Engineering Reference for a detailed discussion of how this is achieved.

### 1.49.18.1 Inputs

#### 1.49.18.1.1 Field: Name

A unique, user-assigned name for an instance of an average maximum humidity ratio (dehumidifying) multizone setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.18.1.2 Field: HVAC Air Loop Name

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its dehumidification setpoint (maximum air humidity ratio).

#### 1.49.18.1.3 Field: Minimum Setpoint Humidity Ratio

The minimum humidity ratio (kgWater/kgDryAir) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value. The default value is 0.008 (kgWater/kgDryAir).

#### 1.49.18.1.4 Field: Maximum Setpoint Humidity Ratio

The maximum humidity ratio (kgWater/kgDryAir) that is allowed by this set point manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value. The default value is 0.015 (kgWater/kgDryAir).

#### 1.49.18.1.5 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes, or the HVAC System Node Name, for which humidity ratio setpoints will be established by this setpoint manager.

An example of this object in an input data file (IDF), along with a humidistat object, is shown below:

```
SetpointManager:MultiZone:MaximumHumidity:Average,
  VAV_1_CoolC HUMRAT setpoint,          !- Name
  VAV_1,                                !- HVAC Air Loop Name
  0.005,                                !- Minimum Setpoint Humidity Ratio (
    kgWater/kgDryAir)
  0.015,                                !- Maximum Setpoint Humidity Ratio (
    kgWater/kgDryAir)
  VAV_1 Dehumidifier-Outlet Nodes List;  !- Setpoint Node or NodeList Name

ZoneControl:Humidistat,
  ICU_NURSESTN_LOBBY_FLR_2 Humidistat, !- Name
  ICU_NURSESTN_LOBBY_FLR_2,           !- Zone Name
  MinRelHumSetSch,                     !- Humidifying Relative Humidity Setpoint Schedule Name
  MaxRelHumSetSch;                     !- Dehumidifying Relative Humidity Setpoint Schedule Name
```

### 1.49.19 SetpointManager:MultiZone:Humidity:Minimum

This setpoint manager allows for controlling the minimum humidity level in multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, used in conjunction with one or more **ZoneControl:Humidistat** objects, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate a supply air minimum humidity ratio based on a zone with the critical humidification requirement (i.e., a zone with the highest humidity ratio setpoint) to maintain the zone relative humidity levels near their respective humidifying setpoints. The calculated humidity ratio is then used as the minimum humidity ratio setpoint for the designated setpoint node(s). A humidification component (e.g., **Humidifier:Steam:Electric**) placed upstream of the setpoint node can then use the minimum humidity ratio setpoint to control humidification rate. The use of this object requires that a **ZoneControl:Humidistat** object be specified with a humidifying relative humidity schedule for one or more controlled zones served by the HVAC air loop. If **ZoneControl:Humidistat** object is defined for only one of the zones served by the air loop then the SetpointManager:MultiZone:Humidity:Minimum perform as SepointManager:SingleZone:Humidity:Minimum.

#### 1.49.19.1 Inputs

##### 1.49.19.1.1 Field: Name

A unique, user-assigned name for an instance of a multizone minimum humidity (humidifying) setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

**1.49.19.1.2 Field: HVAC Air Loop Name**

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its humidification setpoint (minimum air humidity ratio).

**1.49.19.1.3 Field: Minimum Setpoint Humidity Ratio**

The minimum humidity ratio (kgWater/kgDryAir) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value. The default value is 0.005 (kgWater/kgDryAir).

**1.49.19.1.4 Field: Maximum Setpoint Humidity Ratio**

The maximum humidity ratio (kgWater/kgDryAir) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value. The default value is 0.012 (kgWater/kgDryAir).

**1.49.19.1.5 Field: Setpoint Node or NodeList Name**

The name of a **NodeList** object containing the names of the HVAC system nodes, or the HVAC System Node Name, for which humidity ratio setpoints will be established by this setpoint manager.

An example of this object in an input data file (IDF), along with a humidistat object, is shown below.

```
SetpointManager:MultiZone:Humidity:Minimum,
Main Humidifier setpoint Mgr,      !- Name
VAV Sys 1,                        !- HVAC Air Loop Name
0.003,                            !- Minimum Setpoint Humidity Ratio (kgWater/
kgDryAir)
0.015,                            !- Maximum Setpoint Humidity Ratio (kgWater/
kgDryAir)
Main Humidifier Outlet Node;      !- Setpoint Node or NodeList Name

ZoneControl:Humidistat,
Space5-1 Humidistat,             !- Name
SPACES5-1,                       !- Zone Name
HumidifyingHumSetSch,            !- Humidifying Relative Humidity Setpoint Schedule Name
DehumidifyingHumSetSch;          !- Dehumidifying Relative Humidity Setpoint Schedule Name
```

---

**1.49.20 SetpointManager:MultiZone:Humidity:Maximum**

This setpoint manager allows for controlling the maximum humidity level in multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, used in conjunction with one or more **ZoneControl:Humidistat** objects, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate the maximum supply air humidity ratio based on a zone with the critical dehumidification requirement (i.e., a zone with the lowest humidity ratio setpoint) to maintain the zone relative humidity levels near their respective dehumidifying setpoints. The calculated humidity ratio is then used as the maximum humidity ratio setpoint for the designated setpoint node(s). A dehumidification component (e.g., desiccant dehumidifiers) placed upstream of the setpoint node can then use the maximum humidity ratio setpoint to control its moisture removal rate. The use of this object requires that a **ZoneControl:Humidistat** object be specified with a dehumidifying relative humidity schedule for one or more controlled zones served by the HVAC air loop. If **ZoneControl:Humidistat** object is defined for only one of the zones served by the air loop then the SetpointManager:MultiZone:Humidity:Maximum perform as **SetpointManager:SingleZone:Humidity:Maximum**.

In the case of a chilled water coil which is used for both temperature and high humidity control, this setpoint manager works in conjunction with a **Controller:WaterCoil** object to determine the supply air

temperature required to meet both the temperature (sensible) and dehumidification (latent) load in the control zone. See object **Controller:WaterCoil** in the EnergyPlus Engineering Reference for a detailed discussion of how this is achieved.

### 1.49.20.1 Inputs

#### 1.49.20.1.1 Field: Name

A unique, user-assigned name for an instance of a multizone maximum humidity ratio (dehumidifying) setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.20.1.2 Field: HVAC Air Loop Name

The name of the **AirLoopHVAC** object (the central air system) which will use this setpoint manager to set its dehumidification setpoint (maximum air humidity ratio).

#### 1.49.20.1.3 Field: Minimum Setpoint Humidity Ratio

The minimum humidity ratio (kgWater/kgDryAir) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value. The default value is 0.008 (kgWater/kgDryAir).

#### 1.49.20.1.4 Field: Maximum Setpoint Humidity Ratio

The maximum humidity ratio (kgWater/kgDryAir) that is allowed by this set point manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value. The default value is 0.015 (kgWater/kgDryAir).

#### 1.49.20.1.5 Field: Setpoint Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes, or the HVAC System Node Name, for which humidity ratio setpoints will be established by this setpoint manager.

An example of this object in an input data file (IDF), along with a humidistat object, is shown below.

```
SetpointManager:MultiZone:Humidity:Maximum,
Maximum Mzone HUMRAT setpoint,      !- Name
VAV Sys 1,                          !- HVAC Air Loop Name
0.003,                              !- Minimum Setpoint Humidity Ratio (kgWater/
kgDryAir)
0.015,                              !- Maximum Setpoint Humidity Ratio (kgWater/
kgDryAir)
Dehumidifier-Outlet Nodes;          !- Setpoint Node or NodeList Name

ZoneControl:Humidistat,
Space5-1 Humidistat,                !- Name
SPACE5-1,                          !- Zone Name
HumidifyingHumSetSch,              !- Humidifying Relative Humidity Setpoint Schedule Name
```

## 1.49.21 SetpointManager:FollowOutdoorAirTemperature

This setpoint manager is used to place a temperature setpoint on a system node that is derived from the current outdoor air environmental conditions. The outdoor air conditions are obtained from the weather information during the simulation.

**1.49.21.1 Inputs****1.49.21.1.1 Field: Name**

A unique user-defined name for an instance of this setpoint manager.

**1.49.21.1.2 Field: Control Variable**

The type of variable that will be controlled. There are three choices available: Temperature, MaximumTemperature, or MinimumTemperature.

**1.49.21.1.3 Field: Reference Temperature Type**

The field specifies the type of temperature value to obtain from the system node referenced in the previous field. The two available options are OutdoorDryBulb and OutdoorWetBulb.

**1.49.21.1.4 Field: Offset Temperature Difference**

This field provides a temperature offset that will be applied to the value of the reference temperature (outdoor air wetbulb/drybulb). If this value is zero, and the limits are met, then the resulting setpoint will be exactly the same as the outdoor air wetbulb/drybulb temperature. The sign convention is that a positive value here will increase the resulting setpoint to higher than the outdoor air wetbulb/drybulb.

**1.49.21.1.5 Field: Maximum Setpoint Temperature**

This field provides an upper limit to the resulting setpoint value.

**1.49.21.1.6 Field: Minimum Setpoint Temperature**

This field provides a lower limit to the resulting setpoint value.

**1.49.21.1.7 Field: Setpoint Node or NodeList Name**

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which setpoints will be established by this setpoint manager.

An IDF example of use:

```
SetpointManager:FollowOutdoorAirTemperature,
MyCondenserControl,           !- Name
Temperature,                  !- Control Variable
OutdoorAirDryBulb,            !- Reference Temperature Type
0.5,                          !- Offset Temperature Difference {deltaC}
200,                          !- Maximum Setpoint Temperature {C}
21.1,                         !- Minimum Setpoint Temperature {C}
CondSupplyOutletNode;         !- Setpoint Node or NodeList Name
```

**1.49.22 SetpointManager:FollowSystemNodeTemperature**

This setpoint manager is used to place a temperature setpoint on a system node that is derived from the current temperatures at a separate system node. The current value of the temperature at a reference node is obtained and used to generate setpoint on a second system node. If the reference node is also designated to be an outdoor air (intake) node, then this setpoint manager can be used to follow outdoor air conditions that are adjusted for altitude.

**1.49.22.1 Inputs****1.49.22.1.1 Field: Name**

A unique user-defined name for an instance of this setpoint manager.

#### 1.49.22.1.2 Field: Control Variable

The type of variable that will be controlled. There are three choices available: Temperature, MaximumTemperature, or MinimumTemperature.

#### 1.49.22.1.3 Field: Reference Node Name

The name of a system node where this setpoint manager will obtain a reference temperature to follow. Note that the temperature to be obtained is the current temperature on the node and not the current value of a temperature *setpoint*.

#### 1.49.22.1.4 Field: Reference Temperature Type

The field specifies the type of temperature value to obtain from the system node referenced in the previous field. The two available options are NodeDryBulb and NodeWetBulb.

#### 1.49.22.1.5 Field: Offset Temperature Difference

This field provides a temperature offset that will be applied to the value obtained from the reference system node. If this value is zero, and the limits are met, then the resulting setpoint will be exactly the same as the reference system node temperature. The sign convention is that a positive value here will increase the resulting setpoint to higher than the temperature at the reference node.

#### 1.49.22.1.6 Field: Maximum Limit Setpoint Temperature

This field provides an upper limit to the resulting setpoint value.

#### 1.49.22.1.7 Field: Minimum Limit Setpoint Temperature

This field provides a lower limit to the resulting setpoint value.

#### 1.49.22.1.8 Field: Setpoint System Node or NodeList Name

The name of a **NodeList** object containing the names of the HVAC system nodes or the HVAC System Node Name for which setpoints will be established by this setpoint manager.

An IDF example of use:

```
SetpointManager:FollowSystemNodeTemperature,
  MyCondenserControl,      !- Name
  Temperature,             !- Control Variable
  MyOAinletNode,           !- Reference Node Name
  NodeDryBulb,             !- Reference Temperature Type
  0.5,                    !- Offset Temperature Difference {deltaC}
  200,                    !- Maximum Setpoint Temperature {C}
  24.0,                   !- Minimum Setpoint Temperature {C}
  CondSupplyOutletNode;    !- Setpoint Node or NodeList Name
```

---

### 1.49.23 SetpointManager:FollowGroundTemperature

This setpoint manager is used to place a temperature setpoint on a system node that is derived from a current ground temperature. The ground temperatures are specified in different Site:GroundTemperature:\* objects and used during the simulation. This setpoint manager is primarily intended for condenser or plant loops using some type of ground heat exchanger.

#### 1.49.23.1 Inputs

##### 1.49.23.1.1 Field: Name

A unique user-defined name for an instance of this setpoint manager.

**1.49.23.1.2 Field: Control Variable**

The type of variable that will be controlled. There are three choices available: Temperature, MaximumTemperature, or MinimumTemperature.

**1.49.23.1.3 Field: Reference Ground Temperature Object Type**

This field is used to specify the type of ground temperature to be used by the setpoint manager. There are four options, `Site:GroundTemperature:BuildingSurface`, `Site:GroundTemperature:Shallow`, `Site:GroundTemperature:Deep`, or `Site:GroundTemperature:FCfactorMethod`. Generally the deep ground temperatures are the most useful for a plant loop serving a vertical borehole ground heat exchanger.

**1.49.23.1.4 Field: Offset Temperature Difference**

This field provides a temperature offset that will be applied to the value of the ground temperature. If this value is zero, and the limits are met, then the resulting setpoint will be exactly the same as the ground temperature. The sign convention is that a positive value here will increase the resulting setpoint to higher than the ground temperature.

**1.49.23.1.5 Field: Maximum Setpoint Temperature**

This field provides an upper limit to the resulting setpoint value.

**1.49.23.1.6 Field: Minimum Setpoint Temperature**

This field provides a lower limit to the resulting setpoint value.

**1.49.23.1.7 Field: Setpoint System Node or NodeList Name**

The name of a `NodeList` object containing the names of the HVAC system nodes or the HVAC System Node Name for which setpoints will be established by this setpoint manager.

An IDF example of use:

```
SetpointManager:FollowGroundTemperature,
  MyCondenserControl,           !- Name
  Temperature,                  !- Control Variable
  Site:GroundTemperature:Deep, !- Reference Ground Temperature Object Type
  1.5,                           !- Offset Temperature Difference {deltaC}
  50.0,                           !- Maximum Setpoint Temperature {C}
  10.0,                           !- Minimum Setpoint Temperature {C}
  CondSupplyOutletNode;          !- Setpoint Node or NodeList Name
```

**1.49.24 SetpointManager:CondenserEnteringReset**

The object resets the condenser entering water temperature setpoint to the optimal setpoint temperature that will result in minimum net energy consumption for the chiller and cooling tower plant. This chiller-tower optimization scheme uses one curve to determine the optimum condenser entering water temperature for a given time step and two other curves to place limit conditions on the optimized setpoint value. Note that this object will work with only one cooling tower object in a plant loop.

**1.49.24.1 Inputs****1.49.24.1.1 Field: Name**

A unique, user assigned name for an instance of the optimized condenser entering water setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

**1.49.24.1.2 Field: Control variable**

The type of variable that will be controlled. The only valid choice for this setpoint manager is **Temperature**.

**1.49.24.1.3 Field: Default Condenser Entering Water Temperature Schedule Name**

This schedule should define the default condenser entering water temperature setpoint. This scheduled setpoint value is only used in a given time step if the optimized setpoint value (see the Optimized Condenser Entering Water Temperature Curve Name field) does not fall within its prescribed boundary conditions.

**1.49.24.1.4 Field: Minimum Design Wetbulb Temperature Curve Name**

The curve name associated with the coefficients in the equation used to determine the minimum design tower wetbulb referenced by the minimum outside air wetbulb temperature curve below. The value from this curve is compared to the tower design wet bulb each timestep to establish one of the governing boundaries over the optimized condenser entering water temperature setpoint calculation. This curve must be quad-linear (**Curve:QuadLinear**) and is defined as:

$$T = C_1 + C_2 \cdot OaWb + C_3 \cdot WPLR + C_4 TwrWb + C_5 NF \quad (1.206)$$

where,

OaWb = Outside air wet bulb for current timestep, °C

WPLR = Weighted Part Load Ratio, dimensionless

TwrWb = Design tower wet bulb boundary condition, °C

NF = Normalized condenser water flow per unit of tower capacity, m3/s-W

**1.49.24.1.5 Field: Minimum Outside Air Wetbulb Temperature Curve Name**

The curve name associated with the coefficients in the equation used to determine the minimum actual wetbulb referenced by the optimized condenser entering water temperature curve. The value from this curve is compared the actual outside wet bulb each timestep to establish one of the governing boundaries over the optimized condenser entering water temperature setpoint calculation. This curve must be quad-linear (**Curve:QuadLinear**) and is defined as:

$$T = C_1 + C_2 \cdot MinWb + C_3 \cdot WPLR + C_4 \cdot TwrWb + C_5 NF \quad (1.207)$$

Where

MinWb = Minimum design wetbulb for current timestep, °C

WPLR = Weighted Part Load Ratio, dimensionless

TwrWb = Design tower wet bulb boundary condition, °C

NF = Normalized condenser water flow per unit of tower capacity, m3/s-W

**1.49.24.1.6 Field: Optimized Condenser Entering Temperature Curve Name**

The curve name associated with the coefficients in the optimized condenser entering water temperature equation. The value from this curve is used to calculate the optimized condenser entering water temperature for each timestep. If this optimized setpoint does not fall within the bounds established by the two boundary conditions, then the value from the Default Condenser Entering Water Temperature Schedule is used for the Condenser Entering Water Setpoint for that timestep. This curve must be quad-linear (**Curve:QuadLinear**) and is defined as:

$$T = C_1 + C_2 OaWb + C_3 WPLR + C_4 TwrWb + C_5 NF \quad (1.208)$$

where,

OaWb = Outside air wet bulb for current timestep, °C

WPLR = Weighted Part Load Ratio, dimensionless

TwrWb = Design tower wet bulb boundary condition, °C

NF = Normalized condenser water flow per unit of tower capacity, m<sup>3</sup>/s-W

#### 1.49.24.1.7 Field: Minimum Lift

This field establishes the minimum Lift allowed. Lift is generally thought of as the difference between condenser refrigerant pressure and the evaporator refrigerant pressure. Using defined pressure and temperature relationships, lift also can be related to the difference between the leaving chilled water and the leaving condenser water temperature. Further, when the leaving condenser water temperature and condenser water flow are constant, the entering condenser temperature can be used as a proxy for lift. Because most condenser water systems are designed for constant flow, entering condenser temperature is the most common metric for lift, and that is what meant here. If the calculated Condenser Entering Water Setpoint falls below (TEvapLvgWater+ MinimumLift), then the Condenser Entering Water Setpoint is reset to equal TEvapLvgWater+ MinimumLift. The units for this field are deg C TD. Default is 11.1 °C (20 F).

#### 1.49.24.1.8 Field: Maximum Condenser Entering Temperature

This field establishes the maximum condenser entering water setpoint temperature allowed. If the scheduled or calculated setpoint is above TCondEntMax, then TCondEntSetpoint is reset to equal TCondEntMax. The units for this field are deg C.

#### 1.49.24.1.9 Field: Cooling Tower Design Inlet Air Wet-Bulb Temperature

This field defines the reference wet bulb temperature used to size the cooling tower. Typically, the design condenser entering water temperature equals TwrRefOaWb + TowerApproachTD. The units for this field are deg C.

#### 1.49.24.1.10 Field: Setpoint Node or Node List Name

This field defines the condenser node being controlled.

Below is an example input for a CondenserEnteringReset Setpoint Manager.

```
SetpointManager:CondenserEnteringReset,
Condenser Optimized Setpoint Manager,  !- Name
Temperature,                          !- Control Variable
DefaultCondEntSch,                    !- Default Condenser Entering Water Temperature Schedule Name
MinDsnWBCurveName,                   !- Minimum Design Wetbulb Temperature Curve Name
MinActWBCurveName,                   !- Minimum Outside Air Wetbulb Temperature Curve Name
OptCondEntCurveName,                 !- Optimized Cond Entering Water Temperature Curve Name
12,                                  !- Minimum Lift, C
32,                                  !- Maximum Condenser Entering Water Temp, C
25.56,                               !- Cooling Tower Design Inlet Air Wetbulb Temperature, C
Cond Water Setpoint Node;            !- Setpoint Node or Node List Name
```

### 1.49.25 SetpointManager:CondenserEnteringReset:Ideal

The object determines a near-optimal condenser water entering setpoint at each time step that will result in minimum net energy consumption for the chiller and coolingtower plant. The ideal chiller-tower optimization scheme uses a search algorithm to find the ideal optimal setpoint at a given timestep. Note that this object will work with only one chiller object and only one cooling tower object in a plant loop.

### 1.49.25.1 Inputs

#### 1.49.25.1.1 Field: Name

A unique, user assigned name for an instance of the optimized condenser entering water setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

#### 1.49.25.1.2 Field: Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **Temperature**.

#### 1.49.25.1.3 Field: Minimum Lift

This field establishes the minimum lift allowed. Lift is generally thought of as the difference between condenser refrigerant pressure and the evaporator refrigerant pressure. Using defined pressure and temperature relationships, lift also can be related to the difference between the leaving chilled water and the leaving condenser water temperature. Further, when the leaving condenser water temperature and condenser water flow are constant, the entering condenser temperature can be used as a proxy for lift. Because most condenser water systems are designed for constant flow, entering condenser temperature is the most common metric for lift, and that is what meant here. If the optimized condenser entering water setpoint falls below leaving evaporator water temperature plus minimum lift, then the condenser entering water setpoint is reset to equal this field value plus leaving evaporator water temperature. This determines the minimum boundary of condenser entering water setpoint. The unit for this field is deg C TD. Default is 11.1 deg C (20 deg F).

#### 1.49.25.1.4 Field: Maximum Condenser Entering Water Temperature

This field establishes the maximum condenser entering water setpoint temperature allowed. If the optimized condenser entering water setpoint is above this field value, then the condenser entering water setpoint is reset to equal this field value. The units for this field are deg C. Default is 34 deg C

#### 1.49.25.1.5 Field: Setpoint Node or Node List Name

This field defines the condenser node being controlled.

Below is an example input for a IdealCondenserEnteringReset Setpoint Manager.

```
SetpointManager:CondenserEnteringReset:Ideal,
Condenser Optimized Setpoint Manager,    !- Name
Temperature,                             !- Control Variable
12,                                       !- Minimum Lift, C
32,                                       !- Maximum Condenser Entering Water Temp, C
Cond Water Setpoint Node;    !- Setpoint Node or Node List Name
```

## 1.49.26 SetpointManager:SingleZone:OneStageCooling

The single-zone, one-stage cooling setpoint manager allows a component to be controlled based on thermostatic control using the object **ZoneControl:Thermostat:StagedDualSetpoint**. This setpoint manager differs from other parts of EnergyPlus that control based on predicted loads to setpoint. This setpoint manager allows modeling on/off cycling of DX coils using **CoilSystem:Cooling:DX** in continuous fan air handlers. This setpoint manager detects if the zone is calling for a cooling stage and applies one setpoint value if cooling is called for and another setpoint value if cooling is not called for.

This method of control is much more like real world thermostatic control but it requires short zone timesteps. Models using this type of control should use 60 timesteps per hour and will run much slower because of that.

### 1.49.26.1 Inputs

#### 1.49.26.1.1 Field: Name

This alpha field is a unique, user-assigned name for an instance of a single zone one stage cooling setpoint manager.

#### 1.49.26.1.2 Field: Cooling Stage On Supply Air Setpoint Temperature

This numeric field is the setpoint temperature to apply when the manager intends to turn on cooling, in degrees Celsius. The default is -99.0 °C.

#### 1.49.26.1.3 Field: Cooling Stage Off Supply Air Setpoint Temperature

This numeric field is the setpoint temperature to apply when the manager intends to turn off cooling, in degrees Celsius. The value in this field must be higher than the value in the previous field. The default is 99.0 °C.

#### 1.49.26.1.4 Field: Control Zone Name

This alpha field is the name of the control zone for this setpoint manager. This zone needs to be controlled using `ZoneControl:Thermostat:StagedDualSetpoint`.

#### 1.49.26.1.5 Field: Setpoint Node or NodeList Name

This alpha field is the name of a `NodeList` object containing the names of the HVAC system nodes, or the name of a system node, for which temperature setpoints will be established by this setpoint manager.

An example input follows.

```

SetpointManager:SingleZone:OneStageCooling,
  ZSF2 cooling on_off , !- Name
  -99.0 , !- Cooling Stage On Supply Air Setpoint Temperature
  99.0 , !- Cooling Stage Off Supply Air Setpoint Temperature
  ZSF2 , !- Control Zone Name
  DX Cooling Coil 3 Outlet Node ; !- Setpoint Node or NodeList Name

```

---

## 1.49.27 SetpointManager:SingleZone:OneStageHeating

The single-zone, one-stage heating setpoint manager allows a component to be controlled based on thermostatic control using the object `ZoneControl:Thermostat:StagedDualSetpoint`. This setpoint manager differs from other parts of EnergyPlus that control based on predicted loads to setpoint. This setpoint manager allows modeling on/off cycling of heating coils in continuous fan air handlers. This setpoint manager detects if the zone is calling for a heating stage and applies one setpoint value if heating is called for and another setpoint value if heating is not called for.

This method of control is much more like real world thermostatic control but it requires short zone timesteps. Models using this type of control should use 60 timesteps per hour and will run much slower because of that.

### 1.49.27.1 Field: Name

This alpha field is a unique, user-assigned name for an instance of a single zone one stage heating setpoint manager.

### 1.49.27.2 Field: Heating Stage On Supply Air Setpoint Temperature

This numeric field is the setpoint temperature to apply when the manager intends to turn on heating, in degrees Celsius. The default is 99.0 °C.

### 1.49.27.3 Field: Heating Stage Off Supply Air Setpoint Temperature

This numeric field is the setpoint temperature to apply when the manager intends to turn off heating, in degrees Celsius. The value in this field must be lower than the value in the previous field. The default is -99.0 °C.

### 1.49.27.4 Field: Control Zone Name

This alpha field is the name of the control zone for this setpoint manager. This zone needs to be controlled using `ZoneControl:Thermostat:StagedDualSetpoint`.

### 1.49.27.5 Field: Setpoint Node or NodeList Name

This alpha field is the name of a `NodeList` object containing the names of the HVAC system nodes, or the name of a system node, for which temperature setpoints will be established by this setpoint manager.

An example input follows.

```
SetpointManager:SingleZone:OneStageHeating,
  ZNF1 heating on_off , !- Name
  99.0 , !- Heating Stage On Supply Air Setpoint Temperature
  -99.0 , !- Heating Stage Off Supply Air Setpoint Temperature
  ZNF1 , !- Control Zone Name
  Main Heating Coil 2 Air Outlet Node ; !- Setpoint Node or NodeList Name
```

## 1.49.28 SetpointManager:ReturnTemperature:ChilledWater

This setpoint manager allows for the central plant simulation in EnergyPlus to target a specific return water temperature entering the plant supply equipment. This setpoint manager is specifically for “chilled water” (although it could be any fluid) applications. This setpoint manager senses the current supply and return temperatures, calculates the current demand on the loop, and assuming this load remains constant for this time step, it predicts what set-point temperature would provide the desired target return temperature.

Because this is predictive, and the setpoint is only updated once per system timestep (frequency of the call to `ManageSetPoints`), the longer the time step, the less accurate the prediction will be. To make tighter control, the time step can be reduced down even to one minute. However, as described in the *EngineeringReference*, for most realistic building profiles the control works quite well under normal timestep size. If your load profile is highly jagged with step changes in demand, a smaller timestep could help achieve tight control.

### 1.49.28.1 Inputs

#### 1.49.28.1.1 Field: Name

This alpha field is a unique, user-assigned name for an instance of a chilled water return temperature reset setpoint manager.

#### 1.49.28.1.2 Plant Loop Supply Outlet Node

This alpha field is the name of the plant loop supply side outlet node for the plant being managed by this setpoint manager. The current temperature of this node is sensed in order to calculate current loop demand. This node is typically also where the plant loop setpoint is specified, but not necessarily. This setpoint manager looks up the actual setpoint node from the **PlantLoop** internal data structures as it is specified on the **PlantLoop** object. If the plant loop setpoint is on a different node than the supply outlet node, the loop may not maintain return temperature control as expected.

#### 1.49.28.1.3 Plant Loop Supply Inlet Node

This alpha field is the name of the plant loop supply side inlet node whose temperature is controlled using this setpoint manager by resetting the supply setpoint temperature. The current temperature of this node is also sensed in order to calculate current loop demand.

#### 1.49.28.1.4 Minimum Supply Temperature Setpoint

This numeric field plays multiple roles. During initialization, such as before the plant data structures are fully established, this is used as the default plant supply setpoint temperature. During normal calculation, this is used as the minimum chilled water supply temperature to avoid resetting the setpoint too low. During times of no-load, or odd conditions such as a negative load, the setpoint is reset to this design setpoint.

#### 1.49.28.1.5 Maximum Supply Temperature Setpoint

This numeric field is the maximum value to which the supply setpoint can be reset. This ensures that the chilled water temperature does not go too high during reset operations.

#### 1.49.28.1.6 Return Temperature Setpoint Input Type

This alpha field must be one of three strings: “Constant”, “Scheduled”, or “ReturnTemperatureSetpoint”. If the choice is “Constant”, the constant value in the next field is used as the target return temperature. If the choice is “Scheduled”, the current value of the schedule named in the following field is used as the target return temperature. If the choice is “ReturnTemperatureSetpoint”, the actual setpoint temperature on the “Plant Loop Supply Inlet Node” specified above is retrieved and used as the target return temperature. This is convenient as a separate setpoint manager could be established to pre-calculate the desired return temperature, and will assign the Setpoint internally. Then when this return temperature manager executes, the setpoint will be updated and utilized.

#### 1.49.28.1.7 Return Temperature Setpoint Constant Value

If the “Return Temperature Setpoint Input Type” field is “constant”, the numeric value entered here is used as the target return temperature throughout the simulation.

#### 1.49.28.1.8 Return Temperature Setpoint Schedule Name

If the “Return Temperature Setpoint Input Type” field is “scheduled”, this alpha field defines the name of a user-defined schedule storing values of return target temperature. The “current” value is looked up throughout the simulation. This is especially useful as EMS can be employed to do additional sensing and override the schedule value in a given timestep to a new dynamically-calculated return temperature.

An example idf input for a constant return reset setpoint manager is shown here:

```
SetpointManager:ReturnTemperature:ChilledWater,
  Main Loop Setpoint Manager, !- Name
  Supply Outlet Node,         !- Plant Loop Supply Outlet Node
  Supply Inlet Node,          !- Plant Loop Supply Inlet Node
  7.0,                        !- Minimum Supply Temperature Setpoint
```

```

10.0,          !- Maximum Supply Temperature Setpoint
Constant,      !- Return Temperature Setpoint Input Type
12.0,          !- Return Temperature Setpoint Constant Value
;              !- Return Temperature Setpoint Schedule Name

```

---

Another example which uses the “ReturnTemperatureSetpoint” is shown here with the accompanying setpoint being used to set the setpoint on the return node:

```

SetpointManager:Scheduled,
  Return Temperature Setpoint Manager, !- Name
  Temperature,                        !- Control Variable
  Return Temperature Sch,             !- Schedule Name
  Supply Inlet Node;                 !- Setpoint Node or NodeList Name

```

---

```

Schedule:Constant,
  Return Temperature Sch, !- Name
  Any Number,             !- Schedule Limits
  11.75;                  !- Value

```

---

```

SetpointManager:ReturnTemperature:ChilledWater,
  Main Loop Setpoint Manager, !- Name
  Supply Outlet Node,          !- Plant Loop Supply Outlet Node
  Supply Inlet Node,           !- Plant Loop Supply Inlet Node
  7.0,                         !- Minimum Supply Temperature Setpoint
  10.0,                        !- Maximum Supply Temperature Setpoint
  ReturnTemperatureSetpoint, !- Return Temperature Setpoint Input Type
  ,                             !- Return Temperature Setpoint Constant Value
  ;                             !- Return Temperature Setpoint Schedule Name

```

---

## 1.49.29 SetpointManager:ReturnTemperature:HotWater

This setpoint manager allows for the central plant simulation in EnergyPlus to target a specific return water temperature entering the plant supply equipment. This setpoint manager is specifically for “hot water” (although it could be any fluid) applications. This setpoint manager senses the current supply and return temperatures, calculates the current demand on the loop, and assuming this load remains constant for this time step, it predicts what supply set-point temperature would provide the desired target return temperature.

Because this is predictive, and the setpoint is only updated once per system timestep (frequency of the call to ManageSetPoints), the longer the time step, the less accurate the prediction will be. To make tighter control, the time step can be reduced down even to one minute. However, as described in the EngineeringReference, for most realistic building profiles the control works quite well under normal timestep size. If your load profile is highly jagged with step changes in demand, a smaller timestep could help achieve tight control.

### 1.49.29.1 Inputs

#### 1.49.29.1.1 Field: Name

This alpha field is a unique, user-assigned name for an instance of a hot water return temperature reset setpoint manager.

#### 1.49.29.1.2 Plant Loop Supply Outlet Node

This alpha field is the name of the plant loop supply side outlet node for the plant being managed by this setpoint manager. The current temperature of this node is sensed in order to calculate current loop demand. This node is typically also where the plant loop setpoint is specified, but not necessarily. This setpoint manager looks up the actual setpoint node from the **PlantLoop** internal data structures as it is

specified on the **PlantLoop** object. If the plant loop setpoint is on a different node than the supply outlet node, the loop may not maintain return temperature control as expected.

### 1.49.29.1.3 Plant Loop Supply Inlet Node

This alpha field is the name of the plant loop supply side inlet node whose temperature is controlled using this setpoint manager by resetting the supply setpoint temperature. The current temperature of this node is also sensed in order to calculate current loop demand.

### 1.49.29.1.4 Minimum Supply Temperature Setpoint

This numeric field is the minimum value to which the supply setpoint can be reset. This ensures that the hot water temperature does not go too low during reset operations.

### 1.49.29.1.5 Maximum Supply Temperature Setpoint

This numeric field plays multiple roles. During initialization, such as before the plant data structures are fully established, this is used as the default plant supply setpoint temperature. During normal calculation, this is used as the maximum hot water supply temperature to avoid resetting the setpoint too high. During times of no-load, or odd conditions such as a negative load, the setpoint is reset to this design setpoint.

### 1.49.29.1.6 Return Temperature Setpoint Input Type

This alpha field must be one of three strings: “Constant”, “Scheduled”, or “ReturnTemperatureSetpoint”. If the choice is “Constant”, the constant value in the next field is used as the target return temperature. If the choice is “Scheduled”, the current value of the schedule named in the following field is used as the target return temperature. If the choice is “ReturnTemperatureSetpoint”, the actual setpoint temperature on the “Plant Loop Supply Inlet Node” specified above is retrieved and used as the target return temperature. This is convenient as a separate setpoint manager could be established to pre-calculate the desired return temperature, and will assign the Setpoint internally. Then when this return temperature manager executes, the setpoint will be updated and utilized.

### 1.49.29.1.7 Return Temperature Setpoint Constant Value

If the “Return Temperature Setpoint Input Type” field is “constant”, the numeric value entered here is used as the target return temperature throughout the simulation.

### 1.49.29.1.8 Return Temperature Setpoint Schedule Name

If the “Return Temperature Setpoint Input Type” field is “scheduled”, this alpha field defines the name of a user-defined schedule storing values of return target temperature. The “current” value is looked up throughout the simulation. This is especially useful as EMS can be employed to do additional sensing and override the schedule value in a given timestep to a new dynamically-calculated return temperature.

An example idf input for a scheduled return reset setpoint manager is shown here:

```
SetpointManager:ReturnTemperature:HotWater,
Main Loop Setpoint Manager, !- Name
Supply Outlet Node,        !- Plant Loop Supply Outlet Node
Supply Inlet Node,         !- Plant Loop Supply Inlet Node
57.0,                      !- Minimum Supply Temperature Setpoint
60.0,                      !- Maximum Supply Temperature Setpoint
Scheduled,                 !- Return Temperature Setpoint Input Type
,                           !- Return Temperature Setpoint Constant Value
ReturnTempSchedule;        !- Return Temperature Setpoint Schedule Name

Schedule:Compact,
ReturnTempSchedule, !- Name
Any Number,         !- Schedule Type Limits Name
```

---

```

THROUGH: 12/31,      !- Field 1
FOR: AllDays,        !- Field 2
UNTIL: 12:00, 55,    !- Field 3
UNTIL: 17:00, 53,    !- Field 3
UNTIL: 24:00, 55;    !- Field 3

```

---

## 1.50 Group Controllers

### 1.50.1 Controls (Air Loop and Zone Equipment)

A controller mimics the function of an actual physical controller in a somewhat rudimentary way. It can sense one node variable, compare it with its setpoint, and determine the desired value for another node variable. It should be noted that a controller cannot span a loop manager boundary (but a Setpoint Manager can). Thus, in an air loop ([AirLoopHVAC](#)), the sensed node and the controlled device must be in the air loop simulation. This means that a single zone system cannot be modeled with a simple controller sensing zone temperature and controlling coil water flow. Instead this must be modeled as a Setpoint Manager sensing a zone temperature and resetting the supply air temperature setpoint each timestep. This is artificial but should simplify the control modeling task. It should also be noted that there are various types of controllers and that each controller might hook into loops in a slightly different way. As a result, each controller type is described separately below.

### 1.50.2 Controller:WaterCoil

This controller is really a solution inverter. For a water coil the simulation cannot be inverted where the mass flow rate of the water through the coil can be solved directly given an air temperature. Thus, this controller will numerically step through all of the water flow possibilities by an interval-halving technique until the mass flow rate is determined to meet the specified outlet air temperature within a specified user tolerance.

As the reader probably noted when reading the descriptions of the coil syntax shown earlier in this section, there were no controls attached directly to a particular component. This is because the input can be simplified somewhat by entering node names to be controlled. This avoids having to search through multiple lists of component types for the sake of simply controlling components. The Controller:WaterCoil shown below is a way of controlling variables at one node based on conditions at another node. After the identifying name for the controller, the user must define which control variable the controller is managing. These options include Temperature, Humidity Ratio, TemperatureAndHumidityRatio, or Flow.

The next parameter in the input syntax is the Action of the control, which determines how the controlled variable (e.g., mass flow rate through a water coil) is changed based on the control signal. The following input parameter is the actuator variable, which is currently limited to mass flow through a water coil.

The next two parameters in the input syntax are node names corresponding to the node that is being sensed and the actuated node which controls the water mass flow through the coil. For example, in the case of a cooling coil the control variable might be the outlet air temperature of the coil while the actuated variable might be the water flow rate through the coil. These two parameters are followed by the controller convergence tolerance. Finally, the last two input parameters represent the maximum and minimum values allowed for the actuated variable at the actuated node.

#### 1.50.2.1 Inputs

##### 1.50.2.1.1 Field: Name

This is the unique name of the controller.

#### 1.50.2.1.2 Field: Control Variable

This was setup to be generic but to date has only been used for temperature control, or temperature and humidity ratio control, of a water coil in the air loop simulation. The keyword Temperature is used for air temperature control and is normally specified for the coils outlet air node. The keyword TemperatureAndHumidityRatio is used for controlling both air temperature and high humidity levels, and is normally specified for a cooling coils outlet air node. The keyword HumidityRatio is used for humidity control and would normally be specified for a dehumidifier outlet node. These two keywords require a **ZoneControl:Humidistat** object and a maximum humidity setpoint manager object (SetPointManager:SingleZone:Humidity:Maximum, SetPointManager:MultiZone:MaximumHumidity:Average or SetPointManager:MultiZone:Humidity:Maximum). If the coil is located in the outdoor air stream, it may also be necessary to use **SetpointManager:OutdoorAirPretreat**.

#### 1.50.2.1.3 Field: Action

The next input refers to the action of the control. This can be best described by an example. In a coil where water mass flow rate is to be controlled, a coil will increase the mass flow rate through the coil when more heating or cooling is requested. In a heating coil, this increases the value of heat transfer from the water to the air stream. As a result, this is considered a Normal action controller. In a cooling coil, an increase in water mass flow rate through the coil decreases the value of heat transfer from the water to the air stream (absolute value increases, but since cooling is traditionally described as a negative number, an increase in absolute value results in a decrease in the actual heat transfer value). Thus, the cooling coil controller has Reverse action since an increase in flow rate results in a decrease in heat transfer.

#### 1.50.2.1.4 Field: Actuator Variable

This was again meant to be more generic but currently has only been used to control the water mass flow rate of a heating or cooling coil. This actuator variable must be set to the keyword Flow to control the water mass flow rate.

#### 1.50.2.1.5 Field: Sensor Node Name

Name of the node where the temperature, humidity ratio or flow is sensed.

#### 1.50.2.1.6 Field: Actuator Node Name

Name of the actuated node that controls the water mass flow rate through the coil.

#### 1.50.2.1.7 Field: Controller Convergence Tolerance

The coil is controlled by knowing the outlet temperature and/or humidity ratio specified by the setpoint managers, and setting the outlet conditions from the coil to meet these setpoints. The hot and chilled water coils use complex models that cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot or cold water the models are inverted numerically using an iterative procedure. The iterative solution uses an interval-halving routine and needs a termination criterion that is set with the Controller Convergence Tolerance parameter. The convergence tolerance is the maximum difference between the actual temperature at the setpoint node and the setpoint temperature. This control offset is set to a small temperature difference, such as 0.01 to denote 1/100 degree C. The default is 0.1 degree C.

#### 1.50.2.1.8 Field: Maximum Actuated Flow

This is the maximum water flow ( $\text{m}^3/\text{sec}$ ) through the coil. Set to the maximum design water flow for the coil.

### 1.50.2.1.9 Field: Minimum Actuated Flow

Set to the minimum design water flow ( $\text{m}^3/\text{sec}$ ) for the water coil, normally a shut off valve that is set to zero.

An example of this object in an IDF, along with appropriate setpoint managers, is shown below:

```

Controller:WaterCoil,

## 1.50.3 Controller:OutdoorAir

A mixed air box has its own controller type called `Controller:OutdoorAir`. The purpose of the outdoor air controller is to provide outdoor air for ventilation and also provide free cooling (through additional outdoor air and/or bypassing an air-to-air heat exchanger) whenever possible. The outdoor air controller includes a number of user-selectable limit controls. If any of the selected limits are exceeded, the outdoor airflow rate is set to the minimum.

If all the limits are satisfied, the outdoor air controller does the following for continuous air flow systems: if the outdoor air temperature is greater than or equal to the mixed air temperature setpoint, the outdoor air flow rate is set to the maximum; if the outdoor air temperature is less than the mixed air temperature setpoint, the outdoor air controller will modulate the outdoor air flow so that the mixed air temperature will match the mixed air setpoint temperature.

A time-of-day schedule may also be used to simulate an increase in outdoor air flow rate for push-button type economizer applications. When the schedule permits (i.e., schedule values are greater than 0), the outdoor air flow rate is increased to the user-specified maximum outdoor air flow rate.

The outdoor air controller can also account for changes in the outdoor air flow rate during times when indoor humidity levels are high. A zone humidistat must be used with this control option. During high indoor humidity, the outdoor air flow rate is modified in response to a high indoor humidity condition. If high humidity control is based on the outdoor air humidity ratio and the outdoor humidity ratio is greater than the indoor humidity ratio, high humidity control is terminated. When the economizer is used in conjunction with the high humidity control option, high humidity control has priority and controls the change in air flow rates. The Night Ventilation Availability Manager has priority over high humidity control and will use the controllers maximum outdoor air flow rate when this Availability Manager cycles the fan on (Ref. System Availability Managers [AvailabilityManager:NightVentilation](#))

The mixed air box connections are defined separately in the **OutdoorAir:Mixer** object.

Although the mixer will commonly be connected directly to the outdoor air, other components may be placed on the outdoor air path upstream of the mixer. When this is the case, any modulation will be determined by the conditions at the inlet node of the mixer rather than the outdoor air. This means that the controller will account for any heat recovery or other preheating/precooling components that may modify the condition of outdoor air before it reaches the mixer.

If all the limits are satisfied, the outdoor air controller does the following for cycling fan systems: the outdoor air flow rate is set to the maximum when the fan cycles on. If the limits are not satisfied, the outdoor air flow rate is at the minimum when the fan cycles on.

There are various minimum and maximum limits on the outdoor air flow rate which are applied in the following order. Limits that fall later in the list can override earlier limits.

- OA flow rate = Minimum Outdoor Air Flow Rate \* Minimum Outdoor Air Schedule
- Apply economizer controls
- OA flow rate  $\geq$  **Controller:MechanicalVentilation** OA flow rate
- OA flow rate  $\geq$  System exhaust flow rate
- $(\text{OA flow rate})/(\text{Current mixed air flow rate}) \geq$  Minimum Fraction of Outdoor Air Schedule
- $(\text{OA flow rate})/(\text{Current mixed air flow rate}) \leq$  Maximum Fraction of Outdoor Air Schedule (even if this reduces the OA flow rate, can override all minimums and economizer)
- OA flow rate  $\leq$  Maximum Outdoor Air Flow Rate
- Apply OA flow rate specified by demand limiting
- Apply OA flow rate specified by EMS
- OA flow rate  $\leq$  Current mixed air flow rate (system flow rate)

### 1.50.3.1 Inputs

#### 1.50.3.1.1 Field: Name

The unique user-assigned name for an instance of an outdoor air controller. Any other object referencing this outdoor air controller will use this name.

#### 1.50.3.1.2 Field: Relief Air Outlet Node Name

The name of the relief air node of the outdoor air mixer associated with this outdoor air controller.

#### 1.50.3.1.3 Field: Return Air Node Name

The name of the return air node of the outdoor air mixer associated with this outdoor air controller.

#### 1.50.3.1.4 Field: Mixed Air Node Name

Name of the node where the mixed air setpoint is set. The outdoor air controller senses the temperature at this node and attempts to control that temperature to the node setpoint.

#### 1.50.3.1.5 Field: Actuator Node Name

The name of the node that is associated with the outdoor air damper. This should be the outermost air node on the outdoor air path connected to the outdoor air stream for the mixer associated with this outdoor air controller.

#### 1.50.3.1.6 Field: Minimum Outdoor Air Flow Rate

Input for this field is the minimum outdoor air flow rate for the system in cubic meters per second. This field may be autosized. If a Controller Mechanical Ventilation Name is specified, note that this value times the Minimum Outdoor Air Schedule is a hard minimum that may override DCV or other advanced outdoor air controls.

#### 1.50.3.1.7 Field: Maximum Outdoor Air Flow Rate

Input for this field is the maximum outdoor air flow rate for the system in cubic meters per second.

#### 1.50.3.1.8 Field: Economizer Control Type

The options for this field are

- FixedDryBulb
- DifferentialDryBulb
- FixedEnthalpy
- DifferentialEnthalpy
- ElectronicEnthalpy
- FixedDewPointAndDryBulb
- DifferentialDryBulbAndEnthalpy
- NoEconomizer

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the DifferentialDryBulb and DifferentialEnthalpy economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

#### 1.50.3.1.9 Field: Economizer Control Action Type

There are two choices for this Field: **MinimumFlowWithBypass** and **ModulateFlow**, with the default being **ModulateFlow** if this input field is left blank.

**ModulateFlow** means the outdoor air flow rate will be increased to meet the mixed air setpoint temperature, subject to the limits imposed via other inputs for this object (e.g., Economizer Maximum Limit Dry-Bulb Temperature, Maximum Outdoor Air Flow Rate, etc.).

**MinimumFlowWithBypass** is used exclusively in conjunction with air-to-air heat exchanger:objects (Ref. HeatExchanger:\*) for providing free cooling operation in the absence of a conventional air-side economizer (i.e., when outdoor air flow rate is not increased during economizer mode). The Minimum-FlowWithBypass choice forces the outdoor air flow rate to always remain at the minimum. However, when high humidity control is used, the outdoor air flow rate is set to the product of the maximum outdoor air flow rate multiplied by the high humidity outdoor air flow ratio. The heat exchanger uses the limit checking in the outdoor air controller to decide whether or not to bypass the outdoor air around the heat exchanger or turn off the wheel motor in the case of a rotary heat exchanger. Heat exchange is also suspended when high humidity control is active.

The **ModulateFlow** option can also be used with the **HeatExchanger:AirToAir:FlatPlate** or **HeatExchanger:AirToAir:SensibleAndLatent** objects.

#### 1.50.3.1.10 Field: Economizer Maximum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature high limit ( °C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type FixedDryBulb or FixedDewPointAndDryBulb has been specified.

No input (blank) in this field means that there is no outdoor air temperature high limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer. If non-blank, this limit is applied regardless of the specified Economizer Control Type.

#### 1.50.3.1.11 Field: Economizer Maximum Limit Enthalpy

Input for this field is the outdoor air enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type FixedEnthalpy has been specified.

No input (blank) in this field means that there is no outdoor air enthalpy limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer. If non-blank, this limit is applied regardless of the specified Economizer Control Type.

#### 1.50.3.1.12 Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type FixedDewPointAndDryBulb has been specified.

No input (blank) in this field means that there is no outdoor air dewpoint limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer. If non-blank, this limit is applied regardless of the specified Economizer Control Type.

#### 1.50.3.1.13 Field: Electronic Enthalpy Limit Curve Name

Input for this field is the name of a quadratic or cubic curve which provides the maximum outdoor air humidity ratio (function of outdoor air dry-bulb temperature) for economizer operation. If the outdoor air

humidity ratio is greater than the curve's maximum humidity ratio (evaluated at the outdoor air dry-bulb temperature), the outdoor air flow rate will be set to the minimum. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer. No input (blank) in this field means that there is no electronic enthalpy limit control. If non-blank, this limit is applied regardless of the specified Economizer Control Type.

#### **1.50.3.1.14 Field: Economizer Minimum Limit Dry-Bulb Temperature**

Input for this field is the outdoor air temperature low limit ( °C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor airflow rate will be set to the minimum.

No input (blank) in this field means that there is no outdoor air temperature low limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer. If non-blank, this limit is applied regardless of the specified Economizer Control Type.

#### **1.50.3.1.15 Field: Lockout Type**

Choices for this field are NoLockout, LockoutWithHeating, and LockoutWithCompressor. This field is used for packaged systems with DX coils. LockoutWithHeating means that if the packaged unit is in heating mode, the economizer is locked out i.e., the economizer dampers are closed and there is minimum outdoor air flow. LockoutWithCompressor means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is operating to provide cooling. In other words, the economizer must meet the entire cooling load; it is not allowed to operate in conjunction with the DX cooling coil. This option (LockoutWithCompressor) is sometimes called a nonintegrated economizer.

When LockoutWithHeating or LockoutWithCompressor is selected, the lockout may also be applied to non-packaged systems for heating. If any air loop heating coil is operating, the lockout control compares the mixed air temperature at minimum outdoor air flow without heat recovery (if any) to the mixed air temperature set point. If the mixed air temperature at minimum outdoor air flow is less than the mixed air temperature set point, then the economizer is locked out and the outdoor air flow rate is set to the minimum. When the economizer is locked out, the heat recovery bypass control will be set to activate heat recovery (no bypass), if present. This action is meant to minimize heating energy (this action may also disable the heating coil on subsequent iterations, see output variable Air System Outdoor Air Heat Recovery Bypass Heating Coil Activity Status).

The default is NoLockout.

#### **1.50.3.1.16 Field: Minimum Limit Type**

Choices for this field are FixedMinimum or ProportionalMinimum. FixedMinimum means that the minimum outdoor airflow rate is fixed no matter what the actual system flow rate is. ProportionalMinimum means the minimum outdoor airflow rate varies in proportion to the total system air flow rate. The default is ProportionalMinimum.

#### **1.50.3.1.17 Field: Minimum Outdoor Air Schedule Name**

The name of a schedule which uses decimal values (e.g., 0.0 or 1.0). These values are multiplied by the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours. If this field is not entered, the minimum outdoor air flow rate either remains constant during the simulation period (Minimum Outdoor Air Control Type = FixedMinimum) or varies in proportion to the supply air flow rate (Minimum Outdoor Air Control Type = ProportionalMinimum).

**1.50.3.1.18 Field: Minimum Fraction of Outdoor Air Schedule Name**

The name of a schedule with decimal values which are limited between 0.0 and 1.0. The current schedule value is multiplied by the current system mixed air flow rate to set the minimum outdoor air flow rate. If this schedule name is blank, then it is not applied.

If this schedule is 1.0 (and there is no Maximum Fraction of Outdoor Air Schedule Name), then the system works at 100% outdoor air regardless of any other condition as long as the Maximum Outdoor Air Flow Rate is  $\geq$  the system supply air flow rate.

**1.50.3.1.19 Field: Maximum Fraction of Outdoor Air Schedule Name**

The name of a schedule with decimal values which are limited between 0.0 and 1.0. The current schedule value is multiplied by the current system mixed air flow rate to set the maximum outdoor air flow rate. This schedule is applied after all other limits (except EMS and demand-limiting overrides). This schedule can override all minimums and economizer operations. For example, if this schedule is zero, then the outdoor air flow rate will be zero, regardless of any other settings in `Controller:OutdoorAir` or `Controller:MechanicalVentilation`. If this schedule name is blank, then it is not applied.

**1.50.3.1.20 Field: Mechanical Ventilation Controller Name**

This optional field is the name of the mechanical ventilation controller object to be used in conjunction with this outdoor air controller. The `Controller:MechanicalVentilation` object allows the user to define the minimum outdoor air flow rate based on air flow per unit floor area and air flow per person (occupant) for the zones being served by the air loop that utilizes this controller.

This feature allows the user to perform a first-order evaluation of carbon dioxide(CO<sub>2</sub>)-based demand controlled ventilation (outdoor ventilation varied according to occupancy levels).

If a valid name for a `Controller:MechanicalVentilation` object is entered in this field, the minimum outdoor air flow rate delivered will be the greater of:

- the minimum outdoor air flow rate calculated by the fields Minimum Outdoor Air Flow Rate, Minimum Limit Type, and Minimum Outdoor Air Schedule Name as defined for this outdoor air controller, or
- the outdoor air flow rate calculated using the `Controller:MechanicalVentilation` object named in this input field.

Leaving this input field blank will bypass the `Controller:MechanicalVentilation` object calculations and the minimum outdoor air flow rate will be based on the other inputs associated with this outdoor air controller object. Actual outdoor air flow rates may be higher than the minimum if free cooling is available and the object inputs are properly selected. Regardless, the maximum outdoor air flow rate is limited by the field Maximum Outdoor Air Flow Rate.

Note that the Minimum Outdoor Air Flow Rate times the Minimum Outdoor Air Schedule is a hard minimum that may override DCV or other advanced outdoor air controls specified in the `Controller:MechanicalVentilation` object. A recursive warning is provided for users in the error file, when the override occurs at a specific time. The Maximum Fraction of Outdoor Air Schedule (if specified) times the current system supply air flow rate may limit the outdoor air flow rate set by the `Controller:MechanicalVentilation`.

**1.50.3.1.21 Field: Time of Day Economizer Control Schedule Name**

This alpha field is the name of a schedule which controls the outdoor air flow rate based on a time-of-day economizer. Schedule values equal to 0 disable this feature. Schedule values greater than 0 cause the outdoor air flow rate to increase to the maximum. When an economizer is used in conjunction with the high humidity control option, high humidity control has priority.

### 1.50.3.1.22 Field: High Humidity Control

This choice field establishes whether or not the outdoor air flow rate is modified in response to high indoor relative humidity. Valid choices are Yes and No. If Yes is selected, the outdoor air flow rate may be modified when the indoor relative humidity is above the humidstat setpoint. If No is selected, this option is disabled and the following three fields are not used.

### 1.50.3.1.23 Field: Humidistat Control Zone Name

This input defines the zone name where the humidistat is located. This is the same name used in the **ZoneControl:Humidistat** object. This field is required when the input field High Humidity Control is specified as Yes.

### 1.50.3.1.24 Field: High Humidity Outdoor Air Flow Ratio

This input is the ratio of the modified outdoor air flow rate to the maximum outdoor air flow rate. When the high humidity control algorithm determines that the outdoor air flow rate will be changed (i.e., increased or decreased), the operating outdoor air flow rate is equal to the maximum outdoor air flow rate multiplied by this ratio. The minimum value for this field is 0. If this field is blank, the default value is 1. This field is used only when the input field High Humidity Control is specified as Yes. When an economizer is used in conjunction with the high humidity control option, high humidity control has priority.

### 1.50.3.1.25 Field: Control High Indoor Humidity Based on Outdoor Humidity Ratio

This choice field determines if high humidity control is activated based on high indoor relative humidity alone or is activated only when the indoor relative humidity is above the humidstat setpoint *and* the indoor humidity ratio is greater than the outdoor humidity ratio. Valid choices are **Yes** and **No**. If No is selected, high humidity control is active any time the zone humidistat senses a moisture load. If Yes is selected, the model also verifies that the outdoor humidity ratio is less than the humidistat's zone air humidity ratio. This field is used only when the input field High Humidity Control is specified as Yes. The default value is **Yes**.

### 1.50.3.1.26 Field: Heat Recovery Bypass Control Type

This choice field determines if specialized control is used to optimize the use of heat recovery. Valid choices are **BypassWhenWithinEconomizerLimits** and **BypassWhenOAFlowGreaterThanMinimum**. If BypassWhenWithinEconomizerLimits is selected, heat recovery is disabled any time the controller determines that the economizer is active (i.e., all controls are within limits). If BypassWhenOAFlowGreaterThanMinimum is selected, the model first verifies that the economizer is active and then checks to see if the outdoor air flow rate is greater than the minimum. If it is greater than minimum, then heat recovery (if any) is set to bypass. When this option is used with Time of Day Economizer Control or High Humidity Control, this option has priority. The default value is **BypassWhenWithinEconomizerLimits**.

### 1.50.3.2 Outputs

Note that the key value for these outputs is the AirLoopHVAC name, not the name of the Controller:OutdoorAir.

- HVAC,Average,Air System Outdoor Air Economizer Status []
- HVAC,Average,Air System Outdoor Air Heat Recovery Bypass Status []
- HVAC,Average,Air System Outdoor Air Heat Recovery Bypass Heating Coil Activity Status []
- HVAC,Average,Air System Outdoor Air Heat Recovery Bypass Minimum Outdoor Air Mixed Air Temperature [C]
- HVAC,Average,Air System Outdoor Air High Humidity Control Status []
- HVAC,Average,Air System Outdoor Air Limiting Factor []
- HVAC,Average,Air System Outdoor Air Flow Fraction []
- HVAC,Average,Air System Outdoor Air Minimum Flow Fraction []
- HVAC,Average,Air System Outdoor Air Mass Flow Rate [kg/s]
- HVAC,Average,Air System Mixed Air Mass Flow Rate [kg/s]
- HVAC,Average,Air System Relief Air Heat Transfer Rate [W]
- HVAC,Average,Air System Relief Air Sensible Heat Transfer Rate [W]
- HVAC,Average,Air System Relief Air Latent Heat Transfer Rate [W]
- HVAC,Average,Air System Outdoor Air Maximum Flow Fraction []
- HVAC,Average,Air System Outdoor Air Mechanical Ventilation Requested Mass Flow Rate [kg/s]

### 1.50.3.2.1 Air System Outdoor Air Economizer Status []

Reports the average operating status of an air economizer over the reporting interval. The economizer status is set to 1 when the conditions are favorable for the economizer to operate (i.e., none of the control limits have been exceeded). While conditions may be favorable for economizer operation, it does not guarantee that the air-side economizer has increased outdoor air flow above the minimum level since the actual outdoor air flow rate is also governed by other controls (e.g., mixed air set point temperature, time of day economizer control, maximum humidity setpoint, etc.). This variable is set to 0 if conditions disable economizer operation or NoEconomizer (Economizer Control Type) is specified.

### 1.50.3.2.2 Air System Outdoor Air Heat Recovery Bypass Status []

This indicates if the controls have determined if the bypass mode for heat recovery is in effect or not.

### 1.50.3.2.3 Air System Outdoor Air Heat Recovery Bypass Heating Coil Activity Status []

Reports the operating status of any heating coil in the air loop. If the heating coil is active, the heat exchanger will be activated (no air bypassed) and the heating energy will be reduced or eliminated. While conditions may be favorable for economizer operation, it does not guarantee that the air-side economizer has increased outdoor air flow above the minimum level since the actual outdoor air flow rate is also governed by other controls (e.g., mixed air set point temperature, time of day economizer control, maximum humidity setpoint, etc.). This variable is set to 0 if conditions disable economizer operation. This output variable is only available when using Heat Recovery Bypass Control Type = BypassWhenOAFlowGreaterThanMinimum.

### 1.50.3.2.4 Air System Outdoor Air Heat Recovery Bypass Minimum Outdoor Air Mixed Air Temperature [C]

Reports the outdoor air mixer's mixed air node temperature at minimum outdoor air flow rate when the heat exchanger is disabled (off). This temperature is calculated as the return air temperature multiplied by the return air mass flow rate plus the mixer's inlet node temperature multiplied by the minimum outdoor air flow rate. This quantity is then divided by the mixed air mass flow rate. If this temperature is less than the outdoor air mixer's mixed air node set point temperature, and the Heat Recovery Bypass Control Type = BypassWhenOAFlowGreaterThanMinimum, the outdoor air flow rate is set to the minimum. This output variable is only available when using Heat Recovery Bypass Control Type = BypassWhenOAFlowGreaterThanMinimum.

### 1.50.3.2.5 Air System Outdoor Air High Humidity Control Status []

Reports the average operating status of the controller's high humidity control over the reporting interval. The high humidity control status is set to 1 when the controller determines that a zone high humidity condition exists *according to the settings specified in the controller*. This variable is set to 0 if conditions disable high humidity control operation or High Humidity Control is specified as No.

### 1.50.3.2.6 Air System Outdoor Air Limiting Factor []

Reports the average current limiting factor controlling the outdoor air flow rate as one of the following integer values. This variable is used to produce the Outdoor Air Details summary report subtables for Outdoor Air Controller Limiting Factors by AirLoop and Average Outdoor Air for Limiting Factors During Occupancy. Given the nature of this output, it is most useful at the detailed (HVAC timestep) reporting frequency. Averages over time may not be meaningful.

**0 = No Limiting Factor** None of the other limiting factors is active.

- 1 = Limits and Scheduled Limits** Fixed limits such as Controller:OutdoorAir Minimum Outdoor Air Flow Rate, Maximum Outdoor Air Flow Rate, Minimum Fraction of Outdoor Air Schedule Name, Maximum Fraction of Outdoor Air Schedule Name.
- 2 = Economizer** Economizer is active and sets the flow greater than the minimum outdoor air fraction.
- 3 = Exhaust Flow** Outdoor air flow rate equals the total zone exhaust flow rate.
- 4 = Mixed Air Flow** Outdoor air flow rate is limited by the current mixed air flow rate.
- 5 = High Humidity** Controller:OutdoorAir High Humidity Control.
- 6 = Demand Controlled Ventilation** Controller:MechanicalVentilation requested more than the minimum outdoor air fraction.
- 7 = Night Ventilation** AvailabilityManager:NightVentilation is active.
- 8 = Demand Limiting** DemandManager:Ventilation has reduced the outdoor air flow rate.
- 9 = Energy Management System** An EnergyManagementSystem:Actuator has overridden the outdoor air flow rate.

#### 1.50.3.2.7 Air System Outdoor Air Flow Fraction []

Reports the average actual outdoor air fraction for the outdoor air controller over the reporting interval.

#### 1.50.3.2.8 Air System Outdoor Air Minimum Flow Fraction []

Reports the average minimum limit of the outdoor air fraction for the outdoor air controller over the reporting interval.

#### 1.50.3.2.9 Air System Outdoor Air Mass Flow Rate [kg/s]

Reports the average outdoor air mass flow rate introduced by the outdoor air controller over the reporting interval.

#### 1.50.3.2.10 Air System Mixed Air Mass Flow Rate [kg/s]

Reports the average mixed air mass flow rate of the HVAC air loop associated with this outdoor air controller over the reporting interval.

#### 1.50.3.2.11 Air System Relief Air Heat Transfer Rate [W]

#### 1.50.3.2.12 Air System Relief Air Sensible Heat Transfer Rate [W]

#### 1.50.3.2.13 Air System Relief Air Latent Heat Transfer Rate [W]

Reports the HVAC system relieve heat (total, sensible and latent) from the outdoor air relief nodes through outdoor air mixers.

#### 1.50.3.2.14 Air System Outdoor Air Maximum Flow Fraction []

Reports the average maximum limit of the outdoor air fraction for the outdoor air controller over the reporting interval. The maximum flow fraction is used to prevent DX cooling coils from freezing, specified by ASHRAE Standard 90.1. This output variable is available when a corresponding SetpointManager:MixedAir object specifies optional inputs of Cooling Coil Inlet Node Name, Cooling coil Outlet Node Name, and Minimum Temperature at Cooling Coil Outlet Node.

### 1.50.3.2.15 Air System Outdoor Air Mechanical Ventilation Requested Mass Flow Rate [kg/s]

Reports the average outdoor air mass flow rate requested by the Mechanical Ventilation Controller (Controller:MechanicalVentilation, if specified) over the reporting interval.

## 1.50.4 Controller:MechanicalVentilation

This object is used in conjunction with an outdoor air controller (Ref. **Controller:OutdoorAir**, Field: Mechanical Ventilation Controller Name) to establish the minimum outdoor air flow rate provided by a mixed air box.

Ventilation standards provide guidance on appropriate levels of outdoor ventilation air required for acceptable indoor air quality. The Ventilation Rate Procedure (VRP) of ASHRAE Standard 62.1-2007/2010 ([www.ashrae.org](http://www.ashrae.org)) requires outdoor ventilation rates to be determined based on the floor area of each occupied zone plus the number of people in each zone and considers the zone air distribution effectiveness and system ventilation efficiency. The outdoor air ventilation rate can be reset dynamically as operating conditions change (e.g., variations in occupancy). The Controller:MechanicalVentilation object implements the VRP for calculating these outdoor air ventilation requirements and resetting them based on varying occupancy levels and zone diversification. This is particularly useful for large air distribution systems that serve a number of different zone types with varying occupancy levels. This object can also be used to model the Indoor Air Quality Procedure (IAQP) as defined in Standard 62.1

The first five inputs for this object are the name, the availability schedule, the zone outdoor air method, the system outdoor air method, and the zone maximum outdoor air fraction. The next three input fields define the zone name (or zone list name), the design specification outdoor air object name, and the design specification zone air distribution object name to be applied to this zone (or zone list). The last three fields are extensible

### 1.50.4.1 Inputs

#### 1.50.4.1.1 Field: Name

The unique user assigned name for an instance of mechanical ventilation. Any other object referencing this mechanical ventilation object will use this name.

#### 1.50.4.1.2 Field: AvailabilitySchedule Name

The name of a schedule whose values are greater than 0 when mechanical ventilation, as calculated by this object, is desired. If the schedule's value is 0.0, then mechanical ventilation is not available and flow will not be requested. If the schedule's value is  $> 0.0$  (usually 1 is used), mechanical ventilation is available. If this field is blank, the schedule has values of 1 for all time periods. This schedule is useful for purging the building of contaminants prior to occupancy (i.e., ventilation rate per unit floor area will be provided even if the occupancy is zero).

#### 1.50.4.1.3 Field: Demand Controlled Ventilation

This field indicates whether the air loop is capable of doing demand controlled ventilation (DCV) to vary the amount of outdoor air based on actual number of occupants in spaces. Two choices: Yes and No. Default is No.

#### 1.50.4.1.4 Field: System Outdoor Air Method

The method used to calculate the system minimum outdoor air flow. Several choices are allowed: **ZoneSum**, **VentilationRateProcedure**, **IndoorAirQualityProcedure**, **ProportionalControlBasedOnOccupancySchedule**, **ProportionalControlBasedOnDesignOccupancy**, **Proportion-**

**alControlBasedOnDesignOARate**, and **IndoorAirQualityProcedureGenericContaminant**. ZoneSum sums the outdoor air flows across all zones served by the system. VentilationRateProcedure (VRP) uses the multi-zone equations defined in 62.1-2007 to calculate the system outdoor air flow. VRP considers zone air distribution effectiveness and zone diversification of outdoor air fractions. IndoorAirQualityProcedure (IAQP) is the other procedure defined in ASHRAE Standard 62.1-2007 for calculate the amount of outdoor air necessary to maintain the levels of indoor air carbon dioxide at or below the setpoint defined in the **ZoneControl:ContaminantController** object. Appendix A of the ASHRAE 62.1-2010 user's manual discusses another method for implementing CO<sub>2</sub>-based DCV in a single zone system. This method (Proportional Control) calculates the required outdoor air flow rate which varies in proportion to the percentage of the CO<sub>2</sub> signal range and has two choices to calculate occupancy-based outdoor air rate. The ProportionalControlBasedOnOccupancySchedule choice uses the real occupancy at the current time step to calculate outdoor air rate, while the ProportionalControlBasedOnDesignOccupancy uses the design occupancy level to calculate outdoor air rate. The former choice is a good approach to estimate outdoor air rate. However, for practical applications, the zone controller usually does not have the real time occupancy information, and the design occupancy level is assumed. The latter choice is used in the design stage. The ProportionalControlBasedOnDesignOARate uses design outdoor air flow rate to calculate demand outdoor air flow rate. The IndoorAirQualityProcedure-GenericContaminant method calculates the amount of outdoor air necessary to maintain the levels of indoor air generic contaminant at or below the setpoint defined in the **ZoneControl:ContaminantController** object.

Note: When System Outdoor Air Method = IndoorAirQualityProcedure or IndoorAirQualityProcedureGenericContaminant is specified, only the Zone <x> Name fields are used. The other field inputs described below are not used.

#### 1.50.4.1.5 Field: Zone Maximum Outdoor Air Fraction

This positive numeric input is the zone maximum outdoor air fraction. For VAV systems, when a zone requires outdoor air higher than the user specified Zone Maximum Outdoor Air Fraction, the zone supply air flow will be increased (if damper not fully open yet) to cap the outdoor air fraction at the maximum value. This allows the system level outdoor air flow to be reduced while the total supply air flow increases to meet zone outdoor air requirement. Valid values are from 0 to 1.0. Default is 1.0 which indicates zones can have 100% outdoor air maintaining backward compatibility. This input work for single and dual duct VAV systems.

#### 1.50.4.1.6 Field Set (Zone Name, Design Specification Outdoor Air Object Name, and Design Specification Zone Air Distribution Object Name)

The following three fields are needed to define the parameters for the ventilation. This object is extensible by duplicating these three fields.

#### 1.50.4.1.7 Field: Zone or ZoneList <x> Name

The zone name or zone list to apply the ventilation rates specified in the **DesignSpecification:OutdoorAir** object.

#### 1.50.4.1.8 Field: Design Specification Outdoor Air Object Name <x>

The name of the **DesignSpecification:OutdoorAir** object, defining the amount of outdoor air, that applies to the zone or zone list. If this field is blank, the corresponding **DesignSpecification:OutdoorAir** object for the zone will come from the **DesignSpecification:OutdoorAir** object referenced by the **Sizing:Zone** object for the same zone. If no such zone match is found, default values from the IDD will be used for the **DesignSpecification:OutdoorAir** object which is 0.0094 m<sup>3</sup>/s-person.

If an Outdoor Air Schedule Name is specified in the **DesignSpecification:OutdoorAir** object, the schedule will be applied to all types of outdoor air calculations for the corresponding zone, regardless of the System Outdoor Air Method selected. If the schedule value is zero, then the zone will be completely removed from the system outdoor air calculations.

#### 1.50.4.1.9 Field: Design Specification Zone Air Distribution Object Name <x>

The name of the **DesignSpecification:ZoneAirDistribution** object, defining the air distribution effectiveness and secondary recirculation air fraction, that applies to the zone or zone list. If this field is blank, the corresponding **DesignSpecification:ZoneAirDistribution** object for the zone will come from the **DesignSpecification:ZoneAirDistribution** object referenced by the **Sizing:Zone** object for the same zone. If no such zone match is found, default values from the IDD will be used for the **DesignSpecification:ZoneAirDistribution** object which are effectiveness = 1.0 and recirculation = 0.0.

As described previously, the **Controller:MechanicalVentilation** object works in conjunction with **Controller:OutdoorAir**. As such, the minimum quantity of outdoor air delivered via the mixed air box will be the greater of:

- the minimum outdoor air flow rate calculated by the fields Minimum Outdoor Air Flow Rate, Minimum Limit and Minimum Outdoor Air Schedule Name in the associated **Controller:OutdoorAir** object, or
- the outdoor air flow rate calculated by this object.

The actual outdoor air flow rate may be higher than the minimum if free cooling is available. Regardless, the outdoor air flow rate will not exceed the Maximum Outdoor Air Flow Rate specified in the associated **Controller:OutdoorAir** object or the Maximum Fraction of Outdoor Air Schedule (if specified) times the current system supply air flow rate.

An example input for this object is shown below:

```

Controller:MechanicalVentilation,

### 1.50.5 ZoneHVAC:EnergyRecoveryVentilator:Controller

This controller object is used exclusively by the stand alone energy recovery ventilator (**ZoneHVAC:EnergyRecoveryVentilator**, see Figure 1.181). The purpose of this controller is to simulate economizer operation for the stand alone ERV and provide free cooling whenever possible or modify the outdoor air flow rate during high indoor humidity conditions. During economizer operation, if all of the limits are satisfied, the controller activates economizer mode (fully bypassing the fixed-plate air-to-air heat exchanger or stopping the rotation of a rotary heat exchanger). If any of the selected limits are exceeded, economizer operation is terminated. A time-of-day schedule may also be used to simulate a push-button type economizer controller.

In addition, the outdoor air flow rate may be modified and heat exchange suspended in response to high indoor relative humidities. When the indoor relative humidity exceeds the zone humidistat's relative humidity set point, high humidity control is activated. When activated, if high humidity control is based on the outdoor air humidity ratio and the outdoor humidity ratio is greater than the indoor humidity ratio, high humidity control is terminated.

#### 1.50.5.1 Inputs

##### 1.50.5.1.1 Field: Name

A unique user-assigned name for the stand alone ERV controller. Any reference to this controller by another object will use this name.

##### 1.50.5.1.2 Field: Temperature High Limit

The input for this field is the outdoor air temperature high limit ( °C) for economizer operation. If the outdoor air temperature is above this limit, economizer (free cooling) operation is terminated. No input (blank) in this field means that there is no outdoor air temperature high limit control.

##### 1.50.5.1.3 Field: Temperature Low Limit

The input for this field is the outdoor air temperature low limit ( °C) for economizer operation. If the outdoor air temperature is below this limit, economizer (free cooling) operation is terminated. No input (blank) in this field means that there is no outdoor air temperature low limit control.

##### 1.50.5.1.4 Field: Enthalpy High Limit

The input for this field is the outdoor air enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, economizer (free cooling) operation is terminated. No input (blank) in this field means that there is no outdoor air economizer limit control.

##### 1.50.5.1.5 Field: Dewpoint Temperature Limit

Input for this field is the outdoor air dewpoint limit ( °C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. No input (blank) in this field means that there is no outdoor air dewpoint limit control. This limit applies to the conditions at the Actuated Node regardless of whether or not there are any other components on the outdoor air path upstream of the mixer.

Figure 1.181: Schematic of the ZoneHVAC:EnergyRecoveryVentilator compound object

**1.50.5.1.6 Field: Electronic Enthalpy Limit Curve Name**

Input for this field is the name of a quadratic or cubic curve which provides the maximum outdoor air humidity ratio (function of outdoor air dry-bulb temperature) for economizer operation. If the outdoor air humidity ratio is greater than the curve's maximum humidity ratio (evaluated at the outdoor air dry-bulb temperature), the outdoor air flow rate will be set to the minimum. This limit applies to the conditions at the Actuated Node regardless of whether or not there are any other components on the outdoor air path upstream of the mixer. No input (blank) in this field means that there is no electronic enthalpy limit control.

**1.50.5.1.7 Field: Exhaust Air Temperature Limit**

This input establishes whether or not there is a limit control on the exhaust air temperature. The choices are **ExhaustAirTemperatureLimit** or **NoExhaustAirTemperatureLimit**. If **ExhaustAirTemperatureLimit** is chosen, the controller deactivates economizer mode whenever the outdoor air temperature is greater than the exhaust air temperature. If **NoExhaustAirTemperatureLimit** is chosen, no limit check on the exhaust air temperature is performed.

**1.50.5.1.8 Field: Exhaust Air Enthalpy Limit**

This input establishes whether or not there is a limit control on the exhaust air enthalpy. The choices are **ExhaustAirEnthalpyLimit** or **NoExhaustAirEnthalpyLimit**. If **ExhaustAirEnthalpyLimit** is chosen, the controller deactivates economizer mode whenever the outdoor air enthalpy is greater than the exhaust air enthalpy. If **NoExhaustAirEnthalpyLimit** is chosen, no limit check on the exhaust air enthalpy is performed.

**1.50.5.1.9 Field: Time of Day Economizer Flow Control Schedule Name**

This alpha field is the name of a schedule which controls the change in air flow rate based on time-of-day. Schedule values equal to 0 disable this feature. Schedule values greater than 0 activate the economizer. Note that heat exchange between the air streams is suspended when the economizer is active. This schedule can be used with or without the high humidity control option. When an economizer is used in conjunction with the high humidity control option, high humidity control has priority.

**1.50.5.1.10 Field: High Humidity Control Flag**

This optional choice field establishes whether or not the supply and exhaust air flow rates are modified in response to high indoor relative humidity. Valid choices are Yes and No. If Yes is selected, the supply and exhaust air flow rates may be modified when the indoor relative humidity is above the humidistat set point. If No is selected, this option is disabled and the following three fields are not used. Note that heat exchange between the air streams is suspended during times when high humidity control is active. The default value is No.

**1.50.5.1.11 Field: Humidistat Control Zone Name**

This optional input defines the zone name where the humidistat is located. This is the same zone name used in the Zone Control:Humidistat object. This field is required when the High Humidity Control Flag is specified as Yes.

**1.50.5.1.12 Field: High Humidity Outdoor Air Flow Ratio**

This optional input is the ratio of the modified supply (outdoor) air flow rate to the supply air flow rate specified in the Energy Recovery Ventilator:Stand Alone ERV object. When the high humidity control algorithm determines that the supply air flow rate will be changed (i.e. increased or decreased), the operating supply air flow rate is equal to the supply air flow rate specified in the Energy Recovery Ventilator:Stand

Alone ERV object multiplied by this ratio. The minimum value for this field is 0. This field is used to modify both the supply and exhaust air flow rates when high humidity control is active. The supply and exhaust air fan volumetric flow rates must be able to account for the increase in air flow when this input is greater than 1. The default value is 1.

### 1.50.5.1.13 Field: Control High Indoor Humidity based on Outdoor Humidity Ratio

This optional choice field determines if high humidity control is activated based on high indoor relative humidity alone or is activated only when the indoor relative humidity is above the humidistat set point *and* the outdoor humidity ratio is less than the indoor humidity ratio. Valid choices are Yes and No. If No is selected, high humidity control is active any time the zone humidistat senses a moisture load. If yes is selected, the model also verifies that the outdoor humidity ratio is less than the humidistat's zone air humidity ratio. This field is used only when the High Humidity Control Flag is specified as Yes. The default value is Yes.

Following is an example input for this stand alone ERV controller object:

```
ZoneHVAC:EnergyRecoveryVentilator:Controller,
  ERV OA Controller 1,           !- ERV controller name
  19.,                          !- Temperature high limit {C}
  14.,                          !- Temperature low limit {C}
  ,                             !- Enthalpy high limit {J/kg}
  15.55,                        !- dew point temperature limit (C)
  ElectronicEnthalpyCurveA,      !- electronic enthalpy limit curve name
  NoExhaustAirTemperatureLimit,  !- Exhaust air temperature limit
  NoExhaustAirEnthalpyLimit,     !- Exhaust air enthalpy limit
  OutsideAirFlowSchedule,       !- Time of Day Economizer Flow Control Schedule Name
  Yes,                          !- High Humidity Control Flag
  East Zone,                     !- Humidistat Control Zone Name
  1.2,                          !- High Humidity Outdoor air Flow Ratio
  Yes;                           !- Control High Indoor Humidity based on Outdoor Humidity Ratio

Curve:Cubic,
  ElectronicEnthalpyCurveA, !- Name
  0.01342704,               !- Coefficient1 Constant
  -0.00047892,              !- Coefficient2 x
  0.000053352,              !- Coefficient3 x**2
  -0.0000018103,            !- Coefficient4 x**3
  16.6,                     !- Minimum Value of x
  29.13;                    !- Maximum Value of x
```

## 1.51 Group Evaporative Coolers

This group of objects describes the properties and configuration for the evaporative coolers models for the HVAC section.

### 1.51.1 EvaporativeCooler:Direct:CelDekPad

The direct stage, shown in the figure below, consists of a rigid media evaporative pad, with water recirculated from a reservoir. The water is pumped from the reservoir to a water distribution header, for water feed by gravity from above the media. The evaporative pad provides the area for the adiabatic saturation of the air. While the process provides a lower dry-bulb temperature, the moisture content of the leaving air is higher than the entering condition. The direct stage is used for comfort cooling in a building where adding humidity to the air can be tolerated.

Figure 1.182: Direct Stage Evaporative Cooler

The thermodynamic process is a simultaneous heat and mass transfer, or adiabatic cooling, and follows a constant enthalpy line on the psychrometric chart, it is shown in the figure below as a process from A to B. Since the deviation of the constant wet-bulb line and the constant enthalpy line is small, it is assumed that the wet-bulb temperature is constant across the direct evaporative stage.

Figure 1.183: Psychrometric Chart – Constant Enthalpy

If the direct evaporative process were 100% efficient, the leaving dry-bulb temperature would equal the entering wet-bulb temperature. The efficiency of the direct evaporative process is less than 100% and by defining saturation efficiency ( $\epsilon_{se}$ ) for the direct stage or evaporative pad, the leaving dry-bulb temperature can be expressed by the following equation.

$$T_{db\ supout} = T_{db\ supin} - \epsilon_{se} \cdot (T_{db\ supin} - T_{wb\ supin}) \quad (1.209)$$

### 1.51.1.1 Inputs

#### 1.51.1.1.1 Field: Name

A unique identifying name for each evaporative cooler.

#### 1.51.1.1.2 Field:Availability Schedule Name

The name of a schedule which defines when the evaporative cooler is available. A schedule value of 0 indicates that the evaporative cooler is off for that time period. A schedule value greater than 0 indicates that the evaporative cooler can operate during the time period. If this field is blank, the evaporative cooler is always available.

**1.51.1.1.3 Field: Direct Pad Area**

The face area of the evaporative pad in m<sup>2</sup>. With the area and mass flow rate, the air velocity is calculated and is used to determine the saturation efficiency. This field is autosizable.

**1.51.1.1.4 Field: Direct Pad Depth**

The depth of the evaporative pad in meters. The pad depth is used to determine the saturation efficiency. This field is autosizable.

**1.51.1.1.5 Field: Recirculating Water Pump Power Consumption**

This field is used to specify the power consumed by the evaporative cooler recirculating pump in Watts.

**1.51.1.1.6 Field: Air Inlet Node Name**

The name of the evaporative cooler air inlet node from the Air Loop Simulation.

**1.51.1.1.7 Field: Air Outlet Node Name**

The name of the evaporative cooler air outlet node from the Air Loop Simulation.

**1.51.1.1.8 Field: Control Type**

This input field is currently unused and can be left blank.

**1.51.1.1.9 Field: Water Supply Storage Tank Name**

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

An IDF example showing how this object is:

```
EvaporativeCooler:Direct:CelDekPad,
  Evaporative Cooler,           !- Name
  System Availability Schedule,  !- Availability Schedule Name
  0.6,                          !- Direct Pad Area {m2}
  0.2,                          !- Direct Pad Depth {m}
  225,                          !- Recirculating Water Pump Power Consumption {W}
  Evap Cooler Inlet Node,       !- Air Inlet Node Name
  Supply Outlet Node;           !- Air Outlet Node Name
```

**1.51.1.2 Outputs**

The output variables that are available for this direct evaporative cooler are shown below:

- HVAC,Average, Evaporative Cooler Wet Bulb Effectiveness
- HVAC,Average, Evaporative Cooler Electricity Rate [W]
- HVAC,Sum, Evaporative Cooler Electricity Energy [J]
- HVAC,Sum, Evaporative Cooler Water Volume[m3]
- HVAC,Sum,Evaporative Cooler Mains Water Volume [m3]

- HVAC,Sum,Evaporative Cooler Storage Tank Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Mains Water Volume [m3]

#### 1.51.1.2.1 Evaporative Cooler Wet Bulb Effectiveness

The effectiveness, or saturation efficiency, is the temperature change of the supply air divided by the difference between the inlet air dry-bulb and wet-bulb temperatures. In other words, it is a measure of the approach to the inlet air wet-bulb temperature.

#### 1.51.1.2.2 Evaporative Cooler Electricity Rate [W]

#### 1.51.1.2.3 Evaporative Cooler Electricity Energy [J]

These output variables report the electric power and electric energy required to operate the water pump.

#### 1.51.1.2.4 Evaporative Cooler Water Volume [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when mains water is supplied to the cooler.

#### 1.51.1.2.5 Evaporative Cooler Mains Water Volume [m3]

This is the source of the water consumed. This output variable appears when mains water is supplied to the cooler.

#### 1.51.1.2.6 Evaporative Cooler Storage Tank Water Volume [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when storage tank water is supplied to the cooler.

#### 1.51.1.2.7 Evaporative Cooler Starved Water Volume [m3]

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

#### 1.51.1.2.8 Evaporative Cooler Starved Mains Water Volume [m3]

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

### 1.51.2 EvaporativeCooler:Direct:ResearchSpecial

This cooler is similar in principal to the [EvaporativeCooler:Direct:CellDekPad](#). The model differs in that it gives the user a simple way of specify the cooler effectiveness. Using the ResearchSpecial input object also allows the cooler to control the amount of cooling based on node setpoints (controlled by Setpoint-Managers). This avoid problems from over cooling when conditions are such that loads are low and cooling power is high.

The model allows to vary the effectiveness depending on the primary air flow rates. The design effectiveness is modified by multiplying with Effectiveness Flow Fraction Modifier Curve value. The flow fraction is the ratio of the current primary airflow rate to the design flow rate. The recirculating and spray water pump power is assumed to vary with the primary air flow. The design pump power is modified using user specified pump modifier curve value. The normalized pump power modifier curve is a function of primary air flow fraction as a independent variable.

Also the direct evaporative cooler operating range can be controlled depending on the entering air dry bulb and wet bulb temperatures. The operating range controlled based on minimum and maximum inlet node air temperature limits. The evaporative cooler can be turned on or off depending user specified minimum and maximum temperature limits. If the inlet node entering air temperature is lower or higher than the minimum and maximum limits, respectively, then the direct research special evaporative cooler is turned off. If these two input fields are left blank then, no user specified operating temperature control is applied. Operating range control feature is primarily intended for application in data centers.

### 1.51.2.1 Inputs

#### 1.51.2.1.1 Field: Name

This alpha field is a unique identifying name for each cooler.

#### 1.51.2.1.2 Field: Availability Schedule Name

This alpha field is the name of a schedule that defines when the evaporative cooler is available. A schedule value of 0 indicates that the evaporative cooler is off for that time period. A schedule value greater than 0 indicates that the evaporative cooler can operate during the time period. If this field is blank, the evaporative cooler is always available.

#### 1.51.2.1.3 Field: Cooler Design Effectiveness

This numeric field specifies the effectiveness at design flow rate that is applied to the wetbulb depression to determine the conditions leaving the cooler. This model assumes that the effectiveness can vary with supply air flow rate. For effectiveness variation with supply air flow fraction enter the Effectiveness Flow Ratio Modifier Curve Name input field below. The flow fraction is the ratio of the sum of current primary air and secondary air sides flow rates and the sum of the design flow rates.

#### 1.51.2.1.4 Field: Effectiveness Flow Ratio Modifier Curve Name

This alpha field is the name of a curve that modifies the effectiveness design value specified the previous field by multiplying the value by the result of this curve. The modifying curve is a function of flow fraction, which is the ratio of the current primary air flow rates divided by the design primary air flow rates. If this input field is left blank, the effectiveness is assumed to be constant. Any curve or table with one independent variable can be used. Any curve or table with one independent variable can be used: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectuangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**.

#### 1.51.2.1.5 Field: Primary Design Air Flow Rate

This numeric field is the primary air design air flow rate in  $\text{m}^3/\text{s}$ . This input field is autosizable. If the evaporative cooler is on the main air loop branch, the design flow rate is the same as branch design flow rate. If the evaporative cooler is in the outdoor air system the design flow rate will be the maximum of the outdoor air design flow rate and one-half of the primary air flow rate on the main air loop branch.

#### 1.51.2.1.6 Field: Recirculating Water Pump Design Power

This numeric field is the recirculating and spray pump electric power at the Primary Design Air Flow Rate in W. This is the nominal water recirculating and spray pump power of evaporative cooler at primary air design flow rates and cooler design effectiveness. This input field is autosizable, see [Water Pump Power Sizing Factor](#).

#### 1.51.2.1.7 Field: Water Pump Power Sizing Factor

This numeric field value is recirculating water pump sizing factor in  $W/(m^3/s)$ . This field is used when the previous field is set to autosize. The pump design electric power is scaled with the Primary Design Air Flow Rate. This input field is autosizable. Average Pump Power sizing factor was estimated from pump power and primary air design flow rates inputs from energyplus example files and is about  $90.0 W/(m^3/s)$  ( $= 90.0 \sim \text{Pump Power} / \text{Primary Air Design Flow Rate}$ ). The factor ranges from 55.0 to  $150.0 W/(m^3/s)$ .

#### 1.51.2.1.8 Field: Water Pump Power Modifier Curve Name

This alpha field is the name of a dimensionless normalized pump power modifying curve. This curve modifies the pump electric power in the previous field by multiplying the design power by the result of this curve. The normalized curve is a function of the primary air flow fraction as the independent variable. The curve shall yield a value of 1.0 at a flow fraction of 1.0. The flow fraction is the ratio of the primary air flow rate divided by primary air Design Air Flow Rate. If this input field is left blank, the pump power is assumed to vary linearly with the load (including air system cycling, if any). If pump power does not vary linearly with load this curve should be used. Any curve or table with one independent variable can be used: [Curve:Linear](#), [Curve:Quadratic](#), [Curve:Cubic](#), [Curve:Quartic](#), [Curve:Exponent](#), [Curve:ExponentialSkewNormal](#), [Curve:Sigmoid](#), [Curve:RectuangularHyperbola1](#), [Curve:RectangularHyperbola2](#), [Curve:ExponentialDecay](#), [Curve:DoubleExponentialDecay](#), and one-dimensional [Table:Lookup](#).

#### 1.51.2.1.9 Field: Air Inlet Node Name

This alpha field is the name of the air inlet node for the primary air flow path through the cooler.

#### 1.51.2.1.10 Field: Air Outlet Node Name

This alpha field is the name of the air outlet node for the primary air flow path through the cooler.

#### 1.51.2.1.11 Field: Sensor Node Name

This alpha field specifies the name of a node that will provide system air temperature setpoint information. A separate SetpointManager object should be setup to update this node.

#### 1.51.2.1.12 Field: Water Supply Storage Tank Name

This alpha field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a [WaterUse:Storage](#) object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

#### 1.51.2.1.13 Field: Drift Loss Fraction

This numeric field is optional and can be used to model additional water consumed by the cooler from drift. Drift is water that leaves the cooling media as droplets and does not evaporate into the process air stream. For example, water may get blown off the evaporative media and escape the air system. The value

entered here is a simple fraction of the water consumed by the cooler for normal process evaporation. The amount of drift is this fraction times the water evaporated for the normal cooling process. This field can be left blank and then there will be no added water consumption from drift.

#### 1.51.2.1.14 Field: Blowdown Concentration Ratio

This numeric field is optional and can be used to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

#### 1.51.2.1.15 Field: Evaporative Cooler Operation Minimum Drybulb Temperature

This numeric field defines the evaporative cooler inlet node drybulb temperature minimum limit in degrees Celsius. The evaporative cooler will be turned off when the evaporator cooler air inlet node drybulb temperature falls below this value. The typical minimum value is 16 °C. Users are allowed to specify their own limits. If this field is left blank, then there is no drybulb temperature lower limit for evaporative cooler operation.

#### 1.51.2.1.16 Field: Evaporative Operation Maximum Limit Wetbulb Temperature

This numeric field defines the evaporative cooler air inlet node air wetbulb temperature maximum limits in degree Celsius. When the evaporative cooler air inlet node wetbulb temperature exceeds this limit, then the evaporative cooler turns off. The typical maximum value is 24 °C. If this input field is left blank, then there is no wetbulb temperature upper limit for evaporative cooler operation.

#### 1.51.2.1.17 Field: Evaporative Operation Maximum Limit Drybulb Temperature

This numeric field defines the evaporative cooler air inlet node drybulb temperature maximum limits in degree Celsius. The evaporative cooler will be turned off when the evaporative cooler air inlet node drybulb temperature exceeds this value. The typical maximum value is 28 °C. If this input field is left blank, then there is no upper drybulb temperature limit for evaporative cooler operation.

### 1.51.2.2 Outputs

The output variables that are available for this direct evaporative cooler are shown below:

- HVAC,Average, Evaporative Cooler Electricity Rate [W]

- HVAC,Average, Evaporative Cooler Stage Effectiveness []
- HVAC,Sum, Evaporative Cooler Electricity Energy [J]
- HVAC,Sum, Evaporative Cooler Water Volume[m3]
- HVAC,Sum,Evaporative Cooler Mains Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Storage Tank Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Mains Water Volume [m3]

#### **1.51.2.2.1 Evaporative Cooler Electricity Rate [W]**

#### **1.51.2.2.2 Evaporative Cooler Electricity Energy [J]**

These output variables report the electric power and electric energy required to operate the water pump.

#### **1.51.2.2.3 Evaporative Cooler Stage Effectiveness []**

The cooler stage efficiency is defined as the temperature change of the supply air divided by the difference between the outdoor dry-bulb and wet-bulb temperatures, including the effect of the reduction in the primary air flow rate. In other words, it is a measure of the approach to the entering air wet-bulb temperature.

#### **1.51.2.2.4 Evaporative Cooler Water Volume [m3]**

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when mains water is supplied to the cooler.

#### **1.51.2.2.5 Evaporative Cooler Mains Water Volume [m3]**

This is the source of the water consumed. This output variable appears when mains water is supplied to the cooler.

#### **1.51.2.2.6 Evaporative Cooler Storage Tank Water Volume [m3]**

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when storage tank water is supplied to the cooler.

#### **1.51.2.2.7 Evaporative Cooler Starved Water Volume [m3]**

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

#### **1.51.2.2.8 Evaporative Cooler Starved Mains Water Volume [m3]**

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

### 1.51.3 EvaporativeCooler:Indirect:CelDekPad

The dry coil indirect evaporative cooler, shown in the figure below, has a rigid media pad, similar to the direct evaporative stage, where the adiabatic cooling takes place. The secondary air leaves the rigid media pad and enters an air to air heat exchanger where it cools the supply air flowing through the heat exchanger tubes. The moist secondary air is then exhausted to the environment. The secondary air stream has its own fan and consists of a rigid media evaporative pad, with water recirculated from a reservoir. The water is pumped from the reservoir to a water distribution header, for water feed by gravity from above the media. The evaporative pad provides the area for the adiabatic saturation of the air.

Figure 1.184: Evaporative Cooler – Indirect Dry Coil

The process that the secondary air goes through, A to C to D, is shown by the dashed lines in the following figure. Process A to C is adiabatic cooling in the rigid media pad. Then the air enters the shell side of the heat exchanger and is sensibly heated from C to D by the warm supply air passing through the tube side. The secondary air inlet is modeled as a separate stream of outdoor air and the user has the option of defining the name of an outdoor air node.

The advantage of the dry coil heat exchanger is that the heat exchanger does not have the evaporation taking place on the outside of the tubes, thus no mineral deposits are left on the heat exchange surface to reduce the efficiency of the heat exchanger. The rigid media pads are designed to flush the mineral deposits to the sump, so the saturation efficiency of the pad stays relatively constant.

#### 1.51.3.1 Inputs

##### 1.51.3.1.1 Field: Name

A unique identifying name for each evaporative cooler.

##### 1.51.3.1.2 Field:Availability Schedule Name

The name of a schedule which defines when the evaporative cooler is available. A schedule value of 0 indicates that the evaporative cooler is off for that time period. A schedule value greater than 0 indicates

Figure 1.185: Secondary Air Process – Indirect Dry Coil Evap Cooler

that the evaporative cooler can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### **1.51.3.1.3 Field: Direct Pad Area**

The face area of the evaporative pad in  $\text{m}^2$ . With the area and mass flow rate, the air velocity is calculated and is used to determine the saturation efficiency on the secondary side of the evaporative cooler. This field is autosizable.

#### **1.51.3.1.4 Field: Direct Pad Depth**

The depth of the evaporative pad in meters. The pad depth is used to determine the saturation efficiency on the secondary side of the evaporative cooler. This field is autosizable.

#### **1.51.3.1.5 Field: Recirculating Water Pump Power Consumption**

This field is used to specify the power consumed by the evaporative cooler recirculating pump in Watts.

#### **1.51.3.1.6 Field: Secondary Air Fan Flow Rate**

This field is used to specify the secondary air fan flow rate and is specified in  $\text{m}^3/\text{sec}$ .

#### **1.51.3.1.7 Field: Secondary Fan Total Efficiency**

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1.

#### **1.51.3.1.8 Field: Secondary Fan Delta Pressure**

This field is used to specify the delta pressure across the secondary stage of the evaporative cooler in Pascals.

#### **1.51.3.1.9 Field: Indirect Heat Exchanger Effectiveness**

This field is used to specify the effectiveness of the indirect heat exchanger between the primary and secondary air flow.

#### **1.51.3.1.10 Field: Primary Air Inlet Node Name**

The name of the evaporative cooler's primary air inlet node from the Air Loop Simulation. This is the air flow being cooled indirectly.

#### **1.51.3.1.11 Field: Primary Air Outlet Node Name**

The name of the evaporative cooler's primary air outlet node from the Air Loop Simulation.

#### **1.51.3.1.12 Field: Control Type**

This input field is currently unused and can be left blank.

### 1.51.3.1.13 Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

### 1.51.3.1.14 Field: Secondary Air Inlet Node Name

This field is optional. It is used to explicitly define an outdoor air node for the inlet for secondary air stream. Defining an outdoor air node here allows using the height-dependent model for outdoor air conditions.

And an IDF example showing how this object is specified:

```

## 1.51.3.2 Outputs

The output variables that are available for the indirect dry evaporative cooler are shown below:

- HVAC,Average, Evaporative Cooler Wetbulb Effectiveness
- HVAC,Average, Evaporative Cooler Total Stage Effectiveness
- HVAC,Average, Evaporative Cooler Electricity Rate [W]
- HVAC,Sum, Evaporative Cooler Electricity Energy [J]
- HVAC,Sum, Evaporative Cooler Water Volume[m3]
- HVAC,Sum,Evaporative Cooler Mains Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Storage Tank Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Mains Water Volume [m3]

### 1.51.3.2.1 Evaporative Cooler Wetbulb Effectiveness

The dry evaporation saturation efficiency is the saturation efficiency of the secondary or wet side air stream defined as the temperature change of the supply air divided by the difference between the outdoor dry-bulb and wet-bulb temperatures. In other words, it is a measure of the approach to the outdoor wet-bulb temperature.

**1.51.3.2.2 Evaporative Cooler Total Stage Effectiveness**

The total stage efficiency includes the sensible heat exchanger effectiveness of the heat exchanger in the supply air stream. It is the saturation efficiency multiplied by the heat exchanger effectiveness.

**1.51.3.2.3 Evaporative Cooler Electricity Rate [W]****1.51.3.2.4 Evaporative Cooler Electricity Energy [J]**

These output variables report the electric power and energy consumed by the secondary air fan and the sump pump.

**1.51.3.2.5 Evaporative Cooler Water Volume[m3]**

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when mains water is supplied to the cooler.

**1.51.3.2.6 Evaporative Cooler Mains Water Volume [m3]**

This is the source of the water consumed. This output variable appears when mains water is supplied to the cooler.

**1.51.3.2.7 Evaporative Cooler Storage Tank Water Volume [m3]**

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when storage tank water is supplied to the cooler.

**1.51.3.2.8 Evaporative Cooler Starved Water Volume [m3]**

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

**1.51.3.2.9 Evaporative Cooler Starved Mains Water Volume [m3]**

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

**1.51.4 EvaporativeCooler:Indirect:WetCoil**

The wetted coil evaporative cooler shown in the figure below, has water sprayed directly on the tubes of the heat exchanger where latent cooling takes place. The vaporization of the water on the outside of the heat exchanger tubes allows the simultaneous heat and mass transfer which removes heat from the supply air on the tube side. Then the moist secondary air is exhausted. The secondary air stream has its own fan.

The process that the secondary air goes through, A to C on the following figure, is a path of simultaneous heat and mass transfer, but it does not follow a line of constant enthalpy as in the direct stage. The process is not adiabatic due to the heat gain from the supply air flowing through the tubes of the heat exchanger.

The wet coil heat exchanger can have a higher stage efficiency than the dry coil due to a higher heat transfer rate on the outside of the heat exchanger tubes. Over the operating lifetime of the heat exchanger, the vaporization taking place on the heat exchange surface can leave mineral deposits which will decrease the effectiveness of the heat exchanger.

Figure 1.186: Evaporative Cooler Indirect Wet Coil

Figure 1.187: Secondary Air Process Indirect Wet Coil Evap Cooler

#### 1.51.4.1 Inputs

##### 1.51.4.1.1 Field: Name

A unique identifying name for each evaporative cooler.

##### 1.51.4.1.2 Field:Availability Schedule Name

The name of a schedule which defines when the evaporative cooler is available. A schedule value of 0 indicates that the evaporative cooler is off for that time period. A schedule value greater than 0 indicates that the evaporative cooler can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.51.4.1.3 Field: Coil Maximum Efficiency

The maximum efficiency of the stage is a combination of the efficiency due to the simultaneous heat and mass transfer on the outside of the tube and the efficiency of the heat exchanger. This value can be higher than the dry coil overall efficiency since the convective coefficients on the outside of the tube are larger.

##### 1.51.4.1.4 Field: Coil Flow Ratio

The Coil Flow Ratio is determined from performance data. The Coil Flow Ratio tells how quickly the efficiency of the stage would decrease with a mismatch of the supply and secondary flows.

##### 1.51.4.1.5 Field: Recirculating Water Pump Power Consumption

This field is used to specify the power consumed by the evaporative cooler recirculating pump in Watts.

##### 1.51.4.1.6 Field: Secondary Air Fan Flow Rate

This field is used to specify the secondary air fan flow rate and is specified in  $\text{m}^3/\text{sec}$ .

##### 1.51.4.1.7 Field: Secondary Air Fan Total Efficiency

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1..

##### 1.51.4.1.8 Field: Secondary Air Fan Delta Pressure

This field is used to specify the delta pressure across the secondary stage of the evaporative cooler in Pascals.

##### 1.51.4.1.9 Field: Primary Air Inlet Node Name

The name of the evaporative cooler air inlet from the Air Loop Simulation.

##### 1.51.4.1.10 Field: Primary Air Outlet Node Name

The name of the evaporative cooler air outlet from the Air Loop Simulation.

##### 1.51.4.1.11 Field: Control Type

This input field is currently unused and can be left blank.

#### 1.51.4.1.12 Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a [WaterUse:Storage](#) object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

#### 1.51.4.1.13 Field: Secondary Air Inlet Node Name

This field is optional. It is used to explicitly define an outdoor air node for the inlet for secondary air stream. Defining an outdoor air node here allows using the height-dependent model for outdoor air conditions.

And an IDF example showing how this object is specified:

### 1.51.4.2 Outputs

The output variables that are available for the wet indirect evaporative cooler are shown below:

- HVAC,Average, Evaporative Cooler Total Stage Effectiveness
- HVAC,Average, Evaporative Cooler Electricity Rate [W]
- HVAC,Sum, Evaporative Cooler Electricity Energy [J]
- HVAC,Sum, Evaporative Cooler Water Volume[m3]
- HVAC,Sum,Evaporative Cooler Mains Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Storage Tank Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Mains Water Volume [m3]

#### 1.51.4.2.1 Evaporative Cooler Total Stage Effectiveness []

The Total Stage Efficiency is defined as the temperature change of the supply air divided by the difference between the outdoor dry-bulb and wet-bulb temperatures, including the effect of the reduction in flow because of the secondary air stream. In other words, it is a measure of the approach to the outdoor wet-bulb temperature.

**1.51.4.2.2 Evaporative Cooler Electricity Rate [W]****1.51.4.2.3 Evaporative Cooler Electricity Energy [J]**

These output variables report the electric power and energy that are consumed by the secondary air fan and the sump pump.

**1.51.4.2.4 Evaporative Cooler Water Volume [m3]**

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when mains water is supplied to the cooler.

**1.51.4.2.5 Evaporative Cooler Mains Water Volume [m3]**

This is the source of the water consumed. This output variable appears when mains water is supplied to the cooler.

**1.51.4.2.6 Evaporative Cooler Storage Tank Water Volume [m3]**

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when storage tank water is supplied to the cooler.

**1.51.4.2.7 Evaporative Cooler Starved Water Volume [m3]**

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

**1.51.4.2.8 Evaporative Cooler Starved Mains Water Volume [m3]**

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

**1.51.5 EvaporativeCooler:Indirect:ResearchSpecial**

This cooler is similar in principal to the [EvaporativeCooler:Indirect:CelDekPad](#) and [EvaporativeCooler:Indirect:WetCoil](#) (see Figure 1.185, Figure 1.186, and Figure 1.187). The model differs in that it gives the user more flexibility to specify the source of secondary air. The cooler effectiveness with respect to wetbulb depression is allowed to go beyond 1.0. Using the ResearchSpecial object also allows the cooler to control the amount of cooling based on node setpoints (controlled by SetpointManagers). This avoid problems from over cooling when conditions are such that loads are low and cooling power is high. Fan power is assumed to vary linearly when the cooler is operating at less than full capacity (includes air system cycling, if any).

The indirect evaporative cooler research special calculation procedure allows accounting for dry and wet effectiveness value variation with flow fraction. Two effectiveness modifier curves are included as optional user inputs for this purpose. Effectiveness modifier curves operate on the design dry and wet effectiveness values. The flow fraction is calculated as a ratio of the sum of current primary and secondary air flow rates to the sum of the design flow rates. These effectiveness modifier curves are required for proper operation of secondary air flow modulation in dry and wet operating modes when advanced control is desired using the following three input fields *Evaporative Operation Minimum Limit Secondary Air Drybulb Temperature*, *Evaporative Operation Maximum Limit Outdoor Wetbulb Temperature*, and *Operation Maximum Limit*

*Outdoor Drybulb Temperature.* The model also accounts for fan and recirculation water pump power variation with secondary air flow rates using pump power modifying curve. The fan power is calculated by multiplying the design fan power using fan power modify curve value evaluated at current secondary air flow fraction. Similarly, recirculating pump power is calculated by multiplying the design pump power by pump power modifier curve value evaluated at current secondary air flow fraction. If the secondary air fan and recirculating pump power modifier curves are not specified, then fan and pump power are assumed to vary linearly with flow fraction, and if the air system cycles, the air loop cycling ratio (a.k.a. air system part-load ratio).

### 1.51.5.1 Inputs

#### 1.51.5.1.1 Field: Name

This alpha field is a unique identifying name for each cooler.

#### 1.51.5.1.2 Field: Availability Schedule Name

The alpha field is the name of a schedule that defines when the evaporative cooler is available. A schedule value of 0 indicates that the evaporative cooler is off for that time period. A schedule value greater than 0 indicates that the evaporative cooler can operate during the time period. If this field is blank, the evaporative cooler is always available.

#### 1.51.5.1.3 Field: Cooler Wetbulb Design Effectiveness

This numeric field specifies the design effectiveness that is applied to the wetbulb depression to determine the conditions leaving the cooler. This effectiveness is a complicated function of the efficiency with which heat and mass are transferred on the secondary side and the efficiency of heat exchange between the secondary and primary flows. The model assumes that the effectiveness is a function of flow fraction. The flow fraction is the ratio of the sum of primary air and secondary air current flow rates and the sum of the primary air and secondary air design flow rates.

#### 1.51.5.1.4 Field: Wet Bulb Effectiveness Flow Ratio Modifier Curve Name

This alpha field is the name of a curve that modifies the wet bulb effectiveness design value specified in the previous field by multiplying that value by the result of this curve. The modifying curve is a function of flow fraction, which is the ratio of the sum of the primary and secondary flow rates divided by the sum of the design flow rates. If this input field is left blank, the effectiveness is assumed to be constant. The wet bulb effectiveness modifier curve is required for proper operation of secondary air flow modulation in wet cooling operating mode, and is used with the three input fields *Evaporative Operation Minimum Limit Secondary Air Drybulb Temperature*, *Evaporative Operation Maximum Limit Outdoor Wetbulb Temperature*, and *Operation Maximum Limit Outdoor Drybulb Temperature*. Any curve or table with one independent variable can be used: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and one-dimensional **Table:Lookup**.

#### 1.51.5.1.5 Field: Cooler Drybulb Design Effectiveness

This numeric field is the dry bulb design effectiveness of the evaporative cooler. This is the nominal design dry blub effectiveness with respect to the dry bulb temperature difference, i.e., dry operation at design air flow rates, and no water evaporation or spraying on the secondary side.

#### 1.51.5.1.6 Field Drybulb Effectiveness Flow Ratio Modifier Curve Name

This alpha field is the name of a curve that modifies the drybulb effectiveness in the previous field (eff\_db\_design) by multiplying the design effectiveness value by the result of this curve. The curve is evaluated using the flow fraction as the independent variable. The flow fraction is the ratio of sum of the primary and secondary flow rates divided by the sum of the design flow rates. If this input field is left blank, the effectiveness is assumed to be constant. The dry bulb effectiveness modifier curve is required for proper operation of secondary air flow modulation in dry cooling operating mode, and is used with the three input fields *Evaporative Operation Minimum Limit Secondary Air Drybulb Temperature*, *Evaporative Operation Maximum Limit Outdoor Wetbulb Temperature*, and *Operation Maximum Limit Outdoor Drybulb Temperature*. Any curve or table with one independent variable can be used: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and one-dimensional **Table:Lookup**.

#### 1.51.5.1.7 Field: Recirculating Water Pump Design Power

This numeric field is the recirculating pump electric power at Secondary Design Air Flow Rate in W. This is the nominal design pump power water recirculation and spray for evaporation at design secondary air flow rates and cooler design effectiveness. This input field is autosizable.

#### 1.51.5.1.8 Field: Water Pump Power Sizing Factor

This numeric field value is recirculating water pump sizing factor in  $W/(m^3/s)$ . This field is used when the previous field is set to autosize. The pump design electric power is scaled with Secondary Design Air Flow Rate. Average Pump Power sizing factor was estimated from pump power and secondary air design flow rates inputs from energyplus example files and is about  $90.0 W/(m^3/s)$  ( $= 90.0 \sim \text{Pump Power} / \text{Secondary Air Design Flow Rate}$ ). The factor ranges from 55.0 to 150.0  $W/(m^3/s)$ .

#### 1.51.5.1.9 Field: Water Pump Power Modifier Curve Name

This alpha field is the name of a dimensionless normalized pump power modifying curve. This curve modifies the pump electric power in the previous field by multiplying the design power by the result of this curve. The normalized curve is a function of the secondary side flow fraction as the independent variable. The curve shall yield a value of 1.0 at a flow fraction of 1.0. The flow fraction is the secondary air flow rate during operation divided by Secondary Design Air Flow Rate. If this input field is left blank, the pump power is assumed to vary linearly with the load. If pump power does not vary linearly with load this curve should be used. Any curve or table with one independent variable can be used: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and one-dimensional **Table:Lookup**.

#### 1.51.5.1.10 Field: Secondary Air Design Flow Rate

This numeric field is used to specify the secondary air fan flow rate and is specified in  $m^3/s$ . This flow rate would typically be similar in magnitude to the flow through the primary side. This field can be autosized. When it is autosized, the program detects if the component is in the main air loop or on an outdoor air path. If it is on the main air loop, then the flow rate is set to the **AirLoopHVAC** system's design supply air flow rate (which is the maximum required for heating and cooling). If it is on the outdoor air path, then the flow rate is set to the larger of either the design minimum outdoor air flow rate or one-half of the main air loop design flow rate. The flow rate is used to determine parasitic fan energy and cooler effectiveness. The flow rate (and fan power) is effectively reduced by cycling when the amount of cooling needs to be restricted for control purpose. This field can be autosized. When this input is autosized, the

program calculates this input by scaling the Primary Air Design Flow Rate using secondary air scaling factor specified in the input field below.

#### **1.51.5.1.11 Field: Secondary Air Flow Scaling Factor**

This numeric field is used to scale the secondary air design flow rate and is dimensionless. This field is used when the previous field is set to autosize. The Primary Design Air Flow Rate is scaled using this factor to calculate the secondary design air flow rate.

#### **1.51.5.1.12 Field: Secondary Air Fan Design Power**

This numeric field is the fan electric power at the Secondary Design Air Flow Rate. This is the nominal design electric power at full speed of the secondary air fan. This input field is autosizable.

#### **1.51.5.1.13 Field: Secondary Air Fan Sizing Specific Power**

This numeric field is the secondary air fan sizing specific power in W/(m<sup>3</sup>/s). This field is used when the previous field is set to autosize. The fan power is scaled using the Secondary Design Air Flow Rate.

#### **1.51.5.1.14 Field: Secondary Air Fan Power Modifier Curve Name**

This alpha field is the name of a dimensionless normalized curve. The normalized curve modifies the design secondary air fan power in the previous field by multiplying that value by the result of this curve. The normalized curve is a function of the secondary side flow fraction as the independent variable. The curve shall yield a value of 1.0 at a flow fraction of 1.0. The flow fraction is the secondary air flow rate divided by Secondary Design Air Flow Rate. If this input field is left blank, the fan power will vary linearly with load (includes air system cycling, if any). If fan power does not vary linearly with load this curve should be used. Any curve or table with one independent variable can be used: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and one-dimensional **Table:Lookup**.

#### **1.51.5.1.15 Field: Primary Air Inlet Node Name**

This alpha field is the name of the air inlet node for the primary air flow path through the cooler.

#### **1.51.5.1.16 Field: Primary Air Outlet Node Name**

This alpha field is the name of the air outlet node for the primary air flow path through the cooler.

#### **1.51.5.1.17 Field: Primary Design Air Flow Rate**

This numeric field is the primary air design air flow rate in m<sup>3</sup>/s. This input field is autosizable. If the evaporative cooler is on the main air loop branch, the design flow rate is the same as branch design flow rate. If the evaporative cooler is in the outdoor air system primary design flow rate will be the maximum of the the outdoor air design flow rate and one-half of the primary air flow rate on the main air loop branch.

#### **1.51.5.1.18 Field: Dewpoint Effectiveness Factor**

This numeric field specifies an effectiveness that is applied to the dewpoint depression to determine a bound for the conditions leaving the cooler. The model uses the warmer of the two temperatures determined from wetbulb depression and dewpoint depression.

#### **1.51.5.1.19 Field: Secondary Air Inlet Node Name**

This alpha field specifies the name of the node providing air to the secondary/wet side of the cooler. Typically this node could appear in an outdoor air node list or be part of an air system loop.

**1.51.5.1.20 Field: Secondary Air Outlet Node Name**

This alpha field is the name of the secondary air side outlet node.

**1.51.5.1.21 Field: Sensor Node Name**

This alpha field specifies the name of a node that will provide system air temperature setpoint information. A separate SetpointManager object should be setup to update this node.

**1.51.5.1.22 Field: Relief Air Inlet Node Name**

This alpha field is optional, but can be used to feed two sources of secondary air into the wet side of the cooler. Typical use is to run the air system relief air into the system. The model first uses all of the air flow available from this node and then adds the air flow from the secondary air inlet node to make up the total defined by Secondary air Fan Flow Rate.

**1.51.5.1.23 Field: Water Supply Storage Tank Name**

This alpha field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

**1.51.5.1.24 Field: Drift Loss Fraction**

This numeric field is optional and can be used to model additional water consumed by the cooler from drift. Drift is water that leaves the cooling media as droplets and does not evaporate into the process air stream. For example, water may get blown off the evaporative media by winds and escape the air system. The value entered here is a simple fraction of the water consumed by the cooler for normal process evaporation. The amount of drift is this fraction times the water evaporated for the normal cooling process. This field can be left blank and then there will be no added water consumption from drift.

**1.51.5.1.25 Field: Blowdown Concentration Ratio**

This numeric field is optional and can be used to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

**1.51.5.1.26 Field: Evaporative Operation Minimum Limit Drybulb Temperature**

This numeric field defines the secondary air inlet node drybulb temperature limits in degree Celsius. When the secondary side entering air dry bulb temperature drops below this limit, then the evaporative cooler operation mode changes to dry heat exchanger. Users specify their own limits. If this field is left blank, then there is no drybulb temperature lower limit for evaporative cooler operation. If operating range control is desired then this input field and the next two input fields should be specified or all the three should be left blank or left out. If no minimum drybulb temperature limit is required while there are maximum drybulb and wetbulb temperature limits then specify very low temperature limit value (e.g., -99.0 C).

### 1.51.5.1.27 Field: Evaporative Operation Maximum Limit Wetbulb Temperature

This numeric field defines the secondary air inlet node wetbulb temperature limits in degree Celsius. When the secondary side entering air wet bulb temperature exceeds this limit, then the evaporative cooler is turns off and does not attempt to do any cooling. If this field is left blank, then there is no wetbulb temperature maximum limit for evaporative cooler wet operation mode. If no upper wetbulb temperature limits is desired while there are minimum drybulb and maximum drybulb upper temperature limits then then specify very high maximum wetbulb temperature limit value (e.g. 99.0 C).

### 1.51.5.1.28 Field: Evaporative Operation Maximum Limit Drybulb Temperature

This numeric field defines the secondary air inlet node drybulb temperature limits in degree Celsius. When the secondary side entering air drybulb temperature exceeds this limit, the evaporative cooler will not run in dry operation mode or may be turned off depending on its wetbulb temperature. If this field is left blank, then there is no drybulb temperature maximum limit for evaporative cooler dry operation mode. If no drybulb temperature limit is desired while there are minimum drybulb and maximum wetbulb temperature limits then specify very high maximum drybulb temperature limit value (e.g. 99.0 C).

An IDF example is shown below:

## 1.51.5.2 Outputs

The output variables that are available for the EvaporativeCooler:Indirect:ResearchSpecial object are shown below:

- HVAC,Average,Evaporative Cooler Total Stage Effectiveness
- HVAC,Average,Evaporative Cooler Part Load Ratio
- HVAC,Average,Evaporative Cooler Dewpoint Bound Status
- HVAC,Average,Evaporative Cooler Operating Mode Satus []
- HVAC,Sum,Evaporative Cooler Electricity Energy [J]

- HVAC,Average,Evaporative Cooler Electricity Rate [W]
- HVAC,Sum,Evaporative Cooler Storage Tank Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Water Volume [m3]
- HVAC,Sum,Evaporative Cooler Starved Mains Water Volume [m3]

#### 1.51.5.2.1 Evaporative Cooler Total Stage Effectiveness []

The Total Stage Efficiency is defined as the temperature change of the supply air divided by the difference between the primary air entering dry-bulb temperature and the secondary air entering wet-bulb temperature for wet operating mode or the the difference between the primary air entering dry-bulb temperature and the secondary air entering dry-bulb temperature for dry operating mode, including the effect of the reduction in flow because of the secondary air stream. In other words, it is a measure of the approach to the secondary air wet-bulb temperature for wet operating mode, or it is a measure of the approach to the secondary air entering dry-bulb temperature for dry operating mode.

#### 1.51.5.2.2 Evaporative Cooler Operating Mode Status []

This output variable provides the operating modes or status of the indirect evaporative cooler. This output variable can have status indicator integer value of 0, 1, or 2 representing Off, Dry and Wet operating modes, respectively.

#### 1.51.5.2.3 Evaporative Cooler Part Load Ratio []

This output variable provides the part load fraction of the indirect cooler. The ResearchSpecial cooler model is able to modulate to meet a temperature set point to avoid over cooling. This output variable is the fraction formed by the ratio of the capacity needed over the maximum cooling capacity available. A value of 1.0 corresponds to full capacity cooling.

#### 1.51.5.2.4 Evaporative Cooler Dewpoint Bound Status []

This output variable is a flag that indicates if the modeling was based on dewpoint effectiveness rather than wetbulb effectiveness. The ResearchSpecial model is usually based on wet-bulb approach, but since values in excess of 1.0 are allowed, there is a secondary constraint imposed by dewpoint. If the dewpoint effectiveness was applied, then this flag variable will have the value 1.0, otherwise it is 0.0.

#### 1.51.5.2.5 Evaporative Cooler Electricity Rate [W]

#### 1.51.5.2.6 Evaporative Cooler Electricity Energy [J]

These output variables report the electric power and energy that are consumed by the secondary air fan and the sump pump.

#### 1.51.5.2.7 Evaporative Cooler Water Volume [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when mains water is supplied to the cooler.

#### 1.51.5.2.8 Evaporative Cooler Mains Water Volume [m3]

This is the source of the water consumed. This output variable appears when mains water is supplied to the cooler.

#### 1.51.5.2.9 Evaporative Cooler Storage Tank Water Volume [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This output variable appears when storage tank water is supplied to the cooler.

#### 1.51.5.2.10 Evaporative Cooler Starved Water Volume [m3]

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

#### 1.51.5.2.11 Evaporative Cooler Starved Mains Water Volume [m3]

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This output variable appears when storage tank water is supplied to the cooler.

## 1.52 Group Heat Recovery

### 1.52.1 HeatExchanger:AirToAir:FlatPlate

The air-to-air flat plate heat exchanger is an HVAC component typically used for exhaust or relief air heat recovery. The user can choose the flow arrangement type: counter flow, parallel flow, or cross flow with both streams unmixed. The input requires no geometric data. Performance is defined by specifying primary outlet air temperature at nominal (user specified) inlet conditions. In addition, the ratio  $(h \cdot A)_p / (h \cdot A)_s$  at nominal flow needs to be input, where  $h$  is the convective heat transfer coefficient,  $A$  is the surface area,  $p$  stands for primary side,  $s$  for secondary side.

If the heat exchanger is operated in conjunction with an outdoor air economizer (economizer lockout set to *Yes*), the nominal supply air flow rate should be set equal to the minimum outdoor air flow rate specified in the **Controller:OutdoorAir**. The heat exchanger detects that the economizer is operating by the fact that its inlet air flow rate is greater than its nominal supply air flow rate.

#### 1.52.1.1 Inputs

##### 1.52.1.1.1 Field: Name

A unique user-assigned name for a particular air-to-air flat plate heat exchanger unit. Any reference to this unit by another object will use this name.

##### 1.52.1.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.52.1.1.3 Field: Flow Arrangement Type

The user specified flow arrangement of the heat exchanger. The possible inputs are *CounterFlow*, *ParallelFlow*, or *CrossFlowBothUnmixed*.

**1.52.1.1.4 Field: Economizer Lockout**

This input denotes whether the heat exchanger unit is locked out (bypassed) when the air-side economizer is operating. Both the economizer and high humidity control (Ref. **Controller:OutdoorAir**) activate the heat exchanger lockout as specified by this input. The input choices are *Yes* (meaning locked out) or *No*. The default input for this field is *Yes*.

**1.52.1.1.5 Field: Ratio of Supply to Secondary hA Values**

The ratio  $(h \cdot A)_p / (h \cdot A)_s$  at nominal flow.  $h$  is the surface convective heat transfer coefficient,  $A$  is the heat transfer area, and  $p$  and  $s$  stand for primary side and secondary side respectively. A typical value for this ratio is 1.0.

**1.52.1.1.6 Field: Nominal Supply Air Flow Rate**

The nominal primary side air flow rate in cubic meters per second. If the unit is operated in conjunction with an outdoor air economizer this should be equal to the minimum outdoor air flow rate. This field is autosizable.

**1.52.1.1.7 Field: Nominal Supply Air Inlet Temperature**

The nominal primary side air inlet temperature in Celsius.

**1.52.1.1.8 Field: Nominal Supply Air Outlet Temperature**

The nominal primary side air outlet temperature in Celsius.

**1.52.1.1.9 Field: Nominal Secondary Air Flow Rate**

The nominal secondary side air flow rate in cubic meters per second. This field is autosizable. It is equal to the primary side air flow rate defined above, if autosized.

**1.52.1.1.10 Field: Nominal Secondary Air Inlet Temperature**

The nominal secondary side air inlet temperature in Celsius.

**1.52.1.1.11 Field: Nominal Electric Power**

The electric consumption rate of the unit in watts. Electric power is considered constant whenever the unit operates. This input can be used to model electric power consumption by controls (transformers, relays, etc.) and/or a motor for a rotary heat exchanger. None of this electric power contributes thermal load to the supply or exhaust air streams. The default value for this field is 0.

**1.52.1.1.12 Field: Supply Air Inlet Node Name**

The name of the HVAC system node from which the unit draws its primary inlet air.

**1.52.1.1.13 Field: Supply Air Outlet Node Name**

The name of the HVAC system node to which the unit sends its primary outlet air.

**1.52.1.1.14 Field: Secondary Air Inlet Node Name**

The name of the HVAC system node from which the unit draws its secondary inlet air.

### 1.52.1.1.15 Field: Secondary Air Outlet Node Name

The name of the HVAC system node to which the unit sends its secondary outlet air.

### 1.52.1.2 Outputs

- HVAC,Average,Heat Exchanger Sensible Heating Rate [W]
- HVAC,Sum,Heat Exchanger Sensible Heating Energy [J]
- HVAC,Average,Heat Exchanger Latent Gain Rate [W]
- HVAC,Sum,Heat Exchanger Latent Gain Energy [J]
- HVAC,Average,Heat Exchanger Total Heating Rate [W]
- HVAC,Sum,Heat Exchanger Total Heating Energy [J]
- HVAC,Average,Heat Exchanger Sensible Cooling Rate [W]
- HVAC,Sum,Heat Exchanger Sensible Cooling Energy [J]
- HVAC,Average,Heat Exchanger Latent Cooling Rate [W]
- HVAC,Sum,Heat Exchanger Latent Cooling Energy [J]
- HVAC,Average,Heat Exchanger Total Cooling Rate [W]
- HVAC,Sum,Heat Exchanger Total Cooling Energy [J]
- HVAC,Average,Heat Exchanger Electricity Rate [W]
- HVAC,Sum,Heat Exchanger Electricity Energy [J]

#### 1.52.1.2.1 Heat Exchanger Sensible Heating Rate [W]

This output is the sensible heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is heated by the heat exchanger, else the rate is set to zero.

**1.52.1.2.2 Heat Exchanger Sensible Heating Energy [J]**

This output is the sensible heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

**1.52.1.2.3 Heat Exchanger Latent Gain Rate [W]**

This output is the latent heating rate (humidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Heating Rate and the Heat Exchanger Sensible Heating Rate. A positive value is reported if the supply air is humidified by the heat exchanger, else the rate is set to zero.

**1.52.1.2.4 Heat Exchanger Latent Heating Energy [J]**

This output is the latent heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

**1.52.1.2.5 Heat Exchanger Total Heating Rate [W]**

This output is the total heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is increased by the heat exchanger, else the rate is set to zero.

**1.52.1.2.6 Heat Exchanger Total Heating Energy [J]**

This output is the total heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforHeating, GroupKey = System (ref. Output:Meter objects).

**1.52.1.2.7 Heat Exchanger Sensible Cooling Rate [W]**

This output is the sensible cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is cooled by the heat exchanger, else the rate is set to zero.

**1.52.1.2.8 Heat Exchanger Sensible Cooling Energy [J]**

This output is the sensible cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

**1.52.1.2.9 Heat Exchanger Latent Cooling Rate [W]**

This output is the latent cooling rate (dehumidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Cooling Rate and the Heat Exchanger Sensible Cooling Rate. A positive value is reported if the supply air is dehumidified by the heat exchanger, else the rate is set to zero.

**1.52.1.2.10 Heat Exchanger Latent Cooling Energy [J]**

This output is the latent cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

#### 1.52.1.2.11 Heat Exchanger Total Cooling Rate [W]

This output is the total cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is decreased by the heat exchanger, else the rate is set to zero.

#### 1.52.1.2.12 Heat Exchanger Total Cooling Energy [J]

This output is the total cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforCooling, GroupKey = System (ref. Output:Meter objects).

#### 1.52.1.2.13 Heat Exchanger Electricity Rate [W]

This output is the electric consumption rate of the unit in Watts. This rate is applicable whenever the unit operates (i.e., whenever the unit is scheduled to be available and supply and exhaust air flows exist).

#### 1.52.1.2.14 Heat Exchanger Electricity Energy [J]

This output is the electric consumption of the unit in Joules for the timestep being reported. This output is also added to a meter with ResourceType = Electricity, EndUseKey = HeatRecovery, GroupKey = System (ref. Output:Meter objects).

### 1.52.2 HeatExchanger:AirToAir:SensibleAndLatent

Figure 1.188: Schematic of the Sensible and Latent Air-to-Air Heat Exchanger

The sensible and latent air-to-air heat exchanger is an HVAC component typically used for exhaust or relief air heat recovery (Figure 150). Heat exchanger performance can be specified to transfer sensible energy, latent energy or both between the supply and exhaust air streams. The input requires no geometric

data. Performance is defined by specifying sensible and/or latent effectiveness at 75% and 100% of the nominal (rated) supply air flow rate at two operating conditions as shown in Table 1.53.

Table 1.53: Operating Conditions for Defining Heat Exchanger Performance

Parameter	Conditions	
	Heating	Cooling
Entering supply air temperature:		
Dry-bulb:	1.7°C (35°F)	35°C (95°F)
Wet-bulb:	0.6°C (33°F)	26°C (78°F)
Entering exhaust air temperature:		
Dry-bulb:	21°C (70°F)	24°C (75°F)
Wet-bulb:	14°C (58°F)	17°C (63°F)

Note: Conditions consistent with the Air-Conditioning and Refrigeration Institute's (ARI) Standard 1060-2001.

This object models the basic operation of an air-to-air heat exchanger. Heat exchange between the supply and exhaust air streams occurs whenever the unit is scheduled to be available (Availability schedule) and supply/exhaust air flow is present. This heat exchanger object can be used in conjunction with a conventional air-side economizer (i.e., specify `ModulateFlow` in the `Controller:OutdoorAir` object), whereby heat exchange is suspended whenever the air-side economizer (or high humidity control) is active (i.e., air flow is fully bypassed around a fixed-plate heat exchanger or the rotation of a rotary heat exchanger is stopped). This object is also able to suspend heat exchange for the purpose of providing free cooling operation in the absence of a conventional air-side economizer (i.e., specify `MinimumFlowWithBypass` in the `Controller:OutdoorAir` object).

During winter weather, humid exhaust air entering the heat exchanger can form frost on the cold heat exchanger surfaces, which can reduce air flow and the amount of energy recovery. Several methods are used to control or eliminate frost formation, and the following types can be modeled for this heat exchanger object: supply air preheat, minimum exhaust air temperature, exhaust air recirculation and exhaust only. For preheat frost control, a separate heating coil object must be placed in the supply inlet air stream to keep the air temperature above the frost threshold temperature. The other frost control types are modeled within this object itself (i.e., do not require a separate object to be defined) based on alpha and numeric inputs to this heat exchanger object.

Air-to-air heat exchangers are sometimes controlled to maintain a fixed supply air outlet temperature to avoid overheating when the heat exchanger is heating the supply (primary) air. To model this control in EnergyPlus, a set point manager object is used to establish a temperature set point at the supply air outlet node of the heat exchanger. Wheel speed modulation or plate supply air bypass is used to control the supply air exiting conditions to this set point. The set point for supply air temperature control should be set at the minimum economizer temperature set point if an air-side economizer is also being used by the air system. If frost control and supply air outlet temperature control are used, frost control takes precedence over supply air temperature control (e.g., frost control defrost time fraction is determined as if wheel speed modulation or plate supply air bypass is not used).

To model a sensible and latent air-to-air heat exchanger located in an air loop, the input data file should include the following objects:

- `AirLoopHVAC:OutdoorAirSystem`

- **Controller:OutdoorAir**
- **OutdoorAir:Mixer**
- **HeatExchanger:AirToAir:SensibleAndLatent**
- **Coil:Heating:Water**, **Coil:Heating:Electric** or **Coil:Heating:Fuel** (if preheat frost control is to be modeled)
- **SetpointManager:Scheduled** (if supply air outlet temperature control is used)

The sensible and latent air-to-air heat exchanger can also be used in a number of other applications, including conditioning outdoor ventilation air and supplying it directly to a zone without an air loop. See object **ZoneHVAC:EnergyRecoveryVentilator** for further details on this specific application.

A description of each input field for this object is provided below.

### 1.52.2.1 Inputs

#### 1.52.2.1.1 Field: Name

A unique user-assigned name for a particular sensible/latent air-to-air heat exchanger. Any reference to this heat exchanger by another object will use this name.

#### 1.52.2.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can operate during a given time period. A schedule value of less than or equal to 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.52.2.1.3 Field: Nominal Supply Air Flow Rate

The nominal primary side (supply) air flow rate in cubic meters per second. The actual supply and exhaust air flow rates must be between 50% and 130% of this value or a warning will be issued.

#### 1.52.2.1.4 Field: Sensible Effectiveness at 100% Heating Air Flow

The sensible heat exchange effectiveness at the *heating* condition defined in Table 1.53 above with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate specified in the previous input field. The default value for this field is 0.

#### 1.52.2.1.5 Field: Latent Effectiveness at 100% Heating Air Flow

The latent heat exchange effectiveness at the *heating* condition defined in Table 1.53 with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

#### 1.52.2.1.6 Field: Sensible Effectiveness at 75% Heating Air Flow

The sensible heat exchange effectiveness at the *heating* condition defined in Table 1.53 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. The default value for this field is 0.

#### 1.52.2.1.7 Field: Latent Effectiveness at 75% Heating Air Flow

The latent heat exchange effectiveness at the *heating* condition defined in Table 1.53 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

**1.52.2.1.8 Field: Sensible Effectiveness at 100% Cooling Air Flow**

The sensible heat exchange effectiveness at the *cooling* condition defined in Table 1.53 with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. The default value for this field is 0.

**1.52.2.1.9 Field: Latent Effectiveness at 100% Cooling Air Flow**

The latent heat exchange effectiveness at the *cooling* condition defined in Table 1.53 with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

**1.52.2.1.10 Field: Sensible Effectiveness at 75% Cooling Air Flow**

The sensible heat exchange effectiveness at the *cooling* condition defined in Table 1.53 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. The default value for this field is 0.

**1.52.2.1.11 Field: Latent Effectiveness at 75% Cooling Air Flow**

The latent heat exchange effectiveness at the *cooling* condition defined in Table 1.53 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

**1.52.2.1.12 Field: Supply Air Inlet Node Name**

The name of the HVAC system node from which the unit draws its supply (primary) inlet air.

**1.52.2.1.13 Field: Supply Air Outlet Node Name**

The name of the HVAC system node to which the unit sends its supply (primary) outlet air.

**1.52.2.1.14 Field: Exhaust Air Inlet Node Name**

The name of the HVAC system node from which the unit draws its exhaust (secondary) inlet air.

**1.52.2.1.15 Field: Exhaust Air Outlet Node Name**

The name of the HVAC system node to which the unit sends its exhaust (secondary) outlet air.

**1.52.2.1.16 Field: Nominal Electric Power**

The electric consumption rate of the unit in watts. Electric power is considered constant whenever the unit operates. This numeric input can be used to model electric power consumption by controls (transformers, relays, etc.) and/or a motor for a rotary heat exchanger. None of this electric power contributes thermal load to the supply or exhaust air streams. The default value for this field is 0.

**1.52.2.1.17 Field: Supply Air Outlet Temperature Control**

This alpha field determines if the heat exchanger's supply air outlet is controlled to a temperature set point when the heat exchanger is actively conditioning the supply (primary) air. The choices for this input field are Yes or No, with the default being No. When supply air outlet temperature control is used, the wheel rotational speed modulates or supply air is bypassed around the plate heat exchanger to maintain the desired setpoint temperature. A setpoint manager object is required to establish the desired set point at the supply air outlet node (reference: [SetpointManager:Scheduled](#)). When an air-side economizer is also being modeled for this air system, the heat exchanger is deactivated during economizer operation. Additionally, the set point for the supply air outlet temperature control should be equal to the economizer

outdoor air temperature lower limit (reference: **Controller:OutdoorAir**, field Economizer Minimum Limit Dry-Bulb Temperature), however, any temperature set point may be used.

#### 1.52.2.1.18 Field: Heat Exchanger Type

This alpha field denotes the type of heat exchanger being modeled: Plate (e.g., fixed plate) or Rotary (e.g., rotating cylinder or wheel). The default choice for this field is Plate . The heat exchanger type affects the modeling of frost control options and supply air outlet temperature control. For rotary heat exchangers, rotational speed is varied to control frost formation or the supply air outlet temperature. For plate exchangers, air bypass around the heat exchanger is used to obtain the desired effect.

#### 1.52.2.1.19 Field: Frost Control Type

This alpha field has four choices: None, ExhaustAirRecirculation, ExhaustOnly and MinimumExhaust-Temperature. If this field is left blank, the default frost control type is None . For modeling preheat frost control, specify None for this input field and insert a separate heating coil object in the supply inlet air stream to keep the air temperature above the desired frost threshold temperature.

*ExhaustAirRecirculation*: dampers are used to direct exhaust air back into the zone through the supply side of the heat exchanger when the supply (outdoor) air inlet temperature falls below a threshold temperature (defined in the next input field). The fraction of time that exhaust air is circulated through the supply side of the heat exchanger is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time fraction (see *Field: Rate of Defrost Time Fraction Increase*). When exhaust air is being recirculated, no supply (outdoor ventilation) air is being provided through the heat exchanger unit (which may or may not be acceptable regarding ventilation for occupants).

*ExhaustOnly (supply air bypass)*: this control cycles off the supply air flow through the heat exchanger for a certain period of time while the exhaust air continues to flow through the exhaust side of the heat exchanger. The fraction of time that the supply flow through the heat exchanger is cycled off is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time fraction (see *Field: Rate of Defrost Time Fraction Increase*). When implemented in real applications, provisions are usually made to avoid building depressurization when this frost control is operating (automatic or pressure-operated dampers, or a bypass air damper around the supply side of the heat exchanger). For this frost control type, it is assumed that the supply air is bypassed around the heat exchanger during frost control operation (i.e., the total supply flow is not reduced during defrost, but merely bypassed around the heat exchanger).

*MinimumExhaustTemperature*: the temperature of the exhaust air leaving the heat exchanger is monitored and the heat exchanger effectiveness is decreased (by slowing heat exchanger rotation or bypassing supply air around the plate exchanger) to keep the exhaust air from falling below the threshold temperature.

#### 1.52.2.1.20 Field: Threshold Temperature

This numeric field defines the dry-bulb temperature of air which is used to initiate frost control. The default value is 1.7 °C. For ExhaustAirRecirculation and ExhaustOnly frost control, the threshold temperature defines the supply (outdoor) air inlet temperature below which frost control is active. For MinimumExhaustTemperature frost control, heat exchanger effectiveness is controlled to keep the exhaust air outlet temperature from falling below this threshold temperature value.

The appropriate threshold temperature varies with exhaust (inlet) air temperature and humidity, frost control type, heat exchanger type, and whether the heat exchanger transfers sensible energy alone or both sensible and latent energy (enthalpy). Typical threshold temperatures are provided in Table 1.54 below. However, it is recommended that the user consult manufacturer's information for the specific air-to-air heat exchanger being modeled.

Table 1.54: Typical threshold temperatures

Frost Control Type	Heat Exchanger Type	Energy Exchange	Threshold Temperature
Exhaust Air Recirculation	Plate	Sensible-only	-1.1°C (30°F)
Exhaust Air Recirculation	Plate	Sensible + latent	-12.2°C (10°F)
Exhaust Air Recirculation	Rotary	Sensible-only	-12.2°C (10°F)
Exhaust Air Recirculation	Rotary	Sensible + latent	-23.3°C (-10°F)
Exhaust only	Plate	Sensible-only	-1.1°C (30°F)
Exhaust only	Plate	Sensible + latent	-12.2°C (10°F)
Exhaust only	Rotary	Sensible-only	-12.2°C (10°F)
Exhaust only	Rotary	Sensible + latent	-23.3°C (-10°F)
Minimum exhaust temperature	Plate	Sensible-only	1.7°C (35°F)
Minimum exhaust temperature	Plate	Sensible + latent	1.7°C (35°F)
Minimum exhaust temperature	Rotary	Sensible-only	1.7°C (35°F)
Minimum exhaust temperature	Rotary	Sensible + latent	1.7°C (35°F)
Preheat**	Plate	Sensible-only	-1.1°C (30°F)
Preheat**	Plate	Sensible + latent	-12.2°C (10°F)
Preheat**	Rotary	Sensible-only	-12.2°C (10°F)
Preheat**	Rotary	Sensible + latent	-23.3°C (-10°F)

Source: Indoor Humidity Assessment Tool, U.S. Environmental Protection Agency, <http://www.epa.gov/iaq/schooldesign/saves.html>

\*\* To model preheat frost control, specify frost control type as None and place a heating coil in the supply inlet air stream controlled to keep the air temperature above the frost threshold temperature.

#### 1.52.2.1.21 Field: Initial Defrost Time Fraction

This numeric field defines the fraction of the simulation timestep when frost control will be invoked when the threshold temperature is reached. This field is only used for the ExhaustAirRecirculation and ExhaustOnly frost control types. The value for this field must be 0 and 1. The default time fraction is 0.083 (e.g., 5 min / 60 min) which is typical for ExhaustAirRecirculation frost control. Higher initial defrost time fractions (e.g., 0.167 = 10 min / 60 min) are typically required for ExhaustOnly frost control. For best results, the user should obtain this information from the manufacturer.

#### 1.52.2.1.22 Field: Rate of Defrost Time Fraction Increase

This numeric field defines the rate of increase in the defrost time fraction as the supply (outdoor) air inlet temperature falls below the threshold temperature. This field is only used for the ExhaustAirRecirculation

and ExhaustOnly frost control types. The value for this field must be  $\geq 0$ . The default value is 0.012 (e.g., 0.72 min / 60 min per degree C temperature difference) which is typical for ExhaustAirRecirculation frost control. Higher values (e.g., 0.024 = 1.44 min / 60 min per degree C temperature difference) are typically required for ExhaustOnly frost control. For best results, the user should obtain this information from the manufacturer.

This value is used to determine the total defrost time fraction as follows:

Total defrost time fraction = Initial Defrost Time Fraction + Rate of Defrost Time Fraction Increase  
 $\times (T_{\text{threshold}} - T_{\text{supplyairinlet}})$

The model does not allow the total defrost time fraction to exceed 1.0 or be less than 0.

### 1.52.2.1.23 Field: Economizer Lockout

This input denotes whether the heat exchanger unit is locked out (bypassed for plate type heat exchangers or the rotation is suspended for rotary type heat exchangers) when the air-side economizer is operating. Both the economizer and high humidity control (Ref. [Controller:OutdoorAir](#)) activate the heat exchanger lockout as specified by this input. The input choices are *Yes* (meaning locked out) or *No*. The default input for this field is *Yes*.

Following is an example input for this heat exchanger object:

- HVAC,Average,Heat Exchanger Sensible Effectiveness[]
- HVAC,Average,Heat Exchanger Latent Effectiveness[]
- HVAC,Average,Heat Exchanger Supply Air Bypass Mass Flow Rate [kg/s]
- HVAC,Average,Heat Exchanger Exhaust Air Bypass Mass Flow Rate [kg/s] HVAC,Average,Heat Exchanger Defrost Time Fraction[]

#### 1.52.2.2.1 Heat Exchanger Sensible Heating Rate [W]

This output is the sensible heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is heated by the heat exchanger, else the rate is set to zero.

#### 1.52.2.2.2 Heat Exchanger Sensible Heating Energy [J]

This output is the sensible heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

#### 1.52.2.2.3 Heat Exchanger Latent Gain Rate [W]

This output is the latent heating rate (humidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Heating Rate and the Heat Exchanger Sensible Heating Rate. A positive value is reported if the supply air is humidified by the heat exchanger, else the rate is set to zero.

#### 1.52.2.2.4 Heat Exchanger Latent Gain Energy [J]

This output is the latent heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

#### 1.52.2.2.5 Heat Exchanger Total Heating Rate [W]

This output is the total heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is increased by the heat exchanger, else the rate is set to zero.

#### 1.52.2.2.6 Heat Exchanger Total Heating Energy [J]

This output is the total heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforHeating, GroupKey = System (ref. Output:Meter objects).

**1.52.2.2.7 Heat Exchanger Sensible Cooling Rate [W]**

This output is the sensible cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is cooled by the heat exchanger, else the rate is set to zero.

**1.52.2.2.8 Heat Exchanger Sensible Cooling Energy [J]**

This output is the sensible cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

**1.52.2.2.9 Heat Exchanger Latent Cooling Rate [W]**

This output is the latent cooling rate (dehumidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Cooling Rate and the Heat Exchanger Sensible Cooling Rate. A positive value is reported if the supply air is dehumidified by the heat exchanger, else the rate is set to zero.

**1.52.2.2.10 Heat Exchanger Latent Cooling Energy [J]**

This output is the latent cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

**1.52.2.2.11 Heat Exchanger Total Cooling Rate [W]**

This output is the total cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is decreased by the heat exchanger, else the rate is set to zero.

**1.52.2.2.12 Heat Exchanger Total Cooling Energy [J]**

This output is the total cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforCooling, GroupKey = System (ref. Output:Meter objects).

**1.52.2.2.13 Heat Exchanger Electricity Rate [W]**

This output is the electric consumption rate of the unit in Watts. This rate is applicable whenever the unit operates (i.e., whenever the unit is scheduled to be available and supply and exhaust air flows exist).

**1.52.2.2.14 Heat Exchanger Electricity Energy [J]**

This output is the electric consumption of the unit in Joules for the timestep being reported. This output is also added to a meter with ResourceType = Electricity, EndUseKey = HeatRecovery, GroupKey = System (ref. Output:Meter objects).

**1.52.2.2.15 Heat Exchanger Sensible Effectiveness []**

This output is the average sensible effectiveness of the heat exchanger (excluding bypass air, if any) over the timestep being reported.

**1.52.2.2.16 Heat Exchanger Latent Effectiveness []**

This output is the average latent effectiveness of the heat exchanger (excluding bypass air, if any) over the timestep being reported.

**1.52.2.2.17 Heat Exchanger Supply Air Bypass Mass Flow Rate [kg/s]**

This output is the average mass flow rate in kg/second of the supply (primary) air stream that is bypassing the heat exchanger over the timestep being reported. This flow rate is equal to the total supply mass flow rate through the heat exchanger **unit** minus the amount passing through the supply side of the heat exchanger **core**.

**1.52.2.2.18 Heat Exchanger Exhaust Air Bypass Mass Flow Rate [kg/s]**

This output is the average mass flow rate in kg/second of the exhaust (secondary) air stream that is bypassing the heat exchanger over the timestep being reported. This flow rate is equal to the total exhaust mass flow rate through the heat exchanger **unit** minus the amount passing through the exhaust side of the heat exchanger **core**.

**1.52.2.2.19 Heat Exchanger Defrost Time Fraction []**

This output is the average fraction of the reporting timestep when frost control is being implemented.

**1.52.3 HeatExchanger:Desiccant:BalancedFlow**

This desiccant heat exchanger object is an HVAC component used to model both temperature (sensible) and moisture (latent) heat exchange between two air streams (Figure 1.189). The model assumes balanced air flow through the regeneration and process sides of the heat exchanger (i.e., regeneration and process air volume flow rates and face velocities are the same). Heat exchanger performance is specified through a performance data type object (e.g., [HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1](#)).

Figure 1.189: Schematic of the Balanced Flow Desiccant Heat Exchanger

Currently, this desiccant heat exchanger model can be referenced by two compound objects: `CoilSystem:Cooling:DX:HeatExchangerAssisted` and `Dehumidifier:Desiccant:System`, both of which are used to provide enhanced dehumidification over conventional systems. If this heat exchanger is referenced by a compound object, the compound object will control heat exchanger operation (i.e., tell the heat exchanger if heat exchange is needed or not for each simulation timestep).

This desiccant heat exchanger object may also be specified directly in an `AirLoopHVAC` (air loop `BranchList`) or in an `AirLoopHVAC:OutdoorAirSystem` (`AirLoopHVAC:OutdoorAirSystem:EquipmentList`) without being referenced by a compound object. If specified directly in an `AirLoopHVAC` or `AirLoopHVAC:OutdoorAirSystem`, then the heat exchanger can be controlled to provide heat exchange based on a maximum and/or minimum humidity set point placed on the process air outlet node (ref. Setpoint Managers). If no humidity set points are provided on this node, then heat exchange will be provided whenever the heat exchanger is available to operate (via its availability schedule) and there is a temperature and/or humidity ratio difference between the two air streams.

Inputs to this model include an availability schedule name, inlet and outlet air node names, and the type and name of the heat exchanger performance data object. A description of each input field for this object is provided below.

### 1.52.3.1 Inputs

#### 1.52.3.1.1 Field: Name

A unique, user-assigned name for a particular balanced flow desiccant heat exchanger. Any reference to this heat exchanger by another object will use this name.

#### 1.52.3.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the heat exchanger can operate during a given time period. A schedule value of less than or equal to 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.52.3.1.3 Field: Regeneration Air Inlet Node Name

The name of the HVAC system node from which the unit draws its regeneration inlet air.

#### 1.52.3.1.4 Field: Regeneration Air Outlet Node Name

The name of the HVAC system node to which the unit sends its regeneration outlet air.

#### 1.52.3.1.5 Field: Process Air Inlet Node Name

The name of the HVAC system node from which the unit draws its process inlet air.

#### 1.52.3.1.6 Field: Process Air Outlet Node Name

The name of the HVAC system node to which the unit sends its process outlet air.

#### 1.52.3.1.7 Field: Heat Exchanger Performance Object Type

This alpha field contains the type of model used to simulate the desiccant heat exchanger's thermal performance and electrical energy use. Currently, the only valid choice is `HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1`.

### 1.52.3.1.8 Field: Heat Exchanger Performance Name

This alpha field contains the identifying name of the specific heat exchanger performance type object (e.g., `HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1`) that defines the performance for this heat exchanger. A single heat exchanger performance type object may be used to define performance for many `HeatExchanger:Desiccant:BalancedFlow` objects (i.e., the same name may be used in this input field for more than one balanced flow desiccant heat exchanger).

### 1.52.3.1.9 Field: Economizer Lockout

This input denotes whether the heat exchanger unit is locked out (heat exchanger rotation is suspended) when the air-side economizer is operating. Both the economizer and high humidity control (Ref. `Controller:OutdoorAir`) activate the heat exchanger lockout as specified by this input. The input choices are *Yes* (meaning locked out) or *No*. Economizer lockout is typically *not* used for this type of heat exchanger. For this reason, the default input for this field is *No*.

Following is an example input for this heat exchanger object:

```
HeatExchanger:Desiccant:BalancedFlow,
  Desiccant Heat Exchanger 1,           !- Name
  OfficeHeatCoolAvail,                 !- Availability Schedule Name
  DXSystem 1 Mixed Air Node,           !- Regeneration Air Inlet Node Name
  DX Cooling Coil Air Inlet Node,       !- Regeneration Air Outlet Node Name
  DX Cooling Coil Air Outlet Node,      !- Process Air Inlet Node Name
  DXSystem 1 Fan Air Inlet Node,        !- Process Air Outlet Node Name
  HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1, !- Heat Exchanger Performance Object Type
  HXDesPerf1;                          !- Heat Exchanger Performance Name
```

### 1.52.3.2 Outputs

- HVAC,Average,Heat Exchanger Sensible Heating Rate [W]
- HVAC,Sum,Heat Exchanger Sensible Heating Energy [J]
- HVAC,Average,Heat Exchanger Latent Gain Rate [W]
- HVAC,Sum,Heat Exchanger Latent Gain Energy [J]
- HVAC,Average,Heat Exchanger Total Heating Rate [W]
- HVAC,Sum,Heat Exchanger Total Heating Energy [J]
- HVAC,Average,Heat Exchanger Sensible Cooling Rate [W]
- HVAC,Sum,Heat Exchanger Sensible Cooling Energy [J]
- HVAC,Average,Heat Exchanger Latent Cooling Rate [W]
- HVAC,Sum,Heat Exchanger Latent Cooling Energy [J]
- HVAC,Average,Heat Exchanger Total Cooling Rate [W]
- HVAC,Sum,Heat Exchanger Total Cooling Energy [J]
- HVAC,Average,Heat Exchanger Electricity Rate [W]
- HVAC,Sum,Heat Exchanger Electricity Energy [J]

**1.52.3.2.1 Heat Exchanger Sensible Heating Rate [W]**

This output is the sensible heating rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit, the process air inlet and outlet temperatures, and the specific heat of the inlet process air. A positive value is reported if the process air is heated by the heat exchanger, else the rate is set to zero.

**1.52.3.2.2 Heat Exchanger Sensible Heating Energy [J]**

This output is the sensible heating energy added to the process air by the heat exchanger in Joules over the timestep being reported.

**1.52.3.2.3 Heat Exchanger Latent Gain Rate [W]**

This output is the latent heating rate (humidification) of the process air by the heat exchanger in Watts. This rate is determined by taking the difference between the heat exchanger's total heat recovery rate and the sensible heat recovery rate. A positive value is reported if the process air is humidified by the heat exchanger, else the rate is set to zero.

**1.52.3.2.4 Heat Exchanger Latent Gain Energy [J]**

This output is the latent heating energy added to the process air by the heat exchanger in Joules over the timestep being reported.

**1.52.3.2.5 Heat Exchanger Total Heating Rate [W]**

This output is the total heating rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit and the enthalpy of the air entering and leaving the process side of the unit. A positive value is reported if the enthalpy of the process air is increased by the heat exchanger, else the rate is set to zero.

**1.52.3.2.6 Heat Exchanger Total Heating Energy [J]**

This output is the total heating energy added to the process air by the heat exchanger in Joules over the timestep being reported. This output is also added to a meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforHeating, GroupKey = System (ref. Output:Meter objects).

**1.52.3.2.7 Heat Exchanger Sensible Cooling Rate [W]**

This output is the sensible cooling rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit, the process air inlet and outlet temperatures, and the specific heat of the inlet process air. A positive value is reported if the process air is cooled by the heat exchanger, else the rate is set to zero.

**1.52.3.2.8 Heat Exchanger Sensible Cooling Energy [J]**

This output is the sensible cooling energy added to the process air by the heat exchanger in Joules over the timestep being reported.

**1.52.3.2.9 Heat Exchanger Latent Cooling Rate [W]**

This output is the latent cooling rate (dehumidification) of the process air by the heat exchanger in Watts. This rate is determined by taking the difference between the heat exchanger's total heat recovery rate and the sensible heat recovery rate. A positive value is reported if the process air is dehumidified by the heat exchanger, else the rate is set to zero.

**1.52.3.2.10 Heat Exchanger Latent Cooling Energy [J]**

This output is the latent cooling energy added to the process air by the heat exchanger in Joules over the timestep being reported.

**1.52.3.2.11 Heat Exchanger Total Cooling Rate [W]**

This output is the total cooling rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit and the enthalpy of the air entering and leaving the process side of the unit. A positive value is reported if the enthalpy of the process air is decreased by the heat exchanger, else the rate is set to zero.

**1.52.3.2.12 Heat Exchanger Total Cooling Energy [J]**

This output is the total cooling energy added to the process air by the heat exchanger in Joules over the timestep being reported. This output is also added to a meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforCooling, GroupKey = System (ref. Output:Meter objects).

**1.52.3.2.13 Heat Exchanger Electricity Rate [W]**

This output is the average electric consumption rate of the unit in Watts. This average rate includes portions of the simulation timestep when the heat exchanger may be cycled off (i.e., average of on and off periods, as appropriate).

**1.52.3.2.14 Heat Exchanger Electricity Energy [J]**

This output is the electric consumption of the unit in Joules for the timestep being reported. This output is also added to a meter with ResourceType = Electricity, EndUseKey = HeatRecovery, GroupKey = System (ref. Output:Meter objects).

**1.52.4 HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1**

This object specifies a performance model and model coefficients for a balanced flow desiccant heat exchanger. A **HeatExchanger:Desiccant:BalancedFlow** object will reference a **HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1** object. This performance data object is used to specify the thermal performance and electric consumption of the heat exchanger. Some representative inputs for this object are provided in the EnergyPlus Reference DataSets (PerfCurves.idf and AllDataSets.idf).

This model predicts the regeneration air stream outlet temperature and humidity ratio values based on the entering regeneration and process air stream temperature, humidity ratio and face velocity. The process air stream outlet humidity ratio and temperatures are calculated based on a simple heat and moisture balance. The model requires that the user enter the nominal volumetric flow rate and a nominal face velocity, electric power consumption, empirical model coefficients for the regeneration outlet air temperature and humidity ratio equations, and the applicable minimum and maximum values for both the independent and dependent variables for the empirical model coefficients provided. This model is based on the following equations:

- The dry-bulb temperature of the regeneration outlet air is defined using the following equation:

$$RTO = B1 + B2 * RWI + B3 * RTI + B4 * \left( \frac{RWI}{RTI} \right) + B5 * PWI + B6 * PTI + B7 * \left( \frac{PWI}{PTI} \right) + B8 * RFV \quad (1.210)$$

where,

$RTO$  = Regeneration outlet air dry-bulb temperature (C)

$RWI$  = Regeneration inlet air humidity ratio (kgWater/kgDryAir)

$RTI$  = Regeneration inlet air dry-bulb temperature (C)

$PWI$  = Process inlet air humidity ratio (kgWater/kgDryAir)

$PTI$  = Process inlet air dry-bulb temperature (C)

$RFV$  = Regeneration (and process) face velocity (m/s)

- The humidity ratio of the regeneration outlet air is defined using the same empirical equation form; however, different coefficients are used as follows:

$$RWO = C1 + C2 * RWI + C3 * RTI + C4 * \left( \frac{RWI}{RTI} \right) + C5 * PWI + C6 * PTI + C7 * \left( \frac{PWI}{PTI} \right) + C8 * RFV \quad (1.211)$$

where,

$RWO$  = Regeneration outlet air humidity ratio (kgWater/kgDryAir)

- The process outlet air conditions are then calculated based on the regeneration outlet air conditions (temperature or humidity ratio) calculated above, the actual regeneration inlet air conditions entering the heat exchanger, and assuming the same amount of sensible and total energy transfer across both the process and regeneration sides of the heat exchanger. The difference between the actual inlet air conditions and  $RTI/RWI/PTI/PWI$  is made here because user-defined limits for  $RTI/RWI/PTI/PWI$  may result in a difference between the actual conditions and those used in the equations shown above (see the EnergyPlus Engineering Reference for further discussion).

A description of each input field for this object is provided below.

#### 1.52.4.1 Inputs

##### 1.52.4.1.1 Field: Name

This alpha field contains the identifying name for this set of desiccant heat exchanger performance data. Any reference to this performance data set by another object (e.g., **HeatExchanger:Desiccant:BalancedFlow**) will use this name.

##### 1.52.4.1.2 Field: Nominal Air Flow Rate

The nominal air volume flow rate in cubic meters per second. This model assumes balanced air flow (i.e., the same air volume flow rate across the process and regeneration sides of the heat exchanger). The minimum value should be greater than 0. This field is autosizable.

##### 1.52.4.1.3 Field: Nominal Air Face Velocity

This numeric field contains the nominal air velocity across the heat exchanger face area in meters per second. It is assumed that this air velocity is the same for both sides of the heat exchanger. This value, along with the Nominal Air Flow Rate sets the heat exchanger face area. With this fixed face area, the air face velocity is calculated every simulation timestep based on the actual air volume flow rate for the timestep. The minimum value should be greater than 0 and less than or equal to 6. The default value is 3.0.

**1.52.4.1.4 Field: Nominal Electric Power**

This numeric field contains the nominal electric consumption rate of the heat exchanger in watts. This electric power is considered constant and is consumed only when the heat exchanger operates (e.g., for all or a portion of the simulation timestep, as appropriate). This numeric input can be used to model electric power consumption by controls (transformers, relays, etc.) and/or a motor for a rotary heat exchanger. None of this electric power contributes thermal load to the process or regeneration air streams. The minimum value should be greater than or equal to 0. The default value for this field is also 0.

The coefficients for the regeneration air outlet temperature equation described above are defined in the following eight fields:

**1.52.4.1.5 Field: Temperature Equation Coefficient 1**

The constant coefficient ( $B_1$ ) in the temperature equation shown above (RTO).

**1.52.4.1.6 Field: Temperature Equation Coefficient 2**

The coefficient ( $B_2$ ) in the temperature equation shown above (RTO).

**1.52.4.1.7 Field: Temperature Equation Coefficient 3**

The coefficient ( $B_3$ ) in the temperature equation shown above (RTO).

**1.52.4.1.8 Field: Temperature Equation Coefficient 4**

The coefficient ( $B_4$ ) in the temperature equation shown above (RTO).

**1.52.4.1.9 Field: Temperature Equation Coefficient 5**

The coefficient ( $B_5$ ) in the temperature equation shown above (RTO).

**1.52.4.1.10 Field: Temperature Equation Coefficient 6**

The coefficient ( $B_6$ ) in the temperature equation shown above (RTO).

**1.52.4.1.11 Field: Temperature Equation Coefficient 7**

The coefficient ( $B_7$ ) in the temperature equation shown above (RTO).

**1.52.4.1.12 Field: Temperature Equation Coefficient 8**

The coefficient ( $B_8$ ) in the temperature equation shown above (RTO).

The following 16 fields are used to establish the valid range for the dependent and independent variables associated with the coefficients defined above ( $B_1$  through  $B_8$ ) for the regeneration outlet air temperature equation.

**1.52.4.1.13 Field: Minimum Regeneration Inlet Air Humidity Ratio for Temperature Equation**

The minimum allowable value of RWI in the temperature equation shown above (kgWater/kgDryAir). Values of RWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.14 Field: Maximum Regeneration Inlet Air Humidity Ratio for Temperature Equation**

The maximum allowable value of RWI in the temperature equation shown above (kgWater/kgDryAir). Values of RWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.15 Field: Minimum Regeneration Inlet Air Temperature for Temperature Equation**

The minimum allowable value of RTI in the temperature equation shown above (C). Values of RTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued.

**1.52.4.1.16 Field: Maximum Regeneration Inlet Air Temperature for Temperature Equation**

The maximum allowable value of RTI in the temperature equation shown above (C). Values of RTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued.

**1.52.4.1.17 Field: Minimum Process Inlet Air Humidity Ratio for Temperature Equation**

The minimum allowable value of PWI in the temperature equation shown above (kg/kg). Values of PWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.18 Field: Maximum Process Inlet Air Humidity Ratio for Temperature Equation**

The maximum allowable value of PWI in the temperature equation shown above (kg/kg). Values of PWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.19 Field: Minimum Process Inlet Air Temperature for Temperature Equation**

The minimum allowable value of PTI in the temperature equation shown above (C). Values of PTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued.

**1.52.4.1.20 Field: Maximum Process Inlet Air Temperature for Temperature Equation**

The maximum allowable value of PTI in the temperature equation shown above (C). Values of PTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued.

**1.52.4.1.21 Field: Minimum Regeneration Air Velocity for Temperature Equation**

The minimum allowable value of RFV in the temperature equation shown above (m/s). Values of RFV less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued. The minimum value for this input field should be greater than 0.

**1.52.4.1.22 Field: Maximum Regeneration Air Velocity for Temperature Equation**

The maximum allowable value of RFV in the temperature equation shown above (m/s). Values of RFV greater than the maximum will be replaced by this maximum value when calculating the regeneration outlet air temperature and a warning message will be issued. The minimum value for this input field should be greater than 0.

**1.52.4.1.23 Field: Minimum Regeneration Outlet Air Temperature for Temperature Equation**

The minimum value of RTO resulting from the temperature equation shown above (C). If RTO is less than this value, RTO will be replaced by this minimum value and a warning message will be issued.

**1.52.4.1.24 Field: Maximum Regeneration Outlet Air Temperature for Temperature Equation**

The maximum value of RTO resulting from the temperature equation shown above (C). If RTO is greater than this value, RTO will be replaced by this maximum value and a warning message will be issued.

**1.52.4.1.25 Field: Minimum Regeneration Inlet Air Relative Humidity for Temperature Equation**

The minimum relative humidity of the regeneration inlet air for the temperature equation shown above (percent). If the relative humidity of the regeneration inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

**1.52.4.1.26 Field: Maximum Regeneration Inlet Air Relative Humidity for Temperature Equation**

The maximum relative humidity of the regeneration inlet air for the temperature equation shown above (percent). If the relative humidity of the regeneration inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

**1.52.4.1.27 Field: Minimum Process Inlet Air Relative Humidity for Temperature Equation**

The minimum relative humidity of the process inlet air for the temperature equation shown above (percent). If the relative humidity of the process inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

**1.52.4.1.28 Field: Maximum Process Inlet Air Relative Humidity for Temperature Equation**

The maximum relative humidity of the process inlet air for the temperature equation shown above (percent). If the relative humidity of the process inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

The coefficients for the regeneration outlet air humidity ratio equation are defined in the following eight fields:

**1.52.4.1.29 Field: Humidity Ratio Equation Coefficient 1**

The constant coefficient ( $C_1$ ) in the humidity ratio equation shown above (RWO).

**1.52.4.1.30 Field: Humidity Ratio Equation Coefficient 2**

The coefficient ( $C_2$ ) in the humidity ratio equation shown above (RWO).

**1.52.4.1.31 Field: Humidity Ratio Equation Coefficient 3**

The coefficient ( $C_3$ ) in the humidity ratio equation shown above (RWO).

**1.52.4.1.32 Field: Humidity Ratio Equation Coefficient 4**

The coefficient ( $C_4$ ) in the humidity ratio equation shown above (RWO).

**1.52.4.1.33 Field: Humidity Ratio Equation Coefficient 5**

The coefficient ( $C_5$ ) in the humidity ratio equation shown above (RWO).

**1.52.4.1.34 Field: Humidity Ratio Equation Coefficient 6**

The coefficient ( $C_6$ ) in the humidity ratio equation shown above (RWO).

**1.52.4.1.35 Field: Humidity Ratio Equation Coefficient 7**

The coefficient ( $C_7$ ) in the humidity ratio equation shown above (RWO).

**1.52.4.1.36 Field: Humidity Ratio Equation Coefficient 8**

The coefficient ( $C_8$ ) in the humidity ratio equation shown above (RWO).

The following 16 fields are used to establish the valid range for the dependent and independent variables associated with the coefficients defined above ( $C_1$  through  $C_8$ ) for the regeneration outlet air humidity ratio equation.

**1.52.4.1.37 Field: Minimum Regeneration Inlet Air Humidity Ratio for Humidity Ratio Equation**

The minimum allowable value of RWI in the humidity ratio equation shown above (kgWater/kgDryAir). Values of RWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.38 Field: Maximum Regeneration Inlet Air Humidity Ratio for Humidity Ratio Equation**

The maximum allowable value of RWI in the humidity ratio equation shown above (kgWater/kgDryAir). Values of RWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.39 Field: Minimum Regeneration Inlet Air Temperature for Humidity Ratio Equation**

The minimum allowable value of RTI in the humidity ratio equation shown above (C). Values of RTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

**1.52.4.1.40 Field: Maximum Regeneration Inlet Air Temperature for Humidity Ratio Equation**

The maximum allowable value of RTI in the humidity ratio equation shown above (C). Values of RTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

**1.52.4.1.41 Field: Minimum Process Inlet Air Humidity Ratio for Humidity Ratio Equation**

The minimum allowable value of PWI in the humidity ratio equation shown above (kgWater/kgDryAir). Values of PWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.42 Field: Maximum Process Inlet Air Humidity Ratio for Humidity Ratio Equation**

The maximum allowable value of PWI in the humidity ratio equation shown above (kgWater/kgDryAir). Values of PWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

**1.52.4.1.43 Field: Minimum Process Inlet Air Temperature for Humidity Ratio Equation**

The minimum allowable value of PTI in the humidity ratio equation shown above (C). Values of PTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

**1.52.4.1.44 Field: Maximum Process Inlet Air Temperature for Humidity Ratio Equation**

The maximum allowable value of PTI in the humidity ratio equation shown above (C). Values of PTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

**1.52.4.1.45 Field: Minimum Regeneration Air Velocity for Humidity Ratio Equation**

The minimum allowable value of RFV in the humidity ratio equation shown above (m/s). Values of RFV less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The minimum value for this input field should be greater than 0.

**1.52.4.1.46 Field: Maximum Regeneration Air Velocity for Humidity Ratio Equation**

The maximum allowable value of RFV in the humidity ratio equation shown above (m/s). Values of RFV greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The minimum value for this input field should be greater than 0.

**1.52.4.1.47 Field: Minimum Regeneration Outlet Air Humidity Ratio for Humidity Ratio Equation**

The minimum value of RWO resulting from the humidity ratio equation shown above (kgWater/kgDryAir). If RWO is less than this value, RWO will be replaced by this minimum value and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

#### 1.52.4.1.48 Field: Maximum Regeneration Outlet Air Humidity Ratio for Humidity Ratio Equation

The maximum value of RWO resulting from the humidity ratio equation shown above (kgWater/kgDryAir). If RWO is greater than this value, RWO will be replaced by this maximum value and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

#### 1.52.4.1.49 Field: Minimum Regeneration Inlet Air Relative Humidity for Humidity Ratio Equation

The minimum relative humidity of the regeneration inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the regeneration inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

#### 1.52.4.1.50 Field: Maximum Regeneration Inlet Air Relative Humidity for Humidity Ratio Equation

The maximum relative humidity of the regeneration inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the regeneration inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

#### 1.52.4.1.51 Field: Minimum Process Inlet Air Relative Humidity for Humidity Ratio Equation

The minimum relative humidity of the process inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the process inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

#### 1.52.4.1.52 Field: Maximum Process Inlet Air Relative Humidity for Humidity Ratio Equation

The maximum relative humidity of the process inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the process inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

Following is an example input for this heat exchanger performance data type object:

### 1.52.4.2 Outputs

No variables are reported for this object. However, outputs are provided by the HeatExchanger:Desiccant:BalancedFlow object that references this PerformanceDataType1 object.

## 1.53 Group Demand Limiting Controls

Demand limiting, or demand management, is a strategy for reducing a building's demand for utilities, e.g., electricity. Utility companies typically charge a monthly fee for "demand charges" that is based on the peak demand during a certain time period. Often the peak demand charge is set by one exceptional day that is much higher than the peak demand for an average day during the month. Therefore, to save utility costs, it is in the interest of building owners to find ways to manage the demand on peak days. While demand management is generally concerned with the demand for electricity, the future will likely see demand management of other utilities, such as natural gas or water.

Demand limiting controls shut off or reduce the power to non-essential loads in order to reduce the overall building demand. Some typical controls:

- shut off or dim electric lights, equipment, or HVAC systems
- reset the thermostatic set points on HVAC systems

- reduce the load of a set of similar components by rotating one or more components “off” for a short time interval
- turn on generators to meet some or all of the building’s demand.

The demand limiting controls implemented in EnergyPlus are intended to allow some of the more common demand limiting strategies. Currently, only `Exterior:Lights`, `Lights`, `ElectricEquipment`, `ZoneControl:Thermostat`, and `Controller:OutdoorAir` objects can be demand limited. Additional components will be demand limited in future releases.

### 1.53.1 DemandManagerAssignmentList

The DemandManagerAssignmentList object is a high level control that makes demand limiting decisions based on a list of possible demand limiting strategies. Each demand limiting strategy is described in a separate DemandManager object. (This is structured like the relationship between the `AvailabilityManagerAssignmentList` and the `AvailabilityManager` objects.)

Each DemandManagerAssignmentList monitors and demand limits one meter. Only electricity meters are currently allowed. In many cases, the meter will be *Electricity:Facility*. A schedule and safety factor are used to set the demand limit above which the DemandManagers become activated. The billing month schedule and demand window are also taken into account when calculating the demand limit.

DemandManagers in the list are activated based on the *Demand Manager Priority*. If the **Sequential** option is used, each manager in the list is activated in sequence from first to last until demand is reduced below the limit or until all managers are activated. If the **All** option is used, all managers are activated simultaneously to achieve the maximum demand reduction.

A DemandManager is skipped if it cannot reduce the demand. Possible reasons that a manager cannot reduce demand include:

- not enough load to limit
- not available because of its *Availability Schedule*
- already activated; load limited during a previous timestep.

#### 1.53.1.1 Inputs

##### 1.53.1.1.1 Field: Name

The name of the DemandManagerAssignmentList object.

##### 1.53.1.1.2 Field: Meter Name

This field references the meter that is to be monitored and demand limited. Only electricity meters are currently allowed.

##### 1.53.1.1.3 Field: Demand Limit Schedule Name

The reference to the schedule object specifying the target demand limits [schedule values should be in Watts].

##### 1.53.1.1.4 Field: Demand Limit Safety Fraction

This field is a multiplier that is applied to the target demand limit (above). When the metered demand exceeds (target demand limit \* safety fraction), the DemandManagers begin to limit the demand. This helps to ensure that the target limit is not exceeded.

**1.53.1.1.5 Field: Billing Period Schedule Name**

The reference to the schedule object that defines the monthly billing periods. The peak demand during the peak period of the billing period typically determines the demand charge. This should reference the same schedule that is used in the *Month Schedule Name* field of the **UtilityCost:Tariff** object. If left blank, it defaults to the regular divisions between months.

**1.53.1.1.6 Field: Peak Period Schedule Name**

The reference to the schedule object that defines the peak/off-peak time-of-use periods. The peak demand during the peak period of the billing period typically determines the demand charge. This should reference the same schedule that is used in the *Time of Use Period Schedule Name* field of the **UtilityCost:Tariff** object. A value of 1 indicates the peak period; any other value is off-peak. If left blank, it defaults to always on the peak period. The DemandManagerAssignmentList only attempts to demand limit during peak periods.

**1.53.1.1.7 Field: Demand Window Length**

This field is similar to the field of the same name in the **UtilityCost:Tariff** object. However, the user may not want to limit using the same demand window as the utility company. This field allows the user to input the number of minutes over which to calculate the current demand. The minutes are rounded to match the nearest multiple of time steps.

**1.53.1.1.8 Field: Demand Manager Priority**

This field indicates what logic should be used to activate the individual DemandManagers in the list. **Sequential** treats the list of DemandManagers as a sequential priority list, i.e., the first DemandManager in the list is activated first, then the second, etc., until the demand falls below the limit. **All** activates all demand managers to achieve the maximum demand reduction.

**1.53.1.1.9 Field: Demand Manager Type 1**

The key word defining the type of DemandManager.

**1.53.1.1.10 Field: Demand Manager Name 1**

The name of a DemandManager object defined elsewhere in the input file.

DemandManagers are listed by pairs of data items: *Demand Manager Type* and *Demand Manager Name*. Ten managers are accommodated in the list by default. The IDD specification, however, is extensible and additional pairs may be added by directly editing the IDD.

An example IDF showing how this object is used is provided below:

```
DemandManagerAssignmentList,
  Demand Manager,           !- Name
  Electricity:Facility,      !- Meter Name
  Limit Schedule,           !- Demand Limit Schedule Name
  1.0,                       !- Demand Limit Safety Fraction
  ,                           !- Billing Period Schedule Name
  ,                           !- Peak Period Schedule Name
  15,                       !- Demand Window Length {minutes}

### 1.53.1.2 Outputs

The following output variables are reported for the DemandManagerAssignmentList object:

- Zone,Average,Demand Manager Meter Demand Power [W]
- Zone,Average,Demand Manager Average Demand Power [W]
- Zone,Average,Demand Manager Peak Demand Power [W]
- Zone,Average,Demand Manager Scheduled Limit Power [W]
- Zone,Average,Demand Manager Demand Limit Power [W]
- Zone,Average,Demand Manager Avoided Demand [W]
- Zone,Average,Demand Manager Over Limit Power [W]
- Zone,Sum,Demand Manager Over Limit Time [hr]
- Zone,Sum,Demand Manager Exterior Energy Iteration Count []
- Zone,Sum,Demand Manager Heat Balance Iteration Count []
- Zone,Sum,Demand Manager HVAC Iteration Count []

#### 1.53.1.2.1 Demand Manager Meter Demand Power [W]

The current demand for the designated meter.

#### 1.53.1.2.2 Demand Manager Average Demand Power [W]

The current demand for the designated meter averaged over the *Demand Window Length*.

#### 1.53.1.2.3 Demand Manager Peak Demand Power [W]

The peak demand in the billing month so far.

#### 1.53.1.2.4 Demand Manager Scheduled Limit Power [W]

The scheduled target demand limit from the *Demand Limit Schedule*.

#### 1.53.1.2.5 Demand Manager Demand Limit Power [W]

The actual demand limit after multiplication by the *Demand Limit Safety Fraction*.

#### 1.53.1.2.6 Demand Manager Avoided Demand [W]

The demand that was avoided by the active DemandManagers.

#### 1.53.1.2.7 Demand Manager Over Limit Power [W]

The difference between the demand limit and the average demand.

**1.53.1.2.8 Demand Manager Over Limit Time [hr]**

The number of hours that the demand limit was exceeded.

**1.53.1.2.9 Demand Manager Exterior Energy Iteration Count []**

The number times that the exterior energy use was resimulated for demand limiting.

**1.53.1.2.10 Demand Manager Heat Balance Iteration Count []**

The number times that the zone heat balance was resimulated for demand limiting.

**1.53.1.2.11 Demand Manager HVAC Iteration Count []**

The number times that the HVAC system was resimulated for demand limiting.

**1.53.2 DemandManager:ExteriorLights**

The DemandManager:ExteriorLights object is used for demand limiting **Exterior:Lights** objects.

**1.53.2.1 Inputs****1.53.2.1.1 Field: Name**

The name of the DemandManager:ExteriorLights object.

**1.53.2.1.2 Field: Availability Schedule Name**

The reference to the schedule object specifying the availability of this DemandManager. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.53.2.1.3 Field: Limit Control**

This field specifies the type of limiting control. The **Fixed** option reduces the power to the controlled loads by a fixed amount determined by the *Maximum Limit Fraction* field. The **Off** option disables the DemandManager in the simulation.

**1.53.2.1.4 Field: Minimum Limit Duration**

The minimum amount of time [minutes] that the DemandManager will continue to demand limit after being activated. This prevents loads from turning on and off every time step.

**1.53.2.1.5 Field: Maximum Limit Fraction**

This field specifies a fraction of the *Design Level* power for the load that determines the lowest allowable power level. With *Limit Control* set to **Fixed**, the power is reduced to *Maximum Limit Fraction* \* *Design Level* whenever the manager is activated. For example, if the *Maximum Limit Fraction* is 0.8, then a 100 W design level load is reduced to 80 W when limiting. A *Maximum Limit Fraction* of zero means that the load can be shut off entirely.

**1.53.2.1.6 Field: Limit Step Change**

NOT YET IMPLEMENTED.

### 1.53.2.1.7 Field: Selection Control

This field specifies which loads are selected to be limited. The **All** option simultaneously limits all of the loads listed in this DemandManager. The **RotateMany** option limits all loads except for one which rotates sequentially through the loads listed. The **RotateOne** limits only one load which rotates sequentially through the loads listed. The time interval between rotations is set by the *Rotation Duration* field.

### 1.53.2.1.8 Field: Rotation Duration

If the **RotateOne** or **RotateMany** option is used for *Selection Control*, this field sets the time interval [minutes] between rotations.

### 1.53.2.1.9 Field: Exterior Lights 1-10 Name

The names of **Exterior:Lights** objects defined elsewhere in the input file. These are the loads to be limited by this DemandManager.

Ten objects are accommodated in the list by default. The IDD specification, however, is extensible and additional fields may be added by directly editing the IDD.

An example IDF showing how this object is used is provided below:

```
DemandManager:ExteriorLights,
  Ext Lights Manager,          !- Name
  ,                            !- Availability Schedule Name
  Fixed,                      !- Limit Control
  60,                         !- Minimum Limit Duration {minutes}
  0.0,                        !- Maximum Limit Fraction
  ,                            !- Limit Step Change
  All,                        !- Selection Control
  ,                            !- Rotation Duration {minutes}
  Exterior Lights;            !- Exterior Lights 1 Name
```

## 1.53.2.2 Outputs

There are no output variables reported for the DemandManager:ExteriorLights object.

## 1.53.3 DemandManager:Lights

The DemandManager:Lights object is used for demand limiting Lights objects.

### 1.53.3.1 Inputs

#### 1.53.3.1.1 Field: Name

The name of the DemandManager:Lights object.

#### 1.53.3.1.2 Field: Availability Schedule Name

The reference to the schedule object specifying the availability of this DemandManager. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.53.3.1.3 Field: Limit Control

This field specifies the type of limiting control. The **Fixed** option reduces the power to the controlled loads by a fixed amount determined by the *Maximum Limit Fraction* field. The **Off** option disables the DemandManager in the simulation.

#### 1.53.3.1.4 Field: Minimum Limit Duration

The minimum amount of time [minutes] that the DemandManager will continue to demand limit after being activated. This prevents loads from turning on and off every time step.

#### 1.53.3.1.5 Field: Maximum Limit Fraction

This field specifies a fraction of the *Design Level* power for the load that determines the lowest allowable power level. With *Limit Control* set to **Fixed**, the power is reduced to *Maximum Limit Fraction* \* *Design Level* whenever the manager is activated. For example, if the *Maximum Limit Fraction* is 0.8, then a 100 W design level load is reduced to 80 W when limiting. A *Maximum Limit Fraction* of zero means that the load can be shut off entirely.

#### 1.53.3.1.6 Field: Limit Step Change

NOT YET IMPLEMENTED.

#### 1.53.3.1.7 Field: Selection Control

This field specifies which loads are selected to be limited. The **All** option simultaneously limits all of the loads listed in this DemandManager. The **RotateMany** option limits all loads except for one which rotates sequentially through the loads listed. The **RotateOne** limits only one load which rotates sequentially through the loads listed. The time interval between rotations is set by the *Rotation Duration* field.

#### 1.53.3.1.8 Field: Rotation Duration

If the **RotateOne** or **RotateMany** option is used for *Selection Control*, this field sets the time interval [minutes] between rotations.

#### 1.53.3.1.9 Field: Lights 1-10 Name

The names of **Lights** objects defined elsewhere in the input file. These are the loads to be limited by this DemandManager.

Ten objects are accommodated in the list by default. The IDD specification, however, is extensible and additional fields may be added by directly editing the IDD.

If a global lights statement is used (Ref: **Lights**), then only that name need be entered and the demand limiting will be applied to all the zones for that lighting. If only one of a set of zones from a global lights statement is desired, then the name to be entered is: <Zone Name> <Name of **Lights** Global Object>.

An example IDF showing how this object is used is provided below:

```
DemandManager:Lights,
  Lights Manager,          !- Name
  ,                        !- Availability Schedule Name
  Fixed,                  !- Limit Control
  60,                     !- Minimum Limit Duration {minutes}
  0.5,                    !- Maximum Limit Fraction
  ,                        !- Limit Step Change
  All,                    !- Selection Control
  ,                        !- Rotation Duration {minutes}
  Space1-1 Lights 1,      !- Lights 1 Name
  Space2-1 Lights 1,      !- Lights 2 Name
  Space3-1 Lights 1,      !- Lights 3 Name
  Space4-1 Lights 1,      !- Lights 4 Name
  Space5-1 Lights 1;      !- Lights 5 Name
```

### 1.53.3.2 Outputs

There are no output variables reported for the DemandManager:Lights object.

### 1.53.4 DemandManager:ElectricEquipment

The DemandManager:ElectricEquipment object is used for demand limiting ElectricEquipment objects.

#### 1.53.4.1 Inputs

##### 1.53.4.1.1 Field: Name

The name of the DemandManager:ElectricEquipment object.

##### 1.53.4.1.2 Field: Availability Schedule Name

The reference to the schedule object specifying the availability of this DemandManager. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.53.4.1.3 Field: Limit Control

This field specifies the type of limiting control. The **Fixed** option reduces the power to the controlled loads by a fixed amount determined by the *Maximum Limit Fraction* field. The **Off** option disables the DemandManager in the simulation.

##### 1.53.4.1.4 Field: Minimum Limit Duration

The minimum amount of time [minutes] that the DemandManager will continue to demand limit after being activated. This prevents loads from turning on and off every time step.

##### 1.53.4.1.5 Field: Maximum Limit Fraction

This field specifies a fraction of the *Design Level* power for the load that determines the lowest allowable power level. With *Limit Control* set to **Fixed**, the power is reduced to  $\text{Maximum Limit Fraction} * \text{Design Level}$  whenever the manager is activated. For example, if the *Maximum Limit Fraction* is 0.8, then a 100 W design level load is reduced to 80 W when limiting. A *Maximum Limit Fraction* of zero means that the load can be shut off entirely.

##### 1.53.4.1.6 Field: Limit Step Change

NOT YET IMPLEMENTED.

##### 1.53.4.1.7 Field: Selection Control

This field specifies which loads are selected to be limited. The **All** option simultaneously limits all of the loads listed in this DemandManager. The **RotateMany** option limits all loads except for one which rotates sequentially through the loads listed. The **RotateOne** limits only one load which rotates sequentially through the loads listed. The time interval between rotations is set by the *Rotation Duration* field.

##### 1.53.4.1.8 Field: Rotation Duration

If the **RotateOne** or **RotateMany** option is used for *Selection Control*, this field sets the time interval [minutes] between rotations.

#### 1.53.4.1.9 Field: Electric Equipment 1-10 Name

The names of **ElectricEquipment** objects defined elsewhere in the input file. These are the loads to be limited by this DemandManager.

Ten objects are accommodated in the list by default. The IDD specification, however, is extensible and additional fields may be added by directly editing the IDD.

If a global Electric Equipment statement is used (Ref: **ElectricEquipment**), then only that name need be entered and the demand limiting will be applied to all the zones for that equipment. If only one of a set of zones from a global electric equipment statement is desired, then the name to be entered is: <Zone Name> <Name of **ElectricEquipment** Global Object>.

An example IDF showing how this object is used is provided below:

```
DemandManager:ElectricEquipment,
  Eq Mgr Stage 3,           !- Name
  ,                         !- Availability Schedule Name
  Fixed,                   !- Limit Control
  60,                      !- Minimum Limit Duration {minutes}
  0.0,                    !- Maximum Limit Fraction
  ,                        !- Limit Step Change
  All,                    !- Selection Control
  ,                        !- Rotation Duration {minutes}
  Space5-1 ElecEq 1;       !- Electric Equipment 1 Name
```

#### 1.53.4.2 Outputs

There are no output variables reported for the DemandManager:ElectricEquipment object.

### 1.53.5 DemandManager:Thermostats

The DemandManager:Thermostats object is used for demand limiting **ZoneControl:Thermostat** objects.

#### 1.53.5.1 Inputs

##### 1.53.5.1.1 Field: Name

The name of the DemandManager:Thermostats object.

##### 1.53.5.1.2 Field: Availability Schedule Name

The reference to the schedule object specifying the availability of the DemandManager. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.53.5.1.3 Field: Reset Control

This field specifies the type of limiting control. The **Fixed** option resets the thermostats to a fixed temperature determined by the *Maximum Heating Setpoint Reset* and *Maximum Cooling Setpoint Reset* fields. The **Off** option disables the DemandManager in the simulation.

##### 1.53.5.1.4 Field: Minimum Reset Duration

The minimum amount of time [minutes] that the DemandManager will continue to demand limit after being activated. This prevents thermostats from resetting on and off every time step.

#### 1.53.5.1.5 Field: Maximum Heating Setpoint Reset

This field specifies the thermostat heating setpoint temperature [C] that represents the largest allowable temperature reset or setback. With *Reset Control* set to **Fixed**, the setpoint temperature is reset to the *Maximum Heating Setpoint Reset* whenever the manager is activated. For example, if the heating setpoint is normally 22 C and the *Maximum Heating Setpoint Reset* is 20 C, then the setpoint is reset to 20 C when limiting.

#### 1.53.5.1.6 Field: Maximum Cooling Setpoint Reset

This field specifies the thermostat cooling setpoint temperature [C] that represents the largest allowable temperature reset or setback. With *Reset Control* set to **Fixed**, the setpoint temperature is reset to the *Maximum Cooling Setpoint Reset* whenever the manager is activated. For example, if the cooling setpoint is normally 22 C and the *Maximum Cooling Setpoint Reset* is 24 C, then the setpoint is reset to 24 C when limiting.

#### 1.53.5.1.7 Field: Reset Step Change

NOT YET IMPLEMENTED.

#### 1.53.5.1.8 Field: Selection Control

This field specifies which loads are selected to be limited. The **All** option simultaneously limits all of the loads listed in this DemandManager. The **RotateMany** option limits all loads except for one which rotates sequentially through the loads listed. The **RotateOne** limits only one load which rotates sequentially through the loads listed. The time interval between rotations is set by the *Rotation Duration* field.

#### 1.53.5.1.9 Field: Rotation Duration

If the **RotateOne** or **RotateMany** option is used for *Selection Control*, this field sets the time interval [minutes] between rotations.

#### 1.53.5.1.10 Field: Thermostat 1-10 Name

The names of **ZoneControl:Thermostat** objects defined elsewhere in the input file. These are the loads to be limited by this DemandManager.

Ten objects are accommodated in the list by default. The IDD specification, however, is extensible and additional fields may be added by directly editing the IDD.

If a global thermostat statement is used (Ref: **ZoneControl:Thermostat**), then only that name need be entered and the demand limiting will be applied to all the zones for that thermostatic control. If only one of a set of zones from a global thermostat statement is desired, then the name to be entered is: <Zone Name> <Name of Thermostat Global Object>.

An example IDF showing how this object is used is provided below:

```
DemandManager:Thermostats,
  Thermostats Manager,          !- Name
  ,                             !- Availability Schedule Name
  Fixed,                       !- Reset Control
  60,                          !- Minimum Reset Duration {minutes}
  19,                          !- Maximum Heating Setpoint Reset {C}
  26,                          !- Maximum Cooling Setpoint Reset {C}
  ,                             !- Reset Step Change
  All,                          !- Selection Control
  ,                             !- Rotation Duration {minutes}
  SPACE1-1 Control,            !- Thermostat 1 Name
  SPACE2-1 Control,            !- Thermostat 2 Name
  SPACE3-1 Control,            !- Thermostat 3 Name
```

---

```
SPACE4-1 Control,           !- Thermostat 4 Name
SPACE5-1 Control;          !- Thermostat 5 Name
```

---

### 1.53.5.2 Outputs

There are no output variables reported for the DemandManager:Thermostats object.

## 1.53.6 DemandManager:Ventilation

The DemandManager:Ventilation object is used for limiting the ventilation rate calculated from the **Controller:OutdoorAir** object.

### 1.53.6.1 Field: Name

The name of the DemandManager:Ventilation object.

### 1.53.6.2 Field: Availability Schedule Name

The reference to the schedule object specifying the availability of this demand manager. A schedule value of zero indicates that this demand response (DR) is not applicable for that time period. A schedule greater than zero indicates that the demand response applies during the time period. If this field is blank, the schedule has values of one for all time period.

### 1.53.6.3 Field: Limit Control

This field specifies the type of limiting control. There are three options. The **FixedRate** option reduces the ventilation to a specified air flow rate. The **ReductionRatio** specifies the multiplier of the ventilation rate. The **Off** option disables the demand manager in the simulation.

### 1.53.6.4 Field: Minimum Limit Duration

The minimum amount of time [minutes] that the demand manager will continue to demand limit after being activated. This prevent loads from turning on and off every time step.

### 1.53.6.5 Field: Fixed Rate

This field specifies the amount of fixed ventilation rate when the demand manager is active and *FixedRate* limit control is applied. The unit is m3/s.

### 1.53.6.6 Field: Reduction Ratio

This field specifies the multiplier of the ventilation rate when the demand manager is active and *ReductionRatio* limit control is applied.

### 1.53.6.7 Field: Limit Step Change

NOT YET IMPLEMENTED.

### 1.53.6.8 Field: Selection Control

This field specifies which loads (ventilation rates) are selected to be limited. The **All** option simultaneously limits all of the loads listed in the demand manager. The **RotateMany** option limits all loads except for one which rotates sequentially through the loads listed. The **RotateOne** limits only one load which rotates sequentially through the loads listed. The time interval between rotations is set by the *Rotation Duration* field.

### 1.53.6.9 Field: Rotation Duration

If the **RotateOne** or **RotateMany** option is used for *Selection Control*, this field sets the time interval [minutes] between rotations.

### 1.53.6.10 Field: Controller Outdoor Air 1-10 Name

The names of **Controller:OutdoorAir** objects defined elsewhere in the input file. These are the ventilation rates to be limited by this demand manager. Then objects are accommodated in the list by default. The IDD specification, however, is extensible and additional fields may be added by directly editing the IDD.

An example IDF showing how this object is used is provided below:

```
DemandManager:Ventilation,

## 1.53.7 DemandManager:Ventilation Outputs

There are no output variables reported for the **DemandManager:Ventilation** object.

## 1.54 Group – Electric Load Center-Generator Specifications

This group of input objects is related to electric power serving the facility. EnergyPlus has models for various types of electric generators and power conditioning devices that might be part of the electric power system serving the building being modeled. Buildings with simple utility electric power service will not necessarily need any of the models in this group. All EnergyPlus models that have any electric power consumption are assumed to have a straightforward connection to utility grid service and no extra input is needed. The models in this group of inputs are useful for facilities that more complex electric power service such as:

- Utility service is at a voltage higher than used in the building and a transformer conditions power coming into to the building as part of the facility.
- On site generators produce electricity within the facility. For example solar photovoltaic panels or natural gas powered electric generators.
- On site electric storage devices.

For facilities that own their transformer, and the utility services is metered on the high voltage side, the **ElectricLoadCenter:Transformer** object can be used, and may be the only input object needed.

All other applications involving on-site generation or storage will require at least one **ElectricLoadCenter:Distribution** to describe the arrangement and control of a set of electric power devices. Each of these load centers is like a subpanel connected to the main electrical panel for the facility. The main panel is assumed to exist whenever the rest of the model includes something that consumes electricity (and does not require any input object). Each **ElectricLoadCenter:Distribution** input object describes what devices are on a subpanel connected to the main panel, as well as how they are controlled, dispatched, and arranged to provide some service related to the facility’s electric power. The **ElectricLoadCenter:Distribution** object manages and calls the individual generator models that are connected to it by being listed in an **ElectricLoadCenter:Generators** object, such as natural gas powered turbines, photovoltaic panels, wind turbines, etc. Unlike elsewhere in EnergyPlus where there are loops, branches, or generic equipment lists that allow describing custom arrangements, the electric power service modeling is restricted to a collection of predefined arrangements, called “buss types.” Many on site generation and storage configurations common in buildings can be modeled using just one **ElectricLoadCenter:Distribution** object. However, by combining multiple load centers with different equipment and operations schemes, it is possible to model more complex configurations. (Note that when using multiple **ElectricLoadCenter:Distribution** objects, the order of the **ElectricLoadCenter:Distribution** objects within the input file determines the order in which they are called to interact with the main panel.)

The following diagram shows some of the devices and arrangements that can be modeled using the inputs in this group.

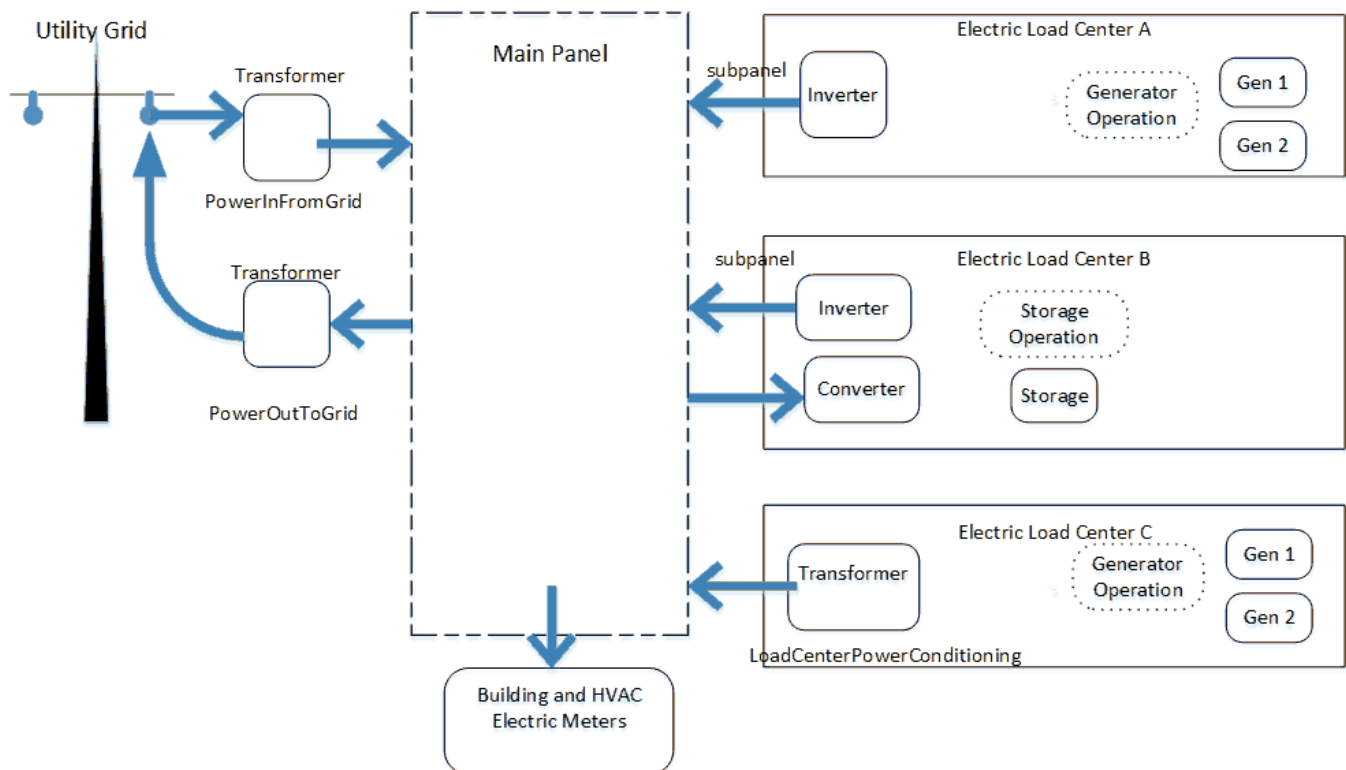

Figure 1.190: PowerServiceOverview

### 1.54.1 ElectricLoadCenter:Transformer

This object is used to model the energy losses of transformers when they are used to transfer electricity from the grid to a building (as distribution transformers) or transfer electricity from onsite generators to the grid. Distribution transformers reduce the voltage on utility distribution lines (34.5 kV or less) to a lower secondary voltage (600 V or less) suitable for customer equipment. According to the medium used for cooling and insulation, distribution transformers can be classified into liquid-immersed and dry type transformers. According to the input voltages, distribution transformers can be classified into medium-voltage (between 600 V and 34.5kV) and low-voltage transformer (less than 600 V). The transformers used to output the surplus electricity from onsite generators to the grid usually match the cogeneration voltage to the grid. This object can be used for all types of distribution transformers and the transformers used to output electricity from onsite generators to the grid, but the model defaults applies to the low-voltage dry type transformers because they are the most common type found in commercial and industrial facilities.

Energy losses in transformers consist of the no load (core) loss and the load (winding) loss. The no load loss comes primarily from the switching of the magnetic fields in the core material. It is roughly constant and exists continuously in the core material as long as the transformer is energized. The load loss comes from the electrical resistance in the windings when there is a load on the transformer. The load loss is proportional to the load squared with a small temperature correction. The energy losses at a given load depend on the transformer's performance. This object provides the user two alternative ways to indicate the transformer's performance. First, the user can provide the no load loss and load loss at rated conditions. Second, the user can provide the nameplate efficiency and the corresponding reference conditions. The detailed algorithms to calculate the energy losses are described in the Engineering Reference.

The user needs to specify which loads are connected to the transformer. This is achieved in different manners depending on the transformer usage. For a distribution transformer, the user needs to provide a number of electric meters wired to that transformer. The input object can currently accommodate up to ten meters, but it is extensible by modifying the Energy+.idd entry. For a transformer used to output electricity from onsite generators to the grid, the user needs to indicate the transformer name in the served electric load center.

#### 1.54.1.1 Inputs

##### 1.54.1.1.1 Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule objects) that contains information on the availability of the transformer. A schedule value greater than 0 (usually 1 is used) indicates that the transformer is available to convert AC power from one voltage to another. A value less than or equal to 0 (usually 0 is used) denotes that the transformer is not available. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.54.1.1.2 Field: Transformer Usage

This field indicates one of the three supported transformer application types: PowerInFromGrid, PowerOutToGrid, and LoadCenterPowerConditioning. A PowerInFromGrid type of transformer is used to step down voltage from the electricity grid to the building. The transformer with this type of use is somewhat free standing and does not need to be referenced in any **ElectricLoadCenter:Distribution** object. There should be only one PowerInFromGrid transformer in the model. A PowerOutToGrid type of transformer is used to match voltage from the building to the electricity grid. This conditions power exported out of the facility and feed back into the grid. This type of transformer will only be needed if the building ever exports power and the building and grid connection have different voltages. There should be only one PowerOutToGrid transformer in the model and it will serve all the surplus electricity produced by electric load center(s). A LoadCenterPowerConditioning type of transformer is used to match voltage between an

electric load center (subpanel) and the facility's main panel. Each electric load center can have its own transformer to condition power fed into the main panel. For electric load centers that also draw power from the main panel, to charge storage, the transformer is assumed to operate in both directions (at the same performance). This type of transformer should be named in an **ElectricLoadCenter:Distribution** object.

#### 1.54.1.1.3 Field: Zone Name

This field contains the name of the thermal zone where the transformer is located. Entering a valid name of zone here will direct EnergyPlus to include the transformer's losses as heat gains to the named thermal zone. If the transformer is not within a thermal zone, this field can be left blank and the thermal energy associated with transformer losses is removed from the building model.

#### 1.54.1.1.4 Field: Radiative Fraction

This field contains the fraction of transformer's losses that enter the zone as long-wave thermal radiation. This numeric field should have a value between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

#### 1.54.1.1.5 Field: Rated Capacity

This field defines the rated capacity of the transformer in VA.

#### 1.54.1.1.6 Field: Phase

This field indicates whether the transformer is a single phase or three phase type. The two alternative values are 1 or 3. The default is 3. This field is currently not used in the model.

#### 1.54.1.1.7 Field: Conductor Material

This field specifies the winding material used by the transformer. There are two options: Copper and Aluminum. The choice will determine the thermal coefficient of resistance used to calculate the temperature correction factor for the transformer load losses. The default is Aluminum.

#### 1.54.1.1.8 Field: Full Load Temperature Rise

This numeric field defines the temperature rise of the windings above the ambient temperature, when the transformer is loaded at its nameplate rating. For liquid-immersed distribution transformers, the full load temperature rise usually takes the value of 65 °C. For dry-type transformers, the temperature rise usually takes three optional values: 80, 115 and 150 °C. This field accepts any value between the minimum (50 °C) and the maximum (180 °C). The default is 150 °C.

#### 1.54.1.1.9 Field: Fraction of Eddy Current Losses

This field defines the fraction of load losses resulting from the eddy currents. Transformer's load losses comprise two parts: the ohmic loss due to the current flowing in the resistance of the windings and the eddy and stray losses due to the eddy currents. This field indicates the fraction of the load losses due to the eddy currents. This numeric field should have a value between 0.0 and 1.0. The default is 0.1.

#### 1.54.1.1.10 Field: Performance Input Method

This alpha field contains the method by which the user will specify the transformer performance: RatedLosses or NominalEfficiency. If this field is left blank in the input data file, the default input method is assumed to be RatedLosses. If the method NominalEfficiency is selected, the user must enter the fields for the nameplate efficiency and the corresponding reference conditions as described below. If the method RatedLosses is selected, then the fields for rated no load loss and load loss must be entered as described below.

**1.54.1.1.11 Field: Rated No Load Loss**

This field defines the no load loss (W) at rated load and conditions. The no load loss is roughly constant and exists whenever the transformer is energized. The no load loss is also called the core loss. This field is used only if the field of Performance Input Method is specified as RatedLosses.

**1.54.1.1.12 Field: Rated Load Loss**

This field defines the load loss (W) at rated load and conditions. The load loss varies with the square of the load being served by the transformer. The load loss is also called the winding loss because the load loss occurs in the primary and secondary windings around the core. This field is used only if the field of Performance Input Method is specified as RatedLosses.

**1.54.1.1.13 Field: Nameplate Efficiency**

This field contains the value for transformer efficiency at a given per unit load and specified reference temperature. This field is used only if the field of Performance Input Method is specified as NominalEfficiency. The default is 0.98.

**1.54.1.1.14 Field: Per Unit Load for Nameplate Efficiency**

This field defines the percentage of the rated capacity at which the nameplate efficiency is measured. According to the NEMA (National Electrical Manufacturers Association) Standard TP-1, the per unit load takes the value of 0.35 for dry-type distribution transformers and it takes the value of 0.50 for liquid-filled distribution transformers. The default is 0.35.

**1.54.1.1.15 Field: Reference Temperature for Nameplate Efficiency**

This field defines the conductor temperature at which the nameplate efficiency is measured. This field is used only if the field of Performance Input Method is specified as NominalEfficiency. According to the NEMA Standard TP-1, the reference temperature takes the value of 75 °C for dry-type distribution transformers and it takes the value of 55 °C for liquid-filled distribution transformers. The default is 75 °C.

**1.54.1.1.16 Field: Per Unit Load for Maximum Efficiency**

This field defines the percentage of the rated capacity at which the maximum efficiency is obtained. This field is used only if the field of Performance Input Method is specified as NominalEfficiency. A blank field indicates that it takes the same value as the per unit load for nameplate efficiency.

**1.54.1.1.17 Field: Consider Transformer Loss for Utility Cost**

This field indicates whether the transformer losses are considered to calculate utility cost. This field applies to a PowerInFromGrid type of transformer. In some cases, the transformer losses are required but they are not part of the energy consumption for utility cost calculation. For example, the transformer is owned by the utility company but it locates in the building. In this case, it might be desired to model transformer energy losses for HVAC operation but the energy losses will not be accounted for utility cost.

**1.54.1.1.18 Field: Electric Meter 1-10 Name**

A transformer may serve different loads such as plug loads, some lighting loads, and some HVAC equipment loads. These fields apply to a PowerInFromGrid type of transformer. The user needs to specify which loads are connected to the transformer. For example the HVAC and Plant equipment might use a higher voltage than the building and only the building loads need power conditioning. This is achieved by providing a list of electric meters wired to the transformer. The input object can currently accommodate up to ten meters, but it is extensible by modifying the Energy+.idd entry. Any valid electric meter name can be used here to wire to the transformer loads. Many different meters are automatically generated

by the program and will depend on the objects used throughout the input file. The typical process of determining the exact name to enter in this field involves doing an initial run of EnergyPlus and then examining the \*.mdd file which will list the meters and their resulting names. A custom meter is also supported. The meter must have electricity as its resource type.

An example input of the ElectricLoadCenter:Transformer input is:

### 1.54.1.2 Outputs

- HVAC,Average,Transformer Efficiency[]
- HVAC,Average,Transformer Output Electricity Rate [W]
- HVAC,Sum,Transformer Output Electric Energy [J]
- HVAC,Average,Transformer Input Electricity Rate [W]
- HVAC,Sum,Transformer Input Electricity Energy [J]
- HVAC,Average,Transformer No Load Loss Rate [W]
- HVAC,Sum,Transformer No Load Loss Energy [J]
- HVAC,Average,Transformer Load Loss Rate [W]
- HVAC,Sum,Transformer Load Loss Energy [J]
- HVAC,Average,Transformer Thermal Loss Rate [W]
- HVAC,Sum,Transformer Thermal Loss Energy [J]
- HVAC,Sum,Transformer Distribution Electric Loss Energy [J]
- HVAC,Sum,Transformer Cogeneration Electric Loss Energy [J]

#### 1.54.1.2.1 Transformer Efficiency

This output field is the efficiency at which the distribution transformer changes alternating current from the higher primary voltage to a lower secondary voltage. The efficiency is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

#### 1.54.1.2.2 Transformer Output Electricity Rate [W]

#### 1.54.1.2.3 Transformer Output Electric Energy [J]

These outputs are the total electricity power or energy provided by the transformer. They are equal to the metered loads which are wired to the transformer. These values are calculated for each HVAC system timestep being simulated, and the results are averaged (for power) or summed (for energy) for the timestep being reported.

#### 1.54.1.2.4 Transformer Input Electricity Rate [W]

#### 1.54.1.2.5 Transformer Input Electricity Energy [J]

These outputs are the total electricity power or energy fed into the transformer. These values are calculated for each HVAC system timestep being simulated, and the results are averaged (for power) or summed (for energy) for the timestep being reported.

#### 1.54.1.2.6 Transformer No Load Loss Rate [W]

#### 1.54.1.2.7 Transformer No Load Loss Energy [J]

These outputs are the no load loss occurred in the transformer. These values are calculated for each HVAC system timestep being simulated, and the results are averaged (for rate) or summed (for energy) for the timestep being reported.

#### 1.54.1.2.8 Transformer Load Loss Rate [W]

#### 1.54.1.2.9 Transformer Load Loss Energy [J]

These outputs are the load loss occurred in the transformer. These values are calculated for each HVAC system timestep being simulated, and the results are averaged (for rate) or summed (for energy) for the timestep being reported.

#### 1.54.1.2.10 Transformer Thermal Loss Rate [W]

#### 1.54.1.2.11 Transformer Thermal Loss Energy [J]

These outputs are the total energy losses occurred in the transformer. They are equal to the sum of the no load loss and the load loss. These values are calculated for each HVAC system timestep being simulated, and the results are averaged (for rate) or summed (for energy) for the timestep being reported.

#### 1.54.1.2.12 Transformer Distribution Electric Loss Energy [J]

This output is the total energy losses occurred in the transformer when it is used for input power from grid to building. It is set as zero if the transformer is used to transfer energy from onsite power generators to the electricity grid. This output is also added to a meter with ResourceType = Electricity, GroupKey = System.

### 1.54.1.2.13 Transformer Cogeneration Electric Loss Energy [J]

This output is the total energy losses occurred in the transformer when it is used for input onsite cogeneration to the grid. It is set as zero if the transformer is used to transfer the electricity grid to building. This output is also added to a meter with ResourceType = ElectricityProduced, EndUseKey = Cogeneration, GroupKey = System.

## 1.54.2 ElectricLoadCenter:Distribution

ElectricLoadCenter:Distribution objects are used to include on-site electricity generators and or storage in a simulation. The electric load center dispatches both generators and storage according to operation schemes and tracks and reports the amount of electricity generated and purchased. When using on-site generators, the program provides various reports for the electricity used, generated on site, stored, exported etc. There are two separate operation schemes, one for generators and a second for storage, and they can be different. The generator operation is managed before the storage operation. Facility electrical demand tracking is done by the internal or custom meters used by EnergyPlus for reporting. The thermal demand tracking uses internal load calculations from the plant simulation. The dispatching of different generators is based on expectations based on their nominal/rated electric power output. If the current conditions are such that the generator model determines that generation was higher or lower, then the results of the dispatch may differ from expectations.

Multiple different ElectricLoadCenter:Distribution objects can be included in an input file. A great deal of flexibility is available by mixing different load centers and operating schemes. If multiple load centers are used, the supervisory control will dispatch generators sequentially across the load centers. Therefore, the order of these input objects in the IDF file becomes important with the generators associated with first load center in the file being the first to be managed. A certain amount of caution is needed to avoid conflicting operating schemes.

### 1.54.2.1 Inputs

#### 1.54.2.1.1 Field: Name

This alpha field contains the identifying name for the electric load center.

#### 1.54.2.1.2 Field: Generator List Name

This alpha field contains the identifying name for the list of generators in the set defined in an **ElectricLoadCenter:Generators** object. All the generators connected to this load center need to be of the same type in terms of all AC or all DC. Currently the only DC generators are photovoltaic panels, the others are all AC. A facility with both AC and DC generators will need to use separate ElectricLoadCenter:Distribution objects. The generator list named here can only be associated with one load center. This field can be left blank if there are no generators.

#### 1.54.2.1.3 Field: Generator Operation Scheme Type

This alpha field specifies the type of operating scheme for the generator set. The available operating schemes are Baseload, DemandLimit, TrackElectrical, TrackSchedule, TrackMeter, FollowThermal, and FollowThermalLimitElectrical. The Baseload scheme operates the generators at their rated (requested) electric power output when the generator is scheduled ON (ref. **ElectricLoadCenter:Generators**). The Baseload scheme requests all generators scheduled ON (available) to operate, even if the amount of electric power generated exceeds the total facility electric power demand. The DemandLimit scheme limits the amount of purchased electrical from the utility to the amount specified in the input object. The DemandLimit scheme tries to have the generators meet all of the demand above the purchased electric limit set by the user in the next field. The TrackElectrical scheme tries to have the generators meet all of the electrical

demand for the building. The TrackSchedule scheme tries to have the generators meet all of the electrical demand determined in a user-defined schedule. The TrackMeter scheme tries to have the generators meet all the electrical demand from a meter, which could also be a user-defined custom meter.

The DemandLimit, TrackElectrical, TrackSchedule, and TrackMeter schemes will sequentially load the available generators. All demand not met by available generator capacity (or storage) will be met by purchased electrical. Therefore, if DemandLimit, TrackElectrical, TrackSchedule, or TrackMeter is utilized and the available generators are not enough to meet demand, then purchased electrical will offset the difference. If a generator is needed in the simulation for a small load and it is less than the minimum part load ratio the generator will operate at the minimum part load ratio and the excess will either reduce demand or the excess energy will be available for returning to the electric grid.

The FollowThermal and FollowThermalLimitElectrical schemes are for heat following cogeneration and run the generators to meet the thermal demand. The FollowThermal schemes allow excess electrical generation to be exported to the grid, while the FollowThermalLimitElectrical scheme restricts generator output to a maximum of the building's current electrical demand (so that no electricity is exported). The thermal demand is determined from the plant modeling and depends on the flow requested by other components on the demand side of the plant loop, the loop temperatures, and the loop temperature set point. The electric load center converts the thermal load to an electrical load using a nominal ratio of the thermal to electrical power production for each generator. For these schemes, the generator needs to be connected to the supply side of a plant loop and components that request hot water need to be on the demand side of the plant loop. This is different than the usual configuration for electrical following schemes where the generator is put on the demand side and request flow for the purposes of cooling the generator. Therefore a switch from one of the electrical-based operating schemes to one of the thermal-based operating schemes requires a substantial change in plant topology.

If the load center includes electrical storage, then the choice of generator operating schemes will also affect how storage is managed. The generator operation scheme and dispatch is modeled before the storage operation scheme so that the current generator production is available for use with the storage operation scheme.

#### **1.54.2.1.4 Field: Demand Limit Scheme Purchased Electric Demand Limit**

This numerical field is the user input for the demand limit above which the generators will try and meet the entire electrical load on the building minus the photovoltaic array if available.

#### **1.54.2.1.5 Field: Track Schedule Name Scheme Schedule Name**

This alpha field is the user input for the name of a schedule defined elsewhere in the input file that contains values for the demand loads placed on the generator(s). The schedule values should be in Watts.

#### **1.54.2.1.6 Field: Track Meter Scheme Meter Name**

This alpha field is the user input for the name of a meter. Any valid meter name can be used here to control the loads that the generator(s) will try to meet. Many different meters are automatically generated by the program and will depend on the objects used throughout the input file. The typical process of determining the exact name to enter in this field involves doing an initial run of EnergyPlus and then examining the \*.rdd file which will list the meters and their resulting names. The \*.mtd file will also be useful to understand what exactly is included in a meter. The user can also use the Output:CustomMeter objects to redefine meter names and to control what electrical loads are included on them in a flexible manner.

#### **1.54.2.1.7 Field: Electrical Buss Type**

This alpha field is used to describe how the electric load center is configured with respect to any power conditioning and/or storage equipment. There are five configurations available for load centers that are selected using one of these keywords: AlternatingCurrent, AlternatingCurrentWithStorage, DirectCurrentWithInverter, DirectCurrentWithInverterDCStorage, or DirectCurrentWithInverterACStorage. This input informs the program which of the five pre-configured arrangements is to be used for this load center. The following diagrams show the kinds of devices and how they are arranged for each of the buss types.

- AlternatingCurrent. This type of load center is for adding one or more on-site generators that produce AC power. If the voltage does not match a transformer can be included but is not needed. AlternatingCurrent is the default.

Figure 1.191: LoadCenterBussType

- AlternatingCurrentWithStorage. This type of load center is for adding one or more on-site generators that produce AC power and one on-site electric storage device that uses AC power. The connection between the load center and the main building panel is bidirectional so that storage can be charged by drawing from the grid. Transformer is optional.
- DirectCurrentWithInverter. This type of load center is for adding one or more on-site generators that produce DC power, typically photovoltaic panels. An inverter is needed to convert generated power from DC to AC. Transformer is optional.
- DirectCurrentWithInverterDCStorage. This type of load center is for adding one or more on-site generators that produce DC power and one on-site storage device that uses DC power. An inverter is needed to convert power from DC to AC and is located between the storage and where the subpanel feeds into the main panel. The connection between the load center and the main building panel is bidirectional so that storage can be charged by drawing from the grid. An AC to DC converter is needed if the storage operation scheme is such that the control might draw power from the main facility panel into the load center in order to charge storage. Transformer is optional.
- DirectCurrentWithInverterACStorage. This type of load center is for adding one or more on-site generators that produce DC power and one on-site storage device that uses AC power. The connection between the load center and the main building panel is bidirectional so that storage can be charged by drawing from the grid. The inverter is located between the generators and the storage device. Transformer is optional.

AlternatingCurrentWithStorage

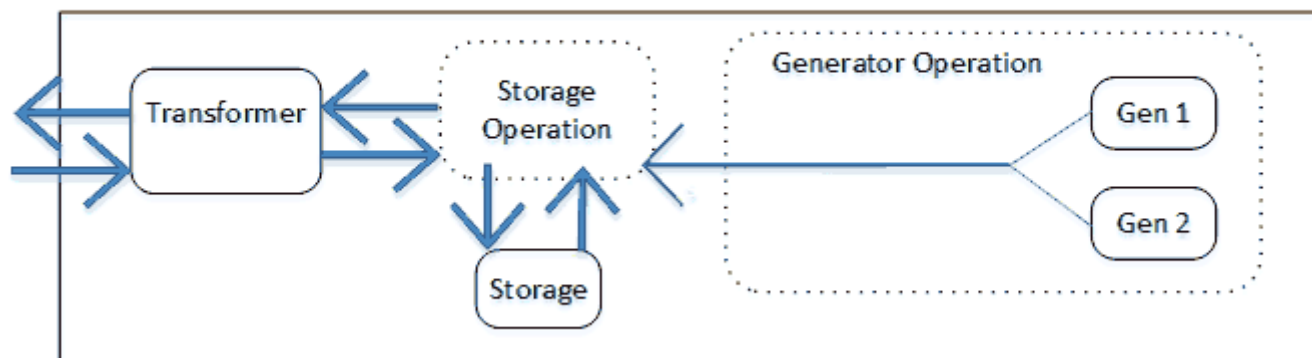

Figure 1.192: LoadCenterBussType

DirectCurrentWithInverter

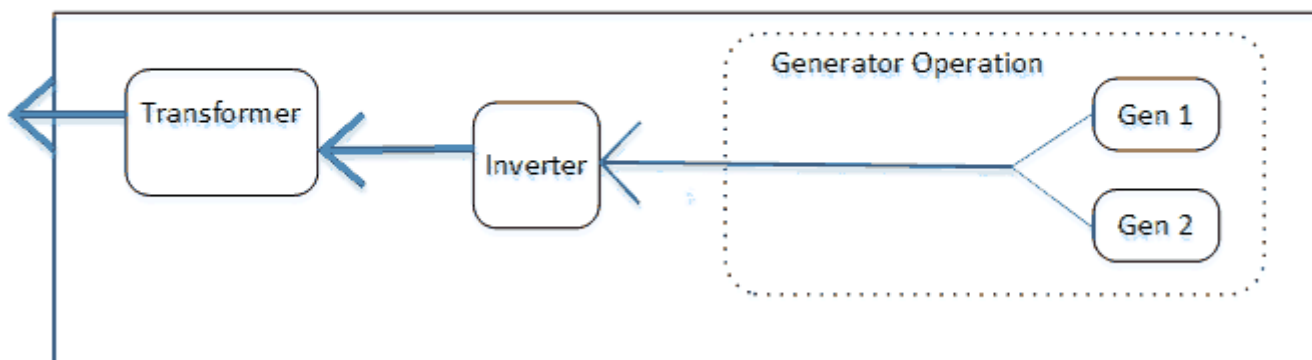

Figure 1.193: LoadCenterBussType

DirectCurrentWithInverterDCStorage

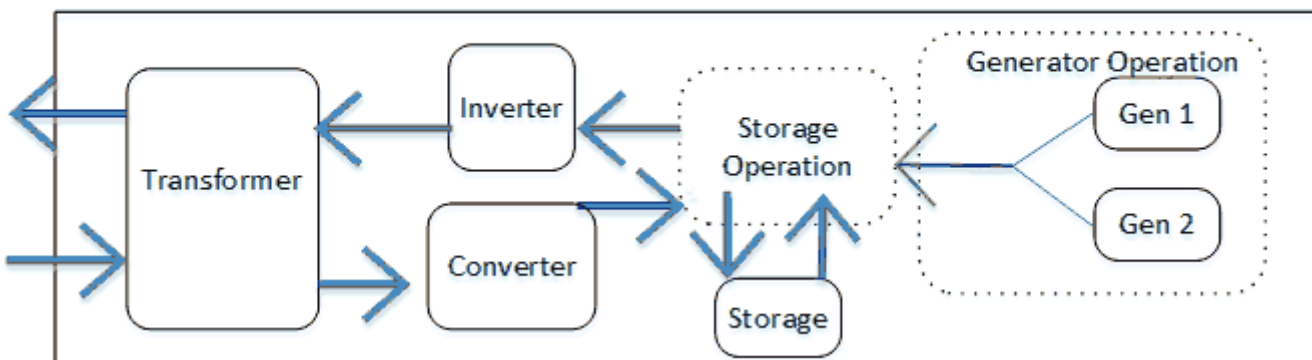

Figure 1.194: LoadCenterBussType

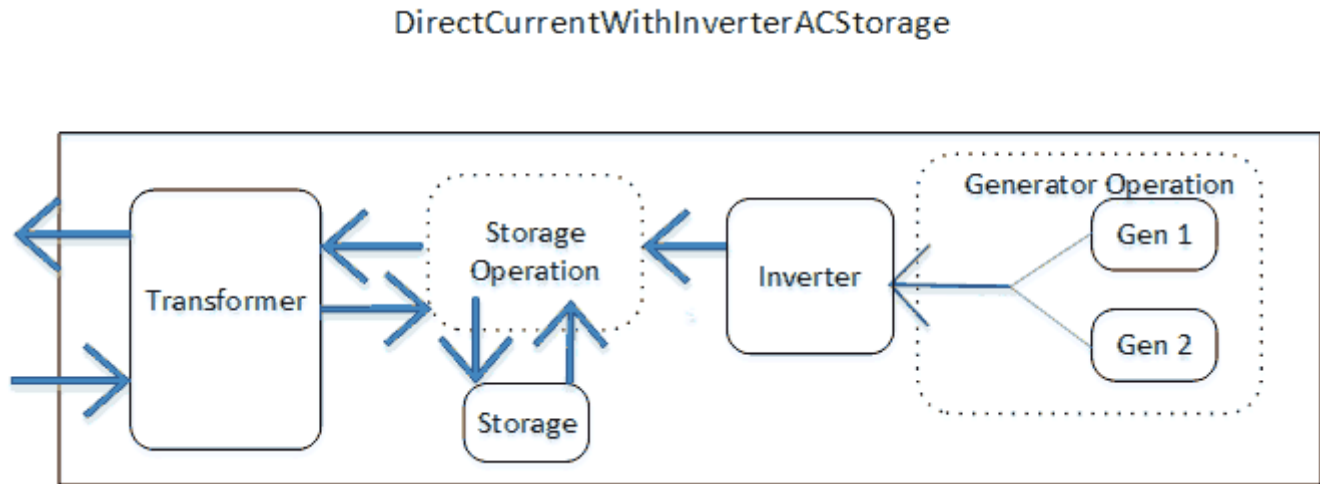

Figure 1.195: LoadCenterBussType

**1.54.2.1.8 Field: Inverter Object Name**

This field is used to identify the inverter connected to this load center (if any). This field is only used if the Electrical Buss Type is set to `DirectCurrentWithInverter`, `DirectCurrentWithInverterDCStorage`, or `DirectCurrentWithInverterACStorage` and should contain the user-defined name of an inverter object. There are three types of inverter models available -see `ElectricLoadCenter:Inverter:Simple`, `ElectricLoadCenter:Inverter:LookUpTable`, `ElectricLoadCenter:Inverter:FunctionOfPower`, or `ElectricLoadCenter:Inverter:PVWatts`. Enter the name of one of these types of inverter objects defined elsewhere in the input file.

**1.54.2.1.9 Field: Electrical Storage Object Name**

This field is used to identify the electrical storage connected to this load center (if any). This field is only used if the Electrical Buss Type is set to `AlternatingCurrentWithStorage`, `DirectCurrentWithInverterDCStorage` or `DirectCurrentWithInverterACStorage`. Enter the name of an `ElectricLoadCenter:Storage:*` object defined elsewhere in the input file.

**1.54.2.1.10 Field: Transformer Object Name**

This field is used to identify the transformer connected to this load center (if any). This field can be used for any electrical buss types. Enter the name of an `ElectricLoadCenter:Transformer` object defined elsewhere in the input file. The transformer should have use type set to `LoadCenterPowerConditioning`.

**1.54.2.1.11 Field: Storage Operation Scheme**

This field is used to select the operation scheme used to govern how storage charge and discharge is controlled. There are four options: `TrackFacilityElectricDemandStoreExcessOnSite`, `TrackMeterDemandStoreExcessOnSite`, `TrackChargeDischargeSchedules`, or `FacilityDemandLeveling`.

`TrackFacilityElectricDemandStoreExcessOnSite` indicates that storage control will follow the facility power demand (meter `Facility:Electricity`) while accounting for any on-site generation. Only excess on site generation gets stored. This is the legacy control behavior before version 8.5 and is the default.

`TrackMeterDemandStoreExcessOnSite` indicates that storage discharge control will follow an electric meter named in the field called `Storage Control Track Meter Name`. This scheme is similar `TrackFacilityElectricDemandStoreExcessOnSite` except that instead of the main facility electric meter, the control is based off of a user-selected meter.

TrackChargeDischargeSchedules indicates that control will follow the charging and discharging power and schedules defined in the fields called Maximum Storage Charge Grid Supply Power, Storage Charge Grid Supply Power Fraction Schedule Name, Design Storage Discharge Grid Export Power, and Storage Discharge Grid Export Fraction Schedule Name.

FacilityDemandLeveling indicates that storage control will attempt to control the facility's power demand drawn from the utility service to a prescribed level. The target utility demand is entered in the fields called Storage Control Utility Demand Limit and Storage Control Utility Demand Limit Fraction Schedule Name. This scheme first accounts for any on-site generation and during times of high use will discharge storage to reduce facility grid demand to meet the target level and during times of low use will charge storage from the grid to increase facility grid demand to meet the target level. This scheme allows controlling the load factor as long as the storage capacity and rates are not limiting what is possible. Negative schedule values can be used so that a negative demand target is exporting power out to the grid.

#### **1.54.2.1.12 Field: Storage Control Track Meter Name**

This field is the name of a meter to use when a custom meter is to be used. This is required when Storage Operation Scheme is set to TrackMeterDemandStoreExcessOnSite.

#### **1.54.2.1.13 Field: Storage Converter Object Name**

This field is the name of an **ElectricLoadCenter:Storage:Converter** object defined elsewhere in the input file that describes the performance when converting AC to DC when charging DC storage from grid supply. This field is required when using DC storage (buss type DirectCurrentWithInverterDCStorage) with grid supplied charging power (Storage Operation Scheme is set to TrackChargeDischargeSchedules or FacilityDemandLeveling.) Although some inverter devices are bidirectional a separate converter object is needed to describe AC to DC performance.

#### **1.54.2.1.14 Field: Maximum Storage State of Charge Fraction**

This numeric field specifies the fraction of storage capacity used as an upper limit for controlling charging. Charging will be constrained so that charging will stop the once this limit is reached. This fraction is the state of charge of the storage device where 1.0 is completely full and 0.0 is completely empty. This allows supervisory control over charging to model behavior intended to protect the battery from damage. The legacy behavior prior to version 8.5 was to charge to full capacity and therefore the default is 1.0.

#### **1.54.2.1.15 Field: Minimum Storage State of Charge Fraction**

This numeric field specifies the fraction of storage capacity used as lower limit for controlling discharging. Discharging will be constrained so that discharging will stop once this limit is reached. This fraction is the state of charge of the storage device where 1.0 is completely full and 0.0 is completely empty. This allows supervisory control over discharging to model behavior intended to protect the battery from damage. The legacy behavior prior to version 8.5 was to discharge to empty and therefore the default is 0.0.

#### **1.54.2.1.16 Field: Design Storage Control Charge Power**

This field is the design maximum rate that electric power can be charged into storage, in Watts. This field is used as an upper limit for most storage control operation schemes. However for TrackChargeDischargeSchedules, this is the design value for how much power to use when charging and it is multiplied by the power fraction schedule in the next field. Required field when using Storage Operation Schemes set to FacilityDemandLeveling or TrackChargeDischargeSchedules.

#### 1.54.2.1.17 Field: Storage Charge Power Fraction Schedule Name

This field contains the name of a schedule that controls the timing and magnitude of charging storage. This is a required field if Storage Operation Scheme is set to TrackChargeDischargeSchedules. Schedule values should be fractions from 0.0 to 1.0, inclusive. This schedule will need to be coordinated with the discharging schedule named below.

#### 1.54.2.1.18 Field: Design Storage Control Discharge Power

This field is the design maximum rate that electric power can be discharged from storage. This field is used as an upper limit for most storage control operation schemes. However for TrackChargeDischargeSchedules, this is the design value for how much power to draw when discharging and it is multiplied by the power fraction schedule in the next field. Required field when using Storage Operation Schemes set to FacilityDemandLeveling or TrackChargeDischargeSchedules.

#### 1.54.2.1.19 Field: Storage Discharge Power Fraction Schedule Name

This field contains the name of a schedule that controls the timing and magnitude of discharging storage. Required field if Storage Operation Scheme is set to TrackChargeDischargeSchedules. Schedule values should be fractions from 0.0 to 1.0, inclusive. This schedule will need to be coordinated with the charging schedule named above.

#### 1.54.2.1.20 Field: Storage Control Utility Demand Target

This field contains the design demand target in Watts. This field is used when the storage operation scheme is set to FacilityDemandLeveling. This becomes the target utility service demand power for discharge control. This design value is multiplied by the fraction schedule named in the next field. This is more than an upper limit, it is also going to call for extra electric power to raise demand up to the target and put the extra power into on-site storage. This field is required for FacilityDemandLimit storage operation scheme.

#### 1.54.2.1.21 Field: Storage Control Utility Demand Target Fraction Schedule Name

This field is the name of schedule that modifies the utility demand power target over time. Schedule values should be fractions from -1.0 to 1.0, inclusive. Negative values indicate export to grid. This field is required if Storage Operation Scheme is set to FacilityDemandLeveling.

Examples of this object are:

[illegible]

### 1.54.2.2 Outputs

There are three levels of results reporting related to electric load centers and generators. The top level of reporting provides results across the whole building and all the different electric load centers and generators. The second level of reporting provides results for individual load centers. The third level is for each type of generator (see individual generator descriptions). This section discusses the first two levels.

Even if no ElectricLoadCenter:Distribution object is included, the following whole-building summary output variables are also available for all simulations that have any electricity consuming equipment.

- HVAC,Average,Facility Total Purchased Electricity Rate [W]
- HVAC,Sum,Facility Total Purchased Electricity Energy [J]
- HVAC,Average,Facility Total Surplus Electricity Rate [W]
- HVAC,Sum,Facility Total Surplus Electricity Energy [J]
- HVAC,Average,Facility Net Purchased Electricity Rate [W]
- HVAC,Sum,Facility Net Purchased Electricity Energy [J]
- HVAC,Average,Facility Total Building Electric Demand Power [W]
- HVAC,Average,Facility Total HVAC Electric Demand Power [W]
- HVAC,Average,Facility Total Electric Demand Power [W]
- HVAC,Average,Facility Total Produced Electricity Rate [W]
- HVAC,Sum,Facility Total Produced Electricity Energy [J]

These output variables all use a default keyword Whole Building.

#### 1.54.2.2.1 Facility Total Purchased Electricity Rate [W]

#### 1.54.2.2.2 Facility Total Purchased Electricity Energy [J]

These outputs are the total of electricity purchased for the entire facility in both power and energy units. This value is always positive and indicates the amount of energy that is purchased from the utility.

#### 1.54.2.2.3 Facility Total Surplus Electricity Rate [W]

#### 1.54.2.2.4 Facility Total Surplus Electricity Energy [J]

These outputs are the total excess electricity exported and sent out to the electrical grid in both power and energy units. This value is always positive and indicates the surplus electric power (from generation and/or storage discharge) exceeds the whole-building demand and electricity is being fed from the facility into the grid.

#### 1.54.2.2.5 Facility Net Purchased Electricity Rate [W]

#### 1.54.2.2.6 Facility Net Purchased Electricity Energy [J]

These outputs are the net electricity purchased in both Power and Energy units. This value can be either positive or negative. Positive values are defined as electricity purchased from the utility. Negative values are defined as surplus electricity fed back into the grid.

#### 1.54.2.2.7 Facility Total Building Electric Demand Power [W]

This output variable includes all of the electric demand from the building (non-HVAC) portion of the simulation, which would contain lights, electrical equipment, exterior lights and equipment, etc.

**1.54.2.2.8 Facility Total HVAC Electric Demand Power [W]**

This output variable includes all of the electric demand from the HVAC portion of the simulation, which would contain fans, electric coils, pumps, chillers, cooling towers, etc.

**1.54.2.2.9 Facility Total Electric Demand Power [W]**

This is the total of the whole Building and HVAC electric demands.

**1.54.2.2.10 Facility Total Produced Electricity Rate [W]****1.54.2.2.11 Facility Total Produced Electricity Energy [J]**

These outputs are the total generator and photovoltaic electricity produced on-site for the entire model, and they are in both Power and Energy units. When the electric power production system includes power conversion devices including DC to AC inverters, AC to DC converters, or transformers, the power conversion losses are included as negative values in these reports. When electrical storage is used with on-site production, the electricity put into storage is decremented from production and the electricity removed storage is added to production. This means that losses from a round trip through electrical storage decrease on-site electricity production.

Each ElectricLoadCenter also collects results from the individual generators that are connected to that load center. The keywords for these reports are the unique names of ElectricLoadCenter:Distribution objects. The output variables available at the ElectricLoadCenter level are:

- HVAC,Average,Electric Load Center Produced Electricity Rate [W]
- HVAC,Sum,Electric Load Center Produced Electricity Energy [J]
- HVAC,Average,Electric Load Center Supplied Electricity Rate [W]
- HVAC,Average,Electric Load Center Drawn Electricity Rate [W]
- HVAC,Average,Electric Load Center Produced Thermal Rate [W]
- HVAC,Sum,Electric Load Center Produced Thermal Energy [J]
- HVAC,Average,Electric Load Center Requested Electricity Rate [W]

**1.54.2.2.12 Electric Load Center Produced Electricity Rate [W]****1.54.2.2.13 Electric Load Center Produced Electricity Energy [J]**

These outputs are the sum of electrical energy and power produced by the generators attached to a particular load center. This could be DC or AC depending on the type of buss. The power actually delivered by the load center may be adjusted by power conversion losses from an inverter or transformer or by interaction with the any electrical storage.

**1.54.2.2.14 Electric Load Center Supplied Electricity Rate [W]**

This output is the power fed from the electric load center into the main distribution panel, in Watts. This power is generated or discharged by on site equipment and has been adjusted to account for any power conversion by an inverter and/or transformer on the load center.

**1.54.2.2.15 Electric Load Center Drawn Electricity Rate [W]**

This output is the power fed from the main distribution panel into the load center, in Watts. This power draw is typically only for charging storage with power from either the grid or another load center.

**1.54.2.2.16 Electric Load Center Produced Thermal Rate [W]**

#### 1.54.2.2.17 Electric Load Center Produced Thermal Energy [J]

These outputs are the sum of the thermal energy and power produced by the generators attached to a particular load center. The keywords for these reports are the unique names of ElectricLoadCenter:Distribution objects.

#### 1.54.2.2.18 Electric Load Center Requested Electricity Rate [W]

This output variable is the average electric power supply (in watts) requested of the load center by the facility's main distribution panel, for the time step being reported. This is used by the load center generator and storage operation control logic when determining how to run the generators and/or storage devices. For the baseload generator operating scheme, this output variable should equal the sum of the power supply requests for the available generators associated with this load center (ref. ElectricLoadCenter:Generators). In other cases, this output could be different from the sum of the power supply requests for the generators associated with this load center. For example, a generator might be requested to provide a certain amount of power but can only provide a fraction of the requested amount. In this case the load center will detect this shortfall and include it when calculating the power request for the next available generator. Therefore, the sum of the power supply requests for the individual generators associated with this load center (ref. ElectricLoadCenter:Generators) could be greater than the Electric Load Center Requested Electric Power output variable.

### 1.54.3 ElectricLoadCenter:Generators

The ElectricLoadCenter:Generators object is used to provide a list of the generators to include in the simulation. The list includes the names and types of all the generators along with separate availability schedules, the rated power output, and thermal-to-electrical power ratio for each. Sets of five input fields are repeated for each generator. If more than 30 generators are needed, EnergyPlus will auto-extend to suit the needs but other interfaces (such as the IDF Editor may not). The user can always modify the Energy+.idd file to accommodate the extra fields necessary, but it is likely the next release of EnergyPlus will overwrite any user modifications.

#### 1.54.3.1 Inputs

##### 1.54.3.1.1 Field: Name

This alpha field contains the identifying name for the generators in the set.

##### 1.54.3.1.2 FieldSet: Name, Object Type, Rated Power Output, Availability, Thermal Ratio up to 30

Each generator is specified by a set of 5 input fields that contain an identifying name, a keyword that indicates the type of generator, the rated output of the generator, the availability schedule of the generator, and the thermal to electrical power production ratio.

##### 1.54.3.1.3 Field: Generator <x> Name

This alpha field contains the identifying name for the first generator in the list.

##### 1.54.3.1.4 Field: Generator <x> Object Type

This alpha field contains the keyword for the type of generator. The available types include:

- Generator:InternalCombustionEngine
- Generator:CombustionTurbine

- Generator:Photovoltaic
- Generator:PVWatts
- Generator:FuelCell
- Generator:MicroCHP
- Generator:MicroTurbine
- Generator:WindTurbine

These keywords are the names of the input objects for the type of generator.

#### 1.54.3.1.5 Field: Generator <x> Rated Electric Power Output

This numeric field contains the nominal electric power output to be requested from generator 1. It is normally equal to the rated power output of the generator in Watts. This value is used only for supervisory control and generator dispatch; the actual power output for each time step is determined by the generator models. This value affects how much a generator is loaded (i.e., requested electric power output) and can also impact the operation of an electric storage unit (e.g., LoadCenter:Storage:Simple) if one is connected to the associated load distribution center (ref. [ElectricLoadCenter:Distribution](#)). Refer to Electrical Storage in the EnergyPlus Engineering Reference for more details regarding this input field and its relationship with electric storage.

#### 1.54.3.1.6 Field: Generator <x> Availability Schedule Name

This alpha field is used as an identifying field for the generator availability schedule. If not blank, this field must contain the name of a schedule defined elsewhere in the input file. A schedule value of < = 0.0 indicates the generator is not available, while a schedule value > 0.0 indicates that the generator is available to operate. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.54.3.1.7 Field: Generator <x> Rated Thermal to Electrical Power Ratio

This numeric field contains the ratio of the rated thermal output to the rated electric output. It is required and used if the operation scheme is set to **FollowThermal** or **FollowThermalLimitElectrical**. This nominal ratio is only used for control and dispatch decisions. This value should be generally consistent with the more detailed performance input for the individual generator component models but it is not used in those component models.

An example IDF showing how this object is used is provided below:

```
ElectricLoadCenter:Generators,
  Backup Generators,          !- Name
  Cat Diesel,                 !- Generator 1 Name
  Generator:InternalCombustionEngine, !- Generator 1 Object Type
  50000,                      !- Generator 1 Rated Electric Power Output
  ON PEAK GENERATOR SCHEDULE, !- Generator 1 Availability Schedule Name
                                !- Generator 1 Rated Thermal to Electrical Power Ratio
,
  Solar Turbine,              !- Generator 2 Name
  Generator:CombustionTurbine, !- Generator 2 Object Type
  30000,                      !- Generator 2 Rated Electric Power Output

```

### 1.54.3.2 Outputs

A single output variable is available for each generator specified via this object as described below:

- HVAC,Average,Generator Requested Electricity Rate [W]

#### 1.54.3.2.1 Generator Requested Electricity Rate [W]

This output variable represents the average electric power supply in Watts that is being requested by the generator operation scheme from a specific generator for the time step being reported. In some instances the output value may be the Rated Electric Power Output specified for the generator in the ElectricLoadCenter:Generators object. If the generator is not available for a simulation time step (as indicated by its availability schedule), then the power supply request will be zero. The power supply request may be less than the rated electric power output if the overall electric power reduction target has already been met, partially or completely, by electric power produced by other generators. If an EnergyPlus Energy Management System is used to specify an electric power supply request for this generator, then that EMS request will be reflected in this output variable.

### 1.54.4 ElectricLoadCenter:Inverter:Simple

This input object is used to model conversion from Direct Current (DC) to Alternating Current (AC) in an electric load center that contains photovoltaic modules. Such a load center has an array of photovoltaic modules that feed an inverter DC power and the inverter produces AC power. This input object is for the simplest inverter model and uses a fixed efficiency. There are two other types of inverters with more complex models described below.

#### 1.54.4.1 Inputs

##### 1.54.4.1.1 Field: Name

This field contains a unique name for the inverter. The name entered must also be unique across all other types of inverters that may also be in the input file.

##### 1.54.4.1.2 Field: Availability Schedule Name

This field contains the name of a schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by scheduling a value of 0, then it cannot produce AC power and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to produce AC power and consume ancillary power during standby. If the Inverter is scheduled to be unavailable but it is being supplied with DC power anyway, then the energy is dissipated as heat. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.54.4.1.3 Field: Zone Name

This field contains the name of the thermal zone where the inverter is located. Entering a valid name of zone here will direct EnergyPlus to include the inverter's losses as heat gains to the named thermal zone. If the inverter is not within a thermal zone, then this field can be left blank (and the thermal energy associated with inverter losses is removed from the building model).

##### 1.54.4.1.4 Field: Radiative Fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

#### 1.54.4.1.5 Field: Inverter Efficiency

This field contains the value for inverter efficiency. In the simple model, efficiency is a constant. This is the so-called 1-term model. Input data for different types of inverters is available at [http://www.gosolarcalifornia.org/equipment/inverter\\_tests/summaries](http://www.gosolarcalifornia.org/equipment/inverter_tests/summaries) where the CEC Efficiency would be the value to enter here.

An example IDF showing how this object is used is provided below:

```
ElectricLoadCenter:Inverter:Simple,
  Simple Ideal Inverter,      !- Name
  Always On,                  !- Availability Schedule Name
  ,                           !- Zone Name
  0.0,                       !- Radiative Fraction
  1.0;                       !- Inverter Efficiency
```

---

### 1.54.5 ElectricLoadCenter:Inverter:FunctionOfPower

This input object is used to model conversion from Direct Current (DC) to Alternating Current (AC) in an electric load center that contains photovoltaic modules. Such a load center has an array of photovoltaic modules that feed an inverter DC power and the inverter produces AC power. This input object is for an inverter model where efficiency is a function of normalized power.

#### 1.54.5.1 Inputs

##### 1.54.5.1.1 Field: Name

This field contains a unique name for the inverter. The name entered must also be unique across all other types of inverters that may also be in the input file.

##### 1.54.5.1.2 Field: Availability Schedule Name

This field contains the name of a schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by scheduling a value of 0, then it cannot produce AC power, nor contribute heat gains to the zone, and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to produce AC power, contribute heat gains to the zone and consume ancillary power during standby. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.54.5.1.3 Field: Zone Name

This field contains the name of the thermal zone where the inverter is located. Entering a valid name of zone here will direct EnergyPlus to include the inverter's losses as heat gains to the named thermal zone. If the inverter is not within a thermal zone, then this field can be left blank (and the thermal energy associated with inverter losses is removed from the building model).

##### 1.54.5.1.4 Field: Radiative Fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

##### 1.54.5.1.5 Field: Efficiency Function of Power Curve Name

This field contains the name of curve representing the relationship between DC power input into the inverter and the efficiency with which that power is converted to AC. The curve can be either a **Curve:Linear**, **Curve:Quadratic**, or **Curve:Cubic**. The curve's x value is DC power input normalized by

the following field. The result of the curve should be power conversion efficiency expressed as a fraction between 0.0 and 1.0.

#### 1.54.5.1.6 Field: Rated Maximum Continuous Input Power

This field contains the rated power input in watts. This is value used to normalize input power for use with the curve named in the previous field. This is DC power from the PV arrays going into the inverter.

#### 1.54.5.1.7 Field: Minimum Efficiency

This field contains a minimum bound on the inverter efficiency. This value will be used as a limit on the curve's result.

#### 1.54.5.1.8 Field: Maximum Efficiency

This field contains a maximum bound on the inverter efficiency. This value will be used as a limit on the curve's result.

#### 1.54.5.1.9 Field: Minimum Power Output

This field contains a lower limit on the AC power produced by the inverter. If the resulting power output would be below this level, then the inverter is assumed to not produce any power and is in standby mode. All DC power input is lost (unless it is going into storage).

#### 1.54.5.1.10 Field: Maximum Power

This field contains an upper limit on the AC power produced by the inverter. If the resulting power output would be above this level, then the power produced is capped at this level with the rest of input power converted to losses (unless it is going into storage).

#### 1.54.5.1.11 Field: Ancillary Power Consumed In Standby

This field contains the ancillary power in watts used by the inverter when not producing AC power. This is AC electricity consumed in standby mode. Standby mode occurs when the inverter is scheduled to be available but the incoming DC power is too low.

An example IDF showing how this object is used is provided below:

```
ElectricLoadCenter:Inverter:FunctionOfPower,
  Curve Inverter,                !- Name
  ALWAYS_ON,                    !- Availability Schedule Name
  ,                              !- Zone Name
  0.3,                          !- Radiative Fraction
  Inverter Curve,               !- Efficiency Function of Power Curve Name
  15000,                        !- Rated Maximum Continuous Input Power {W}
  0.0,                          !- Minimum Efficiency
  1.0,                          !- Maximum Efficiency
  200,                          !- Minimum Power Output {W}
  20000,                        !- Maximum Power Output {W}
  0.0;                          !- Ancillary Power Consumed In Standby {W}
```

### 1.54.6 ElectricLoadCenter:Inverter:LookUpTable

This input object is used to model conversion from Direct Current (DC) to Alternating Current (AC) in an electric load center that contains photovoltaic modules. Such a load center has an array of photovoltaic modules that feed an inverter DC power and the inverter produces AC power. This input object is for an inverter model where efficiency is interpolated using a look up table.

This object was designed for use with data contained in the Inverter Performance Test Summaries available at [http://www.gosolarcalifornia.org/equipment/inverter\\_tests/summaries](http://www.gosolarcalifornia.org/equipment/inverter_tests/summaries). All of the data needed for this object can be found there by make and model of inverter. The core of the data set is a 3x6 matrix of efficiency at different voltage and power levels. These form the look up table used in the model. Note that EnergyPlus PV models currently model only power and not the voltage and current situation. Therefore, only the nominal voltage data are used. This is the middle row of data in the Go Solar summaries.

### **1.54.6.1 Inputs**

#### **1.54.6.1.1 Field: Name**

This field contains a unique name for the inverter. The name entered must also be unique across all other types of inverters that may also be in the input file.

#### **1.54.6.1.2 Field: Availability Schedule Name**

This field contains the name of a schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by setting a value of 0, then it cannot produce AC power, nor contribute heat gains to the zone, and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to produce AC power, contribute heat gains to the zone and consume ancillary power during standby. If this field is blank, the schedule has values of 1 for all time periods.

#### **1.54.6.1.3 Field: Zone Name**

This field contains the name of the thermal zone where the inverter is located. Entering a valid name of zone here will direct EnergyPlus to include the inverter's losses as heat gains to the named thermal zone. If the inverter is not within a thermal zone, then this field can be left blank (and the thermal energy associated with inverter losses is removed from the building model).

#### **1.54.6.1.4 Field: Radiative Fraction**

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

#### **1.54.6.1.5 Field: Rated Maximum Continuous Output Power**

This field contains the rated maximum continuous output power in watts.

#### **1.54.6.1.6 Field: Night Tare Loss Power**

This field contains the night tare loss in watts. This is modeled as ancillary power consumed during standby.

#### **1.54.6.1.7 Field: Nominal Voltage Input**

This field contains the nominal DC input voltage in volts. This is Vnom in the Go Solar test summaries.

#### **1.54.6.1.8 Field: Efficiency at 10% Power and Nominal Voltage**

This field contains the fractional efficiency at nominal voltage and 10% power.

#### **1.54.6.1.9 Field: Efficiency at 20% Power and Nominal Voltage**

This field contains the fractional efficiency at nominal voltage and 20% power.

**1.54.6.1.10 Field: Efficiency at 30% Power and Nominal Voltage**

This field contains the fractional efficiency at nominal voltage and 30% power.

**1.54.6.1.11 Field: Efficiency at 50% Power and Nominal Voltage**

This field contains the fractional efficiency at nominal voltage and 50% power.

**1.54.6.1.12 Field: Efficiency at 75% Power and Nominal Voltage**

This field contains the fractional efficiency at nominal voltage and 75% power.

**1.54.6.1.13 Field: Efficiency at 100% Power and Nominal Voltage**

This field contains the fractional efficiency at nominal voltage and 100% power.

An example IDF showing how this object is used is provided below:

```
ElectricLoadCenter:Inverter:LookUpTable,
  PV Inverter,                !- Name
  ALWAYS_ON,                  !- Availability Schedule Name
  ,                            !- Zone Name
  0.25,                       !- Radiative Fraction
  14000,                       !- Rated Maximum Continuous Output Power {W}
  200.0,                      !- Night Tare Loss Power {W}
  368,                        !- Nominal Voltage Input {V}

```

**1.54.7 ElectricLoadCenter:Inverter:PVWatts**

The ElectricLoadCenter:Inverter:PVWatts is intended to be used in an [ElectricLoadCenter:Distribution](#) with one or more [Generator:PVWatts](#) objects. It is **not** compatible with other Generator objects, such as [Generator:Photovoltaic](#).

**1.54.7.1 Inputs****1.54.7.1.1 Field: Name**

This field contains a unique name for the inverter. The name entered must also be unique across all other types of inverters that may also be in the input file.

**1.54.7.1.2 Field: DC to AC Size ratio**

The DC to AC size ratio is the ratio of the inverter's AC rated size to the array's DC rated size. Increasing the ratio increases the system's output over the year, but also increases the array's cost. The default value is 1.10, which means that a 4 kW system size would be for an array with a 4 DC kW nameplate size at standard test conditions (STC) and an inverter with a 3.63 AC kW nameplate size.

For a system with a high DC to AC size ratio, during times when the array's DC power output exceeds the inverter's rated DC input size, the inverter limits the array's power output by increasing the DC operating voltage, which moves the array's operating point down its current-voltage (I-V) curve. PVWatts models this effect by limiting the inverter's power output to its rated AC size.

The default value of 1.10 is reasonable for most systems. A typical range is 1.10 to 1.25, although some large-scale systems have ratios of as high as 1.50. The optimal value depends on the system's location, array orientation, and module cost.

Default: 1.10

**1.54.7.1.3 Field: Inverter Efficiency**

The inverter's nominal rated DC-to-AC conversion efficiency, defined as the inverter's rated AC power output divided by its rated DC power output.

Default: 0.96

**1.54.7.2 Outputs Description**

- HVAC,Average,Inverter Produced AC Electricity Rate [W]
- HVAC,Sum,Inverter Produced AC Electricity Energy [J]

**1.54.7.3 Outputs**

Each inverter can report the following seven output variables.

- HVAC,Average,Inverter DC to AC Efficiency []
- HVAC,Average,Inverter DC Input Electricity Rate [W]
- HVAC,Sum,Inverter DC Input Electricity Energy [J]
- HVAC,Average,Inverter AC Output Electricity Rate [W]
- HVAC,Sum,Inverter AC Output Electricity Energy [J]
- HVAC,Average,Inverter Conversion Loss Power [W]
- HVAC,Sum,Inverter Conversion Loss Energy [J]
- HVAC,Sum,Inverter Conversion Loss Decrement Energy [J]
- HVAC,Average,Inverter Thermal Loss Rate [W]
- HVAC,Sum,Inverter Thermal Loss Energy [J]
- HVAC,Average,Inverter Ancillary AC Electricity Rate [W]
- HVAC,Sum,Inverter Ancillary AC Electricity Energy [J]

**1.54.7.3.1 Inverter DC to AC Efficiency []**

This is the efficiency with which DC power is converted to AC power by the inverter.

**1.54.7.3.2 Inverter DC Input Electric Power [W]****1.54.7.3.3 Inverter DC Input Electricity Energy [J]**

These outputs are total electricity power or energy fed into the inverter. This is Direct Current from photovoltaics (or DC-based electrical storage) going into the inverter.

**1.54.7.3.4 Inverter AC Output Electricity Rate [W]****1.54.7.3.5 Inverter AC Output Electricity Energy [J]**

These outputs are the total electricity power or energy produced by the inverter. This is Alternating Current going out of the inverter.

**1.54.7.3.6 Inverter Conversion Loss Power [W]****1.54.7.3.7 Inverter Conversion Loss Energy [J]**

#### 1.54.7.3.8 Inverter Conversion Loss Decrement Energy [J]

These outputs are the thermal power or energy losses in the inverter that stem from converting from DC to AC. The decrement energy is negative and is metered as “PowerConversion” on the “ElectricityProduced” resource.

#### 1.54.7.3.9 Inverter Thermal Loss Rate [W]

#### 1.54.7.3.10 Inverter Thermal Loss Energy [J]

These outputs are the thermal power or energy losses in the inverter that stem from converting from DC to AC plus any ancillary electric power.

#### 1.54.7.3.11 Inverter Ancillary AC Electricity Rate [W]

#### 1.54.7.3.12 Inverter Ancillary AC Electricity Energy [J]

These outputs are the Alternating Current electricity consumed by the inverter. These are ancillary, or night tare loss, power uses by the inverter and modeled as if powered by the building’s grid connection. These ancillary power draws generally occur when the inverter is not generating power but waiting in a standby mode ready to begin generating power.

### 1.54.8 ElectricLoadCenter:Storage:Converter

This model is for converting AC to DC for grid-supplied charging of DC storage. The model is only for power conversion and does not consider voltage. There are two methods available for determining the efficiency with which power is converted. The efficiency is defined as the ratio of DC power output divided by AC power input. If the name of a zone is entered the power conversion losses will be added to the zone as internal heat gains. The converter is part of a single electric load center.

#### 1.54.8.1 Field: Name

This field contains a unique name for the AC to DC converter. This name will be referenced in an **ElectricLoadCenter:Distribution** object.

#### 1.54.8.2 Field: Availability Schedule Name

This field contains the name of a schedule that describes when the power converter is available. If power conversion is not available then electric power from the grid cannot be used to charge storage. Any non-zero value means the converter is available. If this field is blank, the schedule has a value of 1 for all time periods and the converter is always available. Standby power consumption is on when converter is available and off when the converter is not available.

#### 1.54.8.3 Field: Power Conversion Efficiency Method

This choice field is used to select which method is used to define the efficiency with which power is converted from AC to DC. There are two options: SimpleFixed or FunctionOfPower. - SimpleFixed indicates that power conversion efficiency is a constant with the value set in the next field. There is no need to size the converter (with a value in the field called Design Maximum Continuous Input Power) and varying levels of power do not affect the efficiency. SimpleFixed is the default. - FunctionOfPower indicates that the power conversion efficiency is a function of the level of power being converted. This method is intended to model the characteristic that converters tend to operate less efficiently when loaded well below their design

size. The converter must be sized with a value in the Design Maximum Continuous Input Power and the functional relationship described in a performance curve or look-up table.

#### 1.54.8.4 Field: Simple Fixed Efficiency

This numeric field is used to set a constant efficiency for conversion of AC to DC at all power levels. This field is only used, and is required, when the Power Conversion Efficiency Method is set to SimpleFixed. The value must be greater than 0.0 and less than equal to 1.0. The default is 0.95.

#### 1.54.8.5 Field: Design Maximum Continuous Input Power

This numeric field describes the size of the power converter in terms of its design input power level, in Watts. This is the AC power going into the converter. This field is only used, and is required, when the Power Conversion Efficiency Method is set to FunctionOfPower. This input serves as an upper limit for the AC power input and is used to normalize power for use in the performance curve or table. The AC power being converted at any given time is divided by the value in this field.

#### 1.54.8.6 Field: Efficiency Function of Power Curve Name

This field is the name of a performance curve or table object that describes how efficiency varies as a function of normalized power. The single independent “x” variable input for the curve or table is the ratio of AC input power at a given time divided by design power in the previous field. The result of the curve should be the power conversion efficiency for that normalized power so that DC power output is the product of efficiency multiplied by the AC power input. Any of the single-variable performance curves or lookup table objects can be used to describe performance. This field is only used, and is required, when the Power Conversion Efficiency Method is set to FunctionOfPower.

#### 1.54.8.7 Field: Ancillary Power Consumed In Standby

This numeric field describes the ancillary power consumed by the converter when it is available but not converting power, in Watts. This field is optional and can be used with any of the efficiency methods. If this converter is really on mode of a bidirectional inverter, take care not to double count the ancillary consumption by including them in both this component and the inverter component.

#### 1.54.8.8 Field: Zone Name

This field is the name of thermal zone where the converter is located. If this field is omitted then the converter is considered outdoors. The power lost during the conversion process is treated as heat gains and added the thermal zone named in this field. The split between radiation and convection can be controlled in the next input field.

#### 1.54.8.9 Field: Radiative Fraction

This numeric field is the fraction of zone heat gains that are handled as infrared thermal radiation. This field is only used if a zone is named in the previous field. The portion of zone gains that are not radiative are added to the zone as convection. If a zone is named and this field left blank or omitted then all the zone heat gains will be convective.

An example IDF showing how this object is used is provided below:

```
ElectricLoadCenter:Storage:Converter,
  Grid Charge Converter , !- Name
```

```

ALWAYS\_ON , !- Availability Schedule Name
SimpleFixed , !- Power Conversion Efficiency Method
0.95 , !- Simple Fixed Efficiency
, !- Design Maximum Continuous Input Power
, !- Efficiency Function of Power Curve Name 20
, !- Ancillary Power Consumed In Standby
, !- Zone Name 0.25; !- Radiative Fraction

```

---

### 1.54.9 Electric Load Center Converter Outputs

Each converter can report the following output variables

- HVAC,Average,Converter AC to DC Efficiency []
- HVAC,Average,Converter AC Input Electricity Rate [W]
- HVAC,Sum,Converter AC Input Electricity Energy [J]
- HVAC,Average,Converter DC Output Electricity Rate [W]
- HVAC,Sum,Converter DC Output Electricity Energy [J]
- HVAC,Average,Converter Electric Loss Power [W]
- HVAC,Sum,Converter Electric Loss Energy [J]
- HVAC,Sum,Converter Electric Loss Decrement Energy [J]
- HVAC,Average,Converter Thermal Loss Rate [W]
- HVAC,Sum,Converter Thermal Loss Energy [J]
- HVAC,Average,Converter Ancillary AC Electricity Rate [W]
- HVAC,Sum,Converter Ancillary AC Electricity Energy [J]

#### 1.54.9.1 Converter AC to DC Efficiency []

This is the efficiency with which AC power is converted to DC power by the converter

#### 1.54.9.2 Converter AC Input Electricity Rate [W]

#### 1.54.9.3 Converter AC Input Electricity Energy [J]

These outputs are the total electric power or energy fed into the converter. This is Alternating Current, or AC, drawn from the main panel into the load center.

#### 1.54.9.4 Converter DC Output Electricity Rate [W]

#### 1.54.9.5 Converter DC Output Electricity Energy [J]

These outputs are the total electric power or energy leaving the converter. This is Direct Current, or DC, that will go into charging storage.

#### 1.54.9.6 Converter Electric Loss Power [W]

#### 1.54.9.7 Converter Electric Loss Energy [J]

#### 1.54.9.8 Converter Electric Loss Decrement Energy [J]

These outputs are the conversion losses that result from inefficiencies in the conversion from AC to DC. The power and energy are positive while the decrement energy is negative and is metered on the “Power-Conversion” end use for “ElectricityProduced”.

**1.54.9.9 Converter Thermal Loss Rate [W]****1.54.9.10 Converter Thermal Loss Energy [J]**

These outputs are the power and energy losses that result from the inefficiencies in the conversion from AC to DC and the ancillary standby power.

**1.54.9.11 Converter Ancillary AC Electricity Rate [W]****1.54.9.12 Converter Ancillary AC Electricity Energy [J]**

These outputs are the power and energy consumed in standby operation when the converter is not being used but is available and ready to be used. The ancillary power consumption is metered on the “Cogeneration” end use for “Electricity.”

**1.54.10 ElectricLoadCenter:Storage:Simple**

This input object is used to model storage of electricity in an electric load center. This can be used to model a battery or other forms of electrical storage in a simplified manner. The type of power, AC or DC, depends on the configuration chosen as the Electrical Buss Type in the **ElectricLoadCenter:Distribution** object.

**1.54.10.1 Inputs****1.54.10.1.1 Field: Name**

This field contains a unique name for the electric storage device.

**1.54.10.1.2 Field: Availability Schedule Name**

This field contains the name of a schedule that describes when the storage device is available. If storage is not available, by scheduling a value of 0, then no electrical energy can be stored or drawn from the device. Any non-zero schedule value means the devices is available. If this field is blank, the schedule has values of 1 for all time periods.

**1.54.10.1.3 Field: Zone Name**

This field contains the name of the thermal zone where the storage device is located. Entering a valid name of a zone here will direct EnergyPlus to include the storage losses as heat gains to the name thermal zone. If the storage is not within a thermal zone, then this field can be left blank.

**1.54.10.1.4 Field: Radiative Fraction for Zone Heat Gains**

This field contains the fraction of storage losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses are convective. This field is not used if the previous field for zone name is left blank.

**1.54.10.1.5 Field: Nominal Energetic Efficiency for Charging**

This field contains the charging efficiency. This is the energetic efficiency of storing electrical energy in the storage device. A value of 1.0 means the device does not lose any energy when charging.

**1.54.10.1.6 Field: Nominal Discharging Energetic Efficiency**

This field contains the discharging efficiency. This is the energetic efficiency of drawing electrical energy from the storage device. A value of 1.0 means the device does not lose any energy when drawing power.

#### 1.54.10.1.7 Field: Maximum Storage Capacity

This field describes the maximum amount of energy that can be stored in the device in Joules. Once the storage device is full, no additional energy can be stored in it.

#### 1.54.10.1.8 Field: Maximum Power for Discharging

This field describes the maximum rate at which electrical power can be discharged from the storage device in watts.

#### 1.54.10.1.9 Field: Maximum Power for Charging

This field describes the maximum rate at which electrical power can be stored in the device in watts.

#### 1.54.10.1.10 Field: Initial State of Charge

This field describes the value for the initial state of charge in Joules. This is used to model the storage device as having some amount of stored energy at the beginning of the simulation period.

An example IDF showing how this object is used is provided below:

```
ElectricLoadCenter:Storage:Simple,
  Battery,                                !- Name
  ALWAYS_ON,                             !- Availability Schedule Name
  ,                                       !- Zone Name
  0.0,                                   !- Radiative Fraction for Zone Heat Gains
  0.7,                                   !- Nominal Energetic Efficiency for Charging
  0.7,                                   !- Nominal Discharging Energetic Efficiency
  1.0E11,                                !- Maximum Storage Capacity {J}
  50000,                                 !- Maximum Power for Discharging {W}
  25000,                                 !- Maximum Power for Charging {W}
  1.0E10;                                !- Initial State of Charge {J}
```

### 1.54.10.2 Outputs

Each electrical storage device can report the following seven output variables.

- HVAC,Average,Electric Storage Simple Charge State [J]
- HVAC,Average,Electric Storage Charge Power [W]
- HVAC,Sum,Electric Storage Charge Energy [J]
- HVAC,Average,Electric Storage Discharge Power [W]
- HVAC,Sum,Electric Storage Discharge Energy [J]
- HVAC,Average,Electric Storage Thermal Loss Rate [W]
- HVAC,Sum,Electric Storage Thermal Loss Energy [J]
- HVAC,Sum,Electric Storage Production Decrement Energy [J]

#### 1.54.10.2.1 Electric Storage Simple Charge State [J]

This output is the state of charge of the storage device. State of charge is the amount of electrical energy stored in the device at a point of time. The amount of energy stored is tracked in Joules.

#### 1.54.10.2.2 Electric Storage Charge Power [W]

**1.54.10.2.3 Electric Storage Charge Energy [J]**

These outputs are total electricity power or energy fed into the storage device. This is the rate or amount of charging.

**1.54.10.2.4 Electric Storage Production Decrement Energy [J]**

This output is the total electricity energy decremented from electricity production because it has fed into the storage device. This output has the opposite sign of Electric Storage Charge Energy but is otherwise similar. This decrement output variable is also a meter associated with the resource type ElectricityProduced that reduces the metered electricity production to account for power that went into storage after production.

**1.54.10.2.5 Electric Storage Discharge Power [W]****1.54.10.2.6 Electric Storage Discharge Energy [J]**

These outputs are total electricity power or energy drawn from the storage device. This is the rate or amount of discharging. The energy from storage output variable is also a meter associated with the resource type ElectricityProduced that increases the metered electricity production to account for power that has come back out of storage.

**1.54.10.2.7 Electric Storage Thermal Loss Rate [W]****1.54.10.2.8 Electric Storage Thermal Loss Energy [J]**

These outputs are the thermal power or energy losses from both charging and drawing electrical power in or out of the storage device. These losses are the result of inefficiencies in charging and drawing.

**1.54.11 ElectricLoadCenter:Storage:Battery**

This object uses the kinetic battery model (KiBaM) to simulate rechargeable battery banks in an electrical load center. This model is intended to represent technologies such as lead-acid that encounter significant rate or kinetic limitations. The battery bank is a collection of one or more individual battery modules. Given the surplus or deficit power from the electrical system and the state of charge from the previous time step, this object can model the voltage, current, and energy losses with charging and discharging during each time step. The cumulative battery damage can be also modeled and reported at the end of each simulation run.

The kinetic battery model assumes that part of the battery's energy storage capacity is immediately available in discharging or charging while the rest is chemically bound. As a function of constant current, the battery capacity is related to three parameters: the maximum capacity at infinitesimal current, the capacity ratio of available charges, and the conversion ratio between available charges and bound charges. These parameters are usually obtained via curve fitting based on battery data sheets or test data.

Each individual battery module is modeled as a voltage source in series with an electrical resistance. KiBaM assumes that the internal resistance is constant and the open circuit voltage varies with the electric current, the state of charge and the operation mode (charging or discharging). For an individual battery module, the open circuit voltage at any time is correlated to the voltage at fully charged/discharged state and three other regression coefficients. These regression coefficients are usually obtained via curve fitting based on battery test data.

The object offers user the option to perform battery life calculation. If battery life is modeled, the user needs to provide a group of coefficients for the correlation between the number of cycles for battery failure and the corresponding cycle range. More detailed information can be found from the Engineering Reference.

### **1.54.11.1 Inputs**

#### **1.54.11.1.1 Field: Name**

This alpha field contains the identifying name for the battery bank.

#### **1.54.11.1.2 Field: Availability Schedule Name**

This alpha field contains the schedule name (ref. Schedule objects) that describes when the battery is available. A schedule value greater than 0 (usually 1 is used) indicates that electrical energy can be stored or drawn from the battery. A value less than or equal to 0 (usually 0 is used) denotes that the battery is not available. If this field is blank, the schedule has values of 1 for all time periods.

#### **1.54.11.1.3 Field: Zone Name**

This field contains the name of the thermal zone where the battery is located. Entering a valid name of zone here will direct EnergyPlus to include the energy storage losses as heat gains to the named thermal zone. If the battery is not within a thermal zone, this field can be left blank and the thermal energy associated with storage losses is removed from the building model.

#### **1.54.11.1.4 Field: Radiative Fraction**

This field contains the fraction of storage losses that enter the zone as long-wave thermal radiation. This numeric field should have a value between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

#### **1.54.11.1.5 Field: Number of Battery Modules in Parallel**

This field defines the number of modules connected in parallel in the battery bank.

#### **1.54.11.1.6 Field: Number of Battery Modules in Series**

This field defines the number of modules connected in series in the battery bank. The total number of modules in a battery bank is equal to the number of modules in parallel times the number of modules in series.

#### **1.54.11.1.7 Field: Maximum Module Capacity**

This field indicates the maximum capacity of one battery module. It is evaluated as the total Amp-hours available when a full battery is discharged at infinitesimal current. This capacity is for an individual battery module, not for the whole battery bank. The maximum capacity can be found from manufacture s data or derived from test data by curve fitting.

#### **1.54.11.1.8 Field: Initial Fractional State of Charge**

This field describes the initial state of charge in terms of the fraction of maximum capacity as defined in the previous field.

#### **1.54.11.1.9 Field: Fraction of Available Charge Capacity**

The kinetic battery model assumes that battery is a two-tank electrical energy storage device: an available tank and a bound tank. The available tank can be immediately charged or discharged, while the bound tank can only be charged or discharged via the available tank. This field specifies the fraction of total charge in the battery that is part of the available tank. The ratio of available charge capacity to total capacity is a parameter usually derived from test data by curve fitting.

**1.54.11.1.10 Field: Change Rate from Bound Charge to Available Charge**

This field specifies the rate at which the charge flows between the available tank and the bound tank. It is a parameter used to calculate the conversion between available charge and chemically bound charge when charging and discharging the battery. This parameter is usually derived from test data by curve fitting.

**1.54.11.1.11 Field: Fully Charged Module Open Circuit Voltage**

This field indicates the open circuit voltage for a fully charged battery module. It can be found from manufacture s data or battery tests.

**1.54.11.1.12 Field: Fully Discharged Module Open Circuit Voltage**

This field indicates the open circuit voltage for a fully discharged battery module. It can be found from manufacture s data or battery tests.

**1.54.11.1.13 Field: Voltage Change Curve Name for Charging**

This field specifies the name of a rectangular hyperbola type 2 performance curve (ref: [Curve:RectangularHyperbola2](#) in Performance Curves) that determines the change of open circuit voltage ( $\Delta E$ ) as a function of the battery state of charge in charging. The change of open circuit voltage is relative to a fully discharged battery.

The curve has the following form:

$$\Delta E = (C_1 * X)/(C_2 + X) + C_3 * X \quad (1.212)$$

where X is the battery charge divided by the maximum capacity at a given current. More details can be found from the Engineering Reference.

**1.54.11.1.14 Field: Voltage Change Curve Name for Discharging**

This field specifies the name of a rectangular hyperbola type 2 performance curve (ref: [Curve:RectangularHyperbola2](#) in Performance Curves) that determines the change of open circuit voltage ( $\Delta E$ ) as a function of the battery state of charge in discharging. The change of open circuit voltage is relative to a fully charged battery.

The curve has the following form:

$$\Delta E = (C_1 * X)/(C_2 + X) + C_3 * X \quad (1.213)$$

where X is the removed charge divided by the maximum capacity at a given current. More details can be found from the Engineering Reference.

**1.54.11.1.15 Field: Module Internal Electrical Resistance**

This field specifies the battery internal resistance in ohms. In theory, the electrical resistance within the battery varies with the state of charge and depends on whether it is in charging or discharging. In the kinetic battery model, the internal resistance is assumed as constant and the terminal voltage varies with current and state of charge. The internal resistance may be obtained from the battery manufacture or battery test data. Note that the field is for an individual module, not for the whole battery bank.

**1.54.11.1.16 Field: Maximum Module Discharging Current**

This field indicates the maximum current at which the battery can be discharged continuously. The limit on discharge current is usually defined by the battery manufacture to avoid battery damage. The limit is for an individual battery module.

**1.54.11.1.17 Field: Module Cut-off Voltage**

This field specifies the minimum allowable voltage, below which the battery is generally regarded as empty. The cut-off voltage is usually defined by the battery manufacture and it is for an individual battery module.

**1.54.11.1.18 Field: Module Charge Rate Limit**

This field specifies the limit on charging current relative to the remaining charge until the battery is full. This limit reflects the common practice that the charge rate is reduced as the battery gets more charged.

**1.54.11.1.19 Field: Battery Life Calculation**

This field indicates whether the battery life model is activated in the simulation. If the battery life model is activated, the following five inputs on curve coefficients are required; otherwise, they are not used.

**1.54.11.1.20 Field: Number of Cycle Bins**

This field specifies the number of equally ranged cycle bins in battery life simulation. If 10 bins are used, the cycle ranges will include 10%, 20%, ..., 100%.

**1.54.11.1.21 Field: Battery Cycle Life Curve Name**

This field specifies the name of a double exponential decay curve (ref: [Curve:DoubleExponentialDecay](#) in Performance Curves) that correlates the cycles of battery failure ( $C_F$ ) and fractional depth of discharge (R). The curve is:

$$C_F = C_1 + C_2 e^{C_3 R} + C_4 e^{C_5 R} \quad (1.214)$$

An example input of the ElectricLoadCenter:Storage: Battery input is:

### 1.54.11.2 Outputs

- HVAC,Average, Electric Storage Operating Mode Index []
- HVAC,Average,Electric Storage Charge State[Ah]
- HVAC,Average, Electric Storage Charge Fraction []
- HVAC,Average,Electric Storage Charge Power[W]
- HVAC,Sum,Electric Storage Charge Energy [J]
- HVAC,Average,Electric Storage Discharge Power[W]
- HVAC,Sum,Electric Storage Discharge Energy [J]
- HVAC,Average,Electric Storage Total Current[A]
- HVAC,Average, Electric Storage Total Voltage [V]
- HVAC,Average,Electric Storage Thermal Loss Rate [W]
- HVAC,Average, Electric Storage Degradation Fraction []
- HVAC,Sum,Electric Storage Production Decrement Energy [J]
- HVAC,Sum,Electric Storage Thermal Loss Energy [J]

#### 1.54.11.2.1 Electric Storage Operating Mode Index []

This output reports the battery mode of operation: 0 for idle; 1 for discharging; 2 for charging. It is expected that more operation modes would be added when a smart and active power dispatch controller is used in future.

#### 1.54.11.2.2 Electric Storage Charge State [Ah]

The state of charge is expressed as the amount of charge stored in the battery at a point of time. It has the same unit as the maximum capacity. This value is given for an individual battery module

**1.54.11.2.3 Electric Storage Charge Fraction []**

This output is the ratio between the electrical storage state of charge and the maximum capacity.

**1.54.11.2.4 Electric Storage Charge Power [W]****1.54.11.2.5 Electric Storage Charge Energy [J]**

These outputs are total electricity power or energy fed into the battery. This is the rate of amount of charging.

**1.54.11.2.6 Electric Storage Production Decrement Energy [J]**

This output is the total electricity energy decremented from electricity production because it has fed into the battery. This output has the opposite sign of Electric Storage Charge Energy but is otherwise similar. This decrement output variable is also a meter associated with the resource type ElectricityProduced that reduces the metered electricity production to account for power that went into storage after production.

**1.54.11.2.7 Electric Storage Discharge Power [W]****1.54.11.2.8 Electric Storage Discharge Energy [J]**

These outputs are total electricity power or energy drawn from the battery. This is the rate or amount of discharging. The energy from storage output variable is also a meter associated with the resource type ElectricityProduced that increases the metered electricity production to account for power that has come back out of storage.

**1.54.11.2.9 Electric Storage Total Current [A]**

This output is the current to or from the battery bank depending on whether the battery is in the state of charging or discharging. The value is positive for discharging and negative for charging.

**1.54.11.2.10 Electric Storage Total Voltage [V]**

This output is the total terminal voltage of the battery bank.

**1.54.11.2.11 Electric Storage Thermal Loss Rate [W]****1.54.11.2.12 Electric Storage Thermal Loss Energy [J]**

These outputs are the thermal power or energy losses from both charging and drawing electrical power in or out of the storage device. These losses are due to the battery internal resistance in charging and discharging.

**1.54.11.2.13 Electric Storage Degradation Fraction []**

This output reports the fractional battery life used up at a point of time. For example, a value of 0.4 at the end of one year simulation means that the 40% of the battery life is used up, so the battery needs to be replaced every two and a half years.

**1.54.12 ElectricLoadCenter:Storage:LiIonNMCBattery**

This object usses the Li-ion NMC battery model from the System Advisor Model (SAM) software.

**1.54.12.1 Inputs****1.54.12.1.1 Field: Name**

This alpha field contains the identifying name for the battery.

**1.54.12.1.2 Field: Availability Schedule Name**

This alpha field contains the schedule name (ref. Schedule objects) that describes when the battery is available. A schedule value greater than 0 (usually 1 is used) indicates that electrical energy can be stored or drawn from the battery. A value less than or equal to 0 (usually 0 is used) denotes that the battery is not available. If this field is blank, the schedule has values of 1 for all time periods.

**1.54.12.1.3 Field: Zone Name**

This field contains the name of the thermal zone where the battery is located. Entering a valid name of zone here will direct EnergyPlus to include the energy storage losses as heat gains to the named thermal zone. If the battery is not within a thermal zone, this field can be left blank and the thermal energy associated with storage losses is removed from the building model.

**1.54.12.1.4 Field: Radiative Fraction**

This field contains the fraction of storage losses that enter the zone as long-wave thermal radiation. This numeric field should have a value between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

**1.54.12.1.5 Field: Lifetime Model**

Which lifetime model to use for the battery. Available choices are:

- None: The battery doesn't degrade over time
- KandlerSmith: Use the lifetime model developed by Kandler Smith. Details at <https://ieeexplore.ieee.org/abstract/document/7963578>

**1.54.12.1.6 Field: Number of Cells in Series**

The number of cells in series. Increasing this number increases the voltage output of the battery.

**1.54.12.1.7 Field: Number of Strings in Parallel**

The number of strings in parallel.

**1.54.12.1.8 Field: Initial Fractional State of Charge**

This field describes the initial state of charge in terms of the fraction of maximum capacity.

**1.54.12.1.9 Field: DC to DC Charging Efficiency**

The charging loss coefficient.

**1.54.12.1.10 Field: Battery Mass**

Battery mass (kg) used in thermal calculation.

**1.54.12.1.11 Field: Battery Surface Area**

Battery surface area (m<sup>2</sup>) used in thermal calculations.

**1.54.12.1.12 Field: Battery Specific Heat Capacity**

Specific heat of the battery (J/kg-K) used in the thermal calculation.

**1.54.12.1.13 Field: Heat Transfer Coefficient Between Battery and Ambient**

Heat transfer coefficient (W/m<sup>2</sup>-K) between battery and ambient.

**1.54.12.1.14 Field: Fully Charged Cell Voltage**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.15 Field: Cell Voltage at End of Exponential Zone**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.16 Field: Cell Voltage at End of Nominal Zone**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.17 Field: Default Nominal Cell Voltage**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.18 Field: Fully Charged Cell Capacity**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.19 Field: Fraction of Cell Capacity Removed at the End of Exponential Zone**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.20 Field: Fraction of Cell Capacity Removed at the End of Nominal Zone**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.21 Field: Charge Rate at Which Voltage vs Capacity Curve Was Generated**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

**1.54.12.1.22 Field: Battery Cell Internal Electrical Resistance**

This field is included for those who want to modify the battery chemistry. Most users should leave this field blank or omit it to use the defaults, which are typical of Lithium-ion batteries.

An example input of the ElectricLoadCenter:Storage:LiIonNMCBattery is:

**1.54.12.2.13 Electric Storage Degradation Fraction []**

This output reports the fractional battery life used up at a point of time. For example, a value of 0.4 at the end of one year simulation means that 40% of the battery life is used up.

**1.54.12.2.14 HVAC,Average,Electric Storage Battery Temperature [C]**

The internal temperature of the battery.

**1.54.13 Generator:InternalCombustionEngine**

The Internal Combustion (IC) Engine generator uses a modified Otto cycle. This generator model uses the electrical load and rated engine generator size to compute part-load ratios (PLR). Fuel energy input and recoverable jacket and lube oil heat are then computed. Finally, the recoverable exhaust heat is calculated.

Manufacturer's curves or tables must be obtained for IC engine generators to derive the equipment performance parameters that are specified in the quadratic curve fits. Note that simple transformation

of the form of the manufacturer's curves may be required. Electric energy output/fuel energy input is related to the part-load ratio (i.e., electric/load generator capacity) with a polynomial. Recoverable jacket heat/fuel energy equipment, recoverable lube oil heat/fuel energy input equipment performance, total exhaust heat/fuel energy input equipment, exhaust gas temperature/fuel energy input equipment performance parameters are all specified with a quadratic curve fit.

When the heat recovery curve fits = 0.0, this means that no heat recovery is done on the IC engine generator exhaust gas; and no heat recovery is specified.

### 1.54.13.1 Inputs

#### 1.54.13.1.1 Field: Name

This alpha field contains the identifying name for the IC engine generator.

#### 1.54.13.1.2 Field: Rated Power Output

The design nominal capacity of the generator in Watts [W].

#### 1.54.13.1.3 Field: Electric Circuit Node Name

This named node contains where the electric power is put in the program simulation for use by the electric equipment in the Load Center.

#### 1.54.13.1.4 Field: Minimum Part Load Ratio

This field contains the minimum allowed operating fraction of full load. The input value must be  $> = 0.0$  and  $< = 1.0$ .

#### 1.54.13.1.5 Field: Maximum Part Load Ratio

This field contains the maximum allowed operating fraction of full load. The input value must be  $> 0.0$  and  $< = 1.0$ .

#### 1.54.13.1.6 Field: Optimum Part Load Ratio

This alpha field contains the optimal operating fraction of full load. This is the part load ratio that gives the optimal production of electric power with the least amount of fuel usage.

#### 1.54.13.1.7 Field: Shaft Power Curve Name

This alpha field contains the name of the shaft power curve. The curve itself is specified separately using a curve object (ref: [Curve:QuadLinear](#)). The Shaft Power Curve is a quadratic equation that determines the electric output versus the fuel used. Used to calculate the electric energy output divided by the fuel energy consumption as a function of part-load ratio. The defining equation is:

$$ShaftPowerToFuelRatio = C_1 + C_2RL + C_3RL^2 \quad (1.215)$$

where RL is the Ratio of Load to Rated Power Output.

#### 1.54.13.1.8 Field: Jacket Heat Recovery Curve Name

This alpha field contains the name of the Recovery Jacket Heat curve. The curve itself is specified separately using a curve object (ref: [Curve:QuadLinear](#)). The Jacket Heat Recovery Curve is a quadratic equation that determines the ratio of recovery jacket heat to fuel energy. Used to calculate the recoverable jacket heat as a function of part-load ratio.

The defining equation is:

$$\text{RecoveryJacketHeatToFuelRatio} = C_1 + C_2RL + C_3RL^2 \quad (1.216)$$

where RL is the Ratio of Load to Rated Power Output.

#### 1.54.13.1.9 Field: Lube Heat Recovery Curve Name

This alpha field contains the name of the Recovery Lube Heat curve. The curve itself is specified separately using a curve object (ref **Curve:QuadLinear**). The Lube Heat Recovery Curve is a quadratic equation that determines the ratio of recovery lube heat to fuel energy. Used to calculate the recoverable lube oil heat as a function of part-load ratio. The defining equation is:

$$\text{RecoveryLubeHeatToFuelRatio} = C_1 + C_2RL + C_3RL^2 \quad (1.217)$$

where RL is the Ratio of Load to Rated Power Output.

#### 1.54.13.1.10 Field: Total Exhaust Energy Curve Name

This alpha field contains the name of the Total Exhaust Energy curve. The curve itself is specified separately using a curve object (ref **Curve:QuadLinear** object). The Total Exhaust Energy Curve is a quadratic equation that determines the ratio of total exhaust energy to fuel energy. Used to calculate the total exhaust heat as a function of part-load ratio. The defining equation is:

$$\text{TotalExhaustToFuelRatio} = C_1 + C_2RL + C_3RL^2 \quad (1.218)$$

where RL is the Ratio of Load to Rated Power Output.

#### 1.54.13.1.11 Field: Exhaust Temperature Curve Name

This alpha field contains the name of the Exhaust Temperature curve. The curve itself is specified separately using a curve object (ref **Curve:QuadLinear** object). The Exhaust Temperature Curve is a quadratic equation that determines the absolute exhaust temperature. Used to determine the exhaust gas temperature as a function of part-load ratio. The defining equation is:

$$\text{AbsoluteExhaustTemperature} = C_1 + C_2RL + C_3RL^2 \quad (1.219)$$

where RL is the Ratio of Load to Rated Power Output.

#### 1.54.13.1.12 U-Factor Times Area (UA) Curve

The UA curve applies to the exhaust gas heat exchanger. The curve is an equation that determines the overall heat transfer coefficient for the exhaust gases with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$\text{UAToCapacityRatio} = C_1 \text{GeneratorRatedPowerOutput}^{C_2} \quad (1.220)$$

The following two fields contain the coefficients for the equation.

#### 1.54.13.1.13 Field: Coefficient 1 of U-Factor Times Area Curve

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

#### 1.54.13.1.14 Field: Coefficient 2 of U-Factor Times Area Curve

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

**1.54.13.1.15 Field: Maximum Exhaust Flow per Unit of Power Output**

Maximum exhaust flow per unit capacity for the generator. The parameter sets an upper limit on exhaust gas flow and exhaust gas heat recovery for the generator. Units: kg/sec per kW capacity

**1.54.13.1.16 Field: Design Minimum Exhaust Temperature**

This is the design engine stack saturated steam temperature in degrees C.

**1.54.13.1.17 Field: Fuel Higher Heating Value**

This numeric field contains the higher heating value of the fuel used in kJ/kg.

**1.54.13.1.18 Field: Design Heat Recovery Water Flow Rate**

Design water volumetric flow rate through heat recovery loop in m<sup>3</sup>/sec.

**1.54.13.1.19 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the generator's heat recovery side inlet node.

**1.54.13.1.20 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the generator's heat recovery side outlet node.

**1.54.13.1.21 Field: Fuel Type**

This alpha field determines the type of fuel that the generator uses. The default is Diesel. Valid values are: **NaturalGas**, **Propane**, **Diesel**, **Gasoline**, **FuelOilNo1**, **FuelOilNo2**, **OtherFuel1**, and **OtherFuel2**.

**1.54.13.1.22 Field: Heat Recovery Maximum Temperature**

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

The temperature is specified in degrees C.

An IDF example showing how it is used is provided below:

### 1.54.13.2 Outputs

The output variables that are available for the IC engine generator are:

- HVAC,Average,Generator Produced Electricity Rate [W]
- HVAC,Sum,Generator Produced Electricity Energy [J]
- HVAC,Average,Generator Lube Heat Recovery Rate [W]
- HVAC,Sum,Generator Lube Heat Recovery Energy [J]
- HVAC,Average,Generator Jacket Heat Recovery Rate [W]
- HVAC,Sum,Generator Jacket Heat Recovery Energy [J]

- HVAC,Average,Generator Exhaust Heat Recovery Rate [W]
- HVAC,Sum,Generator Exhaust Heat Recovery Energy [J]
- HVAC,Average,Generator Total Heat Recovery Rate [W]
- HVAC,Sum,Generator Total Heat Recovery [J]
- HVAC,Average,Generator Exhaust Air Temperature [C]
- HVAC,Average,Generator Heat Recovery Inlet Temperature [C]
- HVAC,Average,Generator Heat Recovery Outlet Temperature [C]
- HVAC,Average,Generator Heat Recovery Mass Flow Rate [kg/s]
- HVAC,Average,Generator Fuel HHV Basis Rate [W]
- HVAC,Sum,Generator Fuel HHV Basis Energy [J]
- HVAC,Average,Generator <Fuel Type> Rate [W]
- HVAC,Sum,Generator<Fuel Type> Energy [J]
- HVAC,Average,Generator <Fuel Type> Mass Flow Rate [kg/s]

#### **1.54.13.2.1 Generator Produced Electricity Rate [W]**

#### **1.54.13.2.2 Generator Produced Electricity Energy [J]**

These outputs are the electric power output from the electric generator. Energy is metered on Cogeneration:ElectricityProduced, ElectricityProduced:Plant, and ElectricityProduced:Facility.

#### **1.54.13.2.3 Generator Lube Heat Recovery Rate [W]**

#### **1.54.13.2.4 Generator Lube Heat Recovery Energy [J]**

#### **1.54.13.2.5 Generator Jacket Heat Recovery Rate [W]**

#### **1.54.13.2.6 Generator Jacket Heat Recovery Energy [J]**

#### **1.54.13.2.7 Generator Exhaust Heat Recovery Rate [W]**

#### **1.54.13.2.8 Generator Exhaust Heat Recovery Energy [J]**

#### **1.54.13.2.9 Generator Produced Thermal Rate [W]**

#### **1.54.13.2.10 Generator Produced Thermal Energy [J]**

For electric generators with heat recovery these outputs are the components of recoverable energy available. For the IC engine generator, the following heat recovery components are reported: Lube (engine lubricant), Jacket (engine coolant), and Exhaust (engine exhaust). These components are totaled together for Generator Produced Thermal Rate and Generator Produced Thermal Energy reports. Generator Lube Heat Recovery Energy, Generator Jacket Heat Recovery Energy, and Generator Exhaust Heat Recovery Energy are metered on HeatRecovery:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

**1.54.13.2.11 Generator Exhaust Air Temperature [C]**

This is the exhaust temperature leaving the engine.

**1.54.13.2.12 Generator Heat Recovery Inlet Temperature [C]****1.54.13.2.13 Generator Heat Recovery Outlet Temperature [C]****1.54.13.2.14 Generator Heat Recovery Mass Flow Rate [kg/s]**

These outputs are the heat recovery inlet and outlet temperatures and flow rate for generators with heat recovery.

**1.54.13.2.15 Generator Fuel HHV Basis Rate [W]****1.54.13.2.16 Generator Fuel HHV Basis Energy [J]**

These outputs are the generator's fuel energy and use rate. The energy content of the fuel is based on the higher heating value (HHV).

**1.54.13.2.17 Generator <Fuel Type> Rate [W]****1.54.13.2.18 Generator <Fuel Type> Energy [J]****1.54.13.2.19 Generator <Fuel Type> Mass Flow Rate [kg/s]**

If the fuel type is Diesel, then Diesel is shown as the fuel type. They are the diesel fuel input to the electric generator. Consumption is metered on Cogeneration:Diesel, Diesel:Plant, and Diesel:Facility.

If the fuel type is Natural Gas, then NaturalGas is shown as the fuel type. They are the natural gas fuel input to the electric generator. Consumption is metered on Cogeneration:NaturalGas, NaturalGas:Plant, and NaturalNaturalGas:Facility.

If the fuel type is Propane, then Propane is shown as the fuel type. They are the propane fuel input to the electric generator. Consumption is metered on Cogeneration:Propane, Propane:Plant, and Propane:Facility.

If the fuel type is Gasoline, then Gasoline is shown as the fuel type. They are the gasoline fuel input to the electric generator. Consumption is metered on Cogeneration:Gasoline, Gasoline:Plant, and Gasoline:Facility.

If the fuel type is FuelOilNo1, then FuelOilNo1 is shown as the fuel type. They are the fuel oil input to the electric generator. Consumption is metered on Cogeneration:FuelOilNo1, FuelOilNo1:Plant, and FuelOilNo1:Facility.

If the fuel type is FuelOilNo2, then FuelOilNo2 is shown as the fuel type. They are the fuel oil input to the electric generator. Consumption is metered on Cogeneration:FuelOilNo2, FuelOilNo2:Plant, and FuelOilNo2:Facility.

If the fuel type is OtherFuel1, then OtherFuel1 is shown as the fuel type. They are the fuel oil input to the electric generator. Consumption is metered on Cogeneration:OtherFuel1, OtherFuel1:Plant, and OtherFuel1:Facility.

If the fuel type is OtherFuel2, then OtherFuel2 is shown as the fuel type. They are the fuel oil input to the electric generator. Consumption is metered on Cogeneration:OtherFuel2, OtherFuel2:Plant, and OtherFuel2:Facility.

### 1.54.14 Generator:CombustionTurbine

EnergyPlus has two different models for combustion turbine style generators. This one stems for a model that was originally in the BLAST computer program. A newer model with a different formulation is also available -see the **Generator:MicroTurbine** input object. The basic combustion-turbine cycle is the Brayton Cycle or open cycle, which consists of an adiabatic compression, constant pressure heating, and adiabatic expansion. The Combustion turbine model uses the electrical load and engine generator size to compute part-load ratios (PLR). Fuel energy input and recoverable lube oil heat are then computed. Finally, the recoverable exhaust heat is calculated.

Combustion turbine generators use performance parameters to compute fuel energy consumption as a function of part-load and ambient (entering) air temperature. Recoverable fuel energy equipment, recoverable lube oil heat/fuel energy input equipment performance, total exhaust heat/fuel energy input equipment, exhaust gas temperature/fuel energy input equipment performance parameters are all specified with a quadratic curve fit.

When the heat recovery curve fits = 0.0, this means that no heat recovery is done on the diesel generator exhaust gas; and no heat recovery is specified.

#### 1.54.14.1 Inputs

##### 1.54.14.1.1 Field: Name

Unique name to identify this combustion turbine generator.

##### 1.54.14.1.2 Field: Rated Power Output

The design nominal capacity of the combustion turbine generator in Watts [W].

##### 1.54.14.1.3 Field: Electric Circuit Node Name

This Named node contains where the electric power is put in the program simulation for use by the electric equipment in the Load Center.

##### 1.54.14.1.4 Field: Minimum Part Load Ratio

This field contains the minimum allowed operating fraction of full load. The input value must be  $\geq 0.0$  and  $\leq 1.0$ .

##### 1.54.14.1.5 Field: Maximum Part Load Ratio

This field contains the maximum allowed operating fraction of full load. The input value must be  $>0.0$  and  $\leq 1.0$ .

##### 1.54.14.1.6 Field: Optimum Part Load Ratio

This alpha field contains the optimal operating fraction of full load. This is the part load ratio that gives the optimal production of electric power with the least amount of fuel usage.

##### 1.54.14.1.7 Field: Part Load Based Fuel Input Curve Name

Needs a **Curve:Quadratic** object to be specified.

Fuel Input =  $a + b \cdot \text{PLR} + c \cdot \text{PLR}^2$

PLR = Ratio of Generator Load to Rated Power Output. This curve is multiplied to the Temperature Based Fuel Input Curve to determine Fuel Energy In.

**1.54.14.1.8 Field: Temperature Based Fuel Input Curve Name**

Needs a **Curve:Quadratic** object to be specified.

Fuel Input =  $a + b \cdot AT + c \cdot AT^2$  where: AT = Ambient Delta T

**1.54.14.1.9 Field: Exhaust Flow Curve Name**

The Total Exhaust Energy Curve is a quadratic equation that needs to be specified by a curve object. Used to calculate the total exhaust heat as a function of part-load ratio.

**1.54.14.1.10 Field: Part Load Based Exhaust Temperature Curve Name**

The Exhaust Temperature Curve is a quadratic equation that needs to be specified by a curve object. Used to determine the exhaust gas temperature as a function of part-load ratio.

**1.54.14.1.11 Field: Temperature Based Exhaust Temperature Curve Name**

The Exhaust Temperature Curve is a quadratic equation that needs to be specified by a curve object. Used to determine the exhaust gas temperature as a function of part-load ratio.

**1.54.14.1.12 Field: Heat Recovery Lube Energy Curve Name**

This alpha field contains the name of the Recovery Lube Heat curve. The curve itself is specified separately using a curve object (see **Curve:Quadratic** object). The Recovery Lubricant Heat Curve is a quadratic equation that determines the ratio of recovery lube heat to fuel energy. Used to calculate the recoverable lube oil heat as a function of part-load ratio. The defining equation is:

$$RecoveryLubeHeatToFuelRatio = C_1 + C_2 RL + C_3 RL^2 \quad (1.221)$$

where RL is the Ratio of Load to Rated Power Output.

**1.54.14.1.13 U-Factor Times Area (UA) Curve**

The UA curve applies to the exhaust gas heat exchanger. The curve is an equation that determines the overall heat transfer coefficient for the exhaust gases with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$UA To Capacity Ratio = C_1 Generator Rated Power Output^{C_2} \quad (1.222)$$

The following two fields contain the coefficients for the equation.

**1.54.14.1.14 Field: Coefficient 1 of U-Factor Times Area Curve**

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

**1.54.14.1.15 Field: Coefficient 2 of U-Factor Times Area Curve**

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

**1.54.14.1.16 Field: Maximum Exhaust Flow per Unit of Power Output**

Maximum exhaust flow per unit capacity for diesel engines. The parameter sets an upper limit on exhaust gas flow and exhaust gas heat recovery for diesel engines. Units: kg/sec per kW capacity

**1.54.14.1.17 Field: Design Minimum Exhaust Temperature**

This is the design engine stack saturated steam temperature in degrees C.

**1.54.14.1.18 Field: Design Air Inlet Temperature**

Design air inlet temperature in degrees C.

**1.54.14.1.19 Field: Fuel Higher Heating Value**

This numeric field contains the higher heating value of the fuel used in kJ/kg.

**1.54.14.1.20 Field: Design Heat Recovery Water Flow Rate**

Design water volumetric flow rate through heat recovery loop in m<sup>3</sup>/sec.

**1.54.14.1.21 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the combustion turbine generator heat recovery side inlet node.

**1.54.14.1.22 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the combustion turbine generator heat recovery side outlet node.

**1.54.14.1.23 Field: Fuel Type**

This choice field specifies the type of fuel used by the generator. The fuel type can be NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, OtherFuel1, or OtherFuel2. If the field is left blank, the fuel type will be assumed to be **NaturalGas**.

**1.54.14.1.24 Field: Heat Recovery Maximum Temperature**

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

The temperature is specified in degrees C.

**1.54.14.1.25 Field: Outdoor Air Inlet Node Name**

This field is optional. It is used to explicitly define an outdoor air node for the inlet for combustion air stream. Defining an outdoor air node here allows using the height-dependent model for outdoor air conditions.

An IDF example showing how it is used is provided below:

```
Generator:CombustionTurbine,
  Solar Turbine,                !- Name
  30000,                        !- Rated Power Output {W}
  GT gen Electric Node,        !- Electric Circuit Node Name
  0.15,                        !- Minimum Part Load Ratio
  1.0,                         !- Maximum Part Load Ratio
  0.65,                        !- Optimum Part Load Ratio
```

**1.54.14.2 Outputs**

The output variables that are available for the combustion turbine generator are:

- HVAC,Average,Generator Produced Electricity Rate [W]
- HVAC,Sum,Generator Produced Electricity Energy [J]
- Zone,Meter,ElectricityProduced:Facility [J]
- Zone,Meter,ElectricityProduced:Plant [J]
- Zone,Meter,Cogeneration:ElectricityProduced [J]
- HVAC,Average,Generator Lube Heat Recovery Rate [W]
- HVAC,Sum,Generator Lube Heat Recovery Energy [J]
- HVAC,Average,Generator Exhaust Heat Recovery Rate [W]
- HVAC,Sum,Generator Exhaust Heat Recovery [J]
- HVAC,Average,Generator Total Heat Recovery Rate [W]
- HVAC,Sum,Generator Total Heat Recovery [J]
- HVAC,Average,Generator Exhaust Air Temperature [C]
- HVAC,Average,Generator Heat Recovery Inlet Temperature [C]
- HVAC,Average,Generator Heat Recovery Outlet Temperature [C]
- HVAC,Average,Generator Heat Recovery Mass Flow Rate [kg/s]
- HVAC,Average,Generator <Fuel Type> Rate [W]
- HVAC,Sum,Generator <Fuel Type> Energy [J]
- HVAC,Average,Generator <Fuel Type> Mass Flow Rate [kg/s]

All of these outputs, except for the Combustion use outputs, are described above under “Generator:InternalCombustionEngine Outputs.”

**1.54.14.2.1 Generator <Fuel Type> Rate [W]****1.54.14.2.2 Generator <Fuel Type> Energy [J]****1.54.14.2.3 Generator <Fuel Type> Mass Flow Rate [kg/s]**

These outputs are the fuel input to the electric generator. Consumption is metered on Cogeneration:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

### 1.54.15 Generator:MicroTurbine

MicroTurbine generators are small combustion turbines that produce electricity on a relatively small scale (e.g., 25kW to 500kW). This model uses nominal performance at reference conditions along with several modifier curves to determine electrical power output and fuel use at non-reference conditions. Standby and ancillary power can also be taken into account. Furthermore, energy recovery from exhaust air can be used to heat water. Similar to electrical power output, thermal power (heat recovery) output is calculated using nominal performance at reference conditions with modifier curves to account for variations at non-reference conditions.

The following inputs define the MicroTurbine electric generator. The [ElectricLoadCenter:Generators](#) and [ElectricLoadCenter:Distribution](#) objects are used to define the availability and control of all electric generators included in the simulation (ref. [ElectricLoadCenter:Generators](#) and [ElectricLoadCenter:Distribution](#)).

#### 1.54.15.1 Inputs

##### 1.54.15.1.1 Field: Name

This alpha field specifies a unique user-defined name to identify this generator. This is a required input.

##### 1.54.15.1.2 Field: Reference Electrical Power Output

This numeric field specifies the full-load electrical power output of the microturbine generator in Watts at reference conditions. The reference conditions are defined via additional input fields for this object (see below). This is a required input, and the value entered in this field must be greater than zero.

##### 1.54.15.1.3 Field: Minimum Full Load Electrical Power Output

This numeric field specifies the minimum electrical power output in Watts at full-load conditions. The electrical power output of the generator is determined by multiplying the Reference Electrical Power Output by the Electrical Power Function of Temperature and Elevation modifier curve. If the result is less than the numeric value specified in this input field, then the generator's electrical power output is reset to the minimum full-load value specified in this input field. The value entered in this field must be greater than or equal to zero. If this field is left blank, the default value of 0.0 will be used.

##### 1.54.15.1.4 Field: Maximum Full Load Electrical Power Output

This numeric field specifies the maximum electrical power output in Watts at full-load conditions. The electrical power output of the generator is determined by multiplying the Reference Electrical Power Output by the Electrical Power Function of Temperature and Elevation Modifier curve. If the result is greater than the numeric value specified in this input field, then the generator's electrical power output is reset to the maximum full-load value specified in this input field. The value entered in this field must be greater than zero. If this field is left blank, then the value entered for the Reference Electrical Power Output field (above) will be used as the Maximum Full Load Electrical Power Output.

##### 1.54.15.1.5 Field: Reference Electrical Efficiency Using Lower Heating Value

This numeric field contains the electrical efficiency of the generator at reference conditions, based on the lower heating value of the fuel. The electrical efficiency is the electric power output divided by the fuel energy consumption rate (LHV basis). The reference conditions are defined via additional input fields for this object (see below). This is a required input, and the value entered in this field must be greater than zero and less than or equal to 1.0.

**1.54.15.1.6 Field: Reference Combustion Air Inlet Temperature**

This numeric field specifies the reference temperature for the combustion inlet air in degrees Celsius. If this field is left blank, the default value of 15 °C will be used.

**1.54.15.1.7 Field: Reference Combustion Air Inlet Humidity Ratio**

This numeric field specifies the reference humidity ratio for the combustion inlet air in kgWater/kgDryAir. The value specified for this field must be greater than zero. If this field is left blank, the default value of 0.00638 (kgWater/kgDryAir) will be used.

**1.54.15.1.8 Field: Reference Elevation**

This numeric field specifies the reference elevation in meters (relative to sea level). The value specified for this field must be greater than or equal to -300.0 meters. If this field is left blank, the default value of 0.0 meters will be used.

**1.54.15.1.9 Field: Electrical Power Function of Temperature and Elevation Curve Name**

This alpha field specifies the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of electrical power output as a function of the combustion air inlet temperature and elevation. The output of this curve is multiplied by the Reference Electrical Power Output to give the full-load power output at a specific combustion air inlet temperature and elevation (i.e., at values different from the reference conditions). This curve should be normalized to have a value of 1.0 at the reference conditions, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period and for the actual elevation of the generator.

**1.54.15.1.10 Field: Electrical Efficiency Function of Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of electrical efficiency as a function of the combustion air inlet temperature. The output of this curve is multiplied by the Reference Electrical Efficiency Using Lower Heating Value to give the full-load electrical efficiency at specific combustion air inlet temperatures (i.e., at inlet air temperatures different from the Reference Combustion Air Inlet Temperature). This curve should be normalized to have a value of 1.0 at the Reference Combustion Air Inlet Temperature, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period.

**1.54.15.1.11 Field: Electrical Efficiency Function of Part Load Ratio Curve Name**

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of electrical efficiency as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the Reference Electrical Efficiency Using Lower Heating Value and the output of the Electrical Efficiency Function of Temperature modifier curve to give the electrical efficiency at specific part-load and combustion air inlet (temperature) conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be valid for the range of part-load ratios anticipated for the simulation period.

**1.54.15.1.12 Field: Fuel Type**

This choice field specifies the type of fuel used by the generator. The fuel type can be NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, OtherFuel1, or OtherFuel2. If the field is left blank, the fuel type will be assumed to be **NaturalGas**.

**1.54.15.1.13 Field: Fuel Higher Heating Value**

This numeric field specifies the higher heating value of the fuel used in kJ/kg. The value specified for this field must be greater than zero and greater than the specified Fuel Lower Heating Value. If this field is left blank, the default value of 50,000 kJ/kg will be used.

**1.54.15.1.14 Field: Fuel Lower Heating Value**

This numeric field specifies the lower heating value of the fuel used in kJ/kg. The value specified for this field must be greater than zero but less than the specified Fuel Higher Heating Value. If this field is left blank, the default value of 45,450 kJ/kg will be used.

**1.54.15.1.15 Field: Standby Power**

This numeric field specifies the standby electric power consumed by the generator in Watts. The standby power is the electrical power consumed by the generator (e.g., air fans and controls) when the generator is available to operate but the generator electrical power output is zero (power output is not being requested by the electric load center). The value specified for this field must be greater than or equal to zero. If this field is left blank, the default value of 0.0 W will be used.

**1.54.15.1.16 Field: Ancillary Power**

This numeric field specifies the ancillary electric power consumed by the generator in Watts. The ancillary power is the electrical power consumed by other associated equipment (e.g., external fuel pressurization pumps) when the generator is operating. Specify this input as 0.0 if the Reference Electrical Power Output and Reference Electrical Efficiency Using Lower Heating Value input fields and associated modifier curves reflect the net electrical power output from the generator (i.e., ancillary power already deducted from the generator's gross electrical power output). A value greater than zero indicates that this electrical power is consumed whenever the generator is operating and will be deducted from the generator's overall electrical power output (Generator Produced Electric Power). The value specified for this field must be greater than or equal to zero. If this field is left blank, the default value of 0.0 W will be used.

**1.54.15.1.17 Field: Ancillary Power Function of Fuel Input Curve Name**

This alpha field specifies the name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of ancillary power as a function of the generator's input fuel mass flow rate (kg/s). The output of this curve is multiplied by the ancillary power to give the ancillary power at a specific fuel mass flow rate. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation (i.e., the ancillary power is constant whenever the generator operates).

**1.54.15.1.18 Field: Heat Recovery Water Inlet Node Name**

This alpha field specifies the identifying name for the generator's heat recovery water inlet node.

**1.54.15.1.19 Field: Heat Recovery Water Outlet Node Name**

This alpha field specifies the identifying name for the generator's heat recovery water outlet node.

**1.54.15.1.20 Field: Reference Thermal Efficiency Using Lower Heat Value**

This numeric field specifies the thermal efficiency (heat recovery to water) at reference conditions, based on the lower heating value of the fuel. The thermal efficiency is the thermal power output (to water) divided by the fuel energy consumption rate (LHV basis). The reference conditions are defined via additional input fields for this object. This value must be from 0.0 to 1.0. If this field is left blank, the default value of 0.0 will be used.

**1.54.15.1.21 Field: Reference Inlet Water Temperature**

This numeric field specifies the reference temperature for the inlet water to the heat recovery heat exchanger in degrees Celsius.

**1.54.15.1.22 Field: Heat Recovery Water Flow Operating Mode**

This field is used to choose between different modes of controlling the mass flow rate of water being heated by energy recovered from exhaust air. There are two options available for this field: PlantControl or InternalControl. The PlantControl option indicates that the heat recovery water flow rate through the generator is determined externally (by the wider balance of plant). In this case, the generator will request the Reference Heat Recovery Water Flow Rate whenever it operates but the actual flow rate may be limited by other plant components (e.g., pump). The InternalControl option indicates the flow of water is controlled inside the generator based on current operating conditions. For InternalControl, the generator should (probably) include a bypass branch when connecting to the plant loop.

**1.54.15.1.23 Field: Reference Heat Recovery Water Flow Rate**

This numeric field is the reference heat recovery (volumetric) water flow rate in cubic meters per second. Entered values must be greater than zero.

**1.54.15.1.24 Field: Heat Recovery Water Flow Rate Function of Temperature and Power Curve Name**

This alpha field specifies the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery water flow rate as a function of the inlet water temperature and net electrical power output. This field is only used if the Heat Recovery Water Flow Operating Mode is InternalControl. The output of this curve is multiplied by the Reference Heat Recovery Water Flow Rate to give the water flow rate at the specific inlet water temperature and net power operating conditions. This curve should be normalized to have a value of 1.0 at the reference conditions, and the curve should be valid for the range of inlet water temperatures and net electrical power output anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

**1.54.15.1.25 Field: Thermal Efficiency Function of Temperature and Elevation Curve Name**

This alpha field specifies the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of thermal efficiency as a function of the combustion air inlet temperature and elevation. The output of this curve is multiplied by the Reference Thermal Efficiency Using Lower Heating Value to give the full-load thermal efficiency at a specific combustion air inlet temperature and elevation (i.e., at values different from the reference conditions). This curve should be normalized to have a value of 1.0 at the reference conditions, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period and for the actual elevation of the generator. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

**1.54.15.1.26 Field: Heat Recovery Rate Function of Part Load Ratio Curve Name**

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery to water (thermal power output) as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the steady-state heat recovery at the current combustion inlet air temperature and elevation to give the heat recovery rate (thermal power output) at specific part-load operating conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be

valid for the range of part-load ratios anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

#### **1.54.15.1.27 Field: Heat Recovery Rate Function of Inlet Water Temperature Curve Name**

This alpha field specifies the name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery to water (thermal power output) as a function of the inlet water temperature. The output of this curve is multiplied by the steady-state heat recovery at the current combustion inlet air temperature and elevation to give the heat recovery rate (thermal power output) at non-reference inlet water conditions. This curve should be normalized to have a value of 1.0 at the Reference Inlet Water Temperature, and the curve should be valid for the range of inlet water temperatures anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

#### **1.54.15.1.28 Field: Heat Recovery Rate Function of Water Flow Rate Curve Name**

This alpha field specifies the name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery to water (thermal power output) as a function of the heat recovery water flow rate. The output of this curve is multiplied by the steady-state heat recovery at the current combustion inlet air temperature and elevation to give the heat recovery rate (thermal power output) at non-reference heat recovery water flow rates. This curve should be normalized to have a value of 1.0 at the Reference Heat Recovery Water Flow Rate, and the curve should be valid for the range of water flow rates anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

#### **1.54.15.1.29 Field: Minimum Heat Recovery Water Flow Rate**

This numeric field specifies the minimum (volumetric) water flow rate through the heat recovery heat exchanger in cubic meters per second. The minimum input value is 0.0, and a value of 0.0 is assumed if this field is left blank.

#### **1.54.15.1.30 Field: Maximum Heat Recovery Water Flow Rate**

This numeric field specifies the maximum (volumetric) water flow rate through the heat recovery heat exchanger in cubic meters per second. The minimum input value for this field is 0.0, and a value of 0.0 is assumed if this field is left blank. The maximum heat recovery water flow rate must be greater than or equal to the minimum heat recovery water flow rate.

#### **1.54.15.1.31 Field: Maximum Heat Recovery Water Temperature**

This field sets the maximum water temperature, in degrees Celsius, that this generator can produce via heat recovery. This temperature limit puts an upper bound on the recovered heat and limits the maximum temperatures leaving the component.

As temperatures in the water loop approach this maximum temperature, the temperature difference between the entering water and the surfaces in generator's heat recovery heat exchanger becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The amount of heat recovered will diminish if the inlet water temperature approaches the maximum temperature, and this will show up in the reporting.

**1.54.15.1.32 Field: Combustion Air Inlet Node Name**

This alpha field specifies the name of the combustion air inlet node. If a node name is specified, this node must be an outdoor air node and must also be specified elsewhere in the input (ref: **OutdoorAir:Node** and **OutdoorAir:NodeList**). If this field is left blank, the combustion air inlet conditions are assumed to be the outdoor weather conditions used for the simulation.

**1.54.15.1.33 Field: Combustion Air Outlet Node Name**

This alpha field specifies the name of the combustion air outlet node.

**1.54.15.1.34 Field: Reference Exhaust Air Mass Flow Rate**

This numeric field is the reference exhaust air mass flow rate in kilograms per second. Entered values must be greater than zero.

**1.54.15.1.35 Field: Exhaust Air Flow Rate Function of Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air flow rate as a function of the combustion air inlet temperature. The output of this curve is multiplied by the Reference Exhaust Air Mass Flow Rate to give the exhaust air mass flow rate at non-reference combustion air inlet temperatures. This curve should be normalized to have a value of 1.0 at the Reference Combustion Air Inlet Temperature, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

**1.54.15.1.36 Field: Exhaust Air Flow Rate Function of Part Load Ratio Curve Name**

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air flow rate as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the Reference Exhaust Air Mass Flow Rate to give the exhaust air mass flow rate at specific part-load operating conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be valid for the range of part-load ratios anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

**1.54.15.1.37 Field: Nominal Exhaust Air Outlet Temperature**

This numeric field is the exhaust air outlet temperature at nominal (reference) conditions in degrees Celsius.

**1.54.15.1.38 Field: Exhaust Air Temperature Function of Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air outlet temperature as a function of the combustion air inlet temperature. The output of this curve is multiplied by the Nominal Exhaust Air Outlet Temperature to give the exhaust air temperature at non-reference combustion air inlet temperatures. This curve should be normalized to have a value of 1.0 at the Reference Combustion Air Inlet Temperature, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

### 1.54.15.1.39 Field: Exhaust Air Temperature Function of Part Load Ratio Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air outlet temperature as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the Nominal Exhaust Air Outlet Temperature to give the exhaust air temperature at specific part-load operating conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be valid for the range of part-load ratios anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

### 1.54.15.2 Outputs

The output variables that are available for the microturbine generator are:

- HVAC,Average,Generator Produced Electricity Rate [W]
- HVAC,Sum,Generator Produced Electricity Energy [J]
- HVAC,Average,Generator LHV Basis Electric Efficiency [-]
- HVAC,Average,Generator <Fuel Type> HHV Basis Rate [W]
- HVAC,Average,Generator Fuel HHV Basis Rate [W]
- HVAC,Sum,Generator <Fuel Type> HHV Basis Energy [J]
- HVAC,Sum,Generator Fuel HHV Basis Energy [J]
- HVAC,Average,Generator <Fuel Type> Mass Flow Rate [kg/s]

If Standby Power input field > 0.0:

- HVAC,Average,Generator Standby Electricity Rate [W]
- HVAC,Sum,Generator Standby Electricity Energy [J]

If Ancillary Power input field > 0.0:

- HVAC,Average,Generator Ancillary Electricity Rate [W]

- HVAC,Sum,Generator Ancillary Electricity Energy [J]

If heat recovery water inlet and outlet node names are entered (and valid):

- HVAC,Average,Generator Produced Thermal Rate [W]
- HVAC,Sum,Generator Produced Thermal Energy [J]
- HVAC,Average,Generator Thermal Efficiency LHV Basis [-]
- HVAC,Average,Generator Heat Recovery Inlet Temperature [C]
- HVAC,Average,Generator Heat Recovery Outlet Temperature [C]
- HVAC,Average,Generator Heat Recovery Water Mass Flow Rate [kg/s]

If exhaust air calculations are performed:

- HVAC,Average,Generator Exhaust Air Mass Flow Rate [kg/s]
- HVAC,Average,Generator Exhaust Air Temperature [C]

#### 1.54.15.2.1 Generator Produced Electricity Rate [W]

This output variable is the average electric power produced by the generator in Watts for the timestep being reported. This is the net electric power produced, accounting for ancillary electric power consumed during generator operation.

#### 1.54.15.2.2 Generator Produced Electricity Energy [J]

This output variable is the electric energy produced by the generator in Joules for the timestep being reported. This output is also added to a meter with Resource Type = ElectricityProduced, End Use Key = Cogeneration, Group Key = Plant (Ref. Output:Meter objects). This is the net electric energy produced, accounting for ancillary electric consumption during generator operation.

#### 1.54.15.2.3 Generator LHV Basis Electric Efficiency []

This output variable is the average electric efficiency of the generator (lower heating value basis) for the timestep being reported. The electric efficiency is the Generator Produced Electric Power in Watts divided by the generator's fuel energy consumption rate in Watts (lower heating value basis).

#### 1.54.15.2.4 Generator <Fuel Type> HHV Basis Rate [W]

This output variable is the average fuel-specific energy consumption rate of the electric generator in Watts (higher heating value basis) for the timestep being reported. <Fuel Type> is the name of the fuel used by this electric generator. <Fuel Type> can be one of the following: NaturalGas ( = > Gas ) or Propane.

#### 1.54.15.2.5 Generator Fuel HHV Basis Rate [W]

This output variable is the average fuel energy consumption rate of the electric generator in Watts (higher heating value basis) for the timestep being reported. The output variable name is non-fuel specific.

**1.54.15.2.6 Generator <Fuel Type> HHV Basis Energy [J]**

This output variable is the fuel-specific energy consumption of the electric generator in Joules (higher heating value basis) for the timestep being reported. This output is also added to a meter with Resource Type = <Fuel Type>, End Use Key = Cogeneration, Group Key = Plant (Ref. Output:Meter objects). <Fuel Type> is the name of the fuel used by this electric generator. <Fuel Type> can be one of the following: NaturalGas ( = > Gas ) or Propane.

**1.54.15.2.7 Generator Fuel HHV Basis Energy [J]**

This output variable is the fuel energy consumption of the electric generator in Joules (higher heating value basis) for the timestep being reported. The output variable name is non-fuel specific.

**1.54.15.2.8 Generator <Fuel Type> Mass Flow Rate [kg/s]**

This output variable is the average mass flow rate of fuel being consumed by the electric generator in kg/s for the timestep being reported. <Fuel Type> is the name of the fuel used by this electric generator. <Fuel Type> can be one of the following: Natural Gas ( = > Gas ) or Propane Gas ( = > Propane ).

**1.54.15.2.9 Generator Standby Electricity Rate [W]**

This output variable is the average standby electric power consumed by the generator in Watts for the timestep being reported. Standby power is electrical power consumed by the generator (e.g., air fans and controls) when the generator is available to operate but the generator electrical power output is zero (power output is not being requested by the electric load center). This output variable is only produced when the user enters a value greater than 0.0 for the input field Standby Power.

**1.54.15.2.10 Generator Standby Electricity Energy [J]**

This output variable is the standby electric energy consumption for the generator in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cogeneration, Group Key = Plant (Ref. Output:Meter objects). This output variable is only produced when the user enters a value greater than 0.0 for the input field Standby Power.

**1.54.15.2.11 Generator Ancillary Electricity Rate [W]**

This output variable is the average ancillary electric power consumed by the generator in Watts for the timestep being reported. Ancillary power is the electrical power consumed by other associated equipment (e.g., external fuel pressurization pumps) when the generator is operating. This output variable is only produced when the user enters a value greater than 0.0 for the input field Ancillary Power.

**1.54.15.2.12 Generator Ancillary Electricity Energy [J]**

This output variable is the ancillary electric energy consumption for the generator in Joules for the timestep being reported. This energy consumption is already deducted from the output variable Generator Produced Electricity Energy ( net electric energy produced by the generator). This output variable is only produced when the user enters a value greater than 0.0 for the input field Ancillary Power.

**1.54.15.2.13 Generator Produced Thermal Rate [W]**

This output variable is the average thermal power produced (i.e., exhaust energy recovery to heat water) in Watts for the timestep being reported.

**1.54.15.2.14 Generator Produced Thermal Energy [J]**

This output variable is the thermal energy produced (i.e., exhaust energy recovery to heat water) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = HeatRecovery, Group Key = Plant (Ref. Output:Meter objects).

**1.54.15.2.15 Generator Thermal Efficiency LHV Basis [-]**

This output variable is the average thermal efficiency of the generator (lower heating value basis) for the timestep being reported. The thermal efficiency is the Generator Produced Thermal Rate in Watts divided by the generator's fuel energy consumption rate in Watts (lower heating value basis).

**1.54.15.2.16 Generator Heat Recovery Inlet Temperature [C]**

This output variable is the average heat recovery inlet water temperature in degrees Celsius for the timestep being reported.

**1.54.15.2.17 Generator Heat Recovery Outlet Temperature [C]**

This output variable is the average heat recovery outlet water temperature in degrees Celsius for the timestep being reported.

**1.54.15.2.18 Generator Heat Recovery Water Mass Flow Rate [kg/s]**

This output variable is the average heat recovery water mass flow rate in kilograms per second for the timestep being reported.

**1.54.15.2.19 Generator Exhaust Air Mass Flow Rate [kg/s]**

This is the mass flow rate of exhaust leaving the generator. This output is available when the model input is setup for exhaust conditions.

**1.54.15.2.20 Generator Exhaust Air Temperature [C]**

This is the temperature of exhaust leaving the generator. This output is available when the model input is setup for exhaust conditions.

**1.54.16 Generator:MicroCHP**

This object is used to model small-scale combined heat and power (micro CHP) electric generators using the model developed by IEA/ECBCS [Annex 42](#). The model was developed for both internal combustion and Stirling cycle engines, but might be used for other types of residential CHP devices.

Note that unlike other component models in EnergyPlus, this model is not normalized. Therefore, performance coefficients developed for one type and capacity of CHP device cannot be used for a device with a different capacity.

This model is an empirical, curve fit model. This object describes the connections to the rest of the building model and includes a reference to another object called **Generator:MicroCHP:NonNormalizedParameters** that provides the operating characteristics.

**1.54.16.1 Inputs****1.54.16.1.1 Field: Name**

This field contains a unique name for the residential CHP device.

**1.54.16.1.2 Field: Performance Parameters Name**

This field contains the name of a **Generator:MicroCHP:NonNormalizedParameters** object defined elsewhere in the input.

**1.54.16.1.3 Field: Zone Name**

This field contains the name of the thermal zone where the CHP device is located in the model. If the device is outdoors, or you do not want skin losses to be added to a zone, then leave this field blank.

**1.54.16.1.4 Field: Cooling Water Inlet Node Name**

This field provides the name of a node that is the inlet to the CHP device. The node should be on the plant loop that will receive the heat from the residential CHP unit. This inlet serves as the cooling water for the CHP device.

**1.54.16.1.5 Field: Cooling Water Outlet Node Name**

This field provides the name of a node that is the outlet to the CHP device. The node should be on the plant loop that will receive the heat from the residential CHP unit. This outlet serves as the exit of the cooling water leaving the CHP unit.

**1.54.16.1.6 Field: Air Inlet Node Name**

The name of an air node that supplies the CHP unit with air for use inside the generator.

**1.54.16.1.7 Field: Air Outlet Node Name**

The name of an air node that receives the exhaust from the CHP unit.

**1.54.16.1.8 Field: Generator Fuel Supply Name**

This field contains the name of a **Generator:FuelSupply** object defined elsewhere in the input file.

**1.54.16.1.9 Field: Availability Schedule Name**

This field contains the name of a schedule used to control whether or not the unit is available. It is available any time the value is greater than zero. If it is available, it may consume standby power at times when there is no request for power from the Electric Load Center. If it is not available (schedule value = 0.0) then the CHP unit is in a completely off mode and will not consume standby power. If this field is blank, the schedule has values of 1 for all time periods.

An example IDF showing how this object is used is provided below:

```

```

**1.54.17 Generator:MicroCHP:NonNormalizedParameters**

This object is referenced by a **Generator:MicroCHP** object and provides the non-normalized parameters for the MicroCHP generator model.

### 1.54.17.1 Inputs

#### 1.54.17.1.1 Field: Name

Unique name to identify this set of parameter data.

#### 1.54.17.1.2 Field: Maximum Electric Power

This is the size of the CHP unit in terms of the maximum electrical power it can produce [W]. If the electric load center requests more power than this maximum, then the unit will restrict its output to this level.

#### 1.54.17.1.3 Field: Minimum Electric Power

This is the size of the CHP unit in terms of the minimum electrical power it can produce [W]. If the electric load center requests less power than this minimum, then the unit will hold its output to this level.

#### 1.54.17.1.4 Field: Minimum Cooling Water Flow Rate

This is the minimum flow rate of cooling water that must be available for the unit to operate [kg/s]. If the plant loop is not providing this flow of water, the unit will shut down to protect it from overheating.

#### 1.54.17.1.5 Field: Maximum Cooling Water Temperature

This is the maximum temperature of cooling water inlet or outlet that can occur without the unit shutting down to protect from overheating [°C].

#### 1.54.17.1.6 Field: Electrical Efficiency Curve Name

This is the name of **Curve:Triquadratic** object that defines the steady-state net electrical efficiency. The electrical efficiency,  $\eta_e$ , is a function of the cooling water mass flow rate  $\dot{m}_{cw}$ , the temperature of the cooling water at the inlet,  $T_{cw}$ , the steady-state net electrical power produced,  $P_{net,ss}$ .

$$\eta_e = f(P_{net,ss}, \dot{m}_{cw}, T_{cw}) \quad (1.223)$$

The associated **Curve:Triquadratic** object should be defined with the independent variables  $P_{net,ss}, \dot{m}_{cw}, T_{cw}$  corresponding to  $x, y$ , and  $z$ , respectively.

#### 1.54.17.1.7 Field: Thermal Efficiency Curve Name

This is the name of a **Curve:Triquadratic** object that defines the steady-state net thermal efficiency. The thermal efficiency,  $\eta_q$ , is a function of the cooling water mass flow rate,  $\dot{m}_{cw}$ , the temperature of the cooling water at the inlet,  $T_{cw}$ , the steady-state net electrical power produced,  $P_{net,ss}$ .

$$\eta_q = f(P_{net,ss}, \dot{m}_{cw}, T_{cw}) \quad (1.224)$$

The associated **Curve:Triquadratic** object should be defined with the independent variables  $P_{net,ss}, \dot{m}_{cw}, T_{cw}$  corresponding to  $x, y$ , and  $z$ , respectively.

#### 1.54.17.1.8 Field: Cooling Water Flow Rate Mode

This field is used to choose between different modes of controlling the mass flow rate of cooling water. There are two options available for this field: PlantControl or InternalControl. The PlantControl option indicates that the cooling water flow rate through the CHP device is determined externally (by the wider balance of plant). The InternalControl option indicates the flow of cooling water is controlled inside the CHP device (e.g., like an automobile's thermostat).

For internal control, the following field is used to define a Biquadratic curve that will determine the cooling water flow rate. For internal control, the CHP device should (probably) include a bypass branch when connecting to the plant loop.

#### 1.54.17.1.9 Field: Cooling Water Flow Rate Curve Name

This field contains the name of a **Curve:Biquadratic** object that defines the mass flow rate of cooling water,  $\dot{m}_{cw}$ . This field is only used if the prior field is set to InternalControl. The mass flow of cooling water is a function of steady-state power,  $P_{net,ss}$ , and the inlet temperature of the cooling water,  $T_{cw}$ . The associated **Curve:Biquadratic** should be defined with the independent variables  $P_{net,ss}$  and  $T_{cw}$  corresponding to  $x$  and  $y$ , respectively.

#### 1.54.17.1.10 Field: Air Flow Rate Curve Name

This is the name of a **Curve:Quadratic** object that defines the steady state air flow into the CHP device as a function of the mass flow rate of fuel.

#### 1.54.17.1.11 Field: Maximum Net Electrical Power Rate of Change

This field contains input on the limits for how fast the generator can ramp up or down in terms of the net electrical power.

#### 1.54.17.1.12 Field: Maximum Fuel Flow Rate of Change

This field contains input on the limits for how fast the generator can ramp up or down in terms of the fuel flow rates.

#### 1.54.17.1.13 Field: Heat Exchanger U-Factor Times Area Value

This field describes the effective UA value for the heat exchanger that transfers heat from the generator to the cooling water.

#### 1.54.17.1.14 Field: Skin Loss U-Factor Times Area Value

This field describes the effective UA value for the heat transfer from the generator to the surrounding air.

#### 1.54.17.1.15 Field: Skin Loss Radiative Fraction

This field describes the split between thermal radiation and thermal convection for the heat losses from the skin of the generator.

#### 1.54.17.1.16 Field: Aggregated Thermal Mass of Energy Conversion Portion of Generator

This field describes the aggregated thermal mass of the energy conversion portion of the generator. This includes the engine block in an internal combustion engine.

#### 1.54.17.1.17 Field: Aggregated Thermal Mass of Heat Recovery Portion of Generator

This field describes the aggregated thermal mass of the heat recovery portion of the generator. This includes the encapsulated cooling water and heat exchanger shell in immediate thermal contact.

**1.54.17.1.18 Field: Standby Power**

This field describes the power used by the CHP unit's control systems while in standby operation. Standby operation mode occurs whenever the unit is available but not being called upon to produce power. Power is entered as a positive value but indicates negative generation.

**1.54.17.1.19 Field: Warm Up Mode**

This field is used to choose between different modes of controlling the warm up characteristics. Residential CHP units such as Stirling engines have different warm up characteristics than internal combustion engines. There are two warm up modes available: NominalEngineTemperature or TimeDelay. If the former mode is input in this field, then the next three fields are used to model warm up. If the later mode is input, then the fourth field below is used to model warm up.

**1.54.17.1.20 Field: Warm Up Fuel Flow Rate Coefficient**

This field describes the value for the coefficient used to determine the rate of fuel flow during warm up. The coefficient,  $k_f$ , is used in the following relation,

$$\dot{m}_{fuel,warm-up} = \dot{m}_{fuel,ss-max} + k_f \dot{m}_{fuel,ss-max} \left( \frac{T_{eng,nom} - T_{room}}{T_{eng} - T_{room}} \right) \quad (1.225)$$

**1.54.17.1.21 Field: Nominal Engine Operating Temperature**

This field describes the nominal engine temperature during normal, steady-state operation,  $T_{eng,nom}$  [°C].

**1.54.17.1.22 Field: Warm Up Power Coefficient**

This field describes the value for the coefficient used to determine the rate of power production during warm up. The coefficient  $k_p$  is used in the following relation,

$$P_{net,warm-up} = P_{max} k_p \left( \frac{T_{eng} - T_{room}}{T_{eng,nom} - T_{room}} \right) \quad (1.226)$$

**1.54.17.1.23 Field: Warm Up Fuel Flow Rate Limit Ratio**

This field is used to describe a limit to the fuel flow rate during warm up. The limit is a ratio multiplied by the maximum fuel flow rate during normal operation (corresponding to the fuel flow for maximum electrical power). If the warm up operating fuel flow rate is twice the steady state fuel flow at maximum power, then a value of 2.0 would be entered in this field. This field is only used with the nominal engine temperature warm up mode and is intended for Stirling engines.

**1.54.17.1.24 Field: Warm Up Delay Time**

This field is used to model the warm up operation when the warm up mode is TimeDelay.

Enter the time between activation and power generation in seconds.

**1.54.17.1.25 Field: Cool Down Power**

This field describes the power used by the CHP unit's ancillary systems while in cool down operation mode. Cool down operation mode occurs whenever the unit has recently been told to stop producing power. Power here is consumed and entered as a positive value that indicates negative generation. For example, a component such as a cooling fan might continue to run during cool down.

**1.54.17.1.26 Field: Cool Down Delay Time**

This field is used to describe the time it takes for the CHP unit to cool off and complete the cool down operation. Enter the time between deactivation and the end of a cool down period in seconds.

**1.54.17.1.27 Field: Restart Mode**

This field is used to choose between two different control situations for the cool down operation. The two options for this field are MandatoryCoolDown and OptionalCoolDown. The former is used to direct the model to complete the entire cool down period before the generator can subsequently enter warm up mode. The latter directs the model to allow immediately switching to warm up mode, if power is requested before the cool down period is completed.

An example IDF showing how this object is used is provided below:

```

#### **1.54.17.2.1 Generator Off Mode Time [s]**

This report is the amount of time the generator spent in Off mode in seconds.

#### **1.54.17.2.2 Generator Standby Mode Time [s]**

This report is the amount of time the generator spent in Standby mode in seconds.

#### **1.54.17.2.3 Generator Warm Up Mode Time [s]**

This report is the amount of time the generator spent in Warm Up mode in seconds.

#### **1.54.17.2.4 Generator Normal Operating Mode Time [s]**

This report is the amount of time the generator spent in Normal Operating mode in seconds.

#### **1.54.17.2.5 Generator Cool Down Mode Time [s]**

This report is the amount of time the generator spent in Cool Down mode in seconds.

**1.54.17.2.6 Generator Produced Electricity Rate [W]**

This report is the net electrical power produced by the generator in watts.

**1.54.17.2.7 Generator Produced Electricity Energy [J]**

This report is the net electrical energy produced by the generator in joules. This output variable is also put on the meter for on-site production.

**1.54.17.2.8 Generator Electric Efficiency []**

This is the result for electrical efficiency.

**1.54.17.2.9 Generator Thermal Efficiency []**

This is the result for thermal efficiency.

**1.54.17.2.10 Generator Gross Input Heat Rate [W]**

This is the gross rate of heat input (from fuel consumption) into the engine control volume.

**1.54.17.2.11 Generator Steady State Engine Heat Generation Rate [W]**

This is an interim value in the dynamic thermal calculation that describes the steady-state heat generation in the engine.

**1.54.17.2.12 Generator Engine Heat Exchange Rate [W]**

This is the rate of heat transfer within the generator between the engine section and the heat recovery section, in Watts.

**1.54.17.2.13 Generator Produced Thermal Rate [W]****1.54.17.2.14 Generator Produced Thermal Energy [J]**

These are the rate and energy of thermal heat transferred from the engine to the heat recovery fluid in the coolant control volume.

**1.54.17.2.15 Generator Air Mass Flow Rate [kg/s]**

This is the rate of air flow thru the engine on a mass basis.

**1.54.17.2.16 Generator Fuel Molar Flow Rate [kmol/s]**

This is the rate of fuel flow thru the engine on a molar basis.

**1.54.17.2.17 Generator Fuel Mass Flow Rate [kg/s]**

This is the rate of fuel flow thru the engine on a mass basis.

**1.54.17.2.18 Generator Engine Temperature [C]**

This is the model result for engine temperature in C. This is the lumped temperature for the engine control volume.

**1.54.17.2.19 Generator Coolant Inlet Temperature [C]**

This is the temperature of the inlet water used for heat recovery. It is determined by the balance of plant connected to the generator.

**1.54.17.2.20 Generator Coolant Outlet Temperature [C]**

This report is the model prediction for the leaving temperature of water used for heat recovery. If there is no flow this is the modeled prediction for the mass of cooling water in contact with the engine.

**1.54.17.2.21 Generator Fuel HHV Basis Energy [J]**

This is the energy used by the cogeneration device in terms of higher heating value in joules. This is the output variable is also put on the meter for natural gas.

**1.54.17.2.22 Generator Fuel HHV Basis Rate [W]**

This is the rate of fuel energy use by the cogeneration device in terms of higher heating value in watts.

**1.54.17.2.23 Generator Fuel LHV Basis Energy [J]**

This is the fuel energy used by the cogeneration device in terms of lower heating value in joules.

**1.54.17.2.24 Generator Fuel LHV Basis Rate [W]**

This is the rate of fuel energy use by the cogeneration device in terms of lower heating value in watts

**1.54.17.2.25 Generator Zone Sensible Heat Transfer Rate [W]**

Rate of heat gain to zone from cogeneration unit.

**1.54.17.2.26 Generator Zone Sensible Heat Transfer Energy [J]**

Heat gains to zone from cogeneration unit.

**1.54.17.2.27 Generator Zone Convection Heat Transfer Rate [W]**

Portion of rate of heat gain to zone in the form of surface convection heat transfer.

**1.54.17.2.28 Generator Zone Radiation Heat Transfer Rate [W]**

Portion of heat gains to zone in the form of surface radiation heat transfer (to other surfaces in zone).

**1.54.18 Generator:FuelCell**

This object is used to model small Fuel Cell (FC) generators. IEA/ECBCS Annex 42 see [www.cogen-sim.net](http://www.cogen-sim.net), developed the FC model implemented in EnergyPlus. The model can be used for two general types of fuel cells, solid oxide fuel cells (SOFC) and proton exchange membrane fuel cells (PEMFC). Warning! This is a complicated model, intended primarily for research. Because fuel cells for cogeneration (producing both heat and electricity) are not yet a mature product for building systems, the input data for this model are extremely difficult to obtain. However, the model is designed to allow investigating the relative implications of a broad array of subsystems and interactions with the building.

There should be one Generator:FuelCell object for each individual FC generator in the model. Multiple fuel cell generators can be included in a given simulation. Because there are a large number of inputs to the FC model and numerous, somewhat separable subsystems within a fuel cell, the EnergyPlus input objects have been organized into a number of separate input objects. This object simply refers to the names of all the other input objects that provide the input details for individual subsystems within the fuel cell cogeneration device. The following figure diagrams these separate subsystems. (not shown is an optional stack cooler with separate connections to heat recovery water loop and surrounding zone air).

Note that the FC model is formulated using the Lower Heating Value (LHV) of the fuel, whereas most other parts of EnergyPlus use the Higher Heating Value (HHV). LHV has important advantages over HHV in the context of the quality of heat recovered. While model coefficients for input performance descriptions

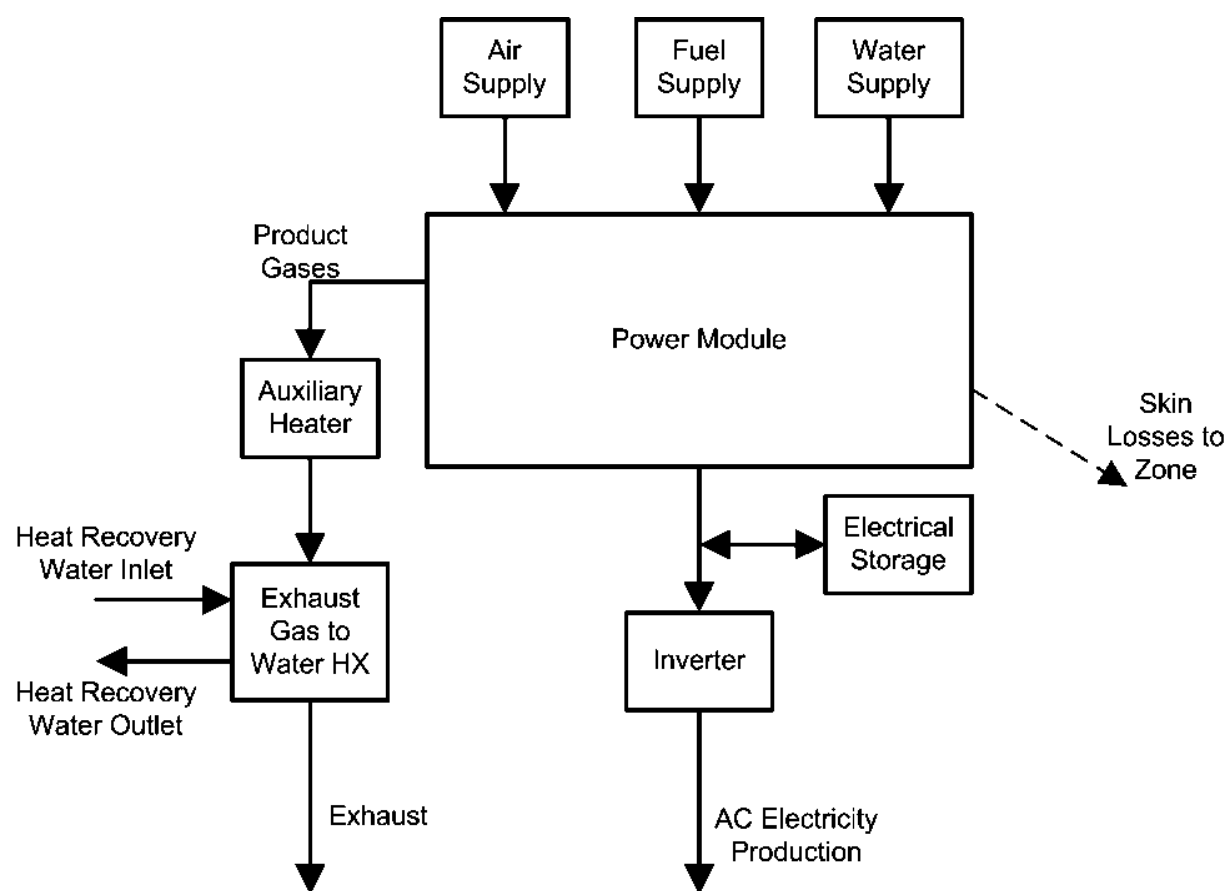

Figure 1.196: Fuel cell subsystems.

are to be based on LHV, energy consumption and tariff calculations are also reported on HHV basis when using this model.

### 1.54.18.1 Inputs

#### 1.54.18.1.1 Field: Name

This field contains a unique name for the fuel cell.

#### 1.54.18.1.2 Field: Power Module Name

This field contains the name of a `Generator:FuelCell:PowerModule` input object.

#### 1.54.18.1.3 Field: Air Supply Name

This field contains the name of a `Generator:FuelCell:AirSupply` input object.

#### 1.54.18.1.4 Field: Fuel Supply Name

This field contains the name of a `Generator:FuelSupply` input object.

#### 1.54.18.1.5 Field: Water Supply Name

This field contains the name of a `Generator:FuelCell:WaterSupply` input object.

#### 1.54.18.1.6 Field: Auxiliary Heater Name

This field contains the name of a `Generator:FuelCell:AuxiliaryHeater` input object.

#### 1.54.18.1.7 Field: Heat Exchanger Name

This field contains the name of a `Generator:FuelCell:ExhaustGasToWaterHeatExchanger` input object.

#### 1.54.18.1.8 Field: Electrical Storage Name

This field contains the name of a `Generator:FuelCell:ElectricalStorage` input object.

#### 1.54.18.1.9 Field: Inverter Name

This field contains the name of a `Generator:FuelCell:Inverter` input object.

#### 1.54.18.1.10 Field: Stack Cooler Name

This field contains the name of a `Generator:FuelCell:StackCooler` input object. This is optional. The presence of a stack cooler distinguishes between SOFC and PEMFC with PEMFC operating at lower temperatures and requiring a separate subsystem to maintain stack temperatures.

An example input data file (IDF) entry for this object is provided below:

```
Generator:FuelCell,
  FCT SOFC,                                !- Name
  FCT SOFC Power Module,                  !- Power Module Name
  FCT SOFC Air Supply,                    !- Air Supply Name
  FCT SOFC Fuel Supply,                   !- Fuel Supply Name
  FCT SOFC Water Supply,                  !- Water Supply Name
  FCT SOFC Auxiliary Heater,              !- Auxiliary Heater Name
  FCT SOFC Exhaust HX,                   !- Heat Exchanger Name
  FCT SOFC Battery,                      !- Electrical Storage Name
  FCT SOFC Inverter;                      !- Inverter Name
```

---

**1.54.18.2 Outputs**

The following output variables are available for the fuel cell model.

- Output:Variable,\*,Generator Produced Electricity Rate,hourly; !- HVAC Average [W]
- Output:Variable,\*,Generator Produced Electricity Energy,hourly; !- HVAC Sum [J]
- Output:Variable,\*,Generator Produced Thermal Rate,hourly; !- HVAC Average [W]
- Output:Variable,\*,Generator Produced Thermal Energy,hourly; !- HVAC Sum [J]
- Output:Variable,\*,Generator Fuel HHV Basis Energy,hourly; !- HVAC Sum [J]
- Output:Variable,\*,Generator Fuel HHV Basis Rate,hourly; !- HVAC Average [W]
- Output:Variable,\*,Generator Fuel LHV Basis Energy,hourly; !- HVAC Sum [J]
- Output:Variable,\*,Generator Fuel Consumption Rate LHV Basis,hourly; !- HVAC Average [W]
- Output:Variable,\*,FuelCell Heat Loss Rate to Zone,hourly; !- HVAC Average [W]
- Output:Variable,\*,FuelCell Heat Loss Energy to Zone,hourly; !- HVAC Sum [J]
- Output:Variable,\*,FuelCell Convection Heat Loss Rate to Zone,hourly; !- HVAC Average [W]
- Output:Variable,\*,FuelCell Radiation Heat Loss Rate to Zone,hourly; !- HVAC Average [W]

**1.54.18.2.1 Generator Produced Electricity Rate [W]**

This report is the net electrical power produced by the generator in watts.

**1.54.18.2.2 Generator Produced Electricity Energy [J]**

This report is the net electrical energy produced by the generator in joules. This output variable is also put on the meter for on-site production.

**1.54.18.2.3 Generator Produced Thermal Rate [W]****1.54.18.2.4 Generator Produced Thermal Energy [J]**

These are the rate and energy of thermal heat transferred from the engine to the heat recovery fluid in the coolant control volume.

**1.54.18.2.5 Generator Fuel HHV Basis Energy [J]**

This is the energy used by the cogeneration device in terms of higher heating value in joules. This is the output variable is also put on the meter for natural gas.

**1.54.18.2.6 Generator Fuel HHV Basis Rate [W]**

This is the rate of fuel energy use by the cogeneration device in terms of higher heating value in watts.

**1.54.18.2.7 Generator Fuel LHV Basis Energy [J]**

This is the fuel energy used by the cogeneration device in terms of lower heating value in joules.

**1.54.18.2.8 Generator Fuel Consumption Rate LHV Basis [W]**

This is the rate of fuel energy use by the cogeneration device in terms of lower heating value in watts.

**1.54.18.2.9 Generator Zone Sensible Heat Transfer Rate [W]**

This variable provides the results for the total rate of skin losses from the fuel cell to the surrounding zone.

**1.54.18.2.10 Generator Zone Sensible Heat Transfer Energy [J]**

This variable provides the results for the total energy in skin losses from the fuel cell to the surrounding zone.

**1.54.18.2.11 Generator Zone Convection Heat Transfer Rate [W]**

This variable provides the results for the rate of skin losses in the form of surface convection heat transfer from the fuel cell to the surrounding zone.

**1.54.18.2.12 Generator Zone Radiation Heat Transfer Rate [W]**

This variable provides the results for the rate of skin losses in the form of radiation heat transfer from the fuel cell to the surrounding zone.

Using the FC model with DisplayAdvancedReportVariables (see Diagnostics object or use of operating system s environment variables) makes the following output variables available as listed in the RDD file. There are a large number of output variables that provide access to the inner workings of the model and individual subsystems that are not likely to be useful for the average user.

- HVAC,Average,Generator Air Inlet Temperature [C]
- HVAC,Average,Generator Power Module Entering Air Temperature [C]
- HVAC,Average,Generator Air Molar Flow Rate [kmol/s]
- HVAC,Average,Generator Power Module Entering Air Enthalpy [W]

#### 1.54.18.2.13 Generator Air Inlet Temperature [C]

This variable provides the temperature of air supplied to the FC.

**1.54.18.2.14 Generator Power Module Entering Air Temperature [C]**

This variable provides the temperature of the air supplied to the power module after it has gone through the blower and received any heat recovered from other subsystems.

**1.54.18.2.15 Generator Air Molar Flow Rate [kmol/s]**

This variable provides the results for  $\dot{N}_{air}$ , the flow rate of air into the FC.

**1.54.18.2.16 Generator Power Module Entering Air Enthalpy [W]**

This variable provides the results for  $\sum_i \left( \dot{N}_i \cdot \left[ \hat{h}_i - \Delta_f \hat{h}_i^0 \right] \right)_{air}$ , which is the enthalpy flow in the air stream entering the power module relative to 25 °C.

**1.54.18.2.17 Generator Blower Electricity Rate [W]**

This variable provides the results for  $P_{blower-el}$ , which is the electrical power used by the air supply blower.

**1.54.18.2.18 Generator Blower Electricity Energy [J]**

This variable provides the results for the energy used by the air supply blower. It is also added to the appropriate meters.

**1.54.18.2.19 Generator Blower Skin Heat Loss Rate [W]**

This variable provides the results for  $q_{blower-heat-loss}$ , which is the rate of energy lost to the surroundings.

**1.54.18.2.20 Generator Fuel Inlet Temperature [C]**

This variable provides the temperature of the fuel supplied to the FC.

**1.54.18.2.21 Generator Power Module Entering Fuel Temperature [C]**

This variable provides the temperature of the fuel supplied to the power module after it has gone through the compressor.

**1.54.18.2.22 Generator Fuel Molar Flow Rate [kmol/s]**

This variable provides the results for  $\dot{N}_{fuel}$ , which is the flow rate of fuel into the FC.

**1.54.18.2.23 Generator Power Module Entering Fuel Enthalpy [W]**

This variable provides the results for  $\sum_i \left( \dot{N}_i \cdot \left[ \hat{h}_i - \Delta_f \hat{h}_i^0 \right] \right)_{fuel}$ , which is the enthalpy flow in the fuel stream entering the power module relative to 25 °C.

**1.54.18.2.24 Generator Fuel Compressor Electricity Rate [W]**

This variable provides the results for  $P_{comp-el}$ , which is the electrical power used by the fuel supply compressor.

**1.54.18.2.25 Generator Fuel Compressor Electricity Energy [J]**

This variable provides the results for the energy used by the fuel supply compressor. It is also added to the appropriate meters.

**1.54.18.2.26 Generator Fuel Compressor Skin Heat Loss Rate [W]**

This variable provides the results for the rate of energy lost to the surroundings.

**1.54.18.2.27 Generator Fuel Reformer Water Inlet Temperature [C]**

This variable provides the temperature of the water supplied to the FC for reforming.

**1.54.18.2.28 Generator Power Module Entering Reforming Water Temperature [C]**

This variable provides the temperature of the water supplied to the power module after it has gone through the pump.

**1.54.18.2.29 Generator Fuel Reformer Water Molar Flow Rate [kmol/s]**

This variable provides the results for  $\dot{N}_{water}$ , which is the flow rate of reforming water into the FC.

**1.54.18.2.30 Generator Fuel Reformer Water Pump Electricity Rate [W]**

This variable provides the results for  $P_{pump-el}$ , which is the electrical power used by the water pump.

**1.54.18.2.31 Generator Fuel Reformer Water Pump Electricity Energy [J]**

This variable provides the results for energy used by the water pump. It is also added to the appropriate meters.

**1.54.18.2.32 Generator Power Module Entering Reforming Water Enthalpy [W]**

This variable provides the results for  $\dot{H}_{liq-water}$  which is the enthalpy flow of the water stream entering the power module relative to 25 °C.

**1.54.18.2.33 Generator Product Gas Temperature [C]**

This variable provides the results for the temperature of the product gas stream leaving the fuel cell power module.

**1.54.18.2.34 Generator Product Gas Enthalpy [W]**

This variable provides the results for  $\sum_i \left( \dot{N}_i \cdot \left[ \hat{h}_i - \Delta_f \hat{h}_i^0 \right] \right)_{FCPM-cg}$ , which is the enthalpy flow in the product gas stream leaving the power module relative to 25 °C.

**1.54.18.2.35 Generator Product Gas Molar Flow Rate [kmol/s]**

This variable provides the results for the flow rate of all the product gases leaving the fuel cell power module.

**1.54.18.2.36 Generator Product Gas Ar Molar Flow Rate [kmol/s]**

This variable provides the results for the flow rate of the argon gas leaving the fuel cell power module.

**1.54.18.2.37 Generator Product Gas CO2 Molar Flow Rate [kmol/s]**

This variable provides the results for the flow rate of the carbon dioxide gas leaving the fuel cell power module.

**1.54.18.2.38 Generator Product Gas H2O Vapor Molar Flow Rate [kmol/s]**

This variable provides the results for the flow rate of the water gas leaving the fuel cell power module.

**1.54.18.2.39 Generator Product Gas N2 Molar Flow Rate [kmol/s]**

This variable provides the results for the flow rate of the nitrogen gas leaving the fuel cell power module.

**1.54.18.2.40 Generator Product Gas O2 Molar Flow Rate [kmol/s]**

This variable provides the results for the flow rate of the oxygen gas leaving the fuel cell power module.

**1.54.18.2.41 Generator Inverter Loss Power [W]**

This variable provides the results for the power losses associated with inefficiencies in the inverter.

**1.54.18.2.42 Generator Produced DC Electricity Rate [W]**

This variable provides the results for  $P_{el}$ , which is the net DC electrical power produced by the fuel cell power module.

**1.54.18.2.43 Generator DC Power Efficiency []**

This variable provides the results for  $\varepsilon_{el}$ , which is the electrical efficiency of the fuel cell power module.

**1.54.18.2.44 Generator Electric Storage Charge State [J]**

This variable provides the results for state of charge of the electrical storage device inside the fuel cell. Although the units are Joules, this is a state variable and is reported as an average rather than a sum.

**1.54.18.2.45 Generator Produced DC Electricity Rate [W]**

This variable provides the rate at which power was stored into the fuel cell's electrical storage subsystem.

**1.54.18.2.46 Generator DC Storage Charging Energy [J]**

This variable provides the energy stored into the fuel cell's electrical storage subsystem.

**1.54.18.2.47 Generator DC Storage Discharging Power [W]**

This variable provides the rate at which power was drawn from the fuel cell's electrical storage subsystem.

**1.54.18.2.48 Generator DC Storage Discharging Energy [J]**

This variable provides the energy drawn from the fuel cell's electrical storage subsystem.

**1.54.18.2.49 Generator Ancillary AC Electricity Rate [W]**

This variable provides the results for  $P_{el,ancillaries-AC}$ , which is the rate at which ancillary devices within the power module use electricity supplied to the fuel cell by an external source.

**1.54.18.2.50 Generator Ancillary AC Electricity Energy [J]**

This variable provides the results for the energy used by AC ancillaries. It is also added to the appropriate meters.

**1.54.18.2.51 Generator Fuel Cell Model Iteration Count []**

This variable provides information on the numerical method used to calculate the FC model. Energy-Plus uses a sequential substitution iterative algorithm to solve the main heat balance equation for the FC model. This output variable indicates the number of iterations needed to converge.

**1.54.18.2.52 Generator Root Solver Iteration Count []**

This variable provides information on the numerical method used to calculate product gas temperature as a function of the product gas's enthalpy. A root solver numerical method is used to invert the Shomate equation for enthalpy as a function of temperature. This output variable indicates the number of iterations needed for the root solver method to converge.

**1.54.18.2.53 Generator Heat Recovery Exit Gas Temperature [C]**

This is the temperature of the exiting gas for heat recovery in C.

**1.54.18.2.54 Generator Heat Recovery Exit Gas H2O Vapor Fraction []**

This is the water vapor fraction in the exit gas.

**1.54.18.2.55 Generator Heat Recovery Water Condensate Molar Flow Rate [kmol/s]**

This is the flow of condensed water in kmol/s.

**1.54.18.2.56 Generator Number of Cycles []**

This is the number of start-stop cycles that the fuel cell power module has experienced so far. It is initialized to the value of **Number of Stops at Start of Simulation** provided in the **Generator:FuelCell:PowerModule** object.

**1.54.18.2.57 Generator Power Module Skin Heat Loss Rate [W]**

This is the which is the rate of energy lost to the surroundings via the skin of the fuel cell power module.

**1.54.19 Generator:FuelCell:PowerModule**

This object is used to describe the core power module subsystem of the FC. This includes the fuel cell stack, fuel reformer, and whatever ancillary devices are included inside. If the model has multiple FC generators that are of the exact same type, then only one of these objects is needed and all the **Generator:FuelCell** can reference it. The model uses a number of curves to describe operating performance. Input data for specific models of FC are not yet available but will be produced by IEA Annex 42 and should be available in the future.

**1.54.19.1 Inputs****1.54.19.1.1 Field: Name**

This field contains a unique name for the fuel cell power module subsystem.

**1.54.19.1.2 Field: Efficiency Curve Mode**

This field is used to choose between different modes of inputting the electrical efficiency curve. There are two options available for this Field: **Annex42** and **Normalized**. The **Annex42** option indicates that the efficiency curves are not normalized and are used for the single size and type of FC product. The **Normalized** option indicates that the efficiency curves are normalized (as is standard practice in EnergyPlus) relative to a single rating point. In the **Annex42** mode, the curves directly represent efficiency as a function of fuel use, but in the **Normalized** mode, the curves represent an efficiency modification that is applied to the efficiency at the rating point.

### 1.54.19.1.3 Field: Efficiency Curve Name

This field contains the name of a **Curve:Quadratic** input object described elsewhere in the input file. The curve is a function of the net DC electric power,  $P_{el}$  (W), produced by the power module and describes either the electrical efficiency or the how the efficiency is modified depending on the mode selected in the previous field. This quadratic curve is just one part of the entire parametric relation used to describe electrical efficiency  $\varepsilon_{el}$ . For the Annex42 mode the full relation for efficiency is,

$$\varepsilon_{el} = [\varepsilon_0 + \varepsilon_1 \cdot P_{el} + \varepsilon_2 \cdot P_{el}^2] \cdot [1 - N_{stops} \cdot D] \cdot \left[ 1 - (MAX(\int dt - t_{threshold}, 0.0)) \cdot L \right] \quad (1.227)$$

where the **Curve:Quadratic** input object named in this field serves to define the quadratic portion in the first set of brackets. For the Normalized mode the full relation for efficiency is,

$$\varepsilon_{el} = \left[ \varepsilon_0 + \varepsilon_1 \cdot \frac{P_{el}}{P_{nom}} + \varepsilon_2 \cdot \left( \frac{P_{el}}{P_{nom}} \right)^2 \right] \cdot \varepsilon_{nom} \cdot [1 - N_{stops} \cdot D] \cdot \left[ 1 - (MAX(\int_0 dt - t_{threshold}, 0.0)) \cdot L \right] \quad (1.228)$$

where  $\varepsilon_{nom}$  is the nominal electrical efficiency at the rating point  $P_{nom}$  which are described in the next two fields. The Normalized mode may be more useful for a simulation study that needs to vary the capacity of the FC.

### 1.54.19.1.4 Field: Nominal Efficiency

This field is used for the Normalized efficiency curve mode and provides the nominal efficiency  $\varepsilon_{nom}$  (dimensionless) at the rating point. This field can be left blank if using the Annex42 mode.

### 1.54.19.1.5 Field: Nominal Electrical Power

This field is used for the Normalized efficiency curve mode and provides the nominal net DC electrical power produced  $P_{nom}$  (W) at the rating point. This field can be left blank if using the Annex42 mode.

### 1.54.19.1.6 Field: Number of Stops at Start of Simulation

This field is used to describe the number of times the FC has been cycled on and off prior to the start of the simulation. FC products might degrade as a result of starting and stopping the fuel cell stack, so the model includes terms to model the degradation effects of cycling FC units on and off. This is the initial value of the  $N_{stops}$  term in the efficiency relation above.

### 1.54.19.1.7 Field: Cycling Performance Degradation Coefficient

This field is used to describe the fixed value representing the fractional performance degradation associated with each start and stop cycle. This is the value of  $D$  in the efficiency relations above. If there is no degradation from cycling, then  $D$  should be 0.0.

### 1.54.19.1.8 Field: Number of Run Hours at Beginning of Simulation

This field is used to describe the amount of time the FC has been operating prior to the start of the simulation. FC products might degrade over time so the model includes terms to model the degradation effects of FC run time. This is the initial value of the integrated run time term  $\int_0 dt$ .

**1.54.19.1.9 Field: Accumulated Run Time Degradation Coefficient**

This field is used to describe the fixed value representing the fractional performance degradation associated with the total amount of run time. This is the value of  $L$  in the efficiency relations above. If there is no degradation from run time, the  $L$  should be 0.0.

**1.54.19.1.10 Field: Run Time Degradation Initiation Time Threshold**

This field is used to describe the time period for which there is no degradation associated with the amount of run time. This provides the ability to model a system that initially operates without degradation for some period time before it starts to degrade. This is the value of  $t_{threshold}$  in the efficiency relations above.

**1.54.19.1.11 Field: Power Up Transient Limit**

This field is used to describe the maximum allowable rate at which the fuel cell can increase the level of power it produces (W/s). This is a time derivative of the net DC electrical power used to limit how fast the FC can ramp up.

**1.54.19.1.12 Field: Power Down Transient Limit**

This field is used to describe the maximum allowable rate at which the fuel cell can decrease the level of power it produces (W/s). This is a time derivative of the net DC electrical power used to limit how fast the FC can ramp down.

**1.54.19.1.13 Field: Start Up Time**

This field is used to describe the length of time (seconds) of the start up period when the FC is turned on.

**1.54.19.1.14 Field: Start Up Fuel**

This field is used to describe the amount of fuel (kmol) used during the entire start up period. The fuel is the same type as what is described in the **Generator:FuelSupply** object elsewhere in the input file.

**1.54.19.1.15 Field: Start Up Electricity Consumption**

This field is used to describe the amount of electricity (Joules) used by ancillary equipment during the entire start up period.

**1.54.19.1.16 Field: Start Up Electricity Produced**

This field is used to describe the amount of electricity (Joules) produced by the power module during the entire start up period.

**1.54.19.1.17 Field: Shut Down Time**

This field is used to describe the length of time (seconds) of the shut down period.

**1.54.19.1.18 Field: Shut Down Fuel**

This field is used to describe the amount of fuel (kmol) used during the entire shut down period. The fuel is the same type as what is described in the **Generator:FuelSupply** object elsewhere in the input file.

**1.54.19.1.19 Field: Shut Down Electricity Consumption**

This field is used to describe the amount of electricity (J) used by ancillary equipment during the entire shut down period.

**1.54.19.1.20 Field: Ancillary Electricity Constant Term**

This field is used to describe the constant term,  $anc_0$ , in a relation that describes the AC electrical power used by ancillary equipment located inside the power module,  $P_{el,ancillaries-AC}$ . The model uses this relation,

$$P_{el,ancillaries-AC} = anc_0 + anc_1 \cdot \dot{N}_{fuel} \quad (1.229)$$

where  $\dot{N}_{fuel}$  is the rate of fuel use in the power module (kmol/s).

**1.54.19.1.21 Field: Ancillary Electricity Linear Term**

This field is used to describe the linear term,  $anc_1$ , in the relation shown in the previous field.

**1.54.19.1.22 Field: Skin Loss Calculation Mode**

This field is used to select the mode for how skin losses are modeled. Skin losses are heat energy lost from the power module and transferred to the surrounding thermal zone named in the following field. There are three alpha options to choose from: ConstantRate, UAForProcessGasTemperature, or QuadraticFunctionOfFuelRate. Enter ConstantRate in this field to model skin losses using a constant rate, e.g. 100 watts. Enter UAForProcessGasTemperature to model skin losses using a UA-Delta-T calculation method with the temperature difference determined by the power module's product gas temperature and the surrounding zone. Enter QuadraticFunctionOfFuelRate to model skin losses as a function of the rate of fuel use.

**1.54.19.1.23 Field: Zone Name**

This field is used to describe the thermal zone that will receive skin and other heat losses from the FC. This should be the name of a Zone input object declared elsewhere in the input file.

**1.54.19.1.24 Field: Skin Loss Radiative Fraction**

This field is used to describe the portion of skin losses that are in the form of thermal radiation. This controls the radiative/convective split for the energy transferred to the zone by the FC.

**1.54.19.1.25 Field: Constant Skin Loss Rate**

This field is used to describe the constant rate of skin losses (W). This field is used with the ConstantRate mode. It can be left blank for other skin loss modes.

**1.54.19.1.26 Field: Skin Loss U-Factor Times Area Term**

This field is used to describe the UA term (W/K). This field is used with the UAForProcessGasTemperature mode. It can be left blank for other skin loss modes. UA is the product of the overall heat transfer coefficient U and the area A.

**1.54.19.1.27 Field: Skin Loss Quadratic Curve Name**

This field is used to refer to the name of a quadratic curve object defined elsewhere in the input file. The quadratic curve should define skin heat loss rate as a function of the fuel use rate (kmol/s) so that,

$$q_{skin-loss} = s_0 + s_1 \cdot \dot{N}_{fuel} + s_2 \cdot \dot{N}_{fuel}^2 \quad (1.230)$$

**1.54.19.1.28 Field: Dilution Air Flow Rate**

This field is used to describe the rate of dilution air (kmol/sec) drawn into, or through, the power module. This air stream may not be present in all FC products. It is used for limiting skin and stack heat losses and for strategies that mitigate potential safety issue were fuel gases to escape the stack.

**1.54.19.1.29 Field: Stack Heat loss to Dilution Air**

This field is used to describe the rate at which the fuel cell stack adds energy to the dilution air stream. It is entered as a constant heat rate (W).

**1.54.19.1.30 Field: Dilution Inlet Air Node Name**

This field is used to describe the air node where the dilution air is drawn from. This would typically be the name of the air node associated with the thermal zone where the FC is located.

**1.54.19.1.31 Field: Dilution Outlet Air Node Name**

This field is used to describe the air node where the dilution air is exhausted to. This could be the inlets to a heat recovery ventilator or an exhaust node.

**1.54.19.1.32 Field: Minimum Operating Point**

This field is used to describe the minimum operating point for the net DC electric power,  $P_{el}$  (W).

**1.54.19.1.33 Field: Maximum Operating Point**

This field is used to describe the maximum operating point for the net DC electric power,  $P_{el}$  (W).

An example input data file (IDF) entry for this object is provided below:

**1.54.20 Generator:FuelCell:StackCooler**

This object is optional and is used to define details needed to model the stack cooler on PEMFC.

**1.54.20.1 Field: Name**

This field contains a unique name for the PEM fuel cell stack cooler

**1.54.20.2 Field: Heat Recovery Water Inlet Node Name**

This field contains the node name for the water inlet to the stack cooler.

**1.54.20.3 Field: Heat Recovery Water Outlet Node Name**

This field contains the node name for the water outlet from the stack cooler.

**1.54.20.4 Field: Nominal Stack Temperature**

This field contains the nominal stack operating temperature for the PEMFC,  $T_{stack}^o$ . This field and the next five provide values for use in the empirical equation for the rate of heat extracted from the fuel cell power module by the stack cooler using the following relation

$$q_{s-cool} = [r_0 + r_1 (T_{stack} - T_{stack}^o)] \cdot [1 + r_2 P_{el} + r_3 P_{el}^2] \quad (1.231)$$

**1.54.20.5 Field: Actual Stack Temperature]**

This field contains the actual stack operating temperature for the PEMFC,  $T_{stack}$ .

**1.54.20.6 Field: Coefficient r0**

This field contains the coefficient  $r_0$  in the equation above.

**1.54.20.7 Field: Coefficient r1**

This field contains the coefficient  $r_1$  in the equation above.

**1.54.20.8 Field: Coefficient r2**

This field contains the coefficient  $r_2$  in the equation above.

**1.54.20.9 Field: Coefficient r3**

This field contains the coefficient  $r_3$  in the equation above.

**1.54.20.10 Field: Stack Coolant Flow Rate**

The stack cooler is assumed to have a closed water circulation loop that is used to extract heat from the stack and move it to a cogeneration heat exchanger and/or an air cooler. This field is used to enter the mass flow rate of coolant in this loop in kg/s.

**1.54.20.11 Field: Stack Cooler U-Factor Times Area Value**

This is the heat transfer coefficient between the stack and the coolant in W/K.

**1.54.20.12 Field: Fs-cogen Adjustment Factor**

This field provides the value for an adjustment factor,  $F_{s-cogen}$ , used in the following relation for the cogeneration heat transfer coefficient,  $(UA)_{s-cogen}$ :

$$(UA)_{s-cogen} = \left[ \frac{1}{(hA)_{s-cogen}} + F_{s-cogen} \right]^{-1} \quad (1.232)$$

**1.54.20.13 Field: Stack Cogeneration Exchanger Area**

This field provides the value for the cogeneration heat exchanger area,  $A_{s-cogen}$  in m<sup>2</sup>.

**1.54.20.14 Field: Stack Cogeneration Exchanger Nominal Flow Rate**

This field provides the value in kg/s for  $\dot{N}_{s-cogen}^0$  in the following relation for the cogeneration heat exchanger convection coefficient,  $h_{s-cogen}$ :

$$h_{s-cogen} = h_{s-cogen}^0 \cdot \left( \frac{\dot{N}_{s-cogen}}{\dot{N}_{s-cogen}^0} \right)^{n_s} \quad (1.233)$$

**1.54.20.15 Field: Stack Cogeneration Exchanger Nominal Heat Transfer Coefficient**

This field provides the value for  $h_{s-cogen}^0$  in the relation above for the cogeneration heat exchanger convection coefficient,  $h_{s-cogen}$  in W/m<sup>2</sup>-K.

**1.54.20.16 Field: Stack Cogeneration Exchanger Nominal Heat Transfer Coefficient Exponent**

This field provides the value for  $n_s$  in the relation above for the cogeneration heat exchanger convection coefficient,  $h_{s-cogen}$ .

**1.54.20.17 Field: Stack Cooler Pump Power**

This field is the power used by the stack cooler's circulating pump in Watts. It is a constant power draw whenever the stack cooler is active.

**1.54.20.18 Field: Stack Cooler Pump Heat Loss Fraction**

This field is the fraction of the pump power consumption that is lost to the surround zone.

**1.54.20.19 Field: Stack Air Cooler Fan Coefficient f0**

This field and the next two are used to define coefficients for the following relation for the power used by the air-cooler's fan to dump excess heat into the surrounding zone:

$$P_{s-air-el} = f_0 + f_1 \cdot q_{s-air} + f_2 \cdot q_{s-air}^2 \quad (1.234)$$

**1.54.20.20 Field: Stack Air Cooler Fan Coefficient f1**

This field provides a value for the coefficient  $f_1$  in the relation above.

#### 1.54.20.21 Field: Stack Air Cooler Fan Coefficient f2

This field provides a value for the coefficient  $f_2$  in the relation above.

### 1.54.21 Generator:FuelCell:AirSupply

This object is used to define details of the air supply subsystem.

#### 1.54.21.1 Inputs

##### 1.54.21.1.1 Field: Name

This field contains a unique name for the fuel cell air supply subsystem.

##### 1.54.21.1.2 Field: Air Inlet Node Name

This field is used to define the air node where the inlet air stream is drawn from. If the FC uses outdoor air then the node named here should be designated an outdoor air node. If the FC draws air from its surroundings, then this would be the name of the air node associated with the thermal zone containing the FC.

##### 1.54.21.1.3 Field: Blower Power Curve Name

This field contains the name of a **Curve:Cubic** input object described elsewhere in the input file. The curve provides the power used by the air blower (W) as a cubic function of the rate of air supply (kmol/s).

$$P_{blower-el} = b_0 + b_1 \cdot \dot{N}_{air} + b_2 \cdot \dot{N}_{air}^2 + b_3 \cdot \dot{N}_{air}^3 \quad (1.235)$$

##### 1.54.21.1.4 Field: Blower Heat Loss Factor

This field describes the portion of blower electrical power that is lost to the surroundings. The rest of the energy is added to the air stream. A heat loss factor of 1.0 indicates that all the heat is lost to the surroundings and no energy is added to the air inlet stream.

##### 1.54.21.1.5 Field: Air Supply Rate Calculation Mode

This field describes how the model will calculate the air supply rate. There are three options to choose from: **AirRatiobyStoics**, **QuadraticFunctionofElectricPower**, and **QuadraticFunctionofFuelRate**. The choice will determine how the model calculates the rate of air and will depend on the formulations used to develop model input data. The choices are described in the next four fields.

##### 1.54.21.1.6 Field: Stoichiometric Ratio

This field describes the excess air ratio beyond stoichiometric air supply. This field is only used if the air supply rate calculation mode is **AirRatiobyStoics**. The total air supply ratio will be the value entered here plus 1.0. Thus if 1.0 is entered in this field, the total air flow will be 2.0 times what is needed to exactly match stoichiometry with the fuel supply.

##### 1.54.21.1.7 Field: Air Rate Function of Electric Power Curve Name

This field contains the name of a **QuadraticCurve** input object described elsewhere in the input file. This field is only used if the air supply rate calculation mode is **QuadraticFunctionofElectricPower**. The quadratic curve named here describes the first part of the relation below used to calculate the rate of inlet air,  $\dot{N}_{air}$  (kmol/s). It is a quadratic function of the net DC electrical power,  $P_{el}$  (W).

$$\dot{N}_{air} = [a_0 + a_1 \cdot P_{el} + a_2 \cdot P_{el}^2] \cdot [1 + a_3 \cdot T_{air}] \quad (1.236)$$

**1.54.21.1.8 Field: Air Rate Air Temperature Coefficient**

This field is used to describe the air temperature coefficient,  $a_3$ , used to adjust inlet air flow rate in the relations for inlet air rate.

**1.54.21.1.9 Field: Air Rate Function of Fuel Rate Curve Name**

This field contains the name of a **Curve:Quadratic** input object described elsewhere in the input file. This field is only used if the air supply rate calculation mode is `QuadraticFunctionofFuelRate`. The quadratic curve named here describes the first part of the relation used to calculate the rate of inlet air,  $\dot{N}_{air}$  (kmol/s). It is a quadratic function of the fuel flow rate,  $\dot{N}_{fuel}$ .

$$\dot{N}_{air} = \left[ a_0 + a_1 \cdot \dot{N}_{fuel} + a_2 \cdot \dot{N}_{fuel}^2 \right] \cdot [1 + a_3 \cdot T_{air}]$$

**1.54.21.1.10 Field: Air Intake Heat Recovery Mode**

This field is used to control how heat losses from three other subsystems within the FC may or may not be recovered by the air inlet. There are six possible choices for what to use in this Field: `NoRecovery` `RecoverBurnerInverterStorage` `RecoverAuxiliaryBurner` `RecoverInverterandStorage` `RecoverInverter` and `RecoverElectricalStorage`. If heat is recovered then that means that energy losses from those subsystems are added to the inlet air and fed back into the FC power module. The following table clarifies the meaning of the six possible choices.

Table 1.55: Air Intake Heat Recovery Mode Choices

Field Choice	Inverter Heat Losses Recovered?	Electrical Heat Losses Recovered?	Storage Recov-ered?	Auxiliary Losses Recovered?	Heater
NoRecovery	No	No		No	
RecoverBurnerInverterStorage	Yes	Yes		Yes	
RecoverAuxiliaryBurner	No	No		Yes	
RecoverInverterandStorage	Yes	Yes		No	
RecoverInverter	Yes	No		No	
RecoverElectricalStorage	No	Yes		No	

**1.54.21.1.11 Field: Air Supply Constituent Mode**

This field is used to choose between two different modes for describing the make up of the inlet air stream. There are two possible choices: `AmbientAir` or `UserDefinedConstituents`. Choosing the `AmbientAir` mode will automatically set the composition of air to be usual at: 77.28% nitrogen, 20.73% oxygen, 1.04% water, 0.92% argon, and 0.03% carbon dioxide. Choosing `UserDefinedConstituents` allows the user to customize the make up the inlet air in the remaining fields.

**1.54.21.1.12 Field: Number of UserDefined Constituents**

This field is used to describe the number of constituents in the inlet air. This field is only used if the air supply constituent mode is set to `UserDefinedConstituents`. The maximum number is 5.

The remaining fields in this object are repeating pairs of fields with one pair for each constituent and the same number as described in the previous field. The pairs consist of the name of the constituent followed by the molar fraction of that constituent.

### 1.54.21.1.13 Field: Constituent 1-5 Name

These fields describe the air stream constituents by name. The name field for each pair must be filled with one of these choices: CarbonDioxide , Nitrogen, Oxygen, Water, or Argon.

### 1.54.21.1.14 Field: Molar Fraction 1-5

These fields describe the molar fraction of the air stream constituents. It is very important that the sum of the molar fractions add up to 1.0.

An example input data file (IDF) entry for this object is provided below:

## 1.54.22 Generator:FuelCell:WaterSupply

This object is used to provide details of the water supply subsystem. This water is used for steam reforming of the fuel and is not the same as the water used for thermal heat recovery.

```
Generator:FuelCell:WaterSupply,
  A1, \field Name
      \required-field
      \reference FCWaterSupNames

      \type object-list
      \object-list ScheduleNames
```

**1.54.22.1 Inputs****1.54.22.1.1 Field: Name**

This field contains a unique name for the fuel cell water supply subsystem.

**1.54.22.1.2 Field: Reformer Water Flow Rate Function of Fuel Rate Curve Name**

This field contains the name of a **Curve:Quadratic** input object described elsewhere in the input file. The curve provides the rate of water flow (kmol/sec) as a function of fuel flow rate (kmol/sec).

$$\dot{N}_{liq-water} = w_0 + w_1 \cdot \dot{N}_{fuel} + w_2 \cdot \dot{N}_{fuel}^2 \quad (1.237)$$

If the unit does not use water for reforming then use a null quadratic where all the coefficients are 0.0.

**1.54.22.1.3 Field: Reformer Water Pump Power Function of Fuel Rate Curve Name**

This field contains the name of a **Curve:Cubic** input object described elsewhere in the input file. The curve provides the power used by the water pump (W) as a cubic function of the rate of water supply (kmol/s).

$$P_{pump-el} = p_0 + p_1 \cdot \dot{N}_{water} + p_2 \cdot \dot{N}_{water}^2 + p_3 \cdot \dot{N}_{water}^3 \quad (1.238)$$

If the unit does not use water for reforming then use a null cubic where all the coefficients are 0.0.

**1.54.22.1.4 Field: Pump Heat Loss Factor**

This field describes the portion of pump electrical power that is lost to the surroundings. The rest of the energy is added to the water stream. A heat loss factor of 1.0 indicates that all the heat is lost to the surroundings and no energy is added to the water inlet stream.

**1.54.22.1.5 Field: Water Temperature Modeling Mode**

This field describes how the model will determine the inlet temperature of the water stream. There are four options to choose from: **TemperatureFromAirNode**, **TemperatureFromWaterNode**, **TemperatureFromSchedule**, and **MainsWaterTemperature**. For the first two options, the temperature of the water inlet is determined by the temperature at the node named in the next field. For the third option, the temperature is determined by the schedule in the last field. Using the **MainsWaterTemperature** option requires also defining a separate **Site:WaterMainsTemperature** input object elsewhere in the input file.

**1.54.22.1.6 Field: Water Temperature Reference Node Name**

This field is used to define the node where the temperature of the inlet water stream is obtained. This can be either an air node or a water node.

**1.54.22.1.7 Field: Water Temperature Schedule Name**

This field is used to define the name of a schedule, defined elsewhere in the input file, that will be used to determine the temperature of the water inlet stream when using the **TemperatureFromSchedule** mode.

An example input data file (IDF) entry for this object is provided below:

```

---

### 1.54.23 Generator:FuelCell:AuxiliaryHeater

This object is intended for modeling an auxiliary heater, however this portion of the model is not yet available in EnergyPlus. An auxiliary heater may be present in fuel cell products so that the unit can meet much higher thermal loads than would be possible using only cogeneration. This portion of the model will be added in the future once suitable cogeneration control capabilities are also available. The input fields are described for future reference but may change. The program still requires one of these objects be included even though the data are not yet used (so that internal data structures can be allocated).

#### 1.54.23.1 Inputs

##### 1.54.23.1.1 Field: Name

This field contains a unique name for the fuel cell auxiliary heater subsystem.

##### 1.54.23.1.2 Field: Excess Air Ratio

This field describes the excess air ratio beyond stoichiometric air supply for the heater. The total air supply ratio will be the value entered here plus 1.0. Thus if 1.0 is entered in this field, the total air flow will be 2.0 times what is needed to exactly match stoichiometry with the fuel supply.

##### 1.54.23.1.3 Field: Ancillary Power Constant Term

This field describes the constant term,  $x_0$ , used to model the auxiliary burner's ancillary devices such as fans and ignition controls. The electrical power for ancillaries is calculated using,

$$P_{el,aux-ancillaries} = x_0 + x_1 \cdot \dot{N}_{aux-fuel} \quad (1.239)$$

##### 1.54.23.1.4 Field: Ancillary Power Linear Term

This field describes the linear term,  $x_1$ , used to model the auxiliary burner's ancillary devices.

##### 1.54.23.1.5 Field: Skin Loss U-Factor Times Area Value

This field describes the UA term (W/K) for calculating skin losses in the auxiliary burner. UA is the product of the overall heat transfer coefficient U and the area A. The skin heat losses are calculated using,

$$q_{aux-skin-losses} = (UA)_{aux} \cdot (T_{aux-mix} - T_{room}) \quad (1.240)$$

where,  $T_{aux-mix}$  is temperature of product gases leaving the auxiliary burner and includes the mixing of the product gases from the fuel cell power module. Thus, the input for UA should reflect this choice of reference temperature rather than an exterior surface temperature of the auxiliary burner.

#### 1.54.23.1.6 Field: Skin Loss Destination

This field describes the user's choice for what happens to the skin losses. There are two options: SurroundingZone and AirInletForFuelCell . Entering SurroundingZone will direct the model to put the lost energy into the surrounding thermal Zone named in the next field. Entering AirInletForFuelCell will direct the model to put the lost energy into the air inlet stream for the fuel cell to preheat that air.

#### 1.54.23.1.7 Field: Zone Name to Receive Skin Losses

This field is used to determine the zone that will receive the skin losses. Enter the name of a Zone declared elsewhere in the input file. This field is only used if the SurroundingZone mode is used in the previous field.

#### 1.54.23.1.8 Field: Heating Capacity Units

This field describes the user's choice for how the capacity of the auxiliary heater will be defined. There are two options: Watts or kmol/s. Entering Watts will direct the program to use the next two fields to determine the maximum and minimum heating capacity. Entering kmol/s will direct the program to use the last two fields to determine the maximum and minimum heating capacities.

#### 1.54.23.1.9 Field: Maximum Heating Capacity in Watts

This field is used to describe the maximum heating capacity of the auxiliary burner (W).

#### 1.54.23.1.10 Field: Minimum Heating Capacity in Watts

This field is used to describe the minimum heating capacity of the auxiliary burner (W).

#### 1.54.23.1.11 Field: Maximum Heating Capacity in Kmol per Second

This field is used to describe the maximum fuel use rate for the auxiliary burner (kmol/s).

#### 1.54.23.1.12 Field: Minimum Heating Capacity in Kmol per Second

This field is used to describe the minimum fuel use rate for the auxiliary burner (kmol/s).

An example input data file (IDF) entry for this object is provided below:

```
Generator:FuelCell:AuxiliaryHeater,
  FCT SOFC Auxiliary Heater,    !- Name
  0.0,                          !- Excess Air Ratio

  Watts,                        !- Heating Capacity Units
  0.0,                          !- Maximum Heating Capacity in Watts
  0.0,                          !- Minimum Heating Capacity in Watts
  ,                             !- Maximum Heating Capacity in Kmol per Second
  ;                             !- Minimum Heating Capacity in Kmol per Second
```

### 1.54.24 Generator:FuelCell:ExhaustGasToWaterHeatExchanger

This object is used to describe the exhaust gas heat exchanger subsystem of the FC used to recovery thermal energy.

**1.54.24.0.1 Field: Name**

This field contains a unique name for the fuel cell power module subsystem.

**1.54.24.0.2 Field: Heat Recovery Water Inlet Node Name**

This field contains the name of the node that connects the heat exchanger's inlet to the plant loop. This water is used for heat recovery.

**1.54.24.0.3 Field: Heat Recovery Water Outlet Node Name**

This field contains the name of the node that connects the heat exchanger's outlet to the plant loop.

**1.54.24.0.4 Field: Heat Recovery Water Maximum Flow Rate**

This field describes the design maximum flow rate of the heat recovery water ( $\text{m}^3/\text{s}$ ). The value should match the design flow rate of the plant loop connected to the FC.

**1.54.24.0.5 Field: Exhaust Outlet Air Node Name**

This field is used to determine which node will receive the exhaust air stream leaving the FC. This node will usually be outside and not be referenced elsewhere. However, if the exhaust stream is used in a heat recovery ventilator (as described in section 11 of the Annex 42 specification) then the node would be reference in the heat recovery ventilator object.

**1.54.24.0.6 Field: Heat Exchanger Calculation Method**

This field is used to direct how EnergyPlus will calculate heat exchanger performance. The Annex 42 model provides for four different methods of modeling the heat exchanger. The choices available for this field are: FixedEffectiveness (method 1 in Annex 42 specification), EmpiricalUAeff (method 2), FundamentalUAeff (method 3), or Condensing (method 4). The remaining fields provide input data for the different methods. The heat exchanger correlations are described below.

**1.54.24.0.7 Field: Method 1 Heat Exchanger Effectiveness**

This field describes constant heat exchanger effectiveness,  $\varepsilon_{HX}$ . This field is only used with the FixedEffectiveness mode, which corresponds to method 1 in the Annex 42 specification. For this mode, the heat exchange between the exhaust gases and the heat recovery water are calculated using,

$$q_{HX} = \varepsilon_{HX} \cdot \left( \dot{N}\hat{c}_p \right)_{\min} \cdot (T_{aux-mix} - T_{water,in}) \quad (1.241)$$

where,  $\left( \dot{N}\hat{c}_p \right)_{\min}$  is the minimum value of  $\left( \dot{N}\hat{c}_p \right)_{aux-mix}$  and  $\left( \dot{N}\hat{c}_p \right)_{water}$ .

**1.54.24.0.8 Field: Method 2 Parameter hxs0**

This field describes the value of  $h_{xs,0}$  in the relation below for effective UA. This field is used with the EmpiricalUAeff mode, which corresponds to method 2 in the Annex 42 specification and with the Condensing mode, which corresponds to method 4. This method uses the log mean temperature difference (LMTD) approach to calculate the heat exchange:

$$q_{HX} = (UA)_{eff} \cdot \frac{(T_{aux-mix} - T_{water,out}) - (T_{HX-exh} - T_{water,in})}{\ln \left( \frac{T_{aux-mix} - T_{water,out}}{T_{HX-exh} - T_{water,in}} \right)} \quad (1.242)$$

The user input in this field, and the next four fields, describe coefficients in an empirical relation for  $(UA)_{eff}$ :

$$(UA)_{eff} = hx_{s,0} + hx_{s,1} \cdot \dot{N}_{water} + hx_{s,2} \cdot \dot{N}_{water}^2 + hx_{s,3} \cdot \dot{N}_{aux-mix} + hx_{s,4} \cdot \dot{N}_{aux-mix}^2 \quad (1.243)$$

#### 1.54.24.0.9 Field: Method 2 Parameter hxs1

This field describes the value of  $hx_{s,1}$  in the relation above for effective UA. This field is used with the EmpiricalUAeff mode, which corresponds to method 2 in the Annex 42 specification and with the Condensing mode, which corresponds to method 4 .

#### 1.54.24.0.10 Field: Method 2 Parameter hxs2

This field describes the value of  $hx_{s,2}$  in the relation above for effective UA. This field is used with the EmpiricalUAeff mode, which corresponds to method 2 in the Annex 42 specification and with the Condensing mode, which corresponds to method 4 .

#### 1.54.24.0.11 Field: Method 2 Parameter hxs3

This field describes the value of  $hx_{s,3}$  in the relation above for effective UA. This field is used with the EmpiricalUAeff mode, which corresponds to method 2 in the Annex 42 specification and with the Condensing mode, which corresponds to method 4 .

#### 1.54.24.0.12 Field: Method 2 Parameter hxs4

This field describes the value of  $hx_{s,4}$  in the relation above for effective UA. This field is used with the EmpiricalUAeff mode, which corresponds to method 2 in the Annex 42 specification and with the Condensing mode, which corresponds to method 4 .

#### 1.54.24.0.13 Field: Method 3 h0Gas Coefficient

This field describes the value of  $h_{gas}^0$  in the relation below. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification. For this mode, the heat exchange is calculated using the LMTD method, but the effective UA is determined using:

$$(UA)_{eff} = \left[ \frac{1}{(hA)_{gas}} + \frac{1}{(hA)_{water}} + F_{HX} \right]^{-1} \quad (1.244)$$

where,

$F_{HX}$  is an adjustment factor,

$$h_{gas} = h_{gas}^0 \cdot \left( \frac{\dot{N}_{gas}}{\dot{N}_{gas}^0} \right)^n ,$$

$$h_{water} = h_{water}^0 \cdot \left( \frac{\dot{N}_{water}}{\dot{N}_{water}^0} \right)^m \quad (1.245)$$

#### 1.54.24.0.14 Field: Method 3 NdotGasRef Coefficient

This field describes the value of  $\dot{N}_{gas}^0$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

#### 1.54.24.0.15 Field: Method 3 n Coefficient

This field describes the value of  $n$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

**1.54.24.0.16 Field: Method 3 Gas Area**

This field describes the value of  $A_{gas}$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

**1.54.24.0.17 Field: Method 3 h0 Water Coefficient**

This field describes the value of  $h_{water}^0$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

**1.54.24.0.18 Field: Method 3 N dot Water ref Coefficient**

This field describes the value of  $\dot{N}_{water}^0$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

**1.54.24.0.19 Field: Method 3 m Coefficient**

This field describes the value of  $m$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

**1.54.24.0.20 Field: Method 3 Area Water Coefficient**

This field describes the value of  $A_{water}$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

**1.54.24.0.21 Field: Method 3 F Adjustment Factor**

This field describes the value of  $F_{HX}$  in the relation above. This field is only used with the FundamentalUAeff mode, which corresponds to method 3 in the Annex 42 specification.

**1.54.24.0.22 Field: Method 4 hxl1 Coefficient**

This field describes the value of  $hx_{l,1}$  in the relation below for the rate of condensation of water from the gas stream,  $\dot{N}_{H_2O-cond}$ . This field is only used with the Condensing mode, which corresponds to method 4 in the Annex 42 specification. This method uses a modified version of the LMTD approach to calculate heat exchange:

$$q_{HX} = (UA)_{eff} \cdot \frac{(T_{aux-mix} - T_{water,out}) - (T_{HX-exh} - T_{water,in})}{\ln \left( \frac{T_{aux-mix} - T_{water,out}}{T_{HX-exh} - T_{water,in}} \right)} + \dot{N}_{H_2O-cond} \cdot \hat{h}_{fg} \quad (1.246)$$

where,

$$\dot{N}_{H_2O-cond} = (T_{cond-threshold} - T_{water,in}) \cdot \left[ hx_{l,1} \cdot \left( \frac{\dot{N}_{H_2O}}{\dot{N}_{aux-mix}} \right) + hx_{l,2} \cdot \left( \frac{\dot{N}_{H_2O}}{\dot{N}_{aux-mix}} \right)^2 \right] \quad (1.247)$$

**1.54.24.0.23 Field: Method 4 hxl2 Coefficient**

This field describes the value of  $hx_{l,2}$  in the relation above for the rate of condensation of water from the gas stream,  $\dot{N}_{H_2O-cond}$ . This field is only used with the Condensing mode, which corresponds to method 4 in the Annex 42 specification.

#### 1.54.24.0.24 Field: Method 4 Condensation Threshold

This field describes the value of  $T_{cond-threshold}$  in the relation above for the rate of condensation of water from the gas stream,  $\dot{N}_{H_2O-cond}$ . This field is only used with the Condensing mode, which corresponds to method 4 in the Annex 42 specification.

An example input data file (IDF) entry for this object is provided below:

### 1.54.25 Generator:FuelCell:ElectricalStorage

This object is used to describe the electrical storage subsystem for the FC. The electrical storage model is a very simple constrained bucket model. Future developments made add additional models for battery systems. Note that this electrical storage is embedded within the FC device.

#### 1.54.25.1 Inputs

##### 1.54.25.1.1 Field: Name

This field contains a unique name for the fuel cell electrical storage subsystem.

##### 1.54.25.1.2 Field: Choice of Model

This field is used to direct how EnergyPlus will model electrical storage. The only choice currently available is SimpleEfficiencyWithConstraints, which should be entered in this field. Future developments may expand the number of models available for electrical storage.

##### 1.54.25.1.3 Field: Nominal Charging Energetic Efficiency

This field describes the value of  $\varepsilon_{charge}$  in the relation for the State of Charge,  $Q_{battery}^{t+\Delta t}$ :

$$Q_{battery}^{t+\Delta t} = Q_{battery}^t + P_{battery-charge} \cdot \varepsilon_{charge} \cdot \Delta t \quad (1.248)$$

This is the energetic efficiency of charging the storage device. A value of 1.0 means that the storage device does not lose any energy when charging. Note that the model can recover the lost energy into the air supply intake.

#### 1.54.25.1.4 Field: Nominal Discharging Energetic Efficiency

This field describes the value of  $\varepsilon_{discharge}$  in the relation for the State of Charge,  $Q_{battery}^{t+\Delta t}$  :

$$Q_{battery}^{t+\Delta t} = Q_{battery}^t + \frac{P_{battery-discharge} \cdot \Delta t}{\varepsilon_{discharge}} \quad (1.249)$$

This is the energetic efficiency of discharging the storage device. A value of 1.0 means that the storage device does not lose any energy when discharging. Note that the model can recover the lost energy into the air supply intake.

#### 1.54.25.1.5 Field: Simple Maximum Capacity

This field describes the maximum amount of electrical energy that can be stored in the device (J).

#### 1.54.25.1.6 Field: Simple Maximum Power Draw

This field describes the maximum rate at which electrical power can be discharged from the storage device (W).

#### 1.54.25.1.7 Field: Simple Maximum Power Store

This field describes the maximum rate at which electrical power can charge the storage device (W).

#### 1.54.25.1.8 Field: Initial Charge State

This field describes the value for the initial state of charge (J). This allows the storage device to contain some amount of stored electricity at the beginning of the simulation period.

An example input data file (IDF) entry for this object is provided below:

```
Generator:FuelCell:ElectricalStorage,
  FCT SOFC Battery,          !- Name

  0,                          !- Simple Maximum Power Draw {W}
  0,                          !- Simple Maximum Power Store {W}
  0;                          !- Initial Charge State {J}
```

---

### 1.54.26 Generator:FuelCell:Inverter

This object is used to describe the power condition unit subsystem of the FC. This object models an inverter system contained within a fuel cell system that converts from direct current (DC) to alternating current (AC).

#### 1.54.26.1 Inputs

##### 1.54.26.1.1 Field: Name

This field contains a unique name for the fuel cell inverter subsystem.

##### 1.54.26.1.2 Field: Inverter Efficiency Calculation Mode

This field is used to direct how EnergyPlus will calculate the inverter efficiency. There are two possible choices: Constant or Quadratic .

##### 1.54.26.1.3 Field: Inverter Efficiency

This field describes the value for inverter efficiency when using the **Constant** mode.

#### 1.54.26.1.4 Field: Efficiency Function of DC Power Curve Name

This field names a **Curve:Quadratic** object defined elsewhere in the input file. The curve determines inverter efficiency as a function of the DC power entering the inverter as follows:

$$\eta_{PCU} = u_0 + u_1 \cdot P_{PCU-in} + u_2 \cdot P_{PCU-in}^2 \quad (1.250)$$

An example input data file (IDF) entry for this object is provided below:

```
Generator:FuelCell:Inverter,
  FCT SOFC Inverter,          !- Name
  Quadratic,                  !- Inverter Efficiency Calculation Mode
  ,                            !- Inverter Efficiency
  FCT Inverter Quadratic;    !- Efficiency Function of DC Power Curve Name

Curve:Quadratic,
  FCT Inverter Quadratic,    !- Name
  0.560717,                  !- Coefficient1 Constant
  1.24019E-4,                !- Coefficient2 x
  -2.01648E-8,               !- Coefficient3 x**2
  -1.0E+10,                  !- Minimum Value of x
  1.0E+10;                   !- Maximum Value of x
```

### 1.54.27 Generator:FuelSupply

This object is used to define details of the fuel supply for certain generators. This object allows the user to describe a wide array of possible fuel mixtures. The program contains data and internal methods to calculate the properties of the various mixtures of gaseous fuels. The program will calculate the Lower Heating Value (LHV), Higher Heating Value (HHV), and molecular weight for the fuel mixture. The fuel properties are then use by both fuel cell and Micro CHP models. Results of the gas phase thermochemistry modeling are also reported in the EIO file.

In addition to gaseous mixtures, the Micro CHP model is able to use generic liquid fuels and this object is used to describe the properties.

Note that the fuel consumption metering is currently handled by the Natural Gas meter. So no matter what fuel mixture is defined in this object, the aggregated reports from EnergyPlus meters for (natural) Gas will include the fuel used for the generator (with the Joule content based on HHV).

#### 1.54.27.1 Inputs

##### 1.54.27.1.1 Field: Name

This field contains a unique name for the fuel cell fuel supply subsystem.

##### 1.54.27.1.2 Field: Fuel Temperature Modeling Mode

This field describes how the model will determine the temperature of the fuel. There are two options for this field to choose from: TemperatureFromAirNode and Scheduled. If this field contains TemperatureFromAirNode then the fuel is modeled as having the same temperature as the air node that is named in the next field. If this field contains Scheduled then the fuel is modeled as having the temperature described in a schedule defined elsewhere in the input file.

##### 1.54.27.1.3 Field: Fuel Temperature Reference Node Name

This field contains the name of the air node used to obtain the inlet temperature of the fuel. This field is only used if the Fuel Temperature Modeling Mode is set to TemperatureFromAirNode.

**1.54.27.1.4 Field: Fuel Temperature Schedule Name**

This field contains the name of a temperature schedule defined elsewhere in the input file. This field is only used if the Fuel Temperature Modeling Mode is set to Scheduled. The temperature of the fuel inlet will be obtained from the schedule.

**1.54.27.1.5 Field: Compressor Power Function of Fuel Rate Curve Name**

This field contains the name of a **Curve:Cubic** input object described elsewhere in the input file. The curve provides the electrical power used by the fuel compressor (W) as a cubic function of the rate of fuel supply (kmol/s).

$$P_{comp-el} = c_0 + c_1 \cdot \dot{N}_{fuel} + c_2 \cdot \dot{N}_{fuel}^2 + c_3 \cdot \dot{N}_{fuel}^3 \quad (1.251)$$

**1.54.27.1.6 Field: Compressor Heat Loss Factor**

This field describes the portion of the compressor electrical power that is lost to the surroundings. The rest of the energy is added to the fuel stream. A heat loss factor of 1.0 indicates that all the heat is lost to the surroundings and no energy is added to the fuel inlet stream.

Note with *LiquidGeneric* fuel type, currently this value would not taken into effect. In this case a heat loss factor of 1.0 is always used for this fuel type.

**1.54.27.1.7 Field: Fuel Type**

Choose between GaseousConstituents or LiquidGeneric .

**1.54.27.1.8 Field: Liquid Generic Fuel Lower Heating Value**

For fuel type LiquidGeneric, this field is used to enter the lower heating value of the fuel in units of kJ/kg.

**1.54.27.1.9 Field: Liquid Generic Fuel Higher Heating Value**

For fuel type LiquidGeneric, this field is used to enter the higher heating value of the fuel in units of kJ/kg.

**1.54.27.1.10 Field: Liquid Generic Fuel Molecular Weight**

For fuel type LiquidGeneric, this field is used to enter the molecular weight of the fuel in units of g/mol.

**1.54.27.1.11 Field: Liquid Generic Fuel CO2 Emission Factor**

This field is not used. This part of the Annex 42 model was not implemented in EnergyPlus; see the **FuelFactors** object.

**1.54.27.1.12 Field: Number of Constituents in Gaseous Constituent Fuel Supply**

This field is used to describe the number of constituents in the inlet fuel supply. The maximum number of different types of constituents is currently set to 12.

The remaining fields in this object are repeating pairs of fields with one pair for each constituent and the same number as described in the previous field. The field set pairs consist of the name of the constituent followed by the molar fraction of that constituent.

**1.54.27.1.13 Field: Constituent 1-12 Name**

These fields describe the fuel stream constituents by name. The name field for each pair must be filled with one of these 14 choices: CarbonDioxide , Nitrogen , Oxygen , Water , Argon , Hydrogen , Methane , Ethane , Propane , Butane , Pentane , Hexane , Methanol , and Ethanol . No other fuel constituents can currently be modeled. The properties of the constituents are already contained inside the program as provided in the Annex 42 model specification.

**1.54.27.1.14 Field: Constituent 1-12 Molar Fraction**

These fields describe the molar fraction of the fuel stream constituents. It is very important that the sum of the molar fractions add up to 1.0.

**1.54.27.2 Outputs**

In addition to the following output variables, the resulting fuel heating values are also reported to the eio file.

HVAC,Average,Generator Fuel Compressor Electricity Rate [W]

HVAC,Sum,Generator Fuel Compressor Electricity Energy [J]

HVAC,Average,Generator Fuel Compressor Skin Heat Loss Rate [W]

**1.54.27.2.1 Generator Fuel Compressor Electricity Rate [W]**

This is the rate of energy use by the gas compressor, if any, that provides fuel at a higher pressure.

**1.54.27.2.2 Generator Fuel Compressor Electricity Energy [J]**

This is the energy used by the gas compressor, if any, that provides fuel at a higher pressure.

**1.54.27.2.3 Generator Fuel Compressor Skin Heat Loss Rate [W]**

Convective heat gains to zone from gas compressor, if any, that provides fuel at a higher pressure.

**1.54.28 Photovoltaic Generators**

EnergyPlus offers different options for predicting the electricity produced by solar electric photovoltaic (PV) panels. The three different options are Simple , Equivalent One-Diode and Sandia and the choice will determine the mathematical models used to determine energy production. The first allows the user to input an arbitrary efficiency. The other two models use empirical relationships to predict PV operating performance based on many environmental variables such as cell temperature. The PV models can be used with either normal PV modules or as part of a hybrid photovoltaic/thermal (PVT) flat plat collector.

The generator is connected to an Electric Load Center. The PV models refer to surface input objects defined elsewhere in the input file. This object describes an array that is attached to a surface object in order to describe its orientation and to access results of the solar insolation calculations. These can be either Heat Transfer or Shading objects (see Surfaces). This will define the orientation of the solar panel for the detailed models and also the area for the simple model. The exposure of that surface to incident solar radiation is calculated using the full set of models in EnergyPlus that are used to account for solar thermal loads arising from building windows and walls. Therefore the incident solar radiation is calculated to include the effects of shading and reflections from other surfaces declared in the input file. In addition to the output variables associated with PV models, there are numerous related output variables available for the surfaces including: ‘Surface Outside Face Sunlit Area’, ‘Surface Outside Face Sunlit Fraction’, ‘Surface Outside Face Incident Solar Radiation Rate per Area’, ‘Surface Outside Face Incident Beam Solar Radiation Rate per Area’, ‘Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area’, ‘Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area’, ‘Surface

Outside Face Beam Solar Incident Angle Cosine Value', 'Surface Outside Face Incident Sky Diffuse Ground Reflected Solar Radiation Rate per Area', 'Surface Outside Face Incident Sky Diffuse Surface Reflected Solar Radiation Rate per Area', 'Surface Outside Face Incident Beam To Beam Reflected From Surfaces Solar Radiation Rate per Area', 'Surface Outside Face Incident Beam To Diffuse Surface Reflected Solar Radiation Rate per Area', and 'Surface Outside Face Incident Beam To Diffuse Ground Reflected Solar Radiation Rate per Area. Note that it is possible to define a PV array area that doesn't conform to the surface area (i.e. model a PV array area that is larger or smaller than what is available on the surface) so it is the users responsibility to not over-specify area when determining how many modules will fit onto a surface. However this type of input is allowed.

EnergyPlus does not include models for ancillary equipment for a PV array including charge controllers or power-point trackers. The operation of the entire electrical system that must go along with a PV array is not currently modeled in EnergyPlus and is therefore assumed to operate in ideal ways. The PV production models do not resolve voltage and current, only power (and energy). Electricity production is metered based on the output of the inverter. Output results are available before and after the inverter. One assumption is that the array is assumed to be always operating at the maximum power point. Energy production is based on the assumption that the quasi-steady power prediction is constant and continuous over the simulation timestep.

For a variety of reasons, actual installations of photovoltaics are often observed to exhibit system-level problems that significantly reduce electricity production. Therefore this modeling should be considered a method of bracketing the upper end of electricity production rather than an accurate prediction of what the panels will produce. Also note that the model predictions are closely related to the solar radiation data (typically of TMY2 origin) in the EnergyPlus weather file, that the solar data in these is usually from a model rather than direct measurements, and that solar resources encountered by a real installation in a given year are likely to differ from the weather data file.

## 1.54.29 Generator:Photovoltaic

This object is used to describe an array of PV modules and how they are to be modeled. A series of different PV arrays can be connected to a single electric load center (and inverter) by listing them all in an ElectricLoadCenter:Generator object.

### 1.54.29.1 Inputs

#### 1.54.29.1.1 Field: Name

This field is a unique name for the PV array.

#### 1.54.29.1.2 Field: Surface Name

This field is the name of a surface that defines the location and geometry of the array.

#### 1.54.29.1.3 Field: Photovoltaic Performance Object Type

This field is the type of PV performance model. The choices are the class names for the three modeling options:

- PhotovoltaicPerformance:Simple
- PhotovoltaicPerformance:EquivalentOne-Diode
- PhotovoltaicPerformance:Sandia.

**1.54.29.1.4 Field: Module Performance Name**

This is the name of the PV performance object define elsewhere (corresponding to the object type listed in the previous field)

**1.54.29.1.5 Field: Heat Transfer Integration Mode**

The PV model allows for different ways of integrating with other EnergyPlus heat transfer surfaces and models and calculating cell temperature. For Building Integrated PV (BIPV), the Integrated options allow for the PV modeling to be coupled to the surface heat transfer models elsewhere in EnergyPlus. The user must select one of these options for this field:

- **Decoupled.** The cell temperature of modules in the array is computed based on a energy balance relative to NOCT conditions. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.
- **DecoupledUllebergDynamic** the cell temperature is calculated based on a dynamic model developed by Ulleberg[1]. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are required.
- **IntegratedSurfaceOutsideFace** The cell temperature is obtained from the outside face of the Surface:Heat Transfer named in the previous field. Energy exported by the module is removed from the heat transfer surface (at the position determined by the associated Construction with Internal Source). The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.
- **IntegratedTranspiredCollector** The cell temperature is obtained from the collector surface temperature in the unglazed transpired collector model. Energy exported by the module is removed from the collector surface. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.
- **IntegratedExteriorVentedCavity** The cell temperature is obtained from the exterior baffle temperature in the naturally ventilated exterior cavity model. Energy exported by the module is removed from the exterior baffle surface. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.
- **PhotovoltaicThermalSolarCollector** The cell temperature is obtained from the photovoltaic/thermal solar collector model. If the PV layer is inside the collector, then the incident solar is modified by the photovoltaic/thermal solar collector model.

**1.54.29.1.6 Field: Number of Series Strings in Parallel**

This field is the number of series-wired strings of PV modules that are in parallel to form the PV array. The product of this field and the next field should equal the total number of modules in the array.

**1.54.29.1.7 Field: Number of Modules in Series**

This field is the number of modules wired in series (on each string) to form the PV array. The product of this field and the previous field should equal the total number of modules in the array.

**1.54.29.2 Outputs**

Using the Generator:PV:Simple object makes a number of output variables available.\

- HVAC,Average,Generator Produced DC Electricity Rate [W]

- HVAC,Sum,Generator Produced DC Electricity Energy [J]
- HVAC,Average,Generator PV Cell Temperature [C]
- HVAC,Average,Generator PV Short Circuit Current [A]
- HVAC,Average,Generator PV Open Circuit Voltage [V]
- HVAC,Average,Generator PV Array Efficiency []

#### 1.54.29.2.1 Generator Produced DC Electricity Rate [W]

This output variable is the power of DC electricity produced by the PV array in Watts..

#### 1.54.29.2.2 Generator Produced DC Electricity Energy [J]

This output variable is the energy in DC electricity produced by the PV array, in Joules.

#### 1.54.29.2.3 Generator PV Array Efficiency []

This output variable is the resulting efficiency of the PV array .

The two more detailed PV models also have the following output variables.

#### 1.54.29.2.4 Generator PV Cell Temperature [ °C]

This output variable represents the temperature of the solar cell used in the calculation of cell performance.

#### 1.54.29.2.5 Generator PV Short Circuit Current [A]

This output variable represents the short circuit current of the PV array, in Amps. This is provided to describe the I-V characteristics.

#### 1.54.29.2.6 Generator PV Open Circuit Voltage [V]

This output variable represents the open circuit voltage of the PV array, in Volts. This is provided to describe the I-V characteristics.

### 1.54.30 PhotovoltaicPerformance:Simple

The PhotovoltaicPerformance:Simple object describes a simple model of photovoltaics that may be useful for early phase design analysis. In this model the user has direct access to the efficiency with which surfaces convert incident solar radiation to electricity and need not specify arrays of specific modules. The full geometric model for solar radiation is used, including shading and reflections, to determine the incident solar resource. This model is intended to be useful for design purposes to quickly get an idea of the levels for annual production and peak power. The model can also accept arbitrary conversion efficiencies and does not require actual production units be tested to obtain performance coefficients.

#### 1.54.30.1 Inputs

##### 1.54.30.1.1 Field: Name

This field is the name of the PV array. The name is only used as an identifier. Multiple instances need have unique names.

1.54.30.1.2 Field: Fraction of Surface Area with Active Solar Cells

This field is the user defined fraction for the area of surface named in the parent PV object that will have active PV cells on it. The area actually covered with solar cells will be the net area of the surface (gross area less any subsurfaces like windows) times the fraction entered here. This fraction includes the difference between PV module area and active cells within it and any losses for how closely packed modules can be arranged on surface. The value should be between 0.0 and 1.0.

1.54.30.1.3 Field: Conversion Efficiency Input Mode

This field specifies how the PV array efficiency values are input. There are two choices, **Fixed** and **Scheduled**. If this field is set to Fixed then the PV array always has the efficiency value specified in the next field. If this field is set to Scheduled then the efficiency is determined by a user defined schedule named in the second field to follow.

1.54.30.1.4 Field: Value for Cell Efficiency if Fixed

This field specifies the efficiency with which solar incident energy is converted to electricity. Efficiency = (electrical power generated [W])/(power of incident solar[W]). These efficiency values are dimensionless and should be between 0.0 and 1.0.

1.54.30.1.5 Field: Efficiency Schedule Name

This field should be set to the name of schedule defined elsewhere in the input file. This schedule should specify dimensionless efficiency values between 0.0 and 1.0. This could be used for example to vary the efficiency to match results computed with more detailed models.

An example idf instance of this object follows:

```
PhotovoltaicPerformance:Simple,
  Simple PV Flat, !- Name
  0.1044 , !- Fraction of Surface area that has active solar cells
  FIXED , !- Conversion efficiency input mode
  0.12 , !- Value for cell efficiency if fixed
  ; !- Name of Schedule that Defines Efficiency
```

1.54.31 PhotovoltaicPerformance:EquivalentOne-Diode

This object describes the performance characteristics of Photovoltaic (PV) modules to be modeled using an equivalent one-diode circuit. This model is also known at the 4- or 5-parameter TRNSYS model for photovoltaics.

The following table shows several sample PV array types with their input values.

Table 1.56: Photovoltaics Array Types with Values

	Short Circuit Current	Open Circuit Voltage	Voltage at Max- imum Power	Current at Max- imum Power	Temperature Coeffi- cient of Short Circuit Current	Temperature Coeffi- cient of Open Circuit Voltage	Number of Cells in Se- ries per Module	Cell Temper- ature at NOCT Condi- tions	Module Area

Where:

- Shunt Resistance: the value of shunt resistance is finite only if the PV Module being modeled is a thin film variety. For all crystalline silicon modules the value is essentially infinite
- Shunt Resistance value: 1,000,000 W (ohms)
- Module Heat Loss Coefficient: this value is dependent more on the array configuration than on the module itself.
- Module Heat Loss Coefficient value: 30 W/m<sup>2</sup>-K
- Module Heat Capacity: this is a typical value for a silicon based sandwich construction framed PV panel.
- Module Heat Capacity Value: 50,000 J/m<sup>2</sup>-K
- Reference Temperature: 298K (25C)
- Insolation at Reference Conditions: 1000 W/m<sup>2</sup>
- Ambient Temperature at NOCT conditions: 293K (20C)
- Insolation at NOCT Conditions: 800 W/m<sup>2</sup>
- Average tau-alpha Product: .9
- Semiconductor Bandgap: 1.12 eV

#### 1.54.31.1 Field: Name

This field contains the unique name for the photovoltaic module performance data. The name is only used as an identifier.

#### 1.54.31.2 Field: Cell Type

This field is used to describe the type of technology used in the PV module. There are two options available, **CrystallineSilicon** and **AmorphousSilicon**. The choice affects the modeling.

**1.54.31.3 Field: Number of Cells in Series**

This field is an integer representing the number of individual cells wired in series to make up a single module. The typical number for a 12V crystalline silicon PV module is 36.

**1.54.31.4 Field: Active Area**

This field is the active area of the PV module in  $\text{m}^2$ .

**1.54.31.5 Field: Transmittance Absorptance Product**

This field indicates the transmittance-absorptance product at normal incidence angles for the PV modules. If the ta product is positive, that value will be used for all angles of incidence. If the value specified is negative, then the magnitude of the given value will be used for normal incidence and the IAM modifier correlation will be used for all other angles.

**1.54.31.6 Field: Semiconductor Bandgap**

This field is the semiconductor bandgap for the PV material. The bandgap for silicon is 1.12 eV (electron volts).

**1.54.31.7 Field: Shunt Resistance**

This field is the shunt (parallel) resistance (in  $\Omega$ ) in the single diode electrical model of the PV. The shunt resistance is effectively infinite for crystalline silicon based PV modules and is finite for thin film and exotic metal modules.

**1.54.31.8 Field: Short Circuit Current**

This field is the short circuit current (in Amps) for an individual module in the PV array at reference conditions.

**1.54.31.9 Field: Open Circuit Voltage**

This field is the open circuit voltage (in Volts) for an individual module in the PV array at reference conditions.

**1.54.31.10 Field: Reference Temperature**

This field is the ambient temperature (in Kelvin) at reference conditions. The value is usually 298K

**1.54.31.11 Field: Reference Insolation**

This field is the radiation level (in  $\text{W}/\text{m}^2$ ) at reference conditions. The value is usually  $1000 \text{ W}/\text{m}^2$ .

**1.54.31.12 Field: Module Current at Maximum Power**

This field is module current (in Amps) at the maximum power point and reference conditions.

**1.54.31.13 Field: Module Voltage at Maximum Power**

This field is module voltage (in Volts) at the maximum power point and reference conditions.

**1.54.31.14 Field: Temperature Coefficient of Short Circuit Current**

This field accounts for the fact that the module short circuit current is temperature dependent. The coefficient is given in Amps/Kelvin.

**1.54.31.15 Field: Temperature Coefficient of Open Circuit Voltage**

This field accounts for the fact that the module open circuit voltage is temperature dependent. The coefficient is given in Volts/Kelvin.

**1.54.31.16 Field: Nominal Operating Cell Temperature Test Ambient Temperature**

This field is the ambient temperature (in Kelvin) from the Nominal Operating Cell Temperature (NOCT) test. The value is usually 293 K

**1.54.31.17 Field: Nominal Operating Cell Temperature Test Cell Temperature**

This field is the cell temperature (in Kelvin) from the Nominal Operating Cell Temperature (NOCT) test.

**1.54.31.18 Field: Nominal Operating Cell Temperature Test Insolation**

This field is the insolation level (in  $\text{W}/\text{m}^2$ ) from the Nominal Operating Cell Temperature (NOCT) test. The value is usually  $800 \text{ W}/\text{m}^2$ .

**1.54.31.19 Field: Module Heat Loss Coefficient**

This field is the heat loss coefficient (in  $\text{W}/\text{m}^2.\text{K}$ ) for the array. The heat loss coefficient is dependent upon measures taken to actively or passively promote airflow over the array surface. The heat loss coefficient value is used only if the Integration and Cell Temperature Mode is set to Decoupled Ulleberg Dynamic.

**1.54.31.20 Field: Total Heat Capacity**

This field is the heat capacity (in  $\text{J}/\text{m}^2.\text{K}$ ) of the modules in the array. It describes the module's ability to store incident solar radiation internally. Such energy storage is manifested as a temperature increase in the modules that is considered to be undesirable. The total heat capacity value is used only if the Integration and Cell Temperature Mode is set to Decoupled Ulleberg Dynamic.

### 1.54.32 PhotovoltaicPerformance:Sandia

This PhotovoltaicPerformance:Sandia object describes the performance of a single type of module. The model used with this object for predicting the electricity generated by photovoltaics is referred to as the Sandia model. This model is based on work done at Sandia National Lab, Albuquerque, NM by David King – with the help of many others.

This object describes performance input data needed for specific makes and models of production PV panels using the empirical coefficients assembled by Sandia National Laboratory. There are a large number of empirical coefficients required to use the Sandia model. These data are obtained after extensive measurements and data reduction. This testing has been performed for some types of production panels and Sandia publishes a database of module and array performance parameters on the web at [www.sandia.gov/pv](http://www.sandia.gov/pv). The entries in the database as of January 15, 2004 were converted to idf segments and are included with the EnergyPlus release in the library file SandiaPVDData.imf. There are more than hundred different module types included in the library and identified by the manufacturer’s model names listed at the beginning of the file SandiaPVDData.imf. This data library file is arranged for use with EpMacro but the user can also copy .idf segments directly from the macro data set.

The Sandia model itself can aggregate multiple PV modules. Therefore, an instance of a PhotovoltaicPerformance:Sandia object could actually represent an array of modules as well as the more usual single module. These can be thought of as simple larger modules and used by Generator:PV:Sandia objects in the usual manner.

The many empirical coefficients for the model are listed below and are described in more more detail in the EnergyPlus engineering documentation EngineeringDoc.pdf.

The field descriptions below focus on providing the parameter’s variable name as identified in the Sandia database. See the EngineeringDoc.pdf for details on how the input fields are used in the correlations. The user generally would not need to worry about the details of the fields since he/she is not likely to generate the data on their own.

#### 1.54.32.1 Inputs

##### 1.54.32.1.1 Field: Name

This field provides a unique name for the PV module. This is often the manufacturer’s identifier for a particular model of a PV module.

##### 1.54.32.1.2 Field: Active Area

Units  $\text{m}^2$  , real number, area of active solar electric cell for the entire module.

##### 1.54.32.1.3 Field: Number of Cells in Series

Series\_Cells in Sandia Database.

##### 1.54.32.1.4 Field: Number of Cells in Parallel

Parallel\_Cells in Sandia Database

##### 1.54.32.1.5 Field: Short-Circuit Current

Isc in Sandia Database. Short-circuit current is a basic parameter Typically supplied by manufacturers at Standard Report Conditions. (Amps)

**1.54.32.1.6 Field: Open-Circuit Voltage**

Voco in Sandia Database, Open-circuit voltage is a basic parameter typically provided by manufacturers at Standard Report Conditions. (Volts)

**1.54.32.1.7 Field: Current at Maximum Power Point**

Impo in Sandia Database. Current at maximum powerpoint is a basic parameter provided by manufacturers at Standard Report Conditions. (Amps)

**1.54.32.1.8 Field: Voltage at Maximum PowerPoint**

Vmpo in Sandia Database. Voltage at maximum powerpoint is a a basic parameter typically provided by manufacturers at Standard Report Conditions. (Volts)

**1.54.32.1.9 Field: Sandia Database Parameter aIsc**

aIsc in Sandia Database (1/degC)

**1.54.32.1.10 Field: Sandia Database Parameter aImp**

aImp in Sandia Database (1/degC)

**1.54.32.1.11 Field: Sandia Database Parameter c0**

C0 in Sandia Database, (non-dimensional)

**1.54.32.1.12 Field: Sandia Database Parameter c1**

C1 in Sandia Database (non-dimensional)

**1.54.32.1.13 Field: Sandia Database Parameter Bvoc0**

Bvoco in Sandia Database (Volts/degC)

**1.54.32.1.14 Field: Sandia Database Parameter mBVoc**

mBVoc in Sandia Database (Volts/degC)

**1.54.32.1.15 Field: Sandia Database Parameter BVmp0**

```

When using EpMacro with a typical installation of EnergyPlus, the above entry can be included in an input file by adding the following two lines to an input macro file (\*.imf).

```
##include C:\EnergyPlus\MacroDataSets\SandiaPVdata.imf ASE-50-ATF-17_45[]
```

### 1.54.33 Generator:PVWatts

PVWatts is a web application and module in NREL's System Advisor Model (SAM) software that estimates the electricity production of a grid-connected photovoltaic system based on a few simple inputs. This object brings the same calculations from PVWatts into an EnergyPlus whole building simulation without the need to call the web application API or SAM SDK. It provides a good alternative to the **Generator:Photovoltaic** object when detailed information about the PV array is not available such as in a first pass analysis or when the desire is to achieve comparable results to PVWatts outside of EnergyPlus. To get comparable results to PVWatts, it should be used with the **ElectricLoadCenter:Inverter:PVWatts**. The PVWatts:Generator uses SAM 2020.11.29 Revision 0, SSC Revision 250.

#### 1.54.33.1 Inputs

##### 1.54.33.1.1 Field: Name

This field is a unique name for the PV array.

##### 1.54.33.1.2 Field: PVWatts Version

The version of the PVWatts calculations to use. Available Options:

- 5

##### 1.54.33.1.3 Field: DC System Capacity

DC nameplate capacity of the system in W.

##### 1.54.33.1.4 Field: Module Type

One of:

- **Standard** - typical poly- or mono-crystalline silicon modules with efficiencies in the range of 14-17%
- **Premium** - high efficiency (18-20%) monocrystalline silicon modules that have anti-reflective coatings and lower temperature coefficients
- **ThinFilm** - low efficiency (11%) and a significantly lower temperature coefficient which is representative of most installed thin film modules

##### 1.54.33.1.5 Field: Array Type

One of:

- **FixedOpenRack** - use for ground mounted arrays, assumes air flows freely around the array.
- **FixedRoofMounted** - use for typical residential arrays mounted on the roof, assumes limited airflow around the modules
- **OneAxis** - tilt and azimuth are fixed, the panels can rotate as shown below
- **OneAxisBacktracking** - Backtracking is a tracking algorithm that rotates the array toward the horizontal during early morning and late evening hours to reduce the effect of self shading. The one-axis tracking algorithm assumes a rotation limit of  $\pm 45$  degrees from the horizontal.
- **TwoAxis** - tilt and azimuth track the sun

#### 1.54.33.1.6 Field: System Losses

Fraction of the system output lost due to losses in a real system that are not explicitly calculated by the PVWatts model equations.

Default: 0.14.

#### 1.54.33.1.7 Field: Array Geometry Type

One of:

- **TiltAzimuth** - The tilt and azimuth angles are specified in the next two fields. An unshaded array is assumed.
- **Surface** - The array geometry (tilt and azimuth) as well as shading is determined from surface referenced.

#### 1.54.33.1.8 Field: Tilt Angle

The tilt angle is the angle from horizontal of the photovoltaic modules in the array. For a fixed array, the tilt angle is the angle from horizontal of the array where  $0^\circ$  = horizontal, and  $90^\circ$  = vertical. For arrays with one-axis tracking, the tilt angle is the angle from horizontal of the tracking axis. The tilt angle does not apply to arrays with two-axis tracking.

Default:  $20^\circ$

#### 1.54.33.1.9 Field: Azimuth Angle

For a fixed array, the azimuth angle is the angle clockwise from true north describing the direction that the array faces. An azimuth angle of  $180^\circ$  is for a south-facing array, and an azimuth angle of  $0^\circ$  is for a north-facing array.

For an array with one-axis tracking, the azimuth angle is the angle clockwise from true north of the axis of rotation. The azimuth angle does not apply to arrays with two-axis tracking.

Default:  $180^\circ$

#### 1.54.33.1.10 Field: Surface Name

This is the name of a surface that defines the location and geometry of the array. Required if Array Geometry Type is **Surface**. Shading will be calculated for this surface regardless of whether the array has 1- or 2-axis tracking.

### 1.54.33.1.11 Field: Ground Coverage Ratio

The ground coverage ratio (GCR) applies only to arrays with one-axis tracking, and is the ratio of module surface area to the area of the ground or roof occupied by the array. A GCR of 0.5 means that when the modules are horizontal, half of the surface below the array is occupied by the array. An array with wider spacing between rows of modules has a lower GCR than one with narrower spacing. A GCR of 1 would be for an array with no space between modules, and a GCR of 0 for infinite spacing between rows. Typical values range from 0.3 to 0.6.

Default: 0.4

### 1.54.33.2 Outputs Description

- HVAC,Average,Generator Produced DC Electricity Rate [W]
- HVAC,Sum,Generator Produced DC Electricity Energy [J]
- HVAC,Average,Plane of Array Irradiance [ $\frac{W}{m^2}$ ]
- HVAC,Average,Generator PV Cell Temperature [C]
- HVAC,Average,Shaded Percent [%]

## 1.54.34 Generator:WindTurbine

A wind turbine is a component that converts the kinetic energy of the surrounding airstream into electricity. This model is intended to calculate the electrical power that a wind turbine system produces. The performance of wind turbine systems is dependent on the local environmental conditions such as wind speed and density of air at the height of the systems. An analysis of these conditions is necessary to accurately estimate power output. The model obtains the weather information from the weather data file in EnergyPlus and then determines the wind speed and air density at the specific height of the system. It also requires the user to input the annual average wind speed measured at the local site and the height of the measurement so that it factors in differences between the weather file wind data and the local wind data.

The model employs the general kinetic energy equation to calculate the performance characteristics of the horizontal axis wind turbine (HAWT) systems. It provides a simple approximation algorithm when the power coefficient,  $C_p$ , is available which represents the efficiency of the wind turbine in the wind power extraction from the ambient air stream. It also allows the user to input experimental constants so that the power coefficient can precisely be determined according to the characteristic of the airfoil of the system. As for the vertical axis wind turbine (VAWT) systems, it employs the general mathematical equations for straight-bladed Darrieus-type VAWT systems, which are common to VAWT systems. Various types of VAWT systems such as the Savonius-type and the curved-blade (or Egg-beater) type may be simulated with this same model.

It includes two different types of dynamic power control: FixedSpeedFixedPitch (FSFP) and VariableSpeedFixedPitch (VSFP). Currently, it does not include an algorithm for modeling pitch control such as FixedSpeedVariablePitch (FSVP) and VariableSpeedVariablePitch (VSVP). If the control type of the wind turbine is either FSVP or VSVP, the control type of VSFP will be assumed. In addition, constant power generation is assumed when the ambient wind speed is between the rated wind speed and the cut out wind speed, if the user specifies one of the last three options. The model also has the ability to account for transient losses associate with the power produced during dynamic control by a user-specified fraction.

The model does not include detailed algorithms for generators and inverters due to concerns for computational convergence, time, and usability. Instead, all conversion losses of these subsystems are included

by applying a user-supplied total system efficiency to the maximum power extraction of the wind turbine. The field of the total system efficiency must be specified by the user.

### 1.54.34.1 Inputs

#### 1.54.34.1.1 Field: Name

A unique user assigned name for a particular wind turbine system. Any reference to this unit by another object will use this name.

#### 1.54.34.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the wind turbine system can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off and will not operate for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.54.34.1.3 Field: Rotor Type

This field is the type of axis of the wind turbine. The user specifies either a horizontal axis wind turbine or a vertical axis wind turbine. Each type of wind turbine employs a different algorithm for the calculation of the electrical power output of the wind turbine. The default value is HorizontalAxisWindTurbine.

#### 1.54.34.1.4 Field: Power Control

This field is the type of rotor control for the wind turbine. This protects the system against the overloading for a system with no speed or pitch control and also to maximize the energy yield for the system. Four different control types are classified in the literature: FixedSpeedFixedPitch (FSFP), Fixed-SpeedVariablePitch (FSVP), VariableSpeedFixedPitch (VSFP), and VariableSpeedVariablePitch (VSVP). Currently, FSFP and VSFP types can be modeled in EnergyPlus. The other two types will be modeled as VSFP. If the first FSFP control type is chosen, the model assumes the maximum power at a fixed rotor speed when the power output predicted is greater than the maximum until the rotor speed reaches the maximum wind speed (see next field). If one of the last three control options is chosen, the model assumes that the system produces a constant power at the rated wind speed when the wind speed is between the rated wind speed and cut-out wind speed. The default value is VariableSpeedFixedPitch (VSFP).

#### 1.54.34.1.5 Field: Rated Rotor Speed

This field is the maximum rotational speed of the rotor at the rated power of the wind turbine in rev/min (revolution per minute). It is used to determine the tip speed ratio of the rotor and relative flow velocity incident on a single blade of the VAWT systems.

#### 1.54.34.1.6 Field: Rotor Diameter

This field is the diameter of the rotor in meters. Note that this field is not the height of the blade, but the diameter of the perpendicular circle from the vertical pole in the VAWT systems. It determines the swept area of the rotor of the HAWT systems and the chordal velocity of the VAWT systems.

#### 1.54.34.1.7 Field: Overall Height

This field is the height of the hub of the HAWT system, or of the pole of the VAWT system in meters. It is necessary to estimate local air density and the wind speed at this particular height where the wind turbine system is installed.

**1.54.34.1.8 Field: Number of Blades**

This field is the number of blades of the wind turbine. The azimuth angle of the rotor of the VAWT system is determined by dividing 360 degree by this field so that the model determines the chordal velocity component and the normal velocity component of the system. The default value is 3.

**1.54.34.1.9 Field: Rated Power**

This field is the nominal power output of the wind turbine system at the rated wind speed in Watts. Note that the user should input the maximum power of the system with no control, i.e., FSFP control type, can physically produce. Manufacturers data also indicates it as peak power or rated capacity . If the local wind speed is greater than the rated wind speed, the model assumes constant power output of this field.

**1.54.34.1.10 Field: Rated Wind Speed**

This field is the wind speed that the wind turbine system indicates the peak in the power curve in m/s. The system produces the maximum power at this speed and the speed of the rotor is managed based on this wind speed.

**1.54.34.1.11 Field: Cut In Wind Speed**

This field is the lowest wind speed where the wind turbine system can be operated in m/s. No power generation is achieved as long as the ambient wind speed is lower than this speed.

**1.54.34.1.12 Field: Cut Out Wind Speed**

This field is the greatest wind speed in m/s. When the wind speed exceeds this value, the wind turbine system needs to be stopped because of inefficiencies in the system. All systems that have either pitch or speed control must be stopped when the ambient wind speed exceeds this speed. Note that the user should input a wind speed above which physical damage to the system might be caused in the case of a FSFP system. It appears as extreme/survival/design wind speed in the literature. The system will be turned off when the ambient wind speed is over this speed.

**1.54.34.1.13 Field: Fraction System Efficiency**

This field is the overall system efficiency of the wind turbine system. It includes all the conversion losses as well as transient losses during the dynamic control when the ambient wind speed is between the rated wind speed and cut-out wind speed (see previous fields). The user also has the ability to specify delivery losses from the system to the local area. If the user does not enter a fraction, the model assumes the default value of 0.835. Note that the fraction must be between zero and one.

**1.54.34.1.14 Field: Maximum Tip Speed Ratio**

This field is the maximum tip speed ratio between the rotor velocity and ambient wind velocity. The rotor speed varies with this ratio to maximize the power output when the rotor control types are variable speed ones. This field allows the user to adjust the power output from the particular system or to find the optimal tip speed ratio of the system. Optimal tip speed ratio is dependent on the number of blades. It is typically about 6, 5, and 3 for two-bladed, three-bladed, and four-bladed rotor, respectively. For the vertical axis wind turbine, it is smaller than horizontal axis wind turbine, and varies with the chord area. The default and maximum values are 5.0 and 12.0.

**1.54.34.1.15 Field: Maximum Power Coefficient**

This field is the maximum fraction of power extraction from ambient wind. If the user inputs this field, the simple approximation model is assumed. The model simply employs the value of this field into the

general kinetic energy equation, so that the power output is obtained. The user can obtain this field with a simple calculation from the power curve published in almost all manufacturers' specifications by using the kinetic energy equation as:

$$C_p = \frac{P}{0.5\rho AV^3} \quad (1.252)$$

where

$P$  = power production at the rated wind speed [W]

$\rho$  = density of air [kg/m<sup>3</sup>]

$A$  = swept area of rotor [m<sup>2</sup>]

$V$  = rated wind speed [m/s]

$C_p$  = power coefficient

The maximum and default values are 0.59 and 0.35.

#### 1.54.34.1.16 Field: Annual Local Average Wind Speed

This field is the local annual average wind speed that represents a representative wind profile at the location of the system in m/s. It is used to factor the difference in wind speed between the weather file wind data and the locally measured wind data so that the model minimizes uncertainties caused by improper wind data at the particular location. Considerable differences between the weather file wind data and the local wind data typically appear. The user thus needs to enter this field in order to obtain accurate local wind data. The model internally determines a multiplier and it is multiplied by the weather file wind data adjusted at the height of the system. If this field is not entered, then the model will use the wind speed from the design day or weather file information with only adjustment at the height of the rotor.

#### 1.54.34.1.17 Field: Height for Local Average Wind Speed

This field is the height that the local wind speed is measured in meters. The annual average wind speed (see previous field) input by the user is internally recalculated by existing EnergyPlus functions at the height of the local station. This modified wind speed is then factored and applied to the weather file wind data. If the annual local average wind speed is not entered, this field is then assumed as zero. The minimum and default values are zero and 50 meters.

#### 1.54.34.1.18 Field: Blade Chord Area

This field is the blade chord area of a single blade of VAWT system in m<sup>2</sup>. It is necessary to determine the net tangential and normal forces of a single blade.

#### 1.54.34.1.19 Field: Blade Drag Coefficient

This field is the blade drag coefficient for a specific blade. It is for determining the tangential and normal force coefficients with the blade lift coefficient (see next field) so that the model can calculate the power output from the system. The user should be able to obtain this parameter for a specific blade from the manufacturers data. This field is only valid for VAWT systems.

#### 1.54.34.1.20 Field: Blade Lift Coefficient

This field is the blade lift coefficient for a specific blade. It is for determining the tangential and normal force coefficients with the blade drag coefficient (see previous field) so that the model can calculate the power output from the system. The user should also be able to obtain it for a specific blade from the manufacturers data. This field is only valid for VAWT systems.

**1.54.34.2 Outputs**

- HVAC,Average, Generator Produced Electricity Rate [W]
- HVAC,Sum, Generator Produced Electricity Energy [J]
- HVAC,Average, Generator Turbine Local Wind Speed [m/s]
- HVAC,Average, Generator Turbine Local Air Density [kg/m<sup>3</sup>]
- HVAC,Average, Generator Turbine Power Coefficient []
- HVAC,Average, Generator Turbine Tip Speed Ratio []
- HVAC,Average, Generator Turbine Chordal Component Velocity [m/s]
- HVAC,Average, Generator Turbine Normal Component Velocity [m/s]
- HVAC,Average, Generator Turbine Relative Flow Velocity [m/s]
- HVAC,Average, Generator Turbine Attack Angle [deg]

**1.54.34.2.1 Generator Produced Electricity Rate [W]**

This report is the electric power that the wind turbine system produces.

**1.54.34.2.2 Generator Produced Electricity Energy [J]**

This report is the electric energy that the wind turbine system produces.

**1.54.34.2.3 Generator Turbine Local Wind Speed [m/s]**

This report is the local wind speed at the specific height of the wind turbine.

**1.54.34.2.4 Generator Turbine Local Air Density [kg/m<sup>3</sup>]**

This report is the local density of the air at the specific height of the wind turbine.

**1.54.34.2.5 Generator Turbine Tip Speed Ratio []**

This report is the ratio between the rotational speed of the tip of the blades and the ambient wind speed at the height of the hub or pole of the wind turbine.

**1.54.34.2.6 Generator Turbine Power Coefficient []**

This report represents the efficiency of the power extraction from the ambient wind of the wind turbine. It is function of the tip speed ratio and pitch angle. It is only valid for HAWT systems.

**1.54.34.2.7 Generator Turbine Chordal Component Velocity [m/s]**

This report is the axial velocity component along the chord of the wind turbine system. It is only valid for VAWT systems.

**1.54.34.2.8 Generator Turbine Normal Component Velocity [m/s]**

This report is the axial velocity component of the rotor of the wind turbine system. It is only valid for VAWT systems.

1.54.34.2.9 Generator Turbine Relative Flow Velocity [m/s]

This report is the local relative flow velocity that represents actual direction and velocity incident on the blades. It is the square root of the sum of both chordal velocity component and normal velocity component. It is only valid for VAWT systems.

1.54.34.2.10 Generator Turbine Attack Angle [deg]

This report is the azimuth angle between the relative flow velocity and the plane of chord. It varies as the wind speed increases, so that the lift and drag forces change.

1.55 Group Water Systems

This group of objects is used to describe the water systems in the building. EnergyPlus offers water modeling capabilities than include not only hot water systems but also the overall water systems including cold water uses, on-site water collection (e.g., from rain, condensate, or well), and storage. HVAC components may consume or collect a significant portion of the water making it appropriate to include water modeling in EnergyPlus.

All water systems are collected into an end use category called Water Systems . This category includes hot and cold water. Water consumed by an HVAC component will be assigned to the end use category for that component. End use subcategories are available to separate hot water from cold water if desired. Simple hot water systems can be configured as stand-alone or use a PlantLoop. The Water Systems can be connected to PlantLoops for modeling heated water end uses. However PlantLoops are not used to model cold water and the WaterUse:Storages portions of the water system. Cold water systems are connected together using WaterUse:Storage objects. WaterUse:Connections are used at the zone level to connect to both cold and hot water.

In addition to the input objects described in this section below, there are a variety of HVAC components that can be configured to interact with the water systems. These component input objects include optional fields that allow describing how the water systems are connected to them by providing the name of a storage tank. The following table lists EnergyPlus input objects that include provisions for connecting to the water systems but are described elsewhere in this document:

Table 1.58: Water Systems Objects

Input Object Name	Type of Water Interactions
Site:Precipitation	Describes rainfall for WaterUse:RainCollector
Coil:Cooling:Water	Condensate collection to WaterUse:Storage
Coil:Cooling:Water:DetailedGeometry	Condensate collection to WaterUse:Storage
Coil:Cooling:DX:SingleSpeed	Optional evaporative condenser can be supplied by WaterUse:Storage

Table 1.58: Water Systems Objects

Input Object Name	Type of Water Interactions
Condensate collection to WaterUse:Storage	
Coil:Cooling:DX:TwoSpeed	Evaporative condenser supplied by WaterUse:Storage
Condensate collection to WaterUse:Storage	
Coil:Cooling:DX:TwoStageWithHumidityControlMode	Evaporative condenser supplied by WaterUse:Storage
Condensate collection to WaterUse:Storage	
Coil:Cooling:DX:MultiSpeed	Evaporative condenser supplied by WaterUse:Storage
Condensate collection to WaterUse:Storage	
Humidifier:Steam:Electric	Water supplied by WaterUse:Storage
CoolingTower:SingleSpeed	Water supplied by WaterUse:Storage
CoolingTower:TwoSpeed	Water supplied by WaterUse:Storage
CoolingTower:VariableSpeed	Water supplied by WaterUse:Storage
ZoneCoolTower:Shower	Water supplied by WaterUse:Storage
Refrigeration:CompressorRack	Water supplied by WaterUse:Storage
Refrigeration:Condenser:EvaporativeCooler	Water supplied by WaterUse:Storage
EvaporativeCooler:Direct:CelDekPad	Evaporation water supplied by WaterUse:Storage
EvaporativeCooler:Indirect:CelDekPad	Evaporation water supplied by WaterUse:Storage
EvaporativeCooler:Indirect:WetCoil	Evaporation water supplied by WaterUse:Storage
EvaporativeCooler:Indirect:ResearchSpeed	Evaporation water supplied by WaterUse:Storage

### 1.55.1 WaterUse:Equipment

The WaterUse:Equipment object is a generalized object for simulating all water end uses. Hot and cold water uses are included, as well as controlled mixing of hot and cold water at the tap. The WaterUse:Equipment object can be used stand-alone, or coupled into a plant loop using the **WaterUse:Connections** object (see below). The **WaterUse:Connections** object allows water uses to be linked to **WaterUse:Storage** objects to store and draw reclaimed water. The **WaterUse:Connections** object can also simulate drainwater heat recovery.

The WaterUse:Equipment object serves all of the same purposes as the existing objects: **Exterior:WaterEquipment**, and **HotWaterEquipment**.

The WaterUse:Equipment object does a better job of modeling domestic hot water by allowing mixing at the tap in order to account for both hot **and cold** water used at sinks, showers, etc. It also improves on the stand-alone energy modeling of domestic hot water. Because all of the temperatures and flow rates can be solved, the energy usage can be accounted for as “Purchased Heating”.

In either stand-alone mode or used with the **WaterUse:Connections** object, the WaterUse:Equipment object will attempt to meet a scheduled target temperature at the tap by mixing hot and cold water flows. If the hot water flow is not hot enough, or if the flow is limited by plant loop constraints, the result is a cooler mixed water temperature and the target temperature will not be met. In stand-alone mode the hot

and cold water temperatures are specified by schedules. However, if the cold water schedule is omitted, the water temperature will be calculated by the [Site:WaterMainsTemperature](#) object. If the hot water schedule or target temperature schedule are omitted, all water is delivered as cold water. If only using cold water, the [WaterUse:Equipment](#) object is similar to the [Exterior:WaterEquipment](#) object.

The [WaterUse:Equipment](#) object improves on the internal gains object [HotWaterEquipment](#) by associating actual water usage with a sensible and latent gain to a zone. Equipment, such as showers, that generate a significant heat gain can be modeled using the Sensible Fraction Schedule and Latent Fraction Schedule fields. The schedules are used to set the fraction of the maximum possible heat gain (based on inlet water conditions and ambient zone conditions) that should be added to the zone. The split between sensible and latent will vary depending on the type of equipment that is to be modeled. Typically, both fractions should be small numbers.

### 1.55.1.1 Inputs

#### 1.55.1.1.1 Field: Name

The unique object name for reference by other objects.

#### 1.55.1.1.2 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Laundry”, “Dish Washing”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Subcategories are also reported in the ABUPS table under the “Water Systems” end-use category and also appear in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the water use will be assigned to the “General” end-use subcategory.

#### 1.55.1.1.3 Field: Peak Flow Rate

The peak demanded hot water flow rate [ $\text{m}^3/\text{s}$ ]. This value is multiplied by the Flow Rate Fraction Schedule (below) to determine the actual volumetric flow rate.

#### 1.55.1.1.4 Field: Flow Rate Fraction Schedule Name

Reference to the schedule object specifying the flow rate fraction relative to the Peak Flow Rate (above). If blank, the schedule defaults to 1.0 at all times.

#### 1.55.1.1.5 Field: Target Temperature Schedule Name

Reference to the schedule object specifying the target water temperature [C]. Hot and cold water are mixed at the tap to attain the target temperature. If insufficient hot water is available to reach the target temperature, the result is cooler water at the tap. If blank, the target temperature defaults to the hot water supply temperature.

#### 1.55.1.1.6 Field: Hot Water Supply Temperature Schedule Name

Reference to the schedule object specifying the hot water temperature [C]. The hot water temperature is used to calculate the “Purchased Heating” energy usage in stand-alone mode. If blank in stand-alone mode, the hot water supply temperature defaults to the cold water supply temperature. This field is ignored if the object is used with the [WaterUse:Connections](#) object.

#### 1.55.1.1.7 Field: Cold Water Supply Temperature Schedule Name

Reference to the Schedule object specifying the cold water temperature [C] from the supply mains that provides the cold water to the tap and makes up for all water lost down the drain. If blank, water temperatures are calculated by the [Site:WaterMainsTemperature](#) object. This field is ignored if the object is used with the [WaterUse:Connections](#) object.

**1.55.1.1.8 Field: Zone Name**

Reference to the zone name where the water equipment will be considered as latent load to the zone.

**1.55.1.1.9 Field: Sensible Fraction Schedule Name**

Reference to the schedule object specifying the fraction of the maximum possible sensible heat gain (based on inlet water conditions and ambient zone conditions) that is added to the zone. If blank, the schedule defaults to 0 at all times.

**1.55.1.1.10 Field: Latent Fraction Schedule Name**

Reference to the schedule object specifying the fraction of the maximum possible latent heat gain (based on inlet water conditions and ambient zone conditions) that is added to the zone. If blank, the schedule defaults to 0 at all times.

**1.55.1.2 Outputs**

The following output variables are reported for the WaterUse:Equipment object:

- HVAC,Average,Water Use Equipment Hot Water Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Equipment Cold Water Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Equipment Total Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Equipment Hot Water Volume Flow Rate [m3/s]
- HVAC,Average,Water Use Equipment Cold Water Volume Flow Rate [m3/s]
- HVAC,Average,Water Use Equipment Total Volume Flow Rate [m3/s]
- HVAC,Sum,Water Use Equipment Hot Water Volume [m3]
- HVAC,Sum,Water Use Equipment Cold Water Volume [m3]

- HVAC,Sum,Water Use Equipment Total Volume [m3]
- HVAC,Sum,Water Use Equipment Mains Water Volume [m3]
- HVAC,Average,Water Use Equipment Hot Water Temperature [C]
- HVAC,Average,Water Use Equipment Cold Water Temperature [C]
- HVAC,Average,Water Use Equipment Target Water Temperature [C]
- HVAC,Average,Water Use Equipment Mixed Water Temperature [C]
- HVAC,Average,Water Use Equipment Drain Water Temperature [C]
- HVAC,Average,Water Use Equipment Heating Rate [W]
- HVAC,Sum,Water Use Equipment Heating Energy [J]
- HVAC,Average,Water Use Equipment Zone Sensible Heat Gain Rate [W]
- HVAC,Sum,Water Use Equipment Zone Sensible Heat Gain Energy [J]
- HVAC,Average,Water Use Equipment Zone Latent Gain Rate [W]
- HVAC,Sum,Water Use Equipment Zone Latent Gain Energy [J]
- HVAC,Average,Water Use Equipment Zone Moisture Gain Mass Flow Rate [kg/s]
- HVAC,Sum,Water Use Equipment Zone Moisture Gain Mass [kg]

#### **1.55.1.2.1 Water Use Equipment Hot Water Mass Flow Rate [kg/s]**

The mass flow rate of hot water supplied to the equipment, in units of kilograms per second (kg/s).

#### **1.55.1.2.2 Water Use Equipment Cold Water Mass Flow Rate [kg/s]**

The mass flow rate of cold water supplied to the equipment, in units of kilograms per second (kg/s).

#### **1.55.1.2.3 Water Use Equipment Total Mass Flow Rate [kg/s]**

The total mass flow rate of water (hot + cold) supplied to the equipment, in units of kilograms per second (kg/s).

#### **1.55.1.2.4 Water Use Equipment Hot Water Volume Flow Rate [m3/s]**

The volumetric flow rate of hot water supplied to the equipment and consumed down the drain, in units of cubic meters per second (m<sup>3</sup>/s).

#### **1.55.1.2.5 Water Use Equipment Cold Water Volume Flow Rate [m3/s]**

The volumetric flow rate of cold water supplied to the equipment and consumed down the drain, in units of cubic meters per second (m<sup>3</sup>/s).

#### **1.55.1.2.6 Water Use Equipment Total Volume Flow Rate [m3/s]**

The total volumetric flow rate of water (hot + cold) supplied to the equipment and consumed down the drain, in units of cubic meters per second (m<sup>3</sup>/s).

**1.55.1.2.7 Water Use Equipment Hot Water Volume [m3]**

The volume of hot water supplied to the equipment and consumed down the drain, in units of cubic meters (m<sup>3</sup>).

**1.55.1.2.8 Water Use Equipment Cold Water Volume [m3]**

The volume of cold water supplied to the equipment and consumed down the drain, in units of cubic meters (m<sup>3</sup>).

**1.55.1.2.9 Water Use Equipment Total Volume [m3]**

The total volume of water (hot+cold) supplied to the equipment and consumed down the drain, in units of cubic meters (m<sup>3</sup>). This output is also added to a meter with Resource Type = Water, End Use Key = WaterSystems, and Group Key = Plant. The sub-categories may be entered as any type (e.g., Laundry, Dish Washing, etc. defined in WaterUse:Equipment object input for End-Use Subcategory) with General being the default sub-category (ref. Output Meter)

**1.55.1.2.10 Water Use Equipment Mains Water Volume [m3]**

The total volume of water (hot+cold) supplied to the equipment and consumed down the drain, in units of cubic meters (m<sup>3</sup>). This output is also added to a meter with Resource Type = MainsWater, End Use Key = WaterSystems, and Group Key = Plant. The sub-categories may be entered as any type (e.g., Laundry, Dish Washing, etc. defined in WaterUse:Equipment object input for End-Use Subcategory) with General being the default sub-category (ref. Output Meter)

**1.55.1.2.11 Water Use Equipment Hot Water Temperature [C]**

The temperature of hot water supplied to the equipment, in units of degrees Celsius (C).

**1.55.1.2.12 Water Use Equipment Cold Water Temperature [C]**

The temperature of cold water supplied to the equipment, in units of degrees Celsius (C).

**1.55.1.2.13 Water Use Equipment Target Water Temperature [C]**

The user-specified target temperature for the mixing of hot and cold supply flows, in units of degrees Celsius (C).

**1.55.1.2.14 Water Use Equipment Mixed Water Temperature [C]**

The actual mixed water temperature possible with the available hot and cold temperatures and flow rates, in units of degrees Celsius (C).

**1.55.1.2.15 Water Use Equipment Drain Water Temperature [C]**

The water temperature at the drain equal to the mixed water temperature minus any heat loss to the zone, in units of degrees Celsius (C).

**1.55.1.2.16 Water Use Equipment Heating Rate [W]**

The heating rate defined by the hot water flow and the temperature difference between the hot water supply and the cold makeup return water, in units of watts (W).

**1.55.1.2.17 Water Use Equipment Heating Energy [J]**

The heating energy accumulated by the heating rate above, in units of Joules (J). This output is also added to a meter with End Use Key = WaterSystems, Group Key = Plant. If the WaterUse:Equipment object is not included in WaterUse:Connections or modeled as stand-alone, then this output is reported with Resource Type = DistrictHeating, or else if the WaterUse:Equipment object is included in WaterUse:Connections (e.g., as part of plant loop), then this output is reported with Resource Type = EnergyTransfer. The sub-categories may be entered as any type (e.g., Laundry, Dish Washing, etc. defined in WaterUse:Equipment object input for End-Use Subcategory) with General being the default sub-category (ref. Output Meter).

**1.55.1.2.18 Water Use Equipment Zone Sensible Heat Gain Rate [W]**

The sensible heat rate to the zone due to the water flow being exposed to zone air, in units of watts (W).

**1.55.1.2.19 Water Use Equipment Zone Sensible Heat Gain Energy [J]**

The sensible heat energy accumulated by the latent heat rate above, in units of Joules (J).

**1.55.1.2.20 Water Use Equipment Zone Latent Gain Rate [W]**

The latent heat rate to the zone due to the water flow being exposed to zone air, in units of watts (W).

**1.55.1.2.21 Water Use Equipment Zone Latent Gain Energy [J]**

The latent heat energy accumulated by the latent heat rate above, in units of Joules (J).

**1.55.1.2.22 Water Use Equipment Zone Moisture Gain Mass Flow Rate [kg/s]**

The moisture rate of evaporation to the zone due to the water flow being exposed to zone air, in units of kilograms per second (kg/s).

**1.55.1.2.23 Water Use Equipment Zone Moisture Gain Mass [kg]**

The moisture mass accumulated by the moisture rate above, in units of kilograms (kg).

**1.55.2 WaterUse:Connections**

The WaterUse:Connections object can be thought of as a subsystem that groups together multiple **WaterUse:Equipment** components. As its name suggests, the object provides connections that are shared by these components, including:

- Inlet node and outlet node connections to a plant loop
- Connections to **WaterUse:Storage** objects to store and draw reclaimed water
- Internal connections to simulate drainwater heat recovery.

The WaterUse:Connections object can be used stand-alone or coupled into a plant loop. In stand-alone mode, the Hot and Cold Water Supply Temperature Schedules override the values for the listed **WaterUse:Equipment** objects. When coupled to the plant, the Hot Water Supply Temperature Schedule is overridden by the actual plant loop inlet water temperature. When coupled to the plant, the WaterUse:Connections object should be on a **Branch** object whose control type is set to Active.

Figure 1.197: Diagram of internal connections for WaterUse:Connections

### 1.55.2.1 Inputs

#### 1.55.2.1.1 Field: Name

The unique object name for reference by other objects.

#### 1.55.2.1.2 Field: Inlet Node Name

The hot water inlet node when connected to a plant loop. The hot water supplies all of the **WaterUse:Equipment** objects that demand hot water. Insufficient supply temperature or flow results in cooler water at the tap.

#### 1.55.2.1.3 Field: Outlet Node Name

The cold water outlet node, i.e. the cold water supply mains, when connected to a plant loop. The return node provides make-up water for the hot water lost down the drain.

#### 1.55.2.1.4 Field: Supply Water Storage Tank Name

Reference to the **WaterUse:Storage** object that supplies cold water to the listed **WaterUse:Equipment** objects. If the field is blank, or the tank is empty, fresh water is supplied from the water mains.

#### 1.55.2.1.5 Field: Reclamation Water Storage Tank Name

Reference to the **WaterUse:Storage** object that stores the resulting graywater from the listed **WaterUse:Equipment** objects. If the field is blank, the graywater is not reclaimed.

#### 1.55.2.1.6 Field: Hot Water Supply Temperature Schedule Name

Reference to the schedule object specifying the hot water temperature [C]. If blank in stand-alone mode, the hot water supply temperature defaults to the cold water supply temperature. This field (even if blank) overrides the Hot Water Supply Temperature Schedule in all of the listed **WaterUse:Equipment** objects.

#### 1.55.2.1.7 Field: Cold Water Supply Temperature Schedule Name

Reference to the schedule object specifying the cold water temperature [C] from the supply mains that provides the cold water to the tap and makes up for all water lost down the drain. If blank, water temperatures are calculated by the **Site:WaterMainsTemperature** object.

This field (even if blank) overrides the Cold Water Supply Temperature Schedule in all of the listed **WaterUse:Equipment** objects.

#### 1.55.2.1.8 Field: Drain Water Heat Exchanger Type

The heat exchanger type to be used for drainwater heat recovery. None indicates no heat recovery is to be simulated. Ideal sets a heat exchanger effectiveness of 1.0. Effectiveness is calculated dynamically for CounterFlow and CrossFlow options.

One popular type of drainwater heat exchanger is the Gravity-Film Heat Exchanger (GFX). The GFX is most closely approximated with the CounterFlow option, but keep in mind that the UA varies more with flow rate for the GFX than for most traditional heat exchangers.

#### 1.55.2.1.9 Field: Drain Water Heat Exchanger Destination

The heat exchanger configuration to be used for drainwater heat recovery. The configuration determines where the heat will be used after it is recovered.

Plant indicates that the all of the recovered heat will be sent to the return flow at the outlet node of the **WaterUse:Connections** object to preheat the make-up cold water from the water mains.

Equipment indicates that the all of the recovered heat will be used to preheat the cold water flow side of the **WaterUse:Equipment** objects listed *in this* WaterUse:Connections object

PlantAndEquipment indicates the recovered heat will be divided between the plant and the **WaterUse:Equipment** objects, as described above. This is the only option where the flow rates are equal in the drain and the heat exchanger.

#### 1.55.2.1.10 Field: Drain Water Heat Exchanger U-Factor Times Area

The UA is the heat transfer coefficient [W/K] for the heat exchanger and is the product of U, the overall heat transfer coefficient, and A, the heat exchanger surface area.

#### 1.55.2.1.11 Field: Water Use Equipment 1-10 Name

References to **WaterUse:Equipment** objects.

### 1.55.2.2 Outputs

The following output variables are reported for the WaterUse:Connections object:

- HVAC,Average,Water Use Connections Hot Water Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Connections Cold Water Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Connections Total Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Connections Drain Water Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Connections Heat Recovery Mass Flow Rate [kg/s]
- HVAC,Average,Water Use Connections Hot Water Volume Flow Rate [m3/s]
- HVAC,Average,Water Use Connections Cold Water Volume Flow Rate [m3/s]
- HVAC,Average,Water Use Connections Total Volume Flow Rate [m3/s]
- HVAC,Sum,Water Use Connections Hot Water Volume [m3]
- HVAC,Sum,Water Use Connections Cold Water Volume [m3]
- HVAC,Sum,Water Use Connections Total Volume [m3]
- HVAC,Average,Water Use Connections Hot Water Temperature [C]

- HVAC,Average,Water Use Connections Cold Water Temperature [C]
- HVAC,Average,Water Use Connections Drain Water Temperature [C]
- HVAC,Average,Water Use Connections Return Water Temperature [C]
- HVAC,Average,Water Use Connections Waste Water Temperature [C]
- HVAC,Average,Water Use Connections Heat Recovery Water Temperature [C]
- HVAC,Average,Water Use Connections Heat Recovery Effectiveness []
- HVAC,Average,Water Use Connections Heat Recovery Rate [W]
- HVAC,Sum,Water Use Connections Heat Recovery Energy [J]
- HVAC,Sum,Water Use Connections Plant Hot Water Energy [J]

#### **1.55.2.2.1 Water Use Connections Hot Water Mass Flow Rate [kg/s]**

The mass flow rate of hot water supplied to all equipment, in units of kilograms per second (kg/s).

#### **1.55.2.2.2 Water Use Connections Cold Water Mass Flow Rate [kg/s]**

The mass flow rate of cold water supplied to all equipment, in units of kilograms per second (kg/s).

#### **1.55.2.2.3 Water Use Connections Total Mass Flow Rate [kg/s]**

The total mass flow rate of water (hot + cold) supplied to all equipment, in units of kilograms per second (kg/s).

#### **1.55.2.2.4 Water Use Connections Drain Water Mass Flow Rate [kg/s]**

The mass flow rate of drainwater from all equipment, in units of kilograms per second (kg/s).

#### **1.55.2.2.5 Water Use Connections Heat Recovery Mass Flow Rate [kg/s]**

The mass flow rate of make-up water in the heat exchanger, in units of kilograms per second (kg/s).

#### **1.55.2.2.6 Water Use Connections Hot Water Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate of hot water supplied to all equipment and consumed down the drain, in units of cubic meters per second (m<sup>3</sup>/s).

#### **1.55.2.2.7 Water Use Connections Cold Water Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate of cold water supplied to all equipment and consumed down the drain, in units of cubic meters per second (m<sup>3</sup>/s).

#### **1.55.2.2.8 Water Use Connections Total Volume Flow Rate [m<sup>3</sup>/s]**

The total volumetric flow rate of water (hot + cold) supplied to all equipment and consumed down the drain, in units of cubic meters per second (m<sup>3</sup>/s).

#### **1.55.2.2.9 Water Use Connections Hot Water Volume [m<sup>3</sup>]**

The volume of hot water supplied to all equipment and consumed down the drain, in units of cubic meters (m<sup>3</sup>).

**1.55.2.2.10 Water Use Connections Cold Water Volume [m3]**

The volume of cold water supplied to all equipment and consumed down the drain, in units of cubic meters (m<sup>3</sup>).

**1.55.2.2.11 Water Use Connections Total Volume [m3]**

The total volume of water (hot+cold) supplied to all equipment and consumed down the drain, in units of cubic meters (m<sup>3</sup>).

**1.55.2.2.12 Water Use Connections Hot Water Temperature [C]**

The temperature of hot water supplied to all equipment, in units of degrees Celsius (C).

**1.55.2.2.13 Water Use Connections Cold Water Temperature [C]**

The temperature of cold water supplied to all equipment, in units of degrees Celsius (C).

**1.55.2.2.14 Water Use Connections Drain Water Temperature [C]**

The water temperature at the drain equal to the mixed water temperature minus any heat losses to the zone, in units of degrees Celsius (C).

**1.55.2.2.15 Water Use Connections Return Water Temperature [C]**

The temperature of make-up water returned to the plant loop, in units of degrees Celsius (C).

**1.55.2.2.16 Water Use Connections Waste Water Temperature [C]**

The temperature of the water leaving the heat exchanger. If no heat exchanger, the waste water temperature equals the drain water temperature, in units of degrees Celsius (C).

**1.55.2.2.17 Water Use Connections Heat Recovery Water Temperature [C]**

The temperature of the water leaving the heat exchanger. If no heat exchanger, the waste water temperature equals the drain water temperature, in units of degrees Celsius (C).

**1.55.2.2.18 Water Use Connections Heat Recovery Effectiveness []**

The effectiveness value of the heat exchanger. The units are dimensionless.

**1.55.2.2.19 Water Use Connections Heat Recovery Rate [W]**

The heat recovered by the heat exchanger and used to preheat the cold make-up water, in units of watts (W).

**1.55.2.2.20 Water Use Connections Heat Recovery Energy [J]**

The energy recovered by the heat exchanger and used to preheat the cold make-up water, in units of Joules (J).

**1.55.2.2.21 Water Use Connections Plant Hot Water Energy [J]**

The plant loop energy consumed by the hot water used, in units of Joules (J). This output is also added to a meter with Resource Type = PlantLoopHeatingDemand, End Use Key = WaterSystems, and Group Key = Plant (ref. Output Meter).

### 1.55.3 WaterUse:Storage

The WaterUse:Storage object is a central component for complex water systems. This object is not needed if the only use of water is directly from the mains, or utility service water. If the building model is to include any on-site collection or wells or storing and reuse of graywater, then a WaterUse:Storage is needed. Each WaterUse:Storage can serve as a central node and make connections to numerous sources of supply or numerous components with demand. If a maximum capacity is not specified, the tank is assumed to have unlimited capacity. This is useful for sizing.

Storage tanks may handle a lot of water but show no use. This is because water usage is metered at the component level where water is used up. The only water a storage tank might use up is overflow water if it is discarded.

#### 1.55.3.1 Inputs

##### 1.55.3.1.1 Field: Name

The unique object name for reference by other objects.

##### 1.55.3.1.2 Field: Water Quality Subcategory

Describes the quality of the water contained in the tank. Used for reporting and to check that the uses and supply match the category of water quality.

##### 1.55.3.1.3 Field: Maximum Capacity

The maximum volumetric capacity [m<sup>3</sup>] of the water tank. If blank, this field defaults to unlimited capacity.

##### 1.55.3.1.4 Field: Initial Volume

The volume of water in the storage tank at the beginning of each simulation environmental period [m<sup>3</sup>]. This provides a starting point for the amount of water in storage.

##### 1.55.3.1.5 Field: Design In Flow Rate

The design flow rate [m<sup>3</sup>/s] of fittings that provide water into the tank from external sources. In a scenario where a heavy rain fall is being harvested, the actual reclamation rate might be limited by pipe size or filtration. If blank, this field defaults to unlimited rate.

##### 1.55.3.1.6 Field: Design Out Flow Rate

The design flow rate [m<sup>3</sup>/s] of fitting that withdraw water from the tank to end uses. Heavy demand (landscaping?) might be limited by pipe size or filtration. If Blank, this field defaults to unlimited rate.

##### 1.55.3.1.7 Field: Overflow Destination

Name of a second WaterUse:Storage that would receive overflow. Overflow could occur if the maximum capacity is reached or if the design in flow rate is exceeded. If left blank, then the overflow is discarded and lost from the water system.

##### 1.55.3.1.8 Field: Type of Supply Controlled by Float Valve

The storage tank can include the capability of modeling a float valve that will call for water to be added to the tank. This field is used to select the type of system used to respond to fill requests made by a float valve. The available options are None , Mains , GroundwaterWell , or OtherTank. The float valve settings are described in the next two fields.

**1.55.3.1.9 Field: Float Valve On Capacity**

The volumetric capacity [m3] of the water tank when a floating valve would turn on to allow filling the tank.

**1.55.3.1.10 Field: Float Valve Off Capacity**

The volumetric capacity [m3] of the water tank when a floating valve would turn off after having been filling the tank.

**1.55.3.1.11 Field: Backup Mains Capacity**

The volumetric capacity of the tank that indicates where a secondary float valve will maintain the volume by calling for mains water. Used if the well or other tank cannot keep up with the needs of the main float valve. If left blank or equal 0.0, then there is no mains water backup. If specified, then mains water will be drawn once the storage tank reaches this level and then the mains water will fill all the way to capacity specified in the previous field.

**1.55.3.1.12 Field: Other Tank Name**

This field contains the name of another WaterUse:Storage defined elsewhere in the input file. This field is only used if the Type of Controlled Supply field is set to OtherTank and the current tank is to be configured to be supplied by a second tank in response to a float valve.

**1.55.3.1.13 Field: Water Thermal Mode**

Controls the method of determining the temperature of the water in the storage tank. The only available option at the current time is ScheduledTemperature.

**1.55.3.1.14 Field: Water Temperature Schedule Name**

Reference to the schedule object specifying the temperature [C] of the water in the tank. This takes the place of a full thermal model of the tank.

**1.55.3.1.15 Field: Ambient Temperature Indicator**

Reserved for future use. The field can be Schedule, Zone, or Outdoors.

**1.55.3.1.16 Field: Ambient Temperature Schedule Name**

Reserved for future use. Schedule name for ambient temperature when previous field is Schedule.

**1.55.3.1.17 Field: Zone Name**

Reserved for future use. Name of zone where the tank is located.

**1.55.3.1.18 Field: Tank Surface Area**

Reserved for future zone thermal model.

**1.55.3.1.19 Field: Tank U Value**

Reserved for future zone thermal model.

### 1.55.3.1.20 Field: Tank Outside Surface Material Name

Reserved for future zone thermal model.

### 1.55.3.2 Outputs

The following output variables are available for reporting for each WaterUse:Storage object.

- HVAC,Average,Water System Storage Tank Volume [m3]
- HVAC,Average,Water System Storage Tank Net Volume Flow Rate [m3/s]
- HVAC,Average,Water System Storage Tank Inlet Volume Flow Rate [m3/s]
- HVAC,Average,Water System Storage Tank Outlet Volume Flow Rate [m3/s]
- HVAC,Sum,Water System Storage Tank Mains Water Volume [m3]
- HVAC,Average,Water System Storage Tank Mains Water Volume Flow Rate [m3/s]
- HVAC,Average,Water System Storage Tank Water Temperature [C]
- HVAC,Average,Water System Storage Tank Overflow Volume Flow Rate [m3/s]
- HVAC,Sum,Water System Storage Tank Overflow Water Volume [m3]
- HVAC,Average,Water System Storage Tank Overflow Temperature [C]

#### 1.55.3.2.1 Water System Storage Tank Volume [m3]

This is the volume of water stored in the storage tank, in units of cubic meters (m<sup>3</sup>).

#### 1.55.3.2.2 Water System Storage Tank Net Volume Flow Rate [m3]

This is the net rate of flows in and out of the storage tank, in units of cubic meters (m<sup>3</sup>).

#### 1.55.3.2.3 Water System Storage Tank Inlet Volume Flow Rate [m3/s]

This is the rate of flows into the storage tank, in units of cubic meters per second (m<sup>3</sup>/s).

**1.55.3.2.4 Water System Storage Tank Outlet Volume Flow Rate [m3]**

This is the rate of flows out of the storage tank, in units of cubic meters ( $\text{m}^3$ ).

**1.55.3.2.5 Water System Storage Tank Mains Water Volume [m3]**

This is the volume of water drawn from the mains in order to fill the tank, in units of cubic meters per second ( $\text{m}^3/\text{s}$ ). This output is also added to a meter with Resource Type = MainsWater, End Use Key = WaterSystem, and Group Key = System. The water quality sub-category may be entered as any type (defined in WaterUse:Storage object input for Water Quality Subcategory) (ref. Output Meter).

**1.55.3.2.6 Water System Storage Tank Mains Water Volume Flow Rate [m3/s]**

This is the rate of water draw from the mains in order to fill the tank, in units of cubic meters per second ( $\text{m}^3/\text{s}$ ).

**1.55.3.2.7 Water System Storage Tank Water Temperature [C]**

This is the temperature of the water in the tank, in units of degrees Celsius (C).

**1.55.3.2.8 Water System Storage Tank Overflow Volume Flow Rate [m3/s]**

This is the rate of water flows that overflow the tank either because of limits on how fast the tank can fill or because the tank is full and cannot handle the water provided, in units of cubic meters per second ( $\text{m}^3/\text{s}$ ).

**1.55.3.2.9 Water System Storage Tank Overflow Water Volume [m3]**

This is the volume of water overflowing the tank because of limits on how fast the tank can fill or because the tank is full and cannot handle the water provided, in units of cubic meters ( $\text{m}^3$ ).

**1.55.3.2.10 Water System Storage Tank Overflow Temperature [C]**

This the temperature of overflow water leaving the tank.

**1.55.4 WaterUse:RainCollector**

The WaterUse:RainCollector object is used for harvesting rainwater falling on building surfaces. The rainwater is sent to a **WaterUse:Storage** object. In order to use this object it is necessary to also include a **Site:Precipitation** object to describe the rates of rainfall.

**1.55.4.1 Inputs****1.55.4.1.1 Field: Name**

The unique object name for reference by other objects.

**1.55.4.1.2 Field: Storage Tank Name**

A reference to a **WaterUse:Storage** object where the rainwater will be collected and stored for later use.

**1.55.4.1.3 Field: Loss Factor Mode**

The WaterUse:RainCollector model includes a loss factor that indicates the portion of incident rain that is not successfully collected. Two modes are available: Constant and Scheduled. Enter Constant in this field for the model to use a simple fixed loss factor defined in the next field. For versatility, the loss factor can follow a schedule by entering Scheduled in this field and then the name of a schedule in the second field below.

#### 1.55.4.1.4 Field: Collection Loss Factor

Constant loss factor for how much of the incident rainwater is lost and not collected. The factor should be between 0 and 1.

#### 1.55.4.1.5 Field: Collection Loss Factor Schedule Name

Name of a schedule that defines a variable collection loss factor if the mode is selected as Scheduled.

#### 1.55.4.1.6 Field: Maximum Collection Rate

The maximum flow rate [m<sup>3</sup>/s] for rainwater collection. In a scenario where a heavy rain fall is being harvested, the actual reclamation rate might be limited by pipe size or the filtration system.

#### 1.55.4.1.7 Field: Collection Surface 1-10 Name

A reference to the name of a surface object which will collect the rain. Typically the collection surfaces would correspond to roof surfaces on the building. The effective area for rainwater collection is the horizontal component (area \* cosine of the slope, etc.). More detailed modeling of rainwater collection can be added later to account for factors such as wind speed and direction, etc.

IDF examples:

```
WaterUse:RainCollector,
  My Test Rain Collector ,!- Name
  My Test Tank ,    !- Storage Tank Name
  CONSTANT,    !- Loss Factor Mode
  0.9 ,    !- Collection Loss Factor
  ,    !- Collection Loss Factor Schedule Name
  1.0 ,    !- Maximum Collection Rate
  SouthRoof ,    !- Collection Surface 1 Name
  NorthRoof1,    !- Collection Surface 2 Name
  NorthRoof3 ,    !- Collection Surface 3 Name
  NorthRoof2 ;    !- Collection Surface 4 Name
```

### 1.55.4.2 Outputs

- HVAC,Average,Water System Rainwater Collector Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Water System Rainwater Collector Volume [m<sup>3</sup>]

#### 1.55.4.2.1 Water System Rainwater Collector Volume Flow Rate [m<sup>3</sup>/s]

This output variable provides the rate of water collected by the WaterUse:RainCollector, in units of cubic meters per second (m<sup>3</sup>/s).

#### 1.55.4.2.2 Water System Rainwater Collector Volume [m<sup>3</sup>]

This output variable provides the volume of water collected by the WaterUse:RainCollector, in units of cubic meters per second (m<sup>3</sup>/s). This output is also added to a meter with Resource Type = OnSiteWater, End Use Key = RainWater, and Group Key = System (ref. Output Meter).

### 1.55.5 WaterUse:Well

The WaterUse:Well object is for simulating on-site water supply from a well. Well water is pumped out of the ground and into a [WaterUse:Storage](#). The operation of the ground water well is controlled by the associated [WaterUse:Storage](#) which is assumed to be operated as a vented cistern with no pressure tank. The current implementation is very simple and only requires two numeric inputs: the rated pump flow

and power. A more elaborate well model may be added and many input fields are reserved for this future expansion.

### 1.55.5.1 Inputs

#### 1.55.5.1.1 Field: Name

Unique name of this well.

#### 1.55.5.1.2 Field: Storage Tank Name

A reference to a [WaterUse:Storage](#) object where the rainwater will be collected and stored for later use.

#### 1.55.5.1.3 Field: Pump Depth

Reserved for future use. Effective depth of well [m]

#### 1.55.5.1.4 Field: Pump Rated Flow Rate

This is the nominal pump flow rate [m<sup>3</sup>/s]. This field is required.

#### 1.55.5.1.5 Field: Pump Rated Head

Reserved for future use [Pa]. Pump head at rated conditions in Pascals.

#### 1.55.5.1.6 Field: Pump Rated Power Consumption

This is the pump power at the nominal pump flow rate [W]. This field is required.

#### 1.55.5.1.7 Field: Pump Efficiency

Reserved for future use.

#### 1.55.5.1.8 Field: Well Recovery Rate

Reserved for future use. Rate at which ground water enters well during a sustained draw, e.g., 2 hour well test [m<sup>3</sup>/s].

#### 1.55.5.1.9 Field: Nominal Well Storage Volume

Reserved for future use. Capacity in well after long period of inactivity and the usual water table depth. [m<sup>3</sup>]

#### 1.55.5.1.10 Field: Water Table Depth Mode

Reserved for future use. Two options available: Constant or Scheduled

#### 1.55.5.1.11 Field: Water Table Depth

Reserved for future use. Depth of water table from [WaterUse:Storage](#)

#### 1.55.5.1.12 Field: Water Table Depth Schedule Name

Reserved for future use.

An example input object:

```
WaterUse:Well,
  My Test Well,    !- Name
  Tower 1 Water Tank,    !- Storage Tank Name
  ,    !- Pump Depth
  0.1,    !- Pump Rated Flow Rate {m3/s}
```

```

,      !- Pump Rated Head {Pa}
120,   !- Pump Rated Power Consumption {W}
,      !- Pump Efficiency
,      !- Well Recovery Rate {m3/s}
,      !- Nominal Well Storage Volume {m3}
,      !- Water Table Depth Mode
,      !- Water Table Depth
;      !- Water Table Depth Schedule Name

```

---

### 1.55.5.2 Outputs

The following output variables are available for reporting for each WaterUse:Well object.

- HVAC,Average,Water System Groundwater Well Requested Volume Flow Rate [m3/s]
- HVAC,Average,Water System Groundwater Well Volume Flow Rate [m3/s]
- HVAC,Sum,Water System Groundwater Well Volume [m3]
- HVAC,Average,Water System Groundwater Well Pump Electricity Rate [W]
- HVAC,Sum,Water System Groundwater Well Pump Electricity Energy [J]

#### 1.55.5.2.1 Water System Groundwater Well Requested Volume Flow Rate [m3/s]

This is the volume flow rate that the water system requested from the well, in units of cubic meters per second ( $\text{m}^3/\text{s}$ ).

#### 1.55.5.2.2 Water System Groundwater Well Volume Flow Rate [m3/s]

This is the volume flow water of water actually obtained from the well, in units of cubic meters per second ( $\text{m}^3/\text{s}$ ).

#### 1.55.5.2.3 Water System Groundwater Well Volume [m3]

This is the volume of water obtained from the well, in units of cubic meters ( $\text{m}^3$ ). This output is also added to a meter with Resource Type = OnSiteWater, End Use Key = WellWater, and Group Key = System (ref. Output Meter).

#### 1.55.5.2.4 Water System Groundwater Well Pump Electricity Rate [W]

This is the electrical power of the pump used to extract water from the well, in units of watts (W).

#### 1.55.5.2.5 Water System Groundwater Well Pump Electricity Energy [J]

This is the electricity energy used by the pump to extract water from the well, in units of Joules (J). This output is also added to a meter with Resource Type = Electricity, End Use Key = WaterSystems, and Group Key = System (ref. Output Meter).

## 1.56 Group - Operational Faults

### 1.56.1 Introduction to Operational Faults Modeling

Most of the buildings, either new or old, have operational faults in the sensors, controllers, meters, equipment and systems. Being able to model and simulate these faults and their impact on energy performance of buildings is crucial to improve accuracy of building simulations and to support the retrofit of buildings.

To date, the main practitioner use of EnergyPlus has been for new construction design. With the new high priority attached by USDOE to retrofit and improved operation of existing buildings, there is a need to extend the capabilities of EnergyPlus to model existing buildings, including faulty operation:

- Retrofit analysis: starts with calibrated simulation; the ability to estimate the severity of common faults is expected to improve the accuracy and transparency of the calibrated model and hence the increase accuracy of the analysis of different retrofit measures.
- Commissioning providers can use the fault models to demonstrate the saving to be expected from fixing faults found in retro-commissioning
- Support for building operation by using the calibrated model, including unfixed faults, as a real-time reference model to detect, and verify the diagnosis of, newly occurring faults.

The users in these cases are practitioners, not power users, so it is needed to implement the fault models using conventional EnergyPlus objects rather than the EMS, which, in any case, could only be used to model limited types of faults.

## 1.56.2 Overview of Operational Fault Objects

EnergyPlus contains a number of objects to model operational faults of sensors, meters, equipment and systems. The current implementation allows the modeling of the following fault types: (1) sensor faults with air economizers, (2) thermostat/humidistat offset faults, (3) fouling or scaling at air side or water side components (e.g., heating and cooling coil, air filter, cooling tower), (4) sensor faults with plant components.

The objects used by EnergyPlus to model the faults are as follows:

- FaultModel:TemperatureSensorOffset:OutdoorAir
- FaultModel:HumiditySensorOffset:OutdoorAir
- FaultModel:EnthalpySensorOffset:OutdoorAir
- FaultModel:TemperatureSensorOffset:ReturnAir
- FaultModel:EnthalpySensorOffset:ReturnAir
- FaultModel:Fouling:Coil
- FaultModel:ThermostatOffset
- FaultModel:HumidistatOffset
- FaultModel:Fouling:AirFilter
- FaultModel:TemperatureSensorOffset:ChillerSupplyWater
- FaultModel:TemperatureSensorOffset:CondenserSupplyWater FaultModel:Fouling:Boiler
- FaultModel:Fouling:Chiller
- FaultModel:Fouling:CoolingTower
- FaultModel:TemperatureSensorOffset:CoilSupplyAir
- FaultModel:Fouling:EvaporativeCooler

### 1.56.3 FaultModel:TemperatureSensorOffset:OutdoorAir

This object defines the offset of an outdoor air dry-bulb temperature sensor that is used to determine applicability of an air economizer.

#### 1.56.3.1 Inputs

##### 1.56.3.1.1 Field: Name

This is the user-defined name of the fault.

##### 1.56.3.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.56.3.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined temperature offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.56.3.1.4 Field: Controller Object Type

This field defines the controller object type that this fault is associated with. Choices are from a list of applicable controller types. Current implementation supports air economizer the choice is **Controller:OutdoorAir**.

##### 1.56.3.1.5 Field: Controller Object Name

This field defines the name of the controller object associated with the fault. It should be one of the objects with the defined types.

##### 1.56.3.1.6 Field: Temperature Sensor Offset

This field defines the offset of the temperature sensor. A positive value means the sensor reads a temperature that is higher than the real value. A negative value means the sensor reads a temperature that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in degrees Celsius.

### 1.56.4 FaultModel:HumiditySensorOffset:OutdoorAir

This object defines the offset of an outdoor air humidity sensor that is used to determine applicability of an air economizer.

#### 1.56.4.1 Inputs

##### 1.56.4.1.1 Field: Name

This is the user-defined name of the fault.

**1.56.4.1.2 Field: Availability Schedule Name**

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

**1.56.4.1.3 Field: Severity Schedule Name**

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined humidity offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

**1.56.4.1.4 Field: Controller Object Type**

This field defines the controller object type that this fault is associated with. Choices are from a list of applicable controller types. Current implementation supports air economizer the choice is **Controller:OutdoorAir**.

**1.56.4.1.5 Field: Controller Object Name**

This field defines the name of the controller object associated with the fault. It should be one of the objects with the defined types.

**1.56.4.1.6 Field: Humidity Sensor Offset**

This field defines the offset of the humidity ratio sensor. A positive value means the sensor reads a humidity ratio that is higher than the real value. A negative value means the sensor reads a humidity ratio that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in kgWater/kgDryAir.

**1.56.5 FaultModel:EnthalpySensorOffset:OutdoorAir**

This object defines the offset of an outdoor enthalpy sensor that is used to determine applicability of an air economizer.

**1.56.5.1 Inputs****1.56.5.1.1 Field: Name**

This is the user-defined name of the fault.

**1.56.5.1.2 Field: Availability Schedule Name**

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

**1.56.5.1.3 Field: Severity Schedule Name**

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined enthalpy offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.5.1.4 Field: Controller Object Type

This field defines the controller object type that this fault is associated with. Choices are from a list of applicable controller types. Current implementation supports air economizer the choice is `Controller:OutdoorAir`.

#### 1.56.5.1.5 Field: Controller Object Name

This field defines the name of the controller object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.5.1.6 Field: Enthalpy Sensor Offset

This field defines the offset of the enthalpy sensor. A positive value means the sensor reads an enthalpy that is higher than the real value. A negative value means the sensor reads an enthalpy that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in J/kg.

### 1.56.6 FaultModel:TemperatureSensorOffset:ReturnAir

This object defines the offset of a return air dry-bulb temperature sensor that is used to determine applicability of an air economizer.

#### 1.56.6.1 Inputs

##### 1.56.6.1.1 Field: Name

This is the user-defined name of the fault.

##### 1.56.6.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.56.6.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined temperature offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.56.6.1.4 Field: Controller Object Type

This field defines the controller object type that this fault is associated with. Choices are from a list of applicable controller types. Current implementation supports air economizer the choice is `Controller:OutdoorAir`.

##### 1.56.6.1.5 Field: Controller Object Name

This field defines the name of the controller object associated with the fault. It should be one of the objects with the defined types.

##### 1.56.6.1.6 Field: Temperature Sensor Offset

This field defines the offset of the temperature sensor. A positive value means the sensor reads a temperature that is higher than the real value. A negative value means the sensor reads a temperature that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in degrees Celsius.

## 1.56.7 FaultModel:EnthalpySensorOffset:ReturnAir

This object defines the offset of a return air enthalpy sensor that is used to determine applicability of an air economizer.

### 1.56.7.1 Inputs

#### 1.56.7.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.7.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.7.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined enthalpy offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.7.1.4 Field: Controller Object Type

This field defines the controller object type that this fault is associated with. Choices are from a list of applicable controller types. Current implementation supports air economizer the choice is **Controller:OutdoorAir**.

#### 1.56.7.1.5 Field: Controller Object Name

This field defines the name of the controller object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.7.1.6 Field: Enthalpy Sensor Offset

This field defines the offset of the enthalpy sensor. A positive value means the sensor reads an enthalpy that is higher than the real value. A negative value means the sensor reads an enthalpy that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in J/kg.

## 1.56.8 FaultModel:Fouling:Coil

This object defines the fouling for a simple water cooling coil or simple water heating coil.

### 1.56.8.1 Inputs

#### 1.56.8.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.8.1.2 Field: Coil Name

This field defines the name of the simple cooling coil or simple heating coil that has the fouling fault.

### 1.56.8.1.3 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then user-defined fouling and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods

### 1.56.8.1.4 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. If this field is blank, the schedule has values of 1 (no changes to fouling) for all time periods. This is used to increase or decrease the fouling by a percentage. For example, if the schedule has a value of 1.2, it implies 20% more fouling: if the Fouling Factor is 0.8, then resulting Fouling Factor would be  $0.8/1.2 = 0.67$ .

### 1.56.8.1.5 Field: Fouling Input Method

There are two methods to input the fouling, i.e. FouledUARated and FoulingFactor. User chooses the appropriate method to determine the coil fouling.

### 1.56.8.1.6 Field: UAFouled

This is the overall coil UA value including the coil fouling when the “FouledUARated” method is used. The unit is W/K.

### 1.56.8.1.7 Field: Water Side Fouling Factor

The following four fields specify the required inputs when the “FoulingFactor” method is used. This field defines the fouling factor for the water side. The units are in  $\text{m}^2\text{-K/W}$ .

### 1.56.8.1.8 Field: Air Side Fouling Factor

This field defines the fouling factor for the air side. The units are in  $\text{m}^2\text{-K/W}$ .

### 1.56.8.1.9 Field: Outside Coil Surface Area

This field defines outside surface area (the surface in contact with the air) of the cooling or heating coil. The units are in  $\text{m}^2$ .

### 1.56.8.1.10 Field: Inside to Outside Coil Surface Area Ratio

This field specifies the inside to outside surface area ratio of the cooling or heating coil.

## 1.56.9 FaultModel:ThermostatOffset

This object defines the offset fault of a thermostat that leads to inappropriate operations of the HVAC system.

### 1.56.9.1 Inputs

#### 1.56.9.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.9.1.2 Field: Thermostat Name

This field defines the name of the thermostat object associated with the fault. It should be the name of a **ZoneControl:Thermostat** object.

#### 1.56.9.1.3 Field: Availability Schedule Name

This field provides the name of a schedule that will determine whether this fault is applicable or not. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to “1.0” when a fault is applicable and “0.0” when it is not. If this field is blank, the schedule has values of 1.0 for all time periods.

#### 1.56.9.1.4 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the reference thermostat offset value. This schedule should be set to a non-zero value when a fault is applicable and “0.0” when it is not. If this field is blank, the schedule has values of 1.0 for all time periods.

#### 1.56.9.1.5 Field: Reference Thermostat Offset

This field defines the reference offset value of the thermostat. A positive value means the zone air temperature reading is higher than the actual value. A negative value means the reading is lower than the actual value. A “0.0” value means no offset. Default is 2.0. The units are in degrees Celsius.

### 1.56.10 FaultModel:HumidistatOffset

This object defines the offset fault of a humidistat that leads to inappropriate operations of the HVAC system.

#### 1.56.10.1 Inputs

##### 1.56.10.1.1 Field: Name

This is the user-defined name of the fault.

##### 1.56.10.1.2 Field: Humidistat Name

This field defines the name of the humidistat object associated with the fault. It should be the name of a **ZoneControl:Humidistat** object.

##### 1.56.10.1.3 Field: Humidistat Offset Type

This choice field determines the humidistat offset fault type. Two fault types are available: (1) Type ThermostatOffsetIndependent: humidistat offset is not related with thermostat offset. For this type, user needs to specify the Reference Humidistat Offset, Availability Schedule, and Severity Schedule (2) Type ThermostatOffsetDependent: humidistat offset is caused by thermostat offset fault. For this type, user only needs to specify the Related Thermostat Offset Fault Name.

##### 1.56.10.1.4 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. This field is applicable for the Type ThermostatOffsetIndependent. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to “1.0” when a fault is applicable and “0.0” when it is not. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.56.10.1.5 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This field is applicable for the Type ThermostatOffsetIndependent. This is used as a multiplier to the reference humidistat offset value. This schedule should be set to a non-zero value when a fault is applicable and “0.0” when it is not. If this field is blank, the schedule has values of 1.0 for all time periods.

##### 1.56.10.1.6 Field: Reference Humidistat Offset

This field defines the reference offset value of the humidistat. This field is required for the Type ThermostatOffsetIndependent. A positive value means the zone air temperature reading is higher than the actual value. A negative value means the reading is lower than the actual value. A “0.0” value means no offset. Default is 5.0. The units are in percentage.

### 1.56.10.1.7 Field: Related Thermostat Offset Fault Name

This field provides the name of a Thermostat Offset Fault object that causes the humidistat offset fault. It should be the name of a **FaultModel:ThermostatOffset** object. This field is required for the Type **ThermostatOffsetDependent**. This is used as a multiplier to the reference humidistat offset value. This schedule should be set to a non-zero value when a fault is applicable and “0.0” when it is not. If this field is blank, the schedule has values of 1.0 for all time periods.

## 1.56.11 FaultModel:Fouling:AirFilter

This object defines the fault of fouling air filter that leads to inappropriate operations of the corresponding fan.

### 1.56.11.1 Inputs

#### 1.56.11.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.11.1.2 Field: Fan Name

This field defines the name of a fan object associated with the fault. It should be the name of a fan object (**Fan:ConstantVolume**, **Fan:OnOff**, or **Fan:VariableVolume**).

#### 1.56.11.1.3 Field: Fan Object Type

This choice field defines the type of fan. The valid choices are **Fan:OnOff**, **Fan:ConstantVolume**, and **Fan:VariableVolume**. Both cycling and continuous fan operating modes are allowed for **Fan:OnOff**. Only the continuous fan operating mode is allowed for **Fan:ConstantVolume**. The variable airflow rate is allowed for **Fan:VariableVolume**.

#### 1.56.11.1.4 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. This field is applicable for the Type ThermostatOffsetIndependent. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined Pressure Fraction Schedule will be applied. This schedule should be set to “1.0” when a fault is applicable and “0.0” when it is not. If this field is blank, the schedule has values of 1.0 for all time periods.

#### 1.56.11.1.5 Field: Pressure Fraction Schedule Name

This field provides the name of a schedule that describes the pressure rise variations of the fan associated with the fouling air filter. This is used as a multiplier to the fan design pressure rise. Because the fan pressure rise in the faulty case is higher than that in the design case, this schedule should be set to a value that is greater than 1.0 when a fault is applicable. If this field is blank, the schedule has values of 1.0 for all time periods.

#### 1.56.11.1.6 Field: Fan Curve Name

This field provides the name of a fan curve for the fan associated with the fault. The curve describes the relationship between the fan pressure rise and air flow rate. This is used to estimate the variations of the fan air flow rate in the faulty cases, given the Pressure Rise Variation Schedule. For variable speed fans, the curve should be the one corresponding to the maximum fan speed. The fan curve should cover the design operational point specified in the corresponding fan object. It is also required that the faulty fan operational state point falls within the fan selection range that is monotonically decreasing.

## 1.56.12 FaultModel:TemperatureSensorOffset:ChillerSupplyWater

This object defines the operational fault of chiller supply water temperature sensor offset.

### 1.56.12.1 Inputs

#### 1.56.12.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.12.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.12.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined temperature offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.12.1.4 Field: Chiller Object Type

This field defines the chiller object type that this fault is associated with. Choices are from a list of applicable chiller types, including **Chiller:Electric**, **Chiller:Electric:EIR**, **Chiller:Electric:ReformulatedEIR**, **Chiller:ConstantCOP**, **Chiller:EngineDriven**, **Chiller:CombustionTurbine**, **Chiller:Absorption**, **Chiller:Absorption:Indirect**.

#### 1.56.12.1.5 Field: Chiller Object Name

This field defines the name of the chiller object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.12.1.6 Field: Reference Sensor Offset

This field defines the reference offset of the temperature sensor. A positive value means the sensor reads a temperature that is higher than the real value. A negative value means the sensor reads a temperature that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in degrees Celsius.

### 1.56.13 FaultModel:TemperatureSensorOffset:CondenserSupplyWater

This object defines the operational fault of condenser supply water temperature sensor offset.

#### 1.56.13.1 Inputs

##### 1.56.13.1.1 Field: Name

This is the user-defined name of the fault.

##### 1.56.13.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.56.13.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined temperature offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.13.1.4 Field: Cooling Tower Object Type

This field defines the cooling tower object type that this fault is associated with. Choices are from a list of applicable tower types, including `CoolingTower:SingleSpeed`, `CoolingTower:TwoSpeed`, `CoolingTower:VariableSpeed`, and `CoolingTower:VariableSpeed:MERKEL`.

#### 1.56.13.1.5 Field: Cooling Tower Object Name

This field defines the name of the cooling tower object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.13.1.6 Field: Reference Sensor Offset

This field defines the reference offset of the temperature sensor. A positive value means the sensor reads a temperature that is higher than the real value. A negative value means the sensor reads a temperature that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in degrees Celsius.

### 1.56.14 FaultModel:Fouling:CoolingTower

This object defines the operational fault of fouling cooling towers.

### 1.56.14.1 Inputs

#### 1.56.14.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.14.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.14.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods. This is used to increase or decrease the fouling by a percentage. For example, if the schedule has a value of 1.2, it implies 20% more fouling: if the Fouling Factor is 0.8, then resulting Fouling Factor would be  $0.8/1.2 = 0.67$ .

#### 1.56.14.1.4 Field: Cooling Tower Object Type

This field defines the cooling tower object type that this fault is associated with. Choices are from a list of applicable tower types, including **CoolingTower:SingleSpeed**, **CoolingTower:TwoSpeed**, and **CoolingTower:VariableSpeed:MERKEL**.

#### 1.56.14.1.5 Field: Cooling Tower Object Name

This field defines the name of the cooling tower object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.14.1.6 Field: UA Reduction Factor

This field defines the UA reduction factor of the faulty cooling tower. The factor describes the tower UA reduction due to fouling. It is the ratio between the UA value at fouling case and that at fault free case. It is applicable to both the Design UA and Free Convection UA of the tower.

#### 1.56.14.1.7 IDF Examples

## 1.56.15 FaultModel:Fouling:Boiler

This object defines the operational fault of fouling boilers with water-based heat exchangers.

### 1.56.15.1 Inputs

#### 1.56.15.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.15.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.15.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods. This is used to increase or decrease the fouling by a percentage. For example, if the schedule has a value of 1.2, it implies 20% more fouling: if the Fouling Factor is 0.8, then resulting Fouling Factor would be  $0.8/1.2 = 0.67$ .

#### 1.56.15.1.4 Field: Boiler Object Type

This field defines the boiler object type that this fault is associated with. Choices are the boiler types with water-based heat exchangers.

#### 1.56.15.1.5 Field: Boiler Object Name

This field defines the name of the boiler object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.15.1.6 Field: Fouling Factor

This field defines the fouling factor of the faulty boiler. The factor indicates the decrease of the nominal capacity of the boiler. It is the ratio between the nominal capacity at fouling case and that at fault free case.

## 1.56.16 FaultModel:Fouling:Chiller

This object defines the operational fouling fault of chillers with water-cooled condensers.

### 1.56.16.1 Inputs

#### 1.56.16.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.16.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.16.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods. This is used to increase or decrease the fouling by a percentage. For example, if the schedule has a value of 1.2, it implies 20% more fouling: if the Fouling Factor is 0.8, then resulting Fouling Factor would be  $0.8/1.2 = 0.67$ .

#### 1.56.16.1.4 Field: Chiller Object Type

This field defines the chiller object type that this fault is associated with. Choices are the chiller types with water-cooled condensers.

#### 1.56.16.1.5 Field: Chiller Object Name

This field defines the name of the chiller object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.16.1.6 Field: Fouling Factor

This field defines the fouling factor of the faulty chiller. The factor indicates the decrease of the nominal capacity of the chiller. It is the ratio between the nominal capacity at fouling case and that at fault free case.

## 1.56.17 FaultModel:Fouling:EvaporativeCooler

This object defines the operational fault of the wetted coil evaporative cooler.

### 1.56.17.1 Inputs

#### 1.56.17.1.1 Field: Name

This is the user-defined name of the fault.

#### 1.56.17.1.2 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.56.17.1.3 Field: Severity Schedule Name

This field provides the name of a schedule that represents severity of a fault. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods. This is used to increase or decrease the fouling by a percentage. For example, if the schedule has a value of 1.2, it implies 20% more fouling: if the Fouling Factor is 0.8, then resulting Fouling Factor would be  $0.8/1.2 = 0.67$ .

#### 1.56.17.1.4 Field: Evaporative Cooler Object Type

This field defines the evaporative cooler object type that this fault is associated with. Choices are the wetted coil evaporative coolers.

#### 1.56.17.1.5 Field: Evaporative Cooler Object Name

This field defines the name of the evaporative cooler object associated with the fault. It should be one of the objects with the defined types.

#### 1.56.17.1.6 Field: Fouling Factor

This field defines the fouling factor of the faulty evaporative cooler. The factor indicates the decrease of the indirect stage efficiency. It is the ratio between the indirect stage efficiency at fouling case and that at fault free case.

### 1.56.18 FaultModel:TemperatureSensorOffset:CoilSupplyAir

This object defines the operational fault of supply air temperature sensor offset for the coils with temperature-based control.

#### 1.56.18.1 Inputs

##### 1.56.18.1.1 Field: Name

This is the user-defined name of the fault.

**1.56.18.1.2 Field: Availability Schedule Name**

This field provides the name of a schedule that will determine if this fault is applicable. When a fault is not applicable it is not modeled in the simulations. When it is applicable, then a user-defined sensor offset and a severity schedule will be applied. This schedule should be set to 1.0 when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

**1.56.18.1.3 Field: Severity Schedule Name**

This field provides the name of a schedule that represents severity of a fault. This is used as a multiplier to the user-defined temperature offset. This schedule should be set to a non-zero value when a fault is applicable and 0.0 when it is not. If this field is blank, the schedule has values of 1 for all time periods.

**1.56.18.1.4 Field: Coil Object Type**

This field defines the coil object type that this fault is associated with. Choices are from a list of applicable coils with temperature-based control, including **Coil:Heating:Electric**, **Coil:Heating:Gas**, **Coil:Heating:Steam**, **Coil:Heating:Desuperheater**, **Coil:Heating:Water**, **Coil:Cooling:Water**, **Coil:Cooling:Water:Detailed** and **AirloopHVAC:UnitarySystem** using set point control.

**1.56.18.1.5 Field: Coil Object Name**

This field defines the name of the coil associated with the fault. It should be one of the objects with the defined types.

**1.56.18.1.6 Field: Water Coil Controller Name**

This field defines the name of the water coil controller associated with the faulty water coil. This field is only required for the water coils, i.e., the coil type is **Coil:Heating:Water**, **Coil:Cooling:Water**, or **Coil:Cooling:Water:Detailedgeometry**.

**1.56.18.1.7 Field: Reference Sensor Offset**

This field defines the reference offset of the temperature sensor. A positive value means the sensor reads a temperature that is higher than the real value. A negative value means the sensor reads a temperature that is lower than the real value. A 0.0 value means no offset. Default is 0.0. The units are in degrees Celsius.

## 1.57 Group - Performance Curves

This group of objects primarily consists of polynomial curves that are used to characterize the performance of HVAC equipment. Several other non-polynomial curves are also included to characterize the performance of pumps and fans. All of the curves are input, stored, and evaluated entirely within the CurveManager module. The curves are usually derived from fits or regressions to data covering a limited range. Results for independent variable values outside this range are likely to be invalid, so curve input always contains a range of validity (maximum and minimum permitted values) for each independent variable and can optionally have limits on the curve output. No error or warning message is issued if an independent variable is outside the range. Instead, the curve manager uses the minimum value if an independent variable is less than the minimum, and the maximum if a variable exceeds the maximum. Similarly, no error or warning message is issued if the curve output is outside the range of the optional minimum and maximum curve output limits. Instead, the curve manager uses the minimum and maximum curve limits to cap the output of the performance curve.

Curve names must be unique across all curve types.

### 1.57.1 Curve:Linear

Input for the linear curve consists of a curve name, the two coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the linear curve is:

$$y = C_1 + C_2 * x \quad (1.255)$$

#### 1.57.1.1 Inputs

##### 1.57.1.1.1 Field: Name

A user assigned unique name for an instance of a linear curve. When a curve is used, it is referenced by this name.

##### 1.57.1.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

**1.57.1.1.3 Field: Coefficient2 x**

The linear coefficient ( $C_2$ ) in the equation.

**1.57.1.1.4 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.1.1.5 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.1.1.6 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.1.1.7 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.1.1.8 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Distance
- Power

**1.57.1.1.9 Field: Output Unit Type**

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

Following is an example input:

```
Curve:Linear,
  Curve-Linear, ! name
  -1, ! Coefficient1 Constant
  2, ! Coefficient2 x
  0.0, ! min curve output
  1.0; ! max curve output
```

---

The following is another example, as might be applied in the **Fan:ComponentModel** to characterize duct static pressure reset (using a constant duct static pressure set point of 248.84 Pa in this case):

```
Curve:Linear,
  DiagnosticSPR, ! Curve Name f = C1 + C2\*x
  248.84, ! Coefficient1 Constant [Pa]
  0., ! Coefficient 2 Press/Flow [Pa-s/m3]
  0., ! Minimum Value of x (Qfan) [m3/s]
  100., ! Maximum Value of x (Qfan) [m3/s]
  62.5, ! Minimum Curve Output [Pa]
  248.84; ! Maximum Curve Output [Pa]
```

---

## 1.57.2 Curve:QuadLinear

Input consists of the curve name, the five coefficients, and maximum and minimum values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is represented by this curve:

### 1.57.2.1 Inputs

$$1.57.2.1.1 \quad y = C1 + C2 * w + C3 * x + C4 * y + C5 * z$$

#### 1.57.2.1.2 Field: Name

A user assigned unique name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

#### 1.57.2.1.3 Field: Coefficient1 Constant

The constant coefficient (C1) in the equation.

#### 1.57.2.1.4 Field: Coefficient2 w

The coefficient (C2) in the equation.

#### 1.57.2.1.5 Field: Coefficient3 x

The coefficient (C3) in the equation.

#### 1.57.2.1.6 Field: Coefficient4 y

The coefficient (C4) in the equation.

#### 1.57.2.1.7 Field: Coefficient5 z

The coefficient (C5) in the equation.

#### 1.57.2.1.8 Field: Minimum Value of w

The minimum allowable value of w. Values of w less than the minimum will be replaced by the minimum.

**1.57.2.1.9 Field: Maximum Value of w**

The maximum allowable value of w. Values of w greater than the maximum will be replaced by the maximum.

**1.57.2.1.10 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.2.1.11 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.2.1.12 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

**1.57.2.1.13 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

**1.57.2.1.14 Field: Minimum Value of z**

The minimum allowable value of z. Values of z less than the minimum will be replaced by the minimum.

**1.57.2.1.15 Field: Maximum Value of z**

The maximum allowable value of z. Values of z greater than the maximum will be replaced by the maximum.

**1.57.2.1.16 Field: Input Unit Type for w**

This field is used to indicate the kind of units that may be associated with the w values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of w and Maximum Value of w. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance
- VolumetricFlowPerPower

**1.57.2.1.17 Field: Input Unit Type for x**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of x and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance
- VolumetricFlowPerPower

**1.57.2.1.18 Field: Input Unit Type for y**

This field is used to indicate the kind of units that may be associated with the y values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of y and Maximum Value of y. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance
- VolumetricFlowPerPower

**1.57.2.1.19 Field: Input Unit Type for z**

This field is used to indicate the kind of units that may be associated with the z values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of z and Maximum Value of z. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power

- Distance
- VolumetricFlowPerPower

### 1.57.3 Curve:QuintLinear

Input consists of the curve name, the six coefficients, and maximum and minimum values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is represented by this curve:

### 1.57.3.1 Inputs

**1.57.3.1.1**  $y = C1 + C2 * v + C3 * w + C4 * x + C5 * y + C6 * z$

#### 1.57.3.1.2 Field: Name

A user assigned unique name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

#### 1.57.3.1.3 Field: Coefficient1 Constant

The constant coefficient (C1) in the equation.

#### 1.57.3.1.4 Field: Coefficient2 v

The coefficient (C2) in the equation.

#### 1.57.3.1.5 Field: Coefficient3 w

The coefficient (C3) in the equation.

#### 1.57.3.1.6 Field: Coefficient4 x

The coefficient (C4) in the equation.

#### 1.57.3.1.7 Field: Coefficient5 y

The coefficient (C5) in the equation.

#### 1.57.3.1.8 Field: Coefficient6 z

The coefficient (C6) in the equation.

#### 1.57.3.1.9 Field: Minimum Value of v

The minimum allowable value of v. Values of v less than the minimum will be replaced by the minimum.

#### 1.57.3.1.10 Field: Maximum Value of v

The maximum allowable value of v. Values of v greater than the maximum will be replaced by the maximum.

#### 1.57.3.1.11 Field: Minimum Value of w

The minimum allowable value of w. Values of w less than the minimum will be replaced by the minimum.

#### 1.57.3.1.12 Field: Maximum Value of w

The maximum allowable value of w. Values of w greater than the maximum will be replaced by the maximum.

#### 1.57.3.1.13 Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

#### 1.57.3.1.14 Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.3.1.15 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

**1.57.3.1.16 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

**1.57.3.1.17 Field: Minimum Value of z**

The minimum allowable value of z. Values of z less than the minimum will be replaced by the minimum.

**1.57.3.1.18 Field: Maximum Value of z**

The maximum allowable value of z. Values of z greater than the maximum will be replaced by the maximum.

**1.57.3.1.19 Field: Input Unit Type for v**

This field is used to indicate the kind of units that may be associated with the v values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of v and Maximum Value of v. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance
- VolumetricFlowPerPower

**1.57.3.1.20 Field: Input Unit Type for w**

This field is used to indicate the kind of units that may be associated with the w values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of w and Maximum Value of w. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance
- VolumetricFlowPerPower

**1.57.3.1.21 Field: Input Unit Type for x**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of x and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance
- VolumetricFlowPerPower

**1.57.3.1.22 Field: Input Unit Type for y**

This field is used to indicate the kind of units that may be associated with the y values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of y and Maximum Value of y. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance
- VolumetricFlowPerPower

**1.57.3.1.23 Field: Input Unit Type for z**

This field is used to indicate the kind of units that may be associated with the z values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of z and Maximum Value of z. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power

- Distance
- VolumetricFlowPerPower

Below are an example inputs for QuintLinear Curves.

## 1.57.4 Curve:Quadratic

Input for a quadratic curve consists of the curve name, the three coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the quadratic curve is:

$$y = C_1 + C_2 * x + C_3 * x^2 \quad (1.256)$$

### 1.57.4.1 Inputs

#### 1.57.4.1.1 Field: Name

A user assigned unique name for an instance of a quadratic curve. When a curve is used, it is referenced by this name.

#### 1.57.4.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

#### 1.57.4.1.3 Field: Coefficient2 x

The linear coefficient ( $C_2$ ) in the equation.

#### 1.57.4.1.4 Field: Coefficient3 x\*\*2

The quadratic coefficient ( $C_3$ ) in the equation.

#### 1.57.4.1.5 Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.4.1.6 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.4.1.7 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.4.1.8 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.4.1.9 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Distance
- Power

**1.57.4.1.10 Field: Output Unit Type**

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

Following is an example input.

```
Curve:Quadratic,
  WindACCBFFFF, ! name
  -2.277,        ! Coefficient1 Constant
  5.2114,        ! Coefficient2 x
  -1.9344,       ! Coefficient3 x\*\*2
  0.0,          ! Minimum Value of x
  1.0;          ! Maximum Value of x
```

---

### 1.57.5 Curve:Cubic

Input for a cubic curve consists of the curve name, the 4 coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the cubic curve is:

$$y = C_1 + C_2 * x + C_3 * x^2 + C_4 * x^3 \quad (1.257)$$

#### 1.57.5.1 Inputs

##### 1.57.5.1.1 Field: Name

A user assigned unique name for an instance of a cubic curve. When a curve is used, it is referenced by this name.

##### 1.57.5.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

##### 1.57.5.1.3 Field: Coefficient2 x

The linear coefficient ( $C_2$ ) in the equation.

##### 1.57.5.1.4 Field: Coefficient3 x\*\*2

The quadratic coefficient ( $C_3$ ) in the equation.

##### 1.57.5.1.5 Field: Coefficient4 x\*\*3

The cubic coefficient ( $C_4$ ) in the equation.

##### 1.57.5.1.6 Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

##### 1.57.5.1.7 Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

##### 1.57.5.1.8 Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

##### 1.57.5.1.9 Field: Maximum Curve Output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

##### 1.57.5.1.10 Field: Input Unit Type for X

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless

- Temperature
- VolumetricFlow
- MassFlow
- Distance
- Power

#### 1.57.5.1.11 Field: Output Unit Type

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

Following is an input example.

```
Curve:Cubic,
  WindACEIRFPLF, ! name
  .00000273404, ! Coefficient1 Constant
  1.05259, ! Coefficient2 x
  -.0552087, ! Coefficient3 x**2
  .00262236, ! Coefficient4
  0.0, ! min
  1.1; ! max
```

### 1.57.6 Curve:Quartic

Input for a Quartic (fourth order polynomial) curve consists of the curve name, the five coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the quartic curve is:

$$y = C_1 + C_2x + C_3x^2 + C_4x^3 + C_5x^4 \quad (1.258)$$

#### 1.57.6.1 Inputs

##### 1.57.6.1.1 Field: Name

A user assigned unique name for an instance of a Quartic curve. When a curve is used, it is referenced by this name.

##### 1.57.6.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

##### 1.57.6.1.3 Field: Coefficient2 x

The linear coefficient ( $C_2$ ) in the equation.

**1.57.6.1.4 Field: Coefficient3  $x^{**2}$** 

The quadratic coefficient ( $C_3$ ) in the equation.

**1.57.6.1.5 Field: Coefficient4  $x^{**3}$** 

The cubic coefficient ( $C_4$ ) in the equation.

**1.57.6.1.6 Field: Coefficient5  $x^{**4}$** 

The fourth-order coefficient ( $C_5$ ) in the equation.

**1.57.6.1.7 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.6.1.8 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.6.1.9 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.6.1.10 Field: Maximum Value of x**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.6.1.11 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Distance
- Power

**1.57.6.1.12 Field: Output Unit Type**

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity

- Power

Following is an input example.

```
Curve:Quartic,
BGSeries60,
5.5656,
4.7634,
-88.843,
192.68,
-611.41,
0.0,
0.2412;
!- y = -611.41x4 + 192.68x3 - 88.843x2 + 4.7634x + 5.5656
!- Constant
!- 1st coefficient
!- 2nd coefficient
!- 3rd coefficient
!- 4th coefficient
!- Min Phi Value
!- Max Phi Value
```

The following is another example, as might be applied in the **Fan:ComponentModel** to characterize belt maximum efficiency (using a medium efficiency belt in this case):

```
Curve:Quartic,
BeltMaxEffMedium,
-0.09504,
0.03415,
-0.008897,
0.001159,
-0.00006132,
-1.2,
6.2,
-4.6,
0.;
! Curve Name
! CoefficientC1
! CoefficientC2
! CoefficientC3
! CoefficientC4
! CoefficientC5
! Minimum Value of x
! Maximum Value of x
! Minimum Curve Output
! Maximum Curve Output
```

## 1.57.7 Curve:Exponent

Input for a exponent curve consists of the curve name, the 3 coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the exponent curve is:

$$y = C1 + C2 * x^{C3} \quad (1.259)$$

### 1.57.7.1 Inputs

#### 1.57.7.1.1 Field: Name

A user assigned unique name for an instance of an exponent curve. When a curve is used, it is referenced by this name.

#### 1.57.7.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

#### 1.57.7.1.3 Field: Coefficient2 Constant

The linear coefficient ( $C_2$ ) in the equation.

#### 1.57.7.1.4 Field: Coefficient3 Constant

The exponent coefficient ( $C_3$ ) in the equation.

#### 1.57.7.1.5 Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.7.1.6 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.7.1.7 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.7.1.8 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.7.1.9 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Distance
- Power

**1.57.7.1.10 Field: Output Unit Type**

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

Following is an input example.

```
Curve:Exponent,
!      Curve = C1 + C2\*x\*\*C3, x = fan speed ratio
FanPowerExponentCurve, !- Name
0.0,      !- Coefficient1 Constant
1.0,      !- Coefficient2 Constant
3.0,      !- Coefficient3 Constant
0.0,      !- Minimum Value of x
1.5,      !- Maximum Value of x
0.1,      !- Minimum Curve Output
1.5;      !- Maximum Curve Output
```

### 1.57.8 Curve:Bicubic

This curve type is a function of two independent variables. Input consists of the curve name, the ten coefficients, and the minimum and maximum values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the bicubic curve is:

$$z = C_1 + C_2 * x + C_3 * x^2 + C_4 * y + C_5 * y^2 + C_6 * xy + C_7 * x^3 + C_8 * y^3 + C_9 * x^2y + C_{10} * xy^2 \quad (1.260)$$

#### 1.57.8.1 Inputs

##### 1.57.8.1.1 Field: Name

A user assigned unique name for an instance of a bicubic curve. When a curve is used by another object, it is referenced by this name.

##### 1.57.8.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

##### 1.57.8.1.3 Field: Coefficient2 x

The coefficient  $C_2$  in the equation.

##### 1.57.8.1.4 Field: Coefficient3 x\*\*2

The coefficient  $C_3$  in the equation.

##### 1.57.8.1.5 Field: Coefficient4 y

The coefficient  $C_4$  in the equation.

##### 1.57.8.1.6 Field: Coefficient5 y\*\*2

The coefficient  $C_5$  in the equation.

##### 1.57.8.1.7 Field: Coefficient6 x\*y

The coefficient  $C_6$  in the equation.

##### 1.57.8.1.8 Field: Coefficient7 x\*\*3

The coefficient  $C_7$  in the equation.

##### 1.57.8.1.9 Field: Coefficient8 y\*\*3

The coefficient  $C_8$  in the equation.

##### 1.57.8.1.10 Field: Coefficient9 x\*\*2\*y

The coefficient  $C_9$  in the equation.

##### 1.57.8.1.11 Field: Coefficient10 x\*y\*\*2

The coefficient  $C_{10}$  in the equation.

##### 1.57.8.1.12 Field: Minimum Value of x

The minimum allowable value of x. Values of x less than this minimum will be replaced by the minimum.

**1.57.8.1.13 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than this maximum will be replaced by the maximum.

**1.57.8.1.14 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than this minimum will be replaced by the minimum.

**1.57.8.1.15 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than this maximum will be replaced by the maximum.

**1.57.8.1.16 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.8.1.17 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.8.1.18 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

**1.57.8.1.19 Field: Input Unit Type for Y**

This field is used to indicate the kind of units that may be associated with the y values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of Y and Maximum Value of Y. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

### 1.57.8.1.20 Field: Output Unit Type

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

Below is an example input.

```
Curve:Bicubic,
Main Chiller EIRFPLR,      !- Name
7.086284E-02,              !- Coefficient1 Constant
2.787561E-03,              !- Coefficient2 x
-8.917038E-06,             !- Coefficient3 x\*\*2

## 1.57.9 Curve:Biquadratic

This curve is a function of two independent variables. Input consists of the curve name, the six coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the biquadratic curve is:

$$z = C_1 + C_2 * x + C_3 * x^2 + C_4 * y + C_5 * y^2 + C_6 * xy \quad (1.261)$$

### 1.57.9.1 Inputs

#### 1.57.9.1.1 Field: Name

A user assigned unique name for an instance of a biquadratic curve. When a curve is used, it is referenced by this name.

#### 1.57.9.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

#### 1.57.9.1.3 Field: Coefficient2 x

The coefficient  $C_2$  in the equation.

#### 1.57.9.1.4 Field: Coefficient3 x\*\*2

The coefficient  $C_3$  in the equation.

**1.57.9.1.5 Field: Coefficient4 y**

The coefficient  $C_4$  in the equation.

**1.57.9.1.6 Field: Coefficient5 y\*\*2**

The coefficient  $C_5$  in the equation.

**1.57.9.1.7 Field: Coefficient6 x\*y**

The coefficient  $C_6$  in the equation.

**1.57.9.1.8 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.9.1.9 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.9.1.10 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

**1.57.9.1.11 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

**1.57.9.1.12 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.9.1.13 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.9.1.14 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

### 1.57.9.1.15 Field: Input Unit Type for Y

This field is used to indicate the kind of units that may be associated with the y values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of Y and Maximum Value of Y. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

### 1.57.9.1.16 Field: Output Unit Type

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

Below is an example input.

```

## 1.57.10 Curve:CubicLinear

This curve is a function of two independent variables. Input consists of the curve name, the six coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the cubic linear curve:

$$y = (C_1 + C_2 * x + C_3 * x^2 + C_4 * x^3) + (C_5 + C_6 * x) * y \quad (1.262)$$

**1.57.10.1 Inputs****1.57.10.1.1 Field: Name**

A user assigned unique name for an instance of a quadratic-linear curve. When a curve is used, it is referenced by this name.

**1.57.10.1.2 Field: Coefficient1 Constant**

The constant coefficient ( $C_1$ ) in the equation.

**1.57.10.1.3 Field: Coefficient2 x**

The coefficient  $C_2$  in the equation.

**1.57.10.1.4 Field: Coefficient3  $x^2$  The coefficient  $C_3$  in the equation.****1.57.10.1.5 Field: Coefficient4  $x^3$  The coefficient  $C_4$  in the equation.****1.57.10.1.6 Field: Coefficient5 y**

The coefficient  $C_5$  in the equation.

**1.57.10.1.7 Field: Coefficient6  $x*y$  The coefficient  $C_6$  in the equation.****1.57.10.1.8 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.10.1.9 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.10.1.10 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

**1.57.10.1.11 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

**1.57.10.1.12 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.10.1.13 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.10.1.14 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. The only option at this time is **Dimensionless**.

### 1.57.10.1.15 Field: Input Unit Type for Y

This field is used to indicate the kind of units that may be associated with the x values. The only option at this time is **Dimensionless**.

### 1.57.10.1.16 Field: Output Unit Type

This field is used to indicate the kind of units that may be associated with the output values. The only option at this time is **Dimensionless**.

An example input for the CubicLinear equation form is shown below.

```

## 1.57.11 Curve:ChillerPartLoadWithLift

A custom chiller part-load performance curve is a function of three independent variables, i.e., x, y, and z. Input consists of the curve name, the twelve coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve.

The equation represented by the custom curve is:

$$C_1 + C_2 \cdot x + C_3 \cdot x^2 + C_4 \cdot y + C_5 \cdot y^2 + C_6 \cdot x \cdot y + C_7 \cdot x^3 + C_8 \cdot y^3 + C_9 \cdot x^2 \cdot y + C_{10} \cdot x \cdot y^2 + C_{11} \cdot x^2 \cdot y^2 + C_{12} \cdot z \cdot y^3 \quad (1.263)$$

where,

- x represents the normalized fractional lift (the delta of temperature across the leaving condenser water temperature and leaving evaporator water temperature of a chiller).
- y represents the normalized deviation of leaving chilled water temperature from the reference condition.
- z represents the part load ratio.

### 1.57.11.1 Field: Name

A user assigned unique name for an instance of a biquadratic curve. When a curve is used, it is referenced by this name.

### 1.57.11.2 Field: Coefficient1

The constant coefficient (C1) in the equation.

**1.57.11.3 Field: Coefficient2**

The coefficient C2 in the equation.

**1.57.11.4 Field: Coefficient3**

The coefficient C3 in the equation.

**1.57.11.5 Field: Coefficient4**

The coefficient C4 in the equation.

**1.57.11.6 Field: Coefficient5**

The coefficient C5 in the equation.

**1.57.11.7 Field: Coefficient6**

The coefficient C6 in the equation.

**1.57.11.8 Field: Coefficient7**

The constant coefficient (C7) in the equation.

**1.57.11.9 Field: Coefficient8**

The coefficient C8 in the equation.

**1.57.11.10 Field: Coefficient9**

The coefficient C9 in the equation.

**1.57.11.11 Field: Coefficient10**

The coefficient C10 in the equation.

**1.57.11.12 Field: Coefficient11**

The coefficient C11 in the equation.

**1.57.11.13 Field: Coefficient12**

The coefficient C12 in the equation.

**1.57.11.14 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.11.15 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.11.16 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

**1.57.11.17 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

**1.57.11.18 Field: Minimum Value of z**

The minimum allowable value of z. Values of y less than the minimum will be replaced by the minimum.

**1.57.11.19 Field: Maximum Value of z**

The maximum allowable value of z. Values of y greater than the maximum will be replaced by the maximum.

**1.57.11.20 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.11.21 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.11.22 Field: Input Unit Type for x**

This field is used to indicate the kind of units that may be associated with the x values. Select Dimensionless.

**1.57.11.23 Field: Input Unit Type for y**

This field is used to indicate the kind of units that may be associated with the y values. Select Dimensionless.

**1.57.11.24 Field: Input Unit Type for z**

This field is used to indicate the kind of units that may be associated with the y values. Select Dimensionless.

**1.57.11.25 Field: Output Unit Type**

This field is used to indicate the kind of units that may be associated with the output values. Select Dimensionless.

Below is an example input:

### 1.57.12 Curve:QuadraticLinear

This curve is a function of two independent variables. Input consists of the curve name, the six coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the quadratic linear curve:

$$z = (C_1 + C_2 * x + C_3 * x^2) + (C_4 + C_5 * x + C_6 * x^2) * y \quad (1.264)$$

#### 1.57.12.1 Inputs

##### 1.57.12.1.1 Field: Name

A user assigned unique name for an instance of a quadratic-linear curve. When a curve is used, it is referenced by this name.

##### 1.57.12.1.2 Field: Coefficient1 Constant

The constant coefficient ( $C_1$ ) in the equation.

##### 1.57.12.1.3 Field: Coefficient2 x

The coefficient  $C_2$  in the equation.

##### 1.57.12.1.4 Field: Coefficient3 x\*\*2

The coefficient  $C_3$  in the equation.

##### 1.57.12.1.5 Field: Coefficient4 y

The coefficient  $C_4$  in the equation.

##### 1.57.12.1.6 Field: Coefficient5 x\*y

The coefficient  $C_5$  in the equation.

**1.57.12.1.7 Field: Coefficient6  $x^{**2}*y$** 

The coefficient  $C_6$  in the equation.

**1.57.12.1.8 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.12.1.9 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.12.1.10 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

**1.57.12.1.11 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

**1.57.12.1.12 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.12.1.13 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.12.1.14 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

**1.57.12.1.15 Field: Input Unit Type for Y**

This field is used to indicate the kind of units that may be associated with the y values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of Y and Maximum Value of Y. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless

- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

#### 1.57.12.1.16 Field: Output Unit Type

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

Below is an example input.

### 1.57.13 Curve:Triquadratic

This curve is a  $2^{nd}$  order polynomial function of three variable polynomial independent variables. Input consists of the curve name, the twenty seven coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the triquadratic curve:

$$\begin{aligned}
 CurveValue = & A_0 + A_1 * x^2 + A_2 * x + A_3 * y^2 + A_4 * y + A_5 * z^2 + A_6 * z + A_7 * x^2y^2 + A_8 * xy + \\
 & A_9 * xy^2 + A_{10} * x^2y + A_{11} * x^2z^2 + A_{12} * xz + A_{13} * xz^2 + A_{14} * x^2z + A_{15} * y^2z^2 + \\
 & A_{16} * yz + A_{17} * yz^2 + A_{18} * y^2z + A_{19} * x^2y^2z^2 + A_{20} * x^2y^2z + A_{21}x^2yz^2 + A_{22}xy^2z^2 + \\
 & A_{23}x^2yz + A_{24}xy^2z + A_{25}xyz^2 + A_{26}xyz
 \end{aligned}
 \tag{1.265}$$

#### 1.57.13.1 Inputs

##### 1.57.13.1.1 Field: Coefficient1 Constant

The constant coefficient ( $A_0$ ) in the equation.

**1.57.13.1.2 Field: Coefficient2  $x^{**2}$** 

The coefficient ( $A_1$ ) in the equation.

**1.57.13.1.3 Field: Coefficient3  $x$** 

The coefficient ( $A_2$ ) in the equation.

**1.57.13.1.4 Field: Coefficient4  $y^{**2}$** 

The coefficient ( $A_3$ ) in the equation.

**1.57.13.1.5 Field: Coefficient5  $y$** 

The coefficient ( $A_4$ ) in the equation.

**1.57.13.1.6 Field: Coefficient6  $z^{**2}$** 

The coefficient ( $A_5$ ) in the equation.

**1.57.13.1.7 Field: Coefficient7  $z$** 

The coefficient ( $A_6$ ) in the equation.

**1.57.13.1.8 Field: Coefficient8  $x^{**2}*y^{**2}$** 

The coefficient ( $A_7$ ) in the equation.

**1.57.13.1.9 Field: Coefficient9  $x*y$** 

The coefficient ( $A_8$ ) in the equation.

**1.57.13.1.10 Field: Coefficient10  $x*y^{**2}$** 

The coefficient ( $A_9$ ) in the equation.

**1.57.13.1.11 Field: Coefficient11  $x^{**2}*y$** 

The coefficient ( $A_{10}$ ) in the equation.

**1.57.13.1.12 Field: Coefficient12  $x^{**2}*z^{**2}$** 

The coefficient ( $A_{11}$ ) in the equation.

**1.57.13.1.13 Field: Coefficient13  $x*z$** 

The coefficient ( $A_{12}$ ) in the equation.

**1.57.13.1.14 Field: Coefficient14  $x*z^{**2}$** 

The coefficient ( $A_{13}$ ) in the equation.

**1.57.13.1.15 Field: Coefficient15  $x^{**2}*z$** 

The coefficient ( $A_{14}$ ) in the equation.

**1.57.13.1.16 Field: Coefficient16  $y^{**2}*z^{**2}$** 

The coefficient ( $A_{15}$ ) in the equation.

**1.57.13.1.17 Field: Coefficient17  $y*z$** 

The coefficient ( $A_{16}$ ) in the equation.

**1.57.13.1.18 Field: Coefficient18  $y*z^{**2}$** 

The coefficient ( $A_{17}$ ) in the equation.

**1.57.13.1.19 Field: Coefficient19  $y^{**2}*z$** 

The coefficient ( $A_{18}$ ) in the equation.

**1.57.13.1.20 Field: Coefficient20  $x^{**2}*y^{**2}*z^{**2}$** 

The coefficient ( $A_{19}$ ) in the equation.

**1.57.13.1.21 Field: Coefficient21  $x^{**2}*y^{**2}*z$** 

The coefficient ( $A_{20}$ ) in the equation.

**1.57.13.1.22 Field: Coefficient22  $x^{**2}*y*z^{**2}$** 

The coefficient ( $A_{21}$ ) in the equation.

**1.57.13.1.23 Field: Coefficient23  $x*y^{**2}*z^{**2}$** 

The coefficient ( $A_{22}$ ) in the equation.

**1.57.13.1.24 Field: Coefficient24  $x^{**2}*y*z$** 

The coefficient ( $A_{23}$ ) in the equation.

**1.57.13.1.25 Field: Coefficient25  $x*y^{**2}*z$** 

The coefficient ( $A_{24}$ ) in the equation.

**1.57.13.1.26 Field: Coefficient26  $x*y*z^{**2}$** 

The coefficient ( $A_{25}$ ) in the equation.

**1.57.13.1.27 Field: Coefficient27  $x*y*z$** 

The coefficient ( $A_{26}$ ) in the equation.

**1.57.13.1.28 Field: Minimum Value of x**

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

**1.57.13.1.29 Field: Maximum Value of x**

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

**1.57.13.1.30 Field: Minimum Value of y**

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

**1.57.13.1.31 Field: Maximum Value of y**

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

**1.57.13.1.32 Field: Minimum Value of z**

The minimum allowable value of z. Values of z less than the minimum will be replaced by the minimum.

**1.57.13.1.33 Field: Maximum Value of z**

The maximum allowable value of z. Values of z greater than the maximum will be replaced by the maximum.

**1.57.13.1.34 Field: Minimum Curve Output**

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.13.1.35 Field: Maximum Curve Output**

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.13.1.36 Field: Input Unit Type for X**

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

**1.57.13.1.37 Field: Input Unit Type for Y**

This field is used to indicate the kind of units that may be associated with the y values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of Y and Maximum Value of Y. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

**1.57.13.1.38 Field: Input Unit Type for Z**

This field is used to indicate the kind of units that may be associated with the z values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of Z and Maximum Value of Z. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Power
- Distance

**1.57.13.1.39 Field: Output Unit Type**

This field is used to indicate the kind of units that may be associated with the output values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Curve Output and Maximum Curve Output. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Dimensionless
- Capacity
- Power

**1.57.14 Curve:Functional:PressureDrop**

Input for a pressure drop curve consists of the curve name, a varying number of parameters, and the maximum and minimum valid independent variable values. The equation represented by the pressure drop curve is:

$$\Delta P = \left( K + f \frac{L}{D} \right) \frac{\rho V^2}{2} \quad (1.266)$$

**1.57.14.1 Inputs****1.57.14.1.1 Field: Name**

A user assigned unique name for an instance of a pressure drop curve. When a curve is used, it is referenced by this name.

**1.57.14.1.2 Field: Diameter**

This diameter represents an equivalent diameter for the given branch. This is parameter (D) in the equation, and has units of {m}. Since varying components may be found on the same branch, this value must be selected along with the other inputs in order to provide a proper value of pressure drop. This is used to calculate the velocity in addition to being used directly in the frictional pressure drop calculation.

### 1.57.14.1.3 Field: Minor Loss Coefficient

This is the pressure drop coefficient typically applied to components such as fittings and occasionally heat pumps. This is parameter (K) in the equation and is dimensionless. This coefficient is used to describe the amount of dynamic pressure lost during the process. This value may be left blank if the user only wants to account for frictional losses in this branch.

### 1.57.14.1.4 Field: Length

This is the length of a pressure drop process in which friction is applied. This is parameter (L) in the equation and has units of {m}. In a pipe, this would be the length of the pipe, however in many cases, pressure drop in other components are applied as an equivalent length. This is only required if the user is wanting to perform frictional pressure drop calculations.

### 1.57.14.1.5 Field: Roughness

This field represents the first method to simulate frictional losses. This parameter does not appear directly in the equation above, as it is only used to develop the friction factor (f), but the roughness will have units of {m} if entered. If the user enters this roughness value, the pressure system will use it along with an approximation to the Moody chart to estimate the friction factor given the current flow conditions. This allows the friction calculate to be dynamic throughout the simulation.

### 1.57.14.1.6 Field: Fixed Friction Factor

This field represents the second method to simulate frictional losses. This is parameter (f) in the equation and is dimensionless. This parameter is a fixed value of friction factor which would override any calculations performed based on roughness, etc. If the user has a known friction factor for a given component, this is where it should be entered.

In the curve outputs for this object:

- Curve Input 1: MassFlow
- Curve Input 2: Density
- Curve Input 3: Velocity
- Curve Output: the resultant value

Following is an input example.

```
Curve:Functional:PressureDrop,
  PressureMinorAndFriction,!- Name
  0.05,                      !- Diameter
  53.8,                      !- Minor Loss Coefficient
  200,                      !- Length
  ,                          !- Roughness
  0.008;                    !- Fixed Friction Factor
```

## 1.57.15 Curve:FanPressureRise

Input for the fan total pressure rise curve consists of the curve name, the four coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is:

$$\Delta P_{fan,tot} = C_1 * Q_{fan}^2 + C_2 * Q_{fan} + C_3 * Q_{fan} * \sqrt{P_{sm} - P_o} + C_4 * (P_{sm} - P_o) \quad (1.267)$$

where  $\Delta P_{fan,tot}$  is the fan total pressure rise (Pa) as a function of volumetric flow through the fan ( $Q_{fan}, m^3/s$ ), duct static pressure set point ( $P_{sm}$ , Pa), and static pressure surrounding the ducts ( $P_o$ , Pa).  $P_o$  is assumed to be zero.

The first term of the curve looks like the common system curve in which the fan pressure rise is proportional to the square of the fan flow, but here it also depends implicitly on supply and return pressure losses, and in part on the fraction of the fan flow that is outdoor air (essentially “leaks” into and out of the return side of the system). Very often it is the only term considered, but that would only be correct with fixed-position dampers, no distribution system leakage, no linear resistance components, and no duct static pressure control.

The second term accounts for significant flow resistances in the system where the pressure difference is linearly proportional to the flow. Some filters and coils in the return may need this term to be adequately described. This term could be ignored if there are no linear components or if their pressure drops are very small compared to the other terms.

The third term, which depends on the fan flow and square root of the supply duct pressure  $P_{sm}$ , accounts in part for leakage from the supply system when damper positions are fixed or are changed independently of static pressure or fan flow. In this case, reducing or eliminating supply leakage results in a different system curve. This, however, might be only a minor correction to the simple system curves generally used. The third term is zero when the VAV box dampers are modulated to control flow. Consequently, with variable-position supply dampers, reducing or eliminating supply leakage does not change the system curve.

The last term also accounts in part for leakage from the supply system when damper positions are fixed or are changed independently of static pressure or fan flow. This term indicates that the same fan pressure rise can be achieved by raising the duct pressure and closing dampers. The only change in the system in such a case is that the leakage flow may increase. The coefficient for this term is one when the VAV box dampers are modulated to control flow. In both cases, this term may be the most important correction to the simple system curves generally used, especially at low flows.

### 1.57.15.1 Inputs

#### 1.57.15.1.1 Field: Name

The required user-assigned unique alpha name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

#### 1.57.15.1.2 Field: Fan Pressure Rise Coefficient1 C1

The required numeric constant coefficient  $C_1$  ( $\text{Pa s}^2/\text{m}^6$ ) in the curve. Must be greater than zero.

#### 1.57.15.1.3 Field: Fan Pressure Rise Coefficient2 C2

The required numeric constant coefficient  $C_2$  ( $\text{Pa s}/\text{m}^3$ ) in the curve.

#### 1.57.15.1.4 Field: Fan Pressure Rise Coefficient3 C3

The required numeric constant coefficient  $C_3$  ( $\text{Pa}^{0.5} \text{ s}/\text{m}^3$ ) in the curve.

#### 1.57.15.1.5 Field: Fan Pressure Rise Coefficient4 C4

The required numeric constant coefficient  $C_4$  (dimensionless) in the curve.

#### 1.57.15.1.6 Field: Minimum Value of Qfan

The required numeric minimum allowable value of  $Q_{fan}$  ( $\text{m}^3/\text{s}$ ). Values of  $Q_{fan}$  less than the minimum will be replaced within this curve by the minimum.

**1.57.15.1.7 Field: Maximum Value of Qfan**

The required numeric maximum allowable value of  $Q_{fan}$  (m<sup>3</sup>/s). Values of  $Q_{fan}$  greater than the maximum will be replaced within this curve by the maximum.

**1.57.15.1.8 Field: Minimum Value of Psm**

The required numeric minimum allowable value of  $P_{sm}$  (Pa). Values of  $P_{sm}$  less than the minimum will be replaced within this curve by the minimum.

**1.57.15.1.9 Field: Maximum Value of Psm**

The required numeric maximum allowable value of  $P_{sm}$  (Pa). Values of  $P_{sm}$  greater than the maximum will be replaced within this curve by the maximum.

**1.57.15.1.10 Field: Minimum Curve Output**

The optional numeric minimum allowable value of the evaluated curve (Pa). Values less than the minimum will be replaced within this curve by the minimum.

**1.57.15.1.11 Field: Maximum Curve Output**

The optional numeric maximum allowable value of the evaluated curve (Pa). Values greater than the maximum will be replaced within this curve by the maximum.

The following is an input example describing the fan total pressure rise for a VAV system with a constant non-zero duct static pressure set point (the set point is described separately; see the [Curve:Linear](#) object for a related example):

```
Curve:FanPressureRise,
  VSD Example,           ! Curve Name f = C1*Qfan**2+C2*Qfan+C3*Qfan*(Psm-Po)**0.5+C4*(Psm-Po)
    with Po = 0
  1446.75833497653,      ! CoefficientC1 Alpha [Pa s2/m6]
    0.,                  ! CoefficientC2 Beta [Pa s/m3]
    0.,                  ! CoefficientC3 Gamma [Pa0.5 s/m3]
    1.,                  ! CoefficientC4 Delta [-]
    0.,                  ! Minimum Value of Qfan [m3/s]
    100.,                ! Maximum Value of Qfan [m3/s]
    62.5,                ! Minimum Value of Psm [Pa]
    300.,                ! Maximum Value of Psm [Pa]
    0.;                  ! Minimum Curve Output [Pa]
  5000.;                 ! Maximum Curve Output [Pa]
```

**1.57.16 Curve:ExponentialSkewNormal**

Input for the exponential-modified skew normal curve consists of the curve name, the four coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is:

$$y = \frac{e^{(-0.5 \cdot Z_1^2)} [1 + \frac{Z_2}{|Z_2|} \cdot \operatorname{erf} \left( \frac{|Z_2|}{\sqrt{2}} \right)]}{e^{(-0.5 \cdot Z_3^2)} [1 + \frac{Z_3}{|Z_3|} \cdot \operatorname{erf} \left( \frac{|Z_3|}{\sqrt{2}} \right)]} \quad (1.268)$$

where:

$$Z_1 = \frac{x - C_1}{C_2}$$

$$Z_2 = \frac{e^{C_3 \cdot x} \cdot C_4 \cdot x - C_1}{C_2}$$

$$Z_3 = -\frac{C_1}{C_2}$$

### 1.57.16.1 Inputs

#### 1.57.16.1.1 Field: Name

The required user-assigned unique alpha name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

#### 1.57.16.1.2 Field: Coefficient1 C1

The required numeric constant coefficient  $C_1$  in the curve.

#### 1.57.16.1.3 Field: Coefficient2 C2

The required numeric constant coefficient  $C_2$  in the curve. Must be non-zero.

#### 1.57.16.1.4 Field: Coefficient3 C3

The required numeric constant coefficient  $C_3$  in the curve.

#### 1.57.16.1.5 Field: Coefficient4 C4

The required numeric constant coefficient  $C_4$  in the curve.

#### 1.57.16.1.6 Field: Minimum Value of x

The required numeric minimum allowable value of  $x$ . Values of  $x$  less than the minimum will be replaced by the minimum.

#### 1.57.16.1.7 Field: Maximum Value of x

The required numeric maximum allowable value of  $x$ . Values of  $x$  greater than the maximum will be replaced by the maximum.

#### 1.57.16.1.8 Field: Minimum Curve Output

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

#### 1.57.16.1.9 Field: Maximum Curve Output

The optional numeric maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

#### 1.57.16.1.10 Field: Input Unit Type for x

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Value of  $x$  and Maximum Value of  $x$  (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

### 1.57.16.1.11 Field: Output Unit Type

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Curve Output and Maximum Curve Output (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

The following are input examples describing the normalized fan efficiency for the normal (non-stall) and stall operating regions of a backward-curved airfoil centrifugal fan:

```
Curve:ExponentialSkewNormal,
FanEff120CPLANormal,          ! Curve Name
0.072613,                     ! CoefficientC1 Afan

1.844950,                     ! CoefficientC4 Dfan
-4.,                           ! Minimum Value of x
5.,                            ! Maximum Value of x
0.1,                           ! Minimum Curve Output
1.;                            ! Maximum Curve Output
```

## 1.57.17 Curve:Sigmoid

Input for the sigmoid curve consists of the curve name, the five coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is:

$$y = C_1 + \frac{C_2}{\left( (1 + e^{\left[ \frac{(C_3 - x)}{C_4} \right]})^{C_5} \right)} \quad (1.269)$$

### 1.57.17.1 Inputs

#### 1.57.17.1.1 Field: Name

The required user-assigned unique alpha name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

#### 1.57.17.1.2 Field: Coefficient1 C1

The required numeric constant coefficient  $C_1$  in the equation.

#### 1.57.17.1.3 Field: Coefficient2 C2

The required numeric constant coefficient  $C_2$  in the equation.

#### 1.57.17.1.4 Field: Coefficient3 C3

The required numeric constant coefficient  $C_3$  in the equation.

**1.57.17.1.5 Field: Coefficient4 C4**

The required numeric constant coefficient  $C_4$  in the equation.

**1.57.17.1.6 Field: Coefficient5 C5**

The required numeric constant coefficient  $C_5$  in the equation.

**1.57.17.1.7 Field: Minimum Value of x**

The required numeric minimum allowable value of  $x$ . Values of  $x$  less than the minimum will be replaced by the minimum.

**1.57.17.1.8 Field: Maximum Value of x**

The required numeric maximum allowable value of  $x$ . Values of  $x$  greater than the maximum will be replaced by the maximum.

**1.57.17.1.9 Field: Minimum Curve Output**

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

**1.57.17.1.10 Field: Maximum Curve Output**

The optional numeric maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

**1.57.17.1.11 Field: Input Unit Type for x**

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Value of  $x$  and Maximum Value of  $x$  (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

**1.57.17.1.12 Field: Output Unit Type**

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Curve Output and Maximum Curve Output (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

The following are input examples describing the normalized dimensionless flow for normal (non-stall) and stall operating regions of a backward-curved airfoil centrifugal fan:

1.57.18 Curve:RectangularHyperbola1

Input for the single rectangular hyperbola type 1 curve consists of the curve name, the three coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is:

$$y = (C_1 * x) / (C_2 + x) + C_3$$

1.57.18.1 Inputs

1.57.18.1.1 Field: Name

The required user-assigned unique alpha name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

1.57.18.1.2 Field: Coefficient1 C1

The required numeric constant coefficient  $C_1$  in the equation.

1.57.18.1.3 Field: Coefficient2 C2

The required numeric constant coefficient  $C_2$  in the equation.

1.57.18.1.4 Field: Coefficient3 C3

The required numeric constant coefficient  $C_3$  in the equation.

1.57.18.1.5 Field: Minimum Value of x

The required numeric minimum allowable value of  $x$ . Values of  $x$  less than the minimum will be replaced by the minimum.

1.57.18.1.6 Field: Maximum Value of x

The required numeric maximum allowable value of  $x$ . Values of  $x$  greater than the maximum will be replaced by the maximum.

1.57.18.1.7 Field: Minimum Curve Output

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

1.57.18.1.8 Field: Maximum Curve Output

The optional numeric maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

1.57.18.1.9 Field: Input Unit Type for x

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Value of  $x$  and Maximum Value of  $x$  (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

### 1.57.18.1.10 Field: Output Unit Type

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Curve Output and Maximum Curve Output (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

The following is an input example describing the maximum efficiency variation for a mid- or average-efficiency type of motor:

```
Curve:RectangularHyperbola1,
MotorMaxEffAvg,           ! Curve Name
0.29228,                  ! CoefficientC1
3.368739,                 ! CoefficientC2
0.762471,                 ! CoefficientC3
0.,                       ! Minimum Value of x
7.6,                     ! Maximum Value of x
0.01,                    ! Minimum Curve Output
1.;                      ! Maximum Curve Output
```

---

## 1.57.19 Curve:RectangularHyperbola2

Input for the single rectangular hyperbola type 2 curve consists of the curve name, the three coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is:

$$y = (C_1 * x) / (C_2 + x) + C_3 * x$$

### 1.57.19.1 Inputs

#### 1.57.19.1.1 Field: Name

The required user-assigned unique alpha name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

#### 1.57.19.1.2 Field: Coefficient1 C1

The required numeric constant coefficient  $C_1$  in the equation.

#### 1.57.19.1.3 Field: Coefficient2 C2

The required numeric constant coefficient  $C_2$  in the equation.

#### 1.57.19.1.4 Field: Coefficient3 C3

The required numeric constant coefficient  $C_3$  in the equation.

#### 1.57.19.1.5 Field: Minimum Value of x

The required numeric minimum allowable value of  $x$ . Values of  $x$  less than the minimum will be replaced by the minimum.

#### 1.57.19.1.6 Field: Maximum Value of x

The required numeric maximum allowable value of  $x$ . Values of  $x$  greater than the maximum will be replaced by the maximum.

#### 1.57.19.1.7 Field: Minimum Curve Output

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

## 1.57.20 Curve:ExponentialDecay

Input for the exponential decay curve consists of the curve name, the three coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is:

$$y = C_1 + C_2 \cdot e^{C_3 x} \quad (1.270)$$

### 1.57.20.1 Inputs

#### 1.57.20.1.1 Field: Name

The required user-assigned unique alpha name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

#### 1.57.20.1.2 Field: Coefficient1 C1

The required numeric constant coefficient  $C_1$  in the equation.

#### 1.57.20.1.3 Field: Coefficient2 C2

The required numeric constant coefficient  $C_2$  in the equation.

#### 1.57.20.1.4 Field: Coefficient3 C3

The required numeric constant coefficient  $C_3$  in the equation.

#### 1.57.20.1.5 Field: Minimum Value of x

The required numeric minimum allowable value of  $x$ . Values of  $x$  less than the minimum will be replaced by the minimum.

#### 1.57.20.1.6 Field: Maximum Value of x

The required numeric maximum allowable value of  $x$ . Values of  $x$  greater than the maximum will be replaced by the maximum.

#### 1.57.20.1.7 Field: Minimum Curve Output

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

#### 1.57.20.1.8 Field: Maximum Curve Output

The optional numeric maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

#### 1.57.20.1.9 Field: Input Unit Type for x

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Value of  $x$  and Maximum Value of  $x$  (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

### 1.57.20.1.10 Field: Output Unit Type

This optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum Curve Output and Maximum Curve Output (currently dimensionless). At this time, only the **Dimensionless** option is provided so that no unit conversion is used for this curve.

The following is an input example describing the part-load efficiency variation for a medium efficiency type of V-belt (Region 2):

```
Curve:ExponentialDecay,
  BeltPartLoadRegion2,          ! Curve Name
  1.011965,                     ! CoefficientC1

---

### 1.57.21 Curve:DoubleExponentialDecay

Input for the double exponential decay curve consists of the curve name, the five coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve include the minimum and maximum output of the performance curve. The equation is:

$$y = C_1 + C_2 \exp(C_3 x) + C_4 \exp(C_5 x) \quad (1.271)$$

#### 1.57.21.1 Inputs

##### 1.57.21.1.1 Field: Name

This field indicates the required user-assigned name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

##### 1.57.21.1.2 Field: Coefficient1 C1

The required numeric constant coefficient  $C_1$  in the equation.

##### 1.57.21.1.3 Field: Coefficient2 C2

The required numeric constant coefficient  $C_2$  in the equation.

##### 1.57.21.1.4 Field: Coefficient3 C3

The required numeric constant coefficient  $C_3$  in the equation.

##### 1.57.21.1.5 Field: Coefficient4 C4

The required numeric constant coefficient  $C_4$  in the equation.

##### 1.57.21.1.6 Field: Coefficient5 C5

The required numeric constant coefficient  $C_5$  in the equation.

##### 1.57.21.1.7 Field: Minimum Value of x

The required numeric minimum allowable value of  $x$ . Values of  $x$  less than the minimum will be replaced by the minimum

**1.57.21.1.8 Field: Maximum Value of x**

The required numeric maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum

**1.57.21.1.9 Field: Minimum Curve Output**

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum

**1.57.21.1.10 Field: Maximum Curve Output**

The optional numeric maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum

**1.57.21.1.11 Field: Input Unit Type for x**

The optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum and Maximum Value of x. Currently, only Dimensionless option is provided so that no unit conversion is used for this curve

**1.57.21.1.12 Field: Output Unit Type**

The optional field is provided for future purposes so that the IDF Editor could display the appropriate SI or IP units for the Minimum and Maximum Curve Output. Currently, only Dimensionless option is provided so that no unit conversion is used for this curve.

An example input of the Curve:DoubleExponentialDecay input is:

```
Curve:DoubleExponentialDecay,
  BatteryCycleCurve,      !- Name
  1380,                    !- Coefficient1 C1
  6834,                    !- Coefficient2 C2
  -8.75,                   !- Coefficient3 C3
  6747,                    !- Coefficient4 C4
  -6.22,                   !- Coefficient5 C5
  0,                      !- Minimum Value of x
  1.0;                     !- Maximum Value of x
```

**1.57.21.2 Outputs****1.57.21.2.1 Performance Curve Output Value**

The current value of the performance curve. This value is averaged over the time step being reported. Inactive or unused performance curves will show a value of -999 (e.g., equipment is off, a specific performance curve is not required for this aspect of the equipment model at this time step, etc.). This value means that the performance curve was not called during the simulation and, therefore, not evaluated. This inactive state value is only set at the beginning of each environment. When averaging over long periods of time, this inactive state value may skew results. In this case, use a detailed reporting frequency (ref. Output:Variable object) to view results at each HVAC time step.

**1.57.21.2.2 Performance Curve Input Variable 1(-N) Value []**

The current value of the nth independent variable passed to the performance curve. The order of the independent variables is in the same order as the model equation represented by this performance curve object. This value is averaged over the time step being reported.

HVAC,Average,Performance Curve Output Value []

HVAC,Average,Performance Curve Input Variable 1 Value []

HVAC,Average,Performance Curve Input Variable 2 Value []

HVAC,Average,Performance Curve Input Variable 3 Value []

## 1.58 Group Performance Tables

This group of objects consists of tabular data which are used to characterize the performance of HVAC equipment. The use of performance tables eliminate the need to perform a regression analysis to calculate the performance curve equation coefficients. The following descriptions define the input requirements for the performance table objects.

### 1.58.1 Table:Lookup

Input for tables representing data with one or more independent variables.

#### 1.58.1.1 Inputs

##### 1.58.1.1.1 Field: Name

A unique user-assigned name for an instance of a lookup table. When a table is used, it is referenced by this name. The name of this table object may be used anywhere a valid performance curve object is allowed.

##### 1.58.1.1.2 Field: Independent Variable List Name

The name of a Table:IndependentVariableList object that defines the independent variables that comprise the dimensions of the tabular data.

##### 1.58.1.1.3 Field: Normalization Method

Determines if and how this output will be normalized. Choices are:

1. *No*: Do not normalize output.
2. *DivisorOnly*: Normalize the output using only the value entered into the Normalization Divisor field, below.
3. *AutomaticWithDivisor*: Normalize the output by dividing the output data by the value of the table at each of the independent variable normalization reference values in the associated independent variable list AND dividing by the value entered into the Normalization Divisor field, below.

Normalization applies to the Output Value fields as well as the Minimum and Maximum Output fields.

##### 1.58.1.1.4 Field: Normalization Divisor

Defines a value by which output values are normalized if the Normalization Method field is set to *DivisorOnly* or *AutomaticWithDivisor*. Default is 1.0.

##### 1.58.1.1.5 Field: Minimum Output

The (non-normalized) minimum allowable value of the evaluated table after interpolation and extrapolation. Values less than the minimum will be replaced by the minimum. If this field is left blank, no limit is imposed.

**1.58.1.1.6 Field: Maximum Output**

The (non-normalized) maximum allowable value of the evaluated table after interpolation and extrapolation. Values greater than the maximum will be replaced by the maximum. If this field is left blank, no limit is imposed.

**1.58.1.1.7 Field: Output Unit Type**

This field is used to indicate the kind of units that may be associated with the output values. It is used by interfaces or input editors (e.g., IDF Editor) to display the appropriate SI and IP units for the Minimum Output and Maximum Output. If none of these options are appropriate, select *Dimensionless* which will have no unit conversion. Options are:

- *Dimensionless*
- *Capacity*
- *Power*

**1.58.1.1.8 Field: External File Name**

The name of an external CSV file that represents the tabular data. This file should be formatted such that the data for this particular output is ordered according to the order of the corresponding independent variables. For example, for three independent variables (iv1, iv2, iv3) with 3, 2, and 4 values respectively. The output values (out[iv1][iv2][iv3]) should be ordered as:

iv1	iv2	iv3	output
iv1[1]	iv2[1]	iv3[1]	out[1][1][1]
iv1[1]	iv2[1]	iv3[2]	out[1][1][2]
iv1[1]	iv2[1]	iv3[3]	out[1][1][3]
iv1[1]	iv2[1]	iv3[4]	out[1][1][4]
iv1[1]	iv2[2]	iv3[1]	out[1][2][1]
iv1[1]	iv2[2]	iv3[2]	out[1][2][2]
iv1[1]	iv2[2]	iv3[3]	out[1][2][3]
iv1[1]	iv2[2]	iv3[4]	out[1][2][4]
iv1[2]	iv2[1]	iv3[1]	out[2][1][1]
iv1[2]	iv2[1]	iv3[2]	out[2][1][2]
iv1[2]	iv2[1]	iv3[3]	out[2][1][3]
iv1[2]	iv2[1]	iv3[4]	out[2][1][4]
iv1[2]	iv2[2]	iv3[1]	out[2][2][1]
iv1[2]	iv2[2]	iv3[2]	out[2][2][2]
iv1[2]	iv2[2]	iv3[3]	out[2][2][3]
iv1[2]	iv2[2]	iv3[4]	out[2][2][4]
iv1[3]	iv2[1]	iv3[1]	out[3][1][1]
iv1[3]	iv2[1]	iv3[2]	out[3][1][2]
iv1[3]	iv2[1]	iv3[3]	out[3][1][3]
iv1[3]	iv2[1]	iv3[4]	out[3][1][4]
iv1[3]	iv2[2]	iv3[1]	out[3][2][1]
iv1[3]	iv2[2]	iv3[2]	out[3][2][2]

iv1	iv2	iv3	output
iv1[3]	iv2[2]	iv3[3]	out[3][2][3]
iv1[3]	iv2[2]	iv3[4]	out[3][2][4]

Alternatively, the output may be defined using the *Output Value*  $\langle x \rangle$  fields below.

#### 1.58.1.1.9 Field: External File Column Number

The column number (starting at 1) in the CSV file corresponding to this output.

#### 1.58.1.1.10 Field: External File Starting Row Number

The row number (starting at 1) in the CSV file where the data for this output begins. If there are not enough rows of data to fill out the full grid of data an error will be presented to the user.

#### 1.58.1.1.11 Output Value $\langle x \rangle$

If not reading from an external file, this field is repeated to capture the full set of output data in the table (if not otherwise defined in an external file). The data for this particular output is ordered according to the order of the corresponding independent variables. For example, for three independent variables (iv1, iv2, iv3) with 3, 2, and 4 values respectively. The output values (out[iv1][iv2][iv3]) should be ordered as:

iv1	iv2	iv3	output
iv1[1]	iv2[1]	iv3[1]	out[1][1][1]
iv1[1]	iv2[1]	iv3[2]	out[1][1][2]
iv1[1]	iv2[1]	iv3[3]	out[1][1][3]
iv1[1]	iv2[1]	iv3[4]	out[1][1][4]
iv1[1]	iv2[2]	iv3[1]	out[1][2][1]
iv1[1]	iv2[2]	iv3[2]	out[1][2][2]
iv1[1]	iv2[2]	iv3[3]	out[1][2][3]
iv1[1]	iv2[2]	iv3[4]	out[1][2][4]
iv1[2]	iv2[1]	iv3[1]	out[2][1][1]
iv1[2]	iv2[1]	iv3[2]	out[2][1][2]
iv1[2]	iv2[1]	iv3[3]	out[2][1][3]
iv1[2]	iv2[1]	iv3[4]	out[2][1][4]
iv1[2]	iv2[2]	iv3[1]	out[2][2][1]
iv1[2]	iv2[2]	iv3[2]	out[2][2][2]
iv1[2]	iv2[2]	iv3[3]	out[2][2][3]
iv1[2]	iv2[2]	iv3[4]	out[2][2][4]
iv1[3]	iv2[1]	iv3[1]	out[3][1][1]
iv1[3]	iv2[1]	iv3[2]	out[3][1][2]
iv1[3]	iv2[1]	iv3[3]	out[3][1][3]
iv1[3]	iv2[1]	iv3[4]	out[3][1][4]
iv1[3]	iv2[2]	iv3[1]	out[3][2][1]

iv1	iv2	iv3	output
iv1[3]	iv2[2]	iv3[2]	out[3][2][2]
iv1[3]	iv2[2]	iv3[3]	out[3][2][3]
iv1[3]	iv2[2]	iv3[4]	out[3][2][4]

### 1.58.1.2 Example IDF

```

Table:Lookup,

```

### 1.58.1.3 Outputs

#### 1.58.1.3.1 Performance Curve Output Value []

The current value of the performance table. Performance curves and tables use the same output variable. This value is averaged over the time step being reported. Inactive or unused performance curves will show a value of -999 (e.g., equipment is off, a specific performance curve is not required for this aspect of the equipment model at this time step, etc.). This value means that the performance curve was not called during the simulation and, therefore, not evaluated. This inactive state value is only set at the beginning of each environment. When averaging over long periods of time, this inactive state value may skew results. In this case, use a detailed reporting frequency (ref. Output:Variable object) to view results at each HVAC time step.

#### 1.58.1.3.2 Performance Curve Input Variable <x> Value []

### 1.58.2 Table:IndependentVariableList

A list of Table:IndependentVariable references that define the size and dimensions of the data for one or more Table:Lookup objects. The order of this list defines the order that the tabular data must be defined. The output values in the Table:Lookup associated with this list will list the output in an order cycling through the last item in the list first, and then the second to last, and so on with the the first item cycling last. For example, for three independent variables (iv1, iv2, iv3) with 3, 2, and 4 values respectively. The output values (out[iv1][iv2][iv3]) should be ordered as:

iv1	iv2	iv3	output
iv1[1]	iv2[1]	iv3[1]	out[1][1][1]
iv1[1]	iv2[1]	iv3[2]	out[1][1][2]
iv1[1]	iv2[1]	iv3[3]	out[1][1][3]

iv1	iv2	iv3	output
iv1[1]	iv2[1]	iv3[4]	out[1][1][4]
iv1[1]	iv2[2]	iv3[1]	out[1][2][1]
iv1[1]	iv2[2]	iv3[2]	out[1][2][2]
iv1[1]	iv2[2]	iv3[3]	out[1][2][3]
iv1[1]	iv2[2]	iv3[4]	out[1][2][4]
iv1[2]	iv2[1]	iv3[1]	out[2][1][1]
iv1[2]	iv2[1]	iv3[2]	out[2][1][2]
iv1[2]	iv2[1]	iv3[3]	out[2][1][3]
iv1[2]	iv2[1]	iv3[4]	out[2][1][4]
iv1[2]	iv2[2]	iv3[1]	out[2][2][1]
iv1[2]	iv2[2]	iv3[2]	out[2][2][2]
iv1[2]	iv2[2]	iv3[3]	out[2][2][3]
iv1[2]	iv2[2]	iv3[4]	out[2][2][4]
iv1[3]	iv2[1]	iv3[1]	out[3][1][1]
iv1[3]	iv2[1]	iv3[2]	out[3][1][2]
iv1[3]	iv2[1]	iv3[3]	out[3][1][3]
iv1[3]	iv2[1]	iv3[4]	out[3][1][4]
iv1[3]	iv2[2]	iv3[1]	out[3][2][1]
iv1[3]	iv2[2]	iv3[2]	out[3][2][2]
iv1[3]	iv2[2]	iv3[3]	out[3][2][3]
iv1[3]	iv2[2]	iv3[4]	out[3][2][4]

1.58.2.1 Inputs

1.58.2.1.1 Field: Name

A unique user-assigned name for a list of independent variables. This name is referenced by Table:Lookup objects. The name of this list object may be referenced by any number of Table:Lookup objects.

1.58.2.1.2 Field: Independent Variable <x> Name

This field is repeated for the number of independent variables that define the dimensions of any corresponding Table:Lookup objects that refer to this list. Each instance provides the name of a Table:IndependentVariable object that defines the values and properties of an independent variable.

1.58.2.2 Example IDF

```
Table:IndependentVariableList,
  HPACCoolCapFT_IndependentVariableList,  !- Name
  HPACCoolCapFT_Tewb,                    !- Independent Variable 1 Name
  HPACCoolCapFT_Todb;                    !- Independent Variable 2 Name
```

1.58.3 Table:IndependentVariable

Independent variables are used to define the size and dimensions of a Table:Lookup object.

### 1.58.3.1 Inputs

#### 1.58.3.1.1 Field: Name

A unique user-assigned name for an independent variables. This name is referenced by Table:IndependentVariableList objects. The name of this object may be referenced by any number of Table:IndependentVariableList objects.

#### 1.58.3.1.2 Field: Interpolation Method

Method used to determine the value of the table within the bounds of its independent variables. The choices are:

- *Linear*
- *Cubic*

#### 1.58.3.1.3 Field: Extrapolation Method

Method used to determine the value of the table beyond the bounds of its independent variables. The choices are:

- *Constant*: Value is the same as the interpolated value at the closest point along the table's boundary.
- *Linear*: Value is linearly extrapolated in all dimensions from the interpolated value at the closest point along the table's boundary.

#### 1.58.3.1.4 Field: Minimum Value

The minimum allowable value. Table:Lookup output for values between this value and the lowest value provided for this independent variable will be extrapolated according to the extrapolation method. Below this value, extrapolation is held constant and a warning will be issued. If extrapolation method is "Unavailable", the corresponding equipment will be disabled for all values less than the lowest independent variable value, regardless of the minimum value set here.

#### 1.58.3.1.5 Field: Maximum Value

The maximum allowable value. Table:Lookup output for values between this value and the highest value provided for this independent variable will be extrapolated according to the extrapolation method. Above this value, extrapolation is held constant and a warning will be issued. If extrapolation method is "Unavailable", the corresponding equipment will be disabled for all values greater than the highest independent variable value, regardless of the maximum value set here.

#### 1.58.3.1.6 Field: Normalization Reference Value

The value of this independent variable where nominal or rated output is defined. This will be used to normalize the data so that the outputs of any Table:Lookup at this value (and the corresponding Normalization Reference Values of the other independent variables described in the same Table:IndependentVariableList object) are equal to 1.0. If left blank, no normalization will be calculated. If this field is left blank the Normalization Reference Value of all other Table:IndependentVariable objects within the same Table:IndependentVariableList must also be left blank.

#### 1.58.3.1.7 Field: Unit Type

This field is used to indicate the kind of units that may be associated with this independent variable. It is used by interfaces or input editors (e.g., IDF Editor) to display the appropriate SI and IP units for the Minimum Value and Maximum Value. The available options are shown below. If none of these options are appropriate, select *Dimensionless* which will have no unit conversion.

- Dimensionless
- Temperature
- VolumetricFlow
- MassFlow
- Distance
- Power

### 1.58.3.1.8 Field: External File Name

The name of an external CSV file that represents the tabular data. This file should be formatted such that the data for any output is ordered according to the order of the corresponding independent variables. For example, for three independent variables (*iv1*, *iv2*, *iv3*) with 3, 2, and 4 values respectively. The output values (*out*[*iv1*][*iv2*][*iv3*]) should be ordered as:

<i>iv1</i>	<i>iv2</i>	<i>iv3</i>	output
<i>iv1</i> [1]	<i>iv2</i> [1]	<i>iv3</i> [1]	<i>out</i> [1][1][1]
<i>iv1</i> [1]	<i>iv2</i> [1]	<i>iv3</i> [2]	<i>out</i> [1][1][2]
<i>iv1</i> [1]	<i>iv2</i> [1]	<i>iv3</i> [3]	<i>out</i> [1][1][3]
<i>iv1</i> [1]	<i>iv2</i> [1]	<i>iv3</i> [4]	<i>out</i> [1][1][4]
<i>iv1</i> [1]	<i>iv2</i> [2]	<i>iv3</i> [1]	<i>out</i> [1][2][1]
<i>iv1</i> [1]	<i>iv2</i> [2]	<i>iv3</i> [2]	<i>out</i> [1][2][2]
<i>iv1</i> [1]	<i>iv2</i> [2]	<i>iv3</i> [3]	<i>out</i> [1][2][3]
<i>iv1</i> [1]	<i>iv2</i> [2]	<i>iv3</i> [4]	<i>out</i> [1][2][4]
<i>iv1</i> [2]	<i>iv2</i> [1]	<i>iv3</i> [1]	<i>out</i> [2][1][1]
<i>iv1</i> [2]	<i>iv2</i> [1]	<i>iv3</i> [2]	<i>out</i> [2][1][2]
<i>iv1</i> [2]	<i>iv2</i> [1]	<i>iv3</i> [3]	<i>out</i> [2][1][3]
<i>iv1</i> [2]	<i>iv2</i> [1]	<i>iv3</i> [4]	<i>out</i> [2][1][4]
<i>iv1</i> [2]	<i>iv2</i> [2]	<i>iv3</i> [1]	<i>out</i> [2][2][1]
<i>iv1</i> [2]	<i>iv2</i> [2]	<i>iv3</i> [2]	<i>out</i> [2][2][2]
<i>iv1</i> [2]	<i>iv2</i> [2]	<i>iv3</i> [3]	<i>out</i> [2][2][3]
<i>iv1</i> [2]	<i>iv2</i> [2]	<i>iv3</i> [4]	<i>out</i> [2][2][4]
<i>iv1</i> [3]	<i>iv2</i> [1]	<i>iv3</i> [1]	<i>out</i> [3][1][1]
<i>iv1</i> [3]	<i>iv2</i> [1]	<i>iv3</i> [2]	<i>out</i> [3][1][2]
<i>iv1</i> [3]	<i>iv2</i> [1]	<i>iv3</i> [3]	<i>out</i> [3][1][3]
<i>iv1</i> [3]	<i>iv2</i> [1]	<i>iv3</i> [4]	<i>out</i> [3][1][4]
<i>iv1</i> [3]	<i>iv2</i> [2]	<i>iv3</i> [1]	<i>out</i> [3][2][1]
<i>iv1</i> [3]	<i>iv2</i> [2]	<i>iv3</i> [2]	<i>out</i> [3][2][2]
<i>iv1</i> [3]	<i>iv2</i> [2]	<i>iv3</i> [3]	<i>out</i> [3][2][3]
<i>iv1</i> [3]	<i>iv2</i> [2]	<i>iv3</i> [4]	<i>out</i> [3][2][4]

Independent variable values must appear in **ascending** order (an error will be issued if this is not the case).

Alternatively, the independent variables may be defined using the *Value* *<x>* fields below.

**1.58.3.1.9 Field: External File Column Number**

The column number (starting at 1) in the CSV file corresponding to this independent variable. As the values of the independent variables each repeat over a defined cycle, EnergyPlus will only read unique values from this column. EnergyPlus does not validate that the cycles are repeating correctly. In fact, the same data can be read by only defining each value once as it is first encountered:

iv1	iv2	iv3	output
iv1[1]	iv2[1]	iv3[1]	out[1][1][1]
		iv3[2]	out[1][1][2]
		iv3[3]	out[1][1][3]
		iv3[4]	out[1][1][4]
iv1[2]	iv2[2]		out[1][2][1]
			out[1][2][2]

**1.58.3.1.10 Field: External File Starting Row Number**

The row number (starting at 1) in the CSV file where the data for this independent variable begins. Any values in the same column below this row are considered part of the range.

**1.58.3.1.11 Field: Value <x>**

If not reading from an external file, this field is repeated to capture the full set of values for this independent variable. These values must be defined in **ascending** order (an error will be issued if this is not the case).

**1.58.3.2 Example IDF**

```

## 1.59 Group Fluid Properties

The Fluid Property routines in EnergyPlus have been designed for ease of use and to allow users to add refrigerant and glycol data to the input file without having to make any changes to the program code. Fluid properties are calculated by interpolating the tabulated data in the input file. The main input requirement is that in order to add a new fluid, a user must enter a full set of data. The user may determine the interval between data points according to the desired accuracy and range required. Data for a number of common fluids are available in the required format in a reference dataset so that the user may append this data to their input file. In addition, data for Water, Ethylene Glycol (in various concentrations from 0 to 90%), and Propylene Glycol (in various concentrations from 0 to 90%) are available as default values within EnergyPlus.

Each fluid is categorized as either a Refrigerant or Glycol. Refrigerant data is further categorized as either saturated or superheated. Saturated refrigerant data is indexed, in the input data, according to pressure and temperature i.e. the specific heat, density, enthalpy in the input data are given for a given combination of pressure and temperature. Saturated refrigerant data is indexed according to pressure and quality. In the case of saturated pressure data only a temperature index is used. Glycol data is indexed in the input data according to temperature and concentration. The input data structure for each property is essentially two-dimensional (a matrix). However, since all fluid loops are assumed to be of constant concentration, EnergyPlus internally will interpolate from input data to data for the actual concentration being used in a particular loop. This reduces internally to a one-dimensional array of data for various properties where temperature is the only variable. This saves time since it reduces all interpolations for glycols to a single dimension.

In most cases there will be combinations of index variable (e.g. some combination of pressure and temperature) at which either no data is available, or the property data is invalid/irrelevant. For example, in the superheated refrigerant data, some combinations of temperature and pressure may correspond to a state in the saturated rather than superheated region. Similarly, in the case of glycols there may be some combinations of temperature and concentration that would correspond to the frozen state. In these cases, and where data is just not available, a zero should be present in the data at these points to indicate an invalid condition. EnergyPlus uses the presence of zeros to detect invalid conditions and give warning messages.

### 1.59.1 FluidProperties:Name

The names of each fluid for which property data is given in the user input have to be specified in FluidProperties:Name data objects. If data is to be included for a given fluid, either a refrigerant or a glycol, then its name must be included in the FluidProperties:Name objects.

### 1.59.1.1 Inputs

#### 1.59.1.1.1 Field: Fluid Name

Each fluid name is a unique identifier that will be used in conjunction with the data statements described later in this section. The fluid name is either referred to by a component (in the case of a Refrigerant) or by another input line (in the case of a Glycol). This list is simply a list of user defined fluids present in the input data file.

#### 1.59.1.1.2 Field: Fluid Type

Each fluid name must be identified by type - either **Refrigerant** or **Glycol**. This designation determines what type of data EnergyPlus expects for the fluid name. If the fluid name is defined as a Refrigerant, the user must supply valid data for pressure, enthalpy, specific heat, and density in the saturated region and enthalpy and density in the superheated region. If the fluid name is defined as a Glycol, the user must supply valid data for specific heat, conductivity, viscosity, and density at various concentrations (percentage of non-water liquid) and temperatures.

An example of these statements in an input data file is:

```
FluidProperties:Name,  
  R11,Refrigerant;  
  
FluidProperties:Name,  
  R12,Refrigerant;  
  
FluidProperties:Name,  
  R22,Refrigerant;  
  
FluidProperties:Name,  
  NH3,Refrigerant;  
  
FluidProperties:Name,  
  Steam,Refrigerant;  
  
FluidProperties:Name,  
  SaltBrine, Glycol;  
  
FluidProperties:Name,  
  NewGlycol, Glycol;
```

---

## 1.59.2 FluidProperties:GlycolConcentration

This input syntax is used to specify fluids that will be used with HVAC loops such as plant and condenser loops. It allows the user to define a mixture of water and some other substance and the particular concentration being used. The fluid name will be referred to by the loops or components and thus used to identify which value is valid for a particular fluid at a particular temperature. A series of three inputs is required for each fluid concentration definition.

### 1.59.2.1 Inputs

#### 1.59.2.1.1 Field: Name

Each glycol concentration name is a unique identifier that will be used to define a particular combination of water and some other substance (usually another fluid). Other input (such as loop definitions) will refer to this name, linking the other input to the proper fluid definition.

#### 1.59.2.1.2 Field: Glycol Type

This field refers to the substance that is being mixed with water to create the glycol. The user may either select from the two default fluids (**EthyleneGlycol** or **PropyleneGlycol**) or specify **UserDefinedGlycolType** and use a name in the subsequent field for fluids that have been entered elsewhere in the input file. It should be noted that users must enter a complete definition of new glycols -including values for conductivity, specific heat, density, and viscosity at various concentrations and temperatures -in order for them to be used in conjunction with a user defined glycol type.

#### 1.59.2.1.3 Field: User Defined Glycol Name

This field is the name used elsewhere in a **FluidProperties:Name** object for defining your own glycol properties. This field is left blank unless you enter **UserDefinedGlycolType** in the previous field.

#### 1.59.2.1.4 Field: Glycol Concentration

This field allows the user to specify the actual concentration of glycol being used for this particular fluid. A concentration of 0.0 refers to pure water. A concentration of 1.0 would denote 100% of the fluid referenced in the Glycol Name input discussed above. Users should enter this value as a decimal fraction since EnergyPlus will limit the range of valid input values to between 0.0 and 1.0.

An example of this statement in an input data file is:

```
FluidProperties:GlycolConcentration,
  EthGly25Percent, EthyleneGlycol, ,0.25;
FluidProperties:GlycolConcentration,
  ProGly40Percent, PropyleneGlycol, ,0.40;
FluidProperties:GlycolConcentration,
  HalfAndHalf, UserDefinedGlycolType, NewBrine, 0.5;
```

### 1.59.3 FluidProperties:Temperatures

It is assumed that all fluid properties vary with temperature. A common set of temperatures is required for each set of fluid property data. Fluid property data supplied by the user must correspondingly be given at these temperatures. Since in most cases, refrigerant data can be specified at a common set of temperatures, a single set of FluidProperties:Temperatures can be referenced by a number of sets of property data. This provides a more compact input structure and avoids listing the temperatures multiple times. In the case of glycol data the same set of temperatures have to be used for each set of data at a given concentration. Units for the temperatures are degrees Celsius.

#### 1.59.3.1 Inputs

##### 1.59.3.1.1 Field: Name

This field is simply a unique identifier name that is used to cross reference the list of temperatures with a specific list of fluid property data. A single temperature list can be used for more than one thermal property or fluid. For example, the same temperature list can be used for the superheated enthalpy of a refrigerant and the specific heat of a glycol if appropriate.

### 1.59.3.1.2 Field(s) 1-250: Temperature

These fields (up to 250) are the temperatures at which the data for the thermal properties are to be expected. Temperatures are assumed to be in ascending order in units of Celsius.

An example of this statement in an input data file is:

```
FluidProperties:Temperatures,
  R11Temperatures,
  -70,-65,-60,-55,-50,-45,-40,-35,-30,-25,-20,-15,-10,-5,0,2,4,6,8,10,12,
  14,16,18,20,22,24,26,28,30,32,34,36,38,40,42,44,46,48,50,55,60,65,70,
  75,80,85,90,95,100,105,110,115,120,125,130,135,140,145,150,155,160,
  165,170,175,180,185,190,198;
```

---

## 1.59.4 FluidProperties:Saturated

Refrigerant property data for the saturated region is entered with the following syntax. For each set of property data a unique name, the type of property, phase and the corresponding list of temperatures have to be specified along with the property values.

### 1.59.4.1 Inputs

#### 1.59.4.1.1 Field: Name

This name identifies the fluid for which data follows in the remaining syntax. This fluid name must also be given in the fluid names list (ref: **FluidProperties:Names** object) as a **Refrigerant**.

#### 1.59.4.1.2 Field: Fluid Property Type

This field identifies the fluid property for which data is being entered with this statement. The options for the saturated region are **Enthalpy**, **Density**, **SpecificHeat**, and **Pressure**. The units for these properties are J/kg, kg/m<sup>3</sup>, J/kg-K and Pa, respectively.

#### 1.59.4.1.3 Field: Fluid Phase

In the saturated region, each property has two values: one for the saturated liquid state and one for the saturated gaseous state. Accordingly, the phase for which the saturated property data applies is specified as either **Fluid** or **FluidGas**. Data for each phase are required and are interpolated according to quality. However, in the case of saturated pressure data values for only one phase are required (i.e. can be specified with phase specified as either Fluid or FluidGas, as this is irrelevant).

#### 1.59.4.1.4 Field: Temperatures Values Name

This name refers to the corresponding list of temperatures (ref: **FluidProperties:Temperatures** object). Each temperature in the temperature list corresponds to a data item found in the remaining fields of this syntax. The first temperature in the temperature list corresponds to the first fluid property value, the second temperature in the temperature list corresponds to the second fluid property value, etc.

#### 1.59.4.1.5 Field(s) 1-250: Property Value

These fields (up to 250) are the values of the thermal property specified in the fluid property type field for the phase specified in the fluid phase field. The temperature list specified in the temperature list name field links the data with the corresponding temperatures.

An example of this statement in an input data file is:

```
FluidProperties:Saturated,
  R11,Enthalpy,Fluid,R11Temperatures, ! Enthalpy in J/kg
  153580,154600,156310,158580,161300,164380,167740,171330,175100,179020,183060,
```

```
187190,191400,195680,200000,201740,203490,205240,207000,208770,210530,212310,
214080,215870,217650,219860,221230,223030,224830,226630,228860,230250,232060,
233860,235700,237520,239350,241180,243010,246350,249450,254080,258730,263480,
268110,272860,277000,282410,287240,292120,297030,302000,307090,312080,317210,
322400,327670,333020,338460,344010,349680,355500,361480,367690,374100,381060,
388850,397280,426300;
```

---

## 1.59.5 FluidProperties:Superheated

The format of the data for the superheated region is similar to that of the saturated region but with the addition of the pressure for which each set of property values applies. A single temperature specification is required for each set of property data at a number of pressures.

### 1.59.5.1 Inputs

#### 1.59.5.1.1 Field: Fluid Name

This name identifies the fluid for which data follows in the remaining syntax. This fluid name must show up in the fluid names list (ref: **FluidProperties:Names** object) as a **Refrigerant**.

#### 1.59.5.1.2 Field: Fluid Property Type

This field identifies the fluid property for which data is being entered with this statement. The options for the superheated region are **Enthalpy** and **Density**. The units for these properties are J/kg and kg/m<sup>3</sup>, respectively.

#### 1.59.5.1.3 Field: Temperatures Values Name

This name refers to the corresponding list of temperatures (ref: **FluidProperties:Temperatures** object). Each temperature in the temperature list corresponds to a given property data item at each pressure. The first temperature in the temperature list corresponds to the first fluid property value, the second temperature in the temperature list corresponds to the second fluid property value, etc.

#### 1.59.5.1.4 Field: Pressure

In the superheated region, each fluid property is indexed according to temperature and pressure. Thus, a pressure must be listed for each set of property values. The units for pressure are Pascals (Pa). Lists of properties are various pressures and temperatures form a two-dimensional table from which EnergyPlus interpolates to find the property value at a specified temperature and pressure.

#### 1.59.5.1.5 Field(s) 1-250: Property Value

These fields (up to 250) are the values of the thermal property specified in the fluid property type field for the phase specified in the fluid phase field. The temperature list specified in the temperature list name field links the data with the corresponding temperatures.

An example of this statement in an input data file is:

```
FluidProperties:Superheated,
  R11,Density,SuperR11Temperatures, ! Density in kg/m^3
  62000., !Pressure = 62000Pa
  0,0,0,0,0,0,0,0.0139,0.0134,0.0129,0.0124,0.012,0.0116,0.0112,0.0109,0.0105,
  0.0102,0.0099,0.0097,0.0094,0.0092,0.0089,0,0,0,0,0,0,0,0,0,0;
```

---

## 1.59.6 Glycol Fluid Types

A full data set for a glycol fluid type in EnergyPlus includes: a temperature list and lists of values for specific heat at a given concentration. Data have to be given for at least two different concentrations. The syntax lines for the property value lists are described below.

## 1.59.7 FluidProperties:Concentration

The format of the data for the glycols is similar to that of superheated refrigerants except that data at a number of concentrations is given, rather than pressures. The concentration is listed before the rest of the data and is normalized (i.e. in the range 0.0 to 1.0, rather than a percentage). Note that glycol solutions are assumed to exist in liquid form only in EnergyPlus.

### 1.59.7.1 Inputs

#### 1.59.7.1.1 Field: Fluid Name

This name identifies the fluid for which data follows in the remaining syntax. This fluid name must show up in the fluid names list (ref: **FluidProperties:Names** object) as a **Glycol**.. Note that users should not use Water, EthyleneGlycol, or PropyleneGlycol as names since these are default fluids.

#### 1.59.7.1.2 Field: Fluid Property Type

This field identifies the fluid property for which data is being entered with this statement. The required data for glycols includes **SpecificHeat** with units of J/kg-K, **Density** with units of kg/m<sup>3</sup>, **Conductivity** with units of W/m-K, and **Viscosity** with units of N-s/m<sup>2</sup>.

#### 1.59.7.1.3 Field: Temperatures Values Name

This name refers to the corresponding list of temperatures (ref: **FluidProperties:Temperatures** object). Each temperature in the temperature list corresponds to a data item found in the remaining fields of this syntax. The first temperature in the temperature list corresponds to the first fluid property value, the second temperature in the temperature list corresponds to the second fluid property value, etc.

#### 1.59.7.1.4 Field: Concentration

A concentration must be listed for the values of specific heat that follow. Lists of properties are various concentrations and temperatures form a two-dimensional table from which EnergyPlus interpolates to find the property value at a specified temperature and concentration. Concentrations are specified in a normalized form (i.e. in the range 0.0 to 1.0, rather than a percentage)

#### 1.59.7.1.5 Field(s) 1-250: Property Value

These fields (up to 250) are the values of the thermal property specified in the fluid property type field for the phase specified in the fluid phase field. The temperature list specified in the temperature list name field links the data with the corresponding temperatures.

An example of this statement in an input data file is:

```
FluidProperties:Concentration,
  NewGlycol,SpecificHeat ,GlycolTemperatures, ! Spec. heat in J/kg-K
  0.8, ! Concentration
  2572,2600,2627,2655,2683,2710,2738,2766,2793,2821,2849,2876,2904,2931,2959,
  2987,3014,3042,3070,3097,3125,3153,3180,3208,3236,3263,3291,3319,3346,3374,
  3402,3429,3457;
```

## 1.60 Group – Hybrid Model

### 1.60.1 HybridModel:Zone

This object provides a hybrid model feature to enhance energy simulations for existing buildings by inversely solving hard-to-measure model input parameters. More specifically, zone internal thermal mass, air infiltration rate (ACH), and people count are usually hard to be measured directly yet important in building energy simulations. The hybrid model takes measured zone air temperature, humidity ratio, or CO<sub>2</sub> concentration as inputs and inversely solve those unknown parameters based on the zone air heat, moisture, or CO<sub>2</sub> balance algorithms. The inversely solved internal thermal mass, air infiltration rate, and people count can then be used to substitute the original simplified assumptions to enhance the energy simulation.

#### 1.60.1.1 Inputs

##### 1.60.1.1.1 Field: Name

The name of the HybridModel:Zone object.

##### 1.60.1.1.2 Field: Zone Name

This field is the name of the thermal zone (ref: Zone) and attaches a particular hybrid model input to a thermal zone in the building.

##### 1.60.1.1.3 Field: Calculate Zone Internal Thermal Mass

This field is used to provide an option to calculate the temperature capacity multiplier (Ref: ZoneCapacityMultiplier:ResearchSpecial). The temperature capacity multiplier is represented as internal thermal mass multiplier in the hybrid model. When YES is selected, the hybrid model calculates the multiplier based on the inverse heat balance algorithm using the measured zone air temperature.

##### 1.60.1.1.4 Field: Calculate Zone Air Infiltration Rate

This field is used to provide an option to calculate the zone air infiltration rate - air change per hour (ACH). When YES is selected, the hybrid model calculates the zone air infiltration rate based on one of the following balance equations: 1. Heat balance equations, 2. Moisture balance equations, 3. CO<sub>2</sub> balance equations when the corresponding data requirements are met. The HybridModel will be activated with the following options:

1. When Zone Measured Air Temperature Schedule Name is provided, it will calculate the zone air infiltration rate assuming the HVAC system is free-floating using the zone sensible heat balance algorithms;
2. When Zone Measured Air Temperature Schedule Name, Zone Input Supply Air Mass Flow Rate Schedule Name, and Zone Input Supply Air Temperature Schedule Name are provided, it will calculate the zone air infiltration rate assuming the HVAC is on. In this case, the zone air supply air temperature and mass flow rate in the zone sensible heat balance algorithms will be overwritten by the input data;
3. When Zone Measured Air Humidity Ratio Schedule Name is provided, it will calculate the zone air infiltration rate assuming the HVAC system is free-floating using the zone moisture balance algorithms;
4. When Zone Measured Air Humidity Ratio Schedule Name, Zone Input Supply Air Mass Flow Rate Schedule Name, and Zone Input Supply Air Humidity Ratio Schedule Name are provided, it will calculate the zone air infiltration rate assuming the HVAC is on. In this case, the zone air supply air humidity ratio and mass flow rate in the zone moisture balance algorithms will be overwritten by the input data;
5. When Zone Measured Air CO<sub>2</sub> concentration Schedule Name is provided, it will calculate the zone air infiltration rate assuming the HVAC system is free-floating using the zone CO<sub>2</sub> balance algorithms;

6. When Zone Measured Air CO<sub>2</sub> concentration Schedule Name, Zone Input Supply Air Mass Flow Rate Schedule Name, and Zone Input Supply Air CO<sub>2</sub> Concentration Schedule Name are provided, it will calculate the zone air infiltration rate assuming the HVAC is on. In this case, the zone air supply air CO<sub>2</sub> concentration and mass flow rate in the zone CO<sub>2</sub> balance algorithms will be overwritten by the input data;

When YES is selected for Calculate Zone Internal Thermal Mass, this field will be treated as NO.

#### 1.60.1.1.5 Field: Calculate Zone People Count

This field is used to provide an option to calculate the zone people count. When YES is selected, the hybrid model calculates the zone people count based on one of the following balance equations: 1. heat balance equations, 2. Moisture balance equations, 3. CO<sub>2</sub> balance equations when the corresponding data requirements are met. The HybridModel will be activated with the following options:

1. When Zone Measured Air Temperature Schedule Name is provided, it will calculate the zone people count assuming the HVAC system is free-floating using the zone sensible heat balance algorithms. The default people activity level is 130 W. The default sensible heat fraction is 0.6. The default radiant heat fraction is 0.7. Zone Input People Activity Level Schedule Name, Zone Input People Sensible Heat Fraction Schedule Name, and Zone Input People Radiant Heat Fraction Schedule Name are optional. When provided, the default values will be overwritten.

2. When Zone Measured Air Temperature Schedule Name, Zone Input Supply Air Mass Flow Rate Schedule Name, and Zone Input Supply Air Temperature Schedule Name are provided, it will calculate the zone people count assuming the HVAC is on. In this case, the zone air supply air temperature and mass flow rate in the zone sensible heat balance algorithms will be overwritten by the input data. The default people activity level is 130 W. The default sensible heat fraction is 0.6. The default radiant heat fraction is 0.7. Zone Input People Activity Level Schedule Name, Zone Input People Sensible Heat Fraction Schedule Name, and Zone Input People Radiant Heat Fraction Schedule Name are optional. When provided, the default values will be overwritten.

3. When Zone Measured Air Humidity Ratio Schedule Name is provided, it will calculate the zone people count assuming the HVAC system is free-floating using the zone moisture balance algorithms. The default people activity level is 130 W. The default sensible heat fraction is 0.6. The default radiant heat fraction is 0.7. Zone Input People Activity Level Schedule Name, Zone Input People Sensible Heat Fraction Schedule Name, and Zone Input People Radiant Heat Fraction Schedule Name are optional. When provided, the default values will be overwritten.

4. When Zone Measured Air Humidity Ratio Schedule Name, Zone Input Supply Air Mass Flow Rate Schedule Name, and Zone Input Supply Air Humidity Ratio Schedule Name are provided, it will calculate the zone people count assuming the HVAC is on. In this case, the zone air supply air humidity ratio and mass flow rate in the zone moisture balance algorithms will be overwritten by the input data. The default people activity level is 130 W. The default sensible heat fraction is 0.6. The default radiant heat fraction is 0.7. Zone Input People Activity Level Schedule Name, Zone Input People Sensible Heat Fraction Schedule Name, and Zone Input People Radiant Heat Fraction Schedule Name are optional. When provided, the default values will be overwritten.

5. When Zone Measured Air CO<sub>2</sub> concentration Schedule Name is provided, it will calculate the zone people count assuming the HVAC system is free-floating using the zone CO<sub>2</sub> balance algorithms. The default people activity level is 130 W. The default single person CO<sub>2</sub> generation is 0.000000382 [m<sup>3</sup>/(s\*W)]. Zone Input People Activity Level Schedule Name, Zone Input People CO<sub>2</sub> Generation Rate Schedule Name are optional. When provided, the default values will be overwritten.

6. When Zone Measured Air CO<sub>2</sub> concentration Schedule Name, Zone Input Supply Air Mass Flow Rate Schedule Name, and Zone Input Supply Air CO<sub>2</sub> Concentration Schedule Name are provided, it will calculate the zone people count assuming the HVAC is on. In this case, the zone air supply air CO<sub>2</sub> concentration and mass flow rate in the zone CO<sub>2</sub> balance algorithms will be overwritten by the input

data. The default people activity level is 130 W. The default single person CO<sub>2</sub> generation is 0.0000000382 [m<sup>3</sup>/(s\*W)]. Zone Input People Activity Level Schedule Name, Zone Input People CO<sub>2</sub> Generation Rate Schedule Name are optional. When provided, the default values will be overwritten.

When YES is selected for Calculate Zone Internal Thermal Mass or Calculate Zone Air Infiltration Rate, this field will be treated as NO.

#### **1.60.1.1.6 Field: Zone Measured Air Temperature Schedule Name**

This field is the name of the schedule object which contains the zone air temperature measurement data. The date range of the schedule should cover the start and end date of the HybridModel. A Schedule:File object is recommended for inputting the time-series measurements. When a schedule:file object is provided, all the rows for a whole year should be in the file, the rows outside of the start and end date range of the HybridModel should be zeros.

#### **1.60.1.1.7 Field: Zone Measured Air Humidity Ratio Schedule Name**

This field is the name of the schedule object which contains the zone air humidity ration measurement data. The date range of the schedule should cover the start and end date of the HybridModel. A Schedule:File object is recommended for inputting the time-series measurements. When a schedule:file object is provided, all the rows for a whole year should be in the file, the rows outside of the start and end date range of the HybridModel should be zeros.

#### **1.60.1.1.8 Field: Zone Measured Air CO<sub>2</sub> concentration Schedule Name**

This field is the name of the schedule object which contains the zone air CO<sub>2</sub> concentration measurement data. The date range of the schedule should cover the start and end date of the HybridModel. A Schedule:File object is recommended for inputting the time-series measurements. When a schedule:file object is provided, all the rows for a whole year should be in the file, the rows outside of the start and end date range of the HybridModel should be zeros.

#### **1.60.1.1.9 Field: Zone Input People Activity Level Schedule Name**

This field is the name of the schedule referenced by a Schedule object which contains the people activity level data. The date range of the schedule should cover the start and end date of the HybridModel.

#### **1.60.1.1.10 Field: Zone Input People Sensible Heat Fraction Schedule Name**

This field is the name of the schedule referenced by a Schedule object which contains the people sensible heat fraction data. The date range of the schedule should cover the start and end date of the HybridModel.

#### **1.60.1.1.11 Field: Zone Input People Radiant Heat Fraction Schedule Name**

This field is the name of the schedule referenced by a Schedule object which contains the radiant heat fraction of the sensible heat data. The date range of the schedule should cover the start and end date of the HybridModel.

#### **1.60.1.1.12 Field: Zone Input People CO<sub>2</sub> Generation Rate Schedule Name**

This field is the name of the schedule referenced by a Schedule object which contains a single person's CO<sub>2</sub> generation rate data. The date range of the schedule should cover the start and end date of the HybridModel.

**1.60.1.1.13 Field: Zone Input Supply Air Temperature Schedule Name**

This field is the name of the schedule object which contains the measured supply air temperature data. The date range of the schedule should cover the start and end date of the HybridModel. A Schedule:File object is recommended for inputting the time-series measurements. When a schedule:file object is provided, all the rows for a whole year should be in the file, the rows outside of the start and end date range of the HybridModel should be zeros.

**1.60.1.1.14 Field: Zone Input Supply Air Mass Flow Rate Schedule Name**

This field is the name of the schedule object which contains the measured supply air mass flow rate data. The date range of the schedule should cover the start and end date of the HybridModel. A Schedule:File object is recommended for inputting the time-series measurements. When a schedule:file object is provided, all the rows for a whole year should be in the file, the rows outside of the start and end date range of the HybridModel should be zeros.

**1.60.1.1.15 Field: Zone Input Supply Air Humidity Ratio Schedule Name**

This field is the name of the schedule object which contains the measured supply air humidity ratio data. The date range of the schedule should cover the start and end date of the HybridModel. A Schedule:File object is recommended for inputting the time-series measurements. When a schedule:file object is provided, all the rows for a whole year should be in the file, the rows outside of the start and end date range of the HybridModel should be zeros.

**1.60.1.1.16 Field: Zone Input Supply Air CO<sub>2</sub> Concentration Schedule Name**

This field is the name of the schedule object which contains the measured supply air CO<sub>2</sub> concentration data. The date range of the schedule should cover the start and end date of the HybridModel. A Schedule:File object is recommended for inputting the time-series measurements. When a schedule:file object is provided, all the rows for a whole year should be in the file, the rows outside of the start and end date range of the HybridModel should be zeros.

**1.60.1.1.17 Field: Begin Month**

This numeric field should contain the starting month number (1 = January, 2 = February, etc.) for the period of the measured data during which the hybrid model will be active.

**1.60.1.1.18 Field: Begin Day of Month**

This numeric field should contain the starting day of the starting month (must be valid for month) for the period of the measured data during which the hybrid model will be active.

**1.60.1.1.19 Field: End Month**

This numeric field should contain the ending month number (1 = January, 2 = February, etc.) for the period of the measured data during which the hybrid model will be active.

**1.60.1.1.20 Field: End Day of Month**

This numeric field should contain the ending day of the ending month (must be valid for month) for the period of the measured data during which the hybrid model will be active.

Examples of the object in an IDF are:

```
HybridModel:Zone,
  ZONE 1 HybridModel,      !- Name

### 1.60.1.2 Outputs

Zone,Average,Zone Infiltration Hybrid Model Air Change Rate [ACH]

Zone,Average,Zone Infiltration Hybrid Model Mass Flow Rate [kg/s]  
Zone,Average,Zone Hybrid Model People Count

---

**1.60.1.2.1 Zone Infiltration Hybrid Model Air Change Rate [ACH]**

The zone infiltration air change rate calculated by the hybrid model.

**1.60.1.2.2 Zone Infiltration Hybrid Model Mass Flow Rate [kg/s]**

The zone infiltration air mass flow rate calculated by the hybrid model.

**1.60.1.2.3 Zone Hybrid Model People Count**

The zone people count calculated by the hybrid model.

# Chapter 2

## HVAC Template Objects

### 2.1 HVACTemplate Processing

Unlike other EnergyPlus objects, the HVACTemplate objects are not handled by EnergyPlus directly. Instead, they are preprocessed by a program called ExpandObjects. If you use EP-Launch or RunEPlus.bat, this preprocessor step is performed automatically using the following sequence:

- 1) The preprocessor program, ExpandObjects, reads your IDF file and converts all of the HVACTemplate objects into other EnergyPlus objects.
- 2) The ExpandObjects program copies the original idf file with the HVACTemplate objects commented out (i.e., inserts a “!” in front of the object name and its input fields) plus all of the new objects created in Step 1 and writes a new file which is saved with the extension “expidf”. This “expidf” file may be used as a standard EnergyPlus IDF file if the extension is changed to idf; however, for safety’s sake, both filename and extension should be changed.
- 3) The EnergyPlus simulation proceeds using the expidf file as the input stream.
- 4) If there are error messages from EnergyPlus, they will refer to the contents of the expidf file. Specific objects referred to in error messages may exist in the original idf, but they may be objects created by ExpandObjects and only exist in the expidf. Remember that the expidf will be overwritten everytime the original idf is run using EP-Launch or RunEPlus.bat.

If you are trying to go beyond the capabilities of the HVACTemplate objects, one strategy you can use is to start your specification using the HVACTemplate objects, run EnergyPlus using EP-Launch and producing an expidf file, rename that file and start making modifications. This approach may help with getting all of the objects needed and the node names set consistently.

**Users need to remember that no objects related to HVAC except for HVAC template objects are needed in the IDF file.** The existence of other objects (unless specifically described in the following sections) may cause unexpected errors to occur. **Sizing:Zone**, **Sizing:System**, and **Sizing:Plant** objects will be generated by the corresponding HVACTemplate objects; the user does not need to create these elsewhere in the input file.

There are some exceptions to this rule:

- **HVACTemplate:Plant:Chiller:ObjectReference** which requires that the corresponding chiller object be present in the idf file along with any required curve or performance objects. In this case, the HVACTemplate object does not create the chiller object, but adds all of the connections. **HVACTemplate:Plant:Tower:ObjectReference** and **HVACTemplate:Plant:Boiler;ObjectReferences** are similar.

- For HVACTemplate:Zone:\* objects, if Outdoor Air Method = *DetailedSpecification*, then any referenced DesignSpecification:OutdoorAir and DesignSpecification:ZoneAirDistribution objects must be present in the idf file.
- For HVACTemplate:Zone:VAV and HVACTemplate:Zone:DualDuct, if a Design Specification Outdoor Air Object Name for Control is specified, then the referenced DesignSpecification:OutdoorAir object must be present in the idf file.

## 2.2 Group – HVAC Templates

This group of objects allows for the specification of simple zone thermostats and HVAC systems with automatically generated node names. The combinations of HVACTemplate objects are shown below.

For a simple ideal loads system to use for sizing and loads oriented simulations:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:IdealLoadsAirSystem

For baseboard heating systems with optional hot water boiler:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:BaseboardHeat
- HVACTemplate:Plant:HotWaterLoop (optional)
- HVACTemplate:Plant:Boiler (optional)

For fan coil systems with boilers and chillers:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:FanCoil
- HVACTemplate:Plant:ChilledWaterLoop
- HVACTemplate:Plant:HotWaterLoop
- HVACTemplate:Plant:Chiller
- HVACTemplate:Plant:Boiler
- HVACTemplate:Plant:Tower

For packaged terminal air conditioner (PTAC) systems with optional hot water boiler:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:PTAC
- HVACTemplate:Plant:HotWaterLoop (optional)
- HVACTemplate:Plant:Boiler (optional)

For packaged terminal air-to-air heat pump (PTHP) systems:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:PTHP

For water to air heat pumps with boiler and cooling tower:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:WaterToAirHeatPump
- HVACTemplate:Plant:MixedWaterLoop
- HVACTemplate:Plant:Boiler
- HVACTemplate:Plant:Tower

For variable refrigerant flow heat pumps (air-to-air):

- HVACTemplate:Thermostat
- HVACTemplate:Zone:VRF
- HVACTemplate:System:VRF

For variable refrigerant flow heat pumps (water-to-air)with boiler and cooling tower:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:VRF
- HVACTemplate:System:VRF
- HVACTemplate:Plant:MixedWaterLoop
- HVACTemplate:Plant:Boiler
- HVACTemplate:Plant:Tower

For direct-expansion cooling, packaged and split system simulations:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:Unitary
- HVACTemplate:System:Unitary or
- HVACTemplate:System:UnitarySystem

For direct-expansion heat pump systems:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:Unitary
- HVACTemplate:System:UnitaryHeatPump:AirToAir or
- HVACTemplate:System:UnitarySystem

For packaged variable air volume systems using direct-expansion cooling:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:VAV or
- HVACTemplate:Zone:VAV:FanPowered or
- HVACTemplate:Zone:VAV:HeatAndCool
- HVACTemplate:System:PackagedVAV

For variable air volume systems with boilers and air-cooled chillers:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:VAV or
- HVACTemplate:Zone:VAV:FanPowered or
- HVACTemplate:Zone:VAV:HeatAndCool
- HVACTemplate:System:VAV
- HVACTemplate:Plant:ChilledWaterLoop
- HVACTemplate:Plant:HotWaterLoop
- HVACTemplate:Plant:Chiller
- HVACTemplate:Plant:Boiler

For variable air volume systems with boilers and water-cooled chillers, an object related to towers is added:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:VAV or
- HVACTemplate:Zone:VAV:FanPowered or
- HVACTemplate:Zone:VAV:HeatAndCool
- HVACTemplate:System:VAV
- HVACTemplate:Plant:ChilledWaterLoop
- HVACTemplate:Plant:HotWaterLoop
- HVACTemplate:Plant:Chiller
- HVACTemplate:Plant:Boiler
- HVACTemplate:Plant:Tower

For constant air volume systems with boilers and water-cooled chillers:

- HVACTemplate:Thermostat

- HVACTemplate:Zone:ConstantVolume
- HVACTemplate:System:ConstantVolume
- HVACTemplate:Plant:ChilledWaterLoop
- HVACTemplate:Plant:HotWaterLoop
- HVACTemplate:Plant:Chiller
- HVACTemplate:Plant:Boiler
- HVACTemplate:Plant:Tower

For dual-duct systems (constant or variable air volume) with boilers and water-cooled chillers:

- HVACTemplate:Thermostat
- HVACTemplate:Zone:DualDuct
- HVACTemplate:System:DualDuct
- HVACTemplate:Plant:ChilledWaterLoop
- HVACTemplate:Plant:HotWaterLoop
- HVACTemplate:Plant:Chiller
- HVACTemplate:Plant:Boiler
- HVACTemplate:Plant:Tower

For dedicated outdoor air systems (DOAS) combined with a zonal template system:

- HVACTemplate:System:DedicatedOutdoorAir
- HVACTemplate:Thermostat

One of the following for each zone served by the (DOAS) –

- HVACTemplate:Zone:BaseboardHeat
- HVACTemplate:Zone:PTAC
- HVACTemplate:Zone:PTHP
- HVACTemplate:Zone:FanCoil
- HVACTemplate:Zone:WaterToAirHeatPump
- HVACTemplate:Zone:VRF
- HVACTemplate:Plant:\* objects as needed (depending on the type of zonal system and the type of coils specified in the DOAS system:WaterToAirHeatPump).

The *only* other HVAC related objects besides the HVACTemplate objects that need to be specified related to HVAC systems are:

```

Ctg-SetP-Sch,      !- Cooling Setpoint Schedule
;                  !- Constant Cooling Setpoint {C}

```

---

## 2.2.2 HVACTemplate:Zone:IdealLoadsAirSystem

This object provides an ideal system to supply conditioned air to the zone that meets all the load requirements and consumes no energy. It is often used for load calculations, an evaluation where the load components of the building are all that is being investigated, or as the first step to a more realistic model of a building.

This component can be operated with infinite or finite heating and cooling capacity. For either mode – infinite or limited capacity – the user can also specify on/off schedules for heating and cooling and outdoor air controls. There are also optional controls for dehumidification, humidification, economizer, and heat recovery. This component may be used in combination with other HVAC equipment serving the same zone.

This component can be thought of as an ideal unit that mixes air at the zone exhaust condition with the specified amount of outdoor air and then adds or removes heat and moisture at 100% efficiency in order to produce a supply air stream at the specified conditions. The energy required to condition the supply air is metered and reported as **DistrictHeating** and **DistrictCooling**.

### 2.2.2.1 Inputs

#### 2.2.2.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.2.1.2 Field: Template Thermostat Name

Enter the name of a **HVACTemplate:Thermostat** object. Multiple HVACTemplate:Zone:IdealLoadsAirSystem objects can reference the same **HVACTemplate:Thermostat** object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of **HVACTemplate:Thermostat**.

#### 2.2.2.1.3 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. There are additional schedules fields for heating and cooling operation.

#### 2.2.2.1.4 Field: Maximum Heating Supply Air Temperature

The maximum air temperature (degrees C) of the air used for heating the zone. The default is 50C (122F).

#### 2.2.2.1.5 Field: Minimum Cooling Supply Air Temperature

The minimum air temperature (degrees C) of the air used for cooling the zone. The default is 13C (55.4F).

#### 2.2.2.1.6 Field: Maximum Heating Supply Air Humidity Ratio

The maximum humidity ratio (kg of water per kg of dry air) of the hot supply air. The default is 0.0156 kgWater/kgDryAir which corresponds to a 20%RH at 50C (122F) dry bulb.

**2.2.2.1.7 Field: Minimum Cooling Supply Air Humidity Ratio**

The minimum humidity ratio (kg of water per kg of dry air) of the cool supply air. The default is 0.0077 kgWater/kgDryAir which corresponds to a 10C (50F) dew point.

**2.2.2.1.8 Field: Heating Limit**

The input must be either *LimitFlowRate*, *LimitCapacity*, *LimitFlowRateAndCapacity* or *NoLimit*. *LimitFlowRate* means that the heating supply air flow rate will be limited to the value specified in the next input field. *LimitCapacity* means that the sensible heating capacity will be limited to the value specified in the Maximum Sensible Heating Capacity field. *LimitFlowRateAndCapacity* means that both flow rate and capacity will be limited. *NoLimit* (the default) means that there will not be any limit on the heating supply air flow rate or capacity and the subsequent two fields will be ignored.

**2.2.2.1.9 Field: Maximum Heating Air Flow Rate**

The maximum heating supply air flow rate in cubic meters per second if heating limit is set to *LimitFlowRate* or *LimitFlowRateAndCapacity*. This field may be autosized. This field is ignored if heating limit is set to *NoLimit* or *LimitCapacity*. If blank, there is no limit.

**2.2.2.1.10 Field: Maximum Sensible Heating Capacity**

The maximum allowed sensible heating capacity in Watts if Heating Limit is set to *LimitCapacity* or *LimitFlowRateAndCapacity*. This field may be autosized. If blank, there is no limit. If Heating Limit is set to *NoLimit* or *LimitFlowRate*, this field is ignored.

**2.2.2.1.11 Field: Cooling Limit**

The input must be either *LimitFlowRate*, *LimitCapacity*, *LimitFlowRateAndCapacity* or *NoLimit*. *LimitFlowrate* means that the cooling supply air flow rate will be limited to the value specified in the next input field. *LimitCapacity* means that the total cooling capacity will be limited to the value specified in the Maximum Total Cooling Capacity field. *LimitFlowRateAndCapacity* means that both flow rate and capacity will be limited. *NoLimit* (the default) means that there will not be any limit on the cooling supply air flow rate or capacity and the subsequent two fields will be ignored.

**2.2.2.1.12 Field: Maximum Cooling Air Flow Rate**

The maximum cooling supply air flow rate in cubic meters per second if Cooling Limit is set to *LimitFlowRate* or *LimitFlowRateAndCapacity*. This field may be autosized. This field is ignored if cooling limit is set to *NoLimit* or *LimitCapacity*. If blank, there is no limit. If *Cooling Limit is set to NoLimit*, this field is ignored. This field is required if Outdoor Air Control Type is *TemperatureEconomizer* in order to establish an upper limit on outdoor air flow when the economizer is active.

**2.2.2.1.13 Field: Maximum Total Cooling Capacity**

The maximum allowed total (sensible plus latent) cooling capacity in Watts if Cooling Limit is set to *LimitCapacity* or *LimitFlowRateAndCapacity*. This field may be autosized. If blank, there is no limit. If Cooling Limit is set to *NoLimit* or *LimitFlowRate*, this field is ignored.

**2.2.2.1.14 Field: Heating Availability Schedule Name**

The name of a schedule (ref: Schedule) that denotes whether heating is available. A schedule value greater than 0 (usually 1 is used) indicates that heating and humidification are available. A value less than or equal to 0 (usually 0 is used) denotes that heating and humidification are not available. If blank, heating and humidification are always available.

### 2.2.2.1.15 Field: Cooling Availability Schedule Name

The name of a schedule (ref: Schedule) that denotes whether cooling is available. A schedule value greater than 0 (usually 1 is used) indicates that cooling and dehumidification are available. A value less than or equal to 0 (usually 0 is used) denotes that cooling and dehumidification is not available. If blank, cooling and dehumidification are always available.

### 2.2.2.1.16 Field: Dehumidification Control Type

Select from *ConstantSensibleHeatRatio*, *Humidistat*, *None*, or *ConstantSupplyHumidityRatio*. *ConstantSensibleHeatRatio* (the default) means that the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using a constant sensible heat ratio (SHR) (see next field). *Humidistat* means that there is a **ZoneControl:Humidistat** for this zone and the ideal loads system will attempt to meet the humidistat request (i.e. will dehumidify according to the Dehumidifying Relative Humidity Schedule in the **ZoneControl:Humidistat** object). *None* means that there is no dehumidification. *ConstantSupplyHumidityRatio* means that during cooling the supply air will always be at the Minimum Cooling Supply Humidity Ratio. For *ConstantSensibleHeatRatio* and *Humidistat*, if the mixed air humidity ratio is less than the target humidity ratio, then the mixed air humidity ratio will be used. For all options, the supply air humidity ratio will never be allowed to exceed saturation at the supply dry bulb temperature.

The selected dehumidification control type is always applied when the unit is in cooling mode. If the unit is in deadband mode (not actively heating the supply air) control type *Humidistat* will be active. If the unit is in heating mode, control type *Humidistat* will be active if the Humidification Control Type field below is set to *Humidistat* or *None*.

This allows the ideal loads system to heat and dehumidify at the same time.

### 2.2.2.1.17 Field: Cooling Sensible Heat Ratio

When the Dehumidification Control Type is set to *ConstantSensibleHeatRatio* the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using the value of Cooling Sensible Heat Ratio (SHR), where  $SHR = \text{Sensible Cooling} / \text{Total Cooling (sensible plus latent)}$ . The default is 0.7. If Dehumidification Control Type is set to something other than *ConstantSensibleHeatRatio* then this field will be ignored.

### 2.2.2.1.18 Field: Dehumidification Setpoint

This field specifies the zone humidistat relative humidity setpoint for dehumidification in percent (0 to 100). The default is 60%. This field is used only when the Dehumidification Control Type = *Humidistat*.

### 2.2.2.1.19 Field: Humidification Control Type

Select from *None*, *Humidistat*, or *ConstantSupplyHumidityRatio*. *None* means that there is no humidification. *Humidistat* means that there is a **ZoneControl:Humidistat** for this zone and the ideal loads system will attempt to meet the humidistat request (i.e., humidify according to the Humidifying Relative Humidity Setpoint Schedule in the **ZoneControl:Humidistat** object). *ConstantSupplyHumidityRatio* means that during heating the supply air will always be at the Maximum Heating Supply Humidity Ratio. The default is *None*. For *Humidistat*, if the mixed air humidity ratio is greater than the target humidity ratio, then the mixed air humidity ratio will be used. For all options, the supply air humidity ratio will never be allowed to exceed saturation at the supply dry bulb temperature.

The selected humidification control type is always applied when the unit is in heating mode. If the unit is in deadband mode (not actively heating the supply air) control type *Humidistat* will be active. If the unit is in cooling mode, control type *Humidistat* will be active if the Dehumidification Control Type field above is set to *Humidistat* or *None*.

This allows the ideal loads system to cool and humidify at the same time.

**2.2.2.1.20 Field: Humidification Setpoint**

This field specifies the zone humidistat relative humidity setpoint for humidification in percent (0 to 100). The default is 30%. This field is used only when the Humidification Control Type = *Humidistat*.

**2.2.2.1.21 Field: Outdoor Air Method**

The input must be either *None*, *Flow/Zone*, *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *None* means there is no outdoor air provided by this system. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *None*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object referenced in the Design Specification Outdoor Air Object Name field below.

**2.2.2.1.22 Field: Outdoor Air Flow Rate per Person**

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if Outdoor Air Method is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

**2.2.2.1.23 Field: Outdoor Air Flow Rate per Zone Floor Area**

The design outdoor air volumetric flow rate per square meter of floor area (units are m<sup>3</sup>/s-m<sup>2</sup>). This input is multiplied by the zone area to obtain a flow rate. This input is used if Outdoor Air Method is *Flow/Area*, *Sum* or *Maximum*. The default is 0.0.

**2.2.2.1.24 Field: Outdoor Air Flow Rate per Zone**

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if Outdoor Air Method is *Flow/Zone*, *Sum* or *Maximum*. The default is 0.0.

**2.2.2.1.25 Field: Design Specification Outdoor Air Object Name**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the outdoor air requirements and schedule for this system. The outdoor air flow rate may also be affected by the next two fields, Demand Controlled Ventilation Type and Outdoor Air Economizer Type. If this field is blank, this system will have no outdoor air, and all outdoor air control and heat recovery options will be ignored.

**2.2.2.1.26 Field: Demand Controlled Ventilation Type**

This field, along with the Design Specification Outdoor Air Object (if used) specifies how the minimum outdoor air flow rate is calculated. The choices are: *None*, *OccupancySchedule* or *CO2Setpoint*. The default is *None*.

- *None* means that the design occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field).

- **OccupancySchedule** means that the current occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field).
- **CO2Setpoint** means that the design occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field). In addition, the minimum outdoor air flow rate may be increased if necessary to maintain the level of indoor air carbon dioxide at or below the setpoint defined in a **ZoneControl:ContaminantController** object (the user must add this to the idf file along with other related inputs).

#### 2.2.2.1.27 Field: Outdoor Air Economizer Type

This field specifies if there is an outdoor air economizer. The choices are: *NoEconomizer*, *DifferentialDryBulb*, or *DifferentialEnthalpy*. The default is *NoEconomizer*. *DifferentialDryBulb* and *DifferentialEnthalpy* mean that the economizer will increase the outdoor air flow rate above the minimum outdoor air flow (see fields Design Specification Outdoor Air Object Name and Demand Controlled Ventilation Type) when there is a cooling load and the outdoor air temperature or enthalpy is below the zone exhaust air temperature or enthalpy. The *DifferentialDryBulb* and *DifferentialEnthalpy* options require that the Maximum Cooling Air Flow Rate be specified which will be used as the limit for maximum outdoor air flow rate.

#### 2.2.2.1.28 Field: Heat Recovery Type

Select from *None*, *Sensible*, or *Enthalpy*. *None* means that there is no heat recovery. *Sensible* means that there is sensible heat recovery whenever the zone exhaust air temperature is more favorable than the outdoor air temperature. *Enthalpy* means that there is latent and sensible heat recovery whenever the zone exhaust air enthalpy is more favorable than the outdoor air enthalpy. The default is *None*.

#### 2.2.2.1.29 Field: Sensible Heat Recovery Effectiveness

The sensible heat recovery effectiveness, where effectiveness is defined as the change in supply temperature divided by the difference in entering supply and relief air temperatures. The default is 0.70.

#### 2.2.2.1.30 Field: Latent Heat Recovery Effectiveness

The latent heat recovery effectiveness, where effectiveness is defined as the change in supply humidity ratio divided by the difference in entering supply and relief air humidity ratios. The default is 0.65.

---

### 2.2.3 HVACTemplate:Zone:BaseboardHeat

This object simulates a hot water or electric thermostatically controlled baseboard heating system. This object includes optional fields to combine the baseboard heat with a dedicated outdoor air system. If the zone is also served by another HVAC system, such as a PTAC or unitary air handler, then do not use this object. Instead, use the HVACTemplate:Zone:\* object for the forced air system and use the baseboard heating fields in that object.

#### 2.2.3.1 Inputs

##### 2.2.3.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

##### 2.2.3.1.2 Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple HVACTemplate:Zone:IdealLoadsAirSystem objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that detailed thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

##### 2.2.3.1.3 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating load will be multiplied by the number input in this field when the Baseboard Heating Capacity is autosized. If this field is left blank, the Heating Sizing Factor from Sizing:Parameters will be used.

##### 2.2.3.1.4 Field: Baseboard Heating Type

This field specifies the type of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric

The default choice is *HotWater*.

##### 2.2.3.1.5 Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

### 2.2.3.1.6 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the fan coil system. The baseboard heating will be set to heating sequence 2, which means it will meet any remaining heating load not met by the fan coil system.

### 2.2.3.1.7 Field: Dedicated Outdoor Air System Name

Enter the name of an **HVACTemplate:System:DedicatedOutdoorAir** object if this zone is served by a dedicated outdoor air system (DOAS). When a Dedicated Outdoor Air System Name is entered, the DOAS will provide ventilation air to the zone based on the outdoor air specifications in this object. If this field is blank, then the following outdoor air fields are ignored.

### 2.2.3.1.8 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

### 2.2.3.1.9 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if Outdoor Air Method is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

### 2.2.3.1.10 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m<sup>3</sup>/s-m<sup>2</sup>). This input is multiplied by the zone area to obtain a flow rate. This input is used if Outdoor Air Method is *Flow/Area*, *Sum* or *Maximum*. The default is 0.0.

### 2.2.3.1.11 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if Outdoor Air Method is *Flow/Zone*, *Sum* or *Maximum*. The default is 0.0.

### 2.2.3.1.12 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when Outdoor Air Method \* = DetailedSpecification\*.

### 2.2.3.1.13 Field: Design Specification Zone Air Distribution Object Name

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when Outdoor Air Method \* = DetailedSpecification\*.

As shown in an IDF:

```
HVACTemplate:Zone:BaseboardHeat,
SPACE1-1,           !- Zone Name

0.0,                !- Outdoor Air Flow Rate per Zone {m3/s}
,                   !- Design Specification Outdoor Air Object Name
;                   !- Design Specification Zone Air Distribution Object Name
```

## 2.2.4 HVACTemplate:Zone:FanCoil

This object simulates a 4 pipe fan coil unit with hot water heating coil, chilled water cooling coil, and an outdoor air mixer. The coils are served directly by **HVACTemplate:Plant:ChilledWaterLoop** and **HVACTemplate:Plant:HotWaterLoop** objects. No HVACTemplate:System object is required. Reference **ZoneHVAC:FourPipeFanCoil** for more details about the fan coil model.

### 2.2.4.1 Inputs

#### 2.2.4.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.4.1.2 Field: Template Thermostat Name

Enter the name of a **HVACTemplate:Thermostat** object. Multiple HVACTemplate:Zone:\* objects can reference the same **HVACTemplate:Thermostat** object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of **HVACTemplate:Thermostat**.

#### 2.2.4.1.3 Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating **SizingPeriod:DesignDay** and cooling **SizingPeriod:DesignDay**. Note that the zone must have a thermostat specified in order to autosize the flow rate. If a value is entered it is used as the maximum supply air flow rate into the zone. It will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m3/s.

#### 2.2.4.1.4 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from [Sizing:Parameters](#) will be used.

#### 2.2.4.1.5 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from [Sizing:Parameters](#) will be used.

#### 2.2.4.1.6 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a [DesignSpecification:OutdoorAir](#) object and optional [DesignSpecification:ZoneAirDistribution](#) object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

#### 2.2.4.1.7 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all [People](#) statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.4.1.8 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.4.1.9 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.4.1.10 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Fan coil systems are modeled with continuous fan operation, so this is also the supply fan operating schedule. If this field is blank, the schedule has values of 1 for all time periods.

**2.2.4.1.11 Field: Supply Fan Total Efficiency**

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.4.1.12 Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa.

**2.2.4.1.13 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

**2.2.4.1.14 Field: Supply Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

**2.2.4.1.15 Field: Cooling Coil Type**

There are three coil types available:

- *ChilledWater* uses the **Coil:Cooling:Water** object with the DetailedAnalysis option. This is the preferred coil model for most applications.
- *ChilledWaterDetailedFlatModel* uses the **Coil:Cooling:Water:DetailedGeometry** object. This option is available for special applications.
- *HeatExchangerAssistedChilledWater* uses **CoilSystem:Cooling:Water:HeatExchangerAssisted** with **Coil:Cooling:Water** for enhanced dehumidification.

The default is *ChilledWater*.

**2.2.4.1.16 Field: Cooling Coil Availability Schedule Name**

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of one indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.4.1.17 Field: Cooling Coil Design Setpoint**

This is the design supply air temperature in C used to size the cooling supply air flow and the cooling coil. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 14°C.

**2.2.4.1.18 Field: Heating Coil Type**

There are two types available, *HotWater* and *Electric*. The default is *HotWater*.

#### 2.2.4.1.19 Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

#### 2.2.4.1.20 Field: Heating Coil Design Setpoint

This is the design supply air temperature in C used to size the heating supply air flow and the heating coil. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

#### 2.2.4.1.21 Field: Dedicated Outdoor Air System Name

Enter the name of an **HVACTemplate:System:DedicatedOutdoorAir** object if this zone is served by a dedicated outdoor air system (DOAS). When a Dedicated Outdoor Air System Name is entered, the outdoor air flow rate for this zone equipment object will be set to zero and the DOAS will provide the ventilation air to the zone based on the outdoor air specifications in this object. For this fancoil system (ref. **ZoneHVAC:FourPipeFanCoil**);, the “Capacity Control Method” will be set to CyclingFan if a DOAS system is specified. If this field is blank, then the zone served by this fancoil system will not be served by a DOAS, and the fancoil Capacity Control Method will be ConstantFanVariableFlow.

#### 2.2.4.1.22 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Cooling Coil Design Setpoint will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

#### 2.2.4.1.23 Field: Zone Cooling Design Supply Air Temperature Difference

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

#### 2.2.4.1.24 Field: Zone Heating Design Supply Air Temperature Input Method

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Heating Coil Design Setpoint will be used for sizing the zone heating design air flow rate and the heating coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

#### 2.2.4.1.25 Field: Zone Heating Design Supply Air Temperature Difference

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

#### 2.2.4.1.26 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

**2.2.4.1.27 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

**2.2.4.1.28 Field: Fan Coil Capacity Control Method**

This input denotes how the unit's output is controlled in order to meet zone heating or cooling requirement. The choices are:

- *ConstantFanVariableFlow*: The fan speed is held constant to produce a fixed air flow rate whenever the unit is scheduled on. The hot water or chilled flow rate is varied so that the unit output matches the zone heating or cooling requirement.
- *CyclingFan*: The fan speed is chosen so that the unit capacity is greater than or equal to the heating / cooling load and the fan is cycled to match unit output with the load.
- *VariableFanVariableFlow*: Both air and water flow rates are varied to match the load.
- *VariableFanConstantFlow*: The water flow rate is at full flow and the fan speed varies to meet the load.
- *MultiSpeedFan*: The water flow rate is at full flow when there is load or fully closed when there is no load and the supply air flow rate is varied by varying the fan speed in order to match the load.
- *ASHRAE90VariableFan*: The fan air flow rate is reduced according to the low speed supply air flow ratio when the zone sensible load is less than the zone sensible load multiplied by the low speed supply air flow ratio.

The default is *ConstantFanVariableFlow* except when a Dedicated Outdoor Air System is specified (see above) the default is *CyclingFan*.

**2.2.4.1.29 Field: Low Speed Supply Air Flow Ratio**

This numerical field specifies the ratio of the low speed flow rate to the maximum supply air flow rate. Its value should be less than *Medium Speed Supply Air Flow Ratio*. If left blank, the default value is 0.33. This field is ignored if the capacity control method selected is not *CyclingFan*.

**2.2.4.1.30 Field: Medium Speed Supply Air Flow Ratio**

This numerical field specifies the ratio of the medium speed flow rate to the maximum supply air flow rate. Its value should be greater than the *Low Speed Supply Air Flow Ratio* but less than 1. If left blank, the default value is 0.66. This field is ignored if the capacity control method selected is not *CyclingFan*.

**2.2.4.1.31 Field: Outdoor Air Schedule Name**

**2.2.4.1.32** The name of a schedule whose values (0.0 to 1.0) are used as multipliers to alter the outdoor air flow rate. If this field is left blank, the values will default to 1.0. This schedule is ignored if the zone is served by an HVACTemplate dedicated outdoor air system.

```

OUTAIRFANCOILSCHEDULE,  !- Outdoor Air Schedule Name
None,                   !- Baseboard Heating Type
,                       !- Baseboard Heating Availability Schedule Name
Autosize;               !- Baseboard Heating Capacity {W}

```

## 2.2.5 HVACTemplate:Zone:PTAC

This object simulates a packaged terminal air conditioner (PTAC) with a DX cooling coil, a heating coil (electric, gas, or hot water), and an outdoor air mixer. The optional hot water heating coil is served directly by [HVACTemplate:Plant:HotWaterLoop](#) and [HVACTemplate:Plant:Boiler](#) objects. No [HVACTemplate:System](#) object is required. Reference [ZoneHVAC:PackagedTerminalAirConditioner](#) for more details about the PTAC model.

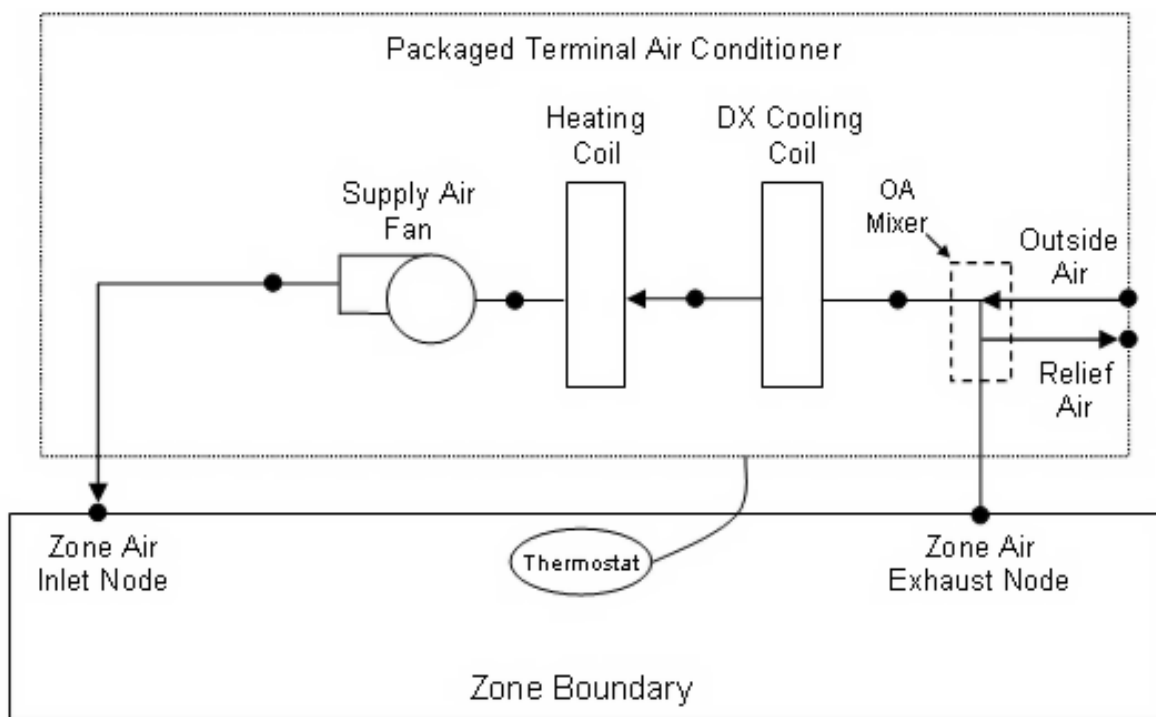

Figure 2.1: Schematic of a packaged terminal air conditioner with draw through fan placement

### 2.2.5.1 Inputs

#### 2.2.5.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.5.1.2 Field: Template Thermostat Name

Enter the name of a [HVACTemplate:Thermostat](#) object. Multiple [HVACTemplate:Zone:\\*](#) objects can reference the same [HVACTemplate:Thermostat](#) object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of [HVACTemplate:Thermostat](#).

### 2.2.5.1.3 Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the DX cooling coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

### 2.2.5.1.4 Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

### 2.2.5.1.5 Field: No Load Supply Air Flow Rate

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. A value entered in this field will *not* be multiplied by the sizing factor or by zone multipliers. It is best to autosize or leave blank when using zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

### 2.2.5.1.6 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Heating Supply Air Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from **Sizing:Parameters** will be used.

### 2.2.5.1.7 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Cooling Supply Air Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from **Sizing:Parameters** will be used.

### 2.2.5.1.8 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are

referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

#### 2.2.5.1.9 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.5.1.10 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.5.1.11 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.5.1.12 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. When the fan operating mode schedule indicates continuous fan operation, the fan will operate whenever this schedule is 1.0. If the fan operating schedule indicates cycling fan operation, then fan will only cycle on as needed to meet a load.

#### 2.2.5.1.13 Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, a schedule of always zero (cycling fan) will be used.

#### 2.2.5.1.14 Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

#### 2.2.5.1.15 Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.5.1.16 Field: Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 75.

**2.2.5.1.17 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. The default is 0.9.

**2.2.5.1.18 Field: Cooling Coil Type**

Enter the type of cooling coil. There is currently only one choices for this field, SingleSpeedDX.

**2.2.5.1.19 Field: Cooling Coil Availability Schedule Name**

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.5.1.20 Field: Cooling Coil Gross Rated Total Capacity**

Enter autosize to let the automatic sizing algorithm determine the cooling coil gross capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is NOT accounted for. The units are in W. The default is autosize.

**2.2.5.1.21 Field: Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the sensible capacity divided by total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for. The default is autosize.

**2.2.5.1.22 Field: Cooling Coil Gross Rated Cooling COP**

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 3.0.

**2.2.5.1.23 Field: Heating Coil Type**

Enter the type of heating coil. The choices for this field are

- Electric
- HotWater

- Gas

If `HotWater` is specified, then a `HVACTemplate:Plant:HotWaterLoop` and a `HVACTemplate:Plant:Boiler` must be included in the input file to serve this hot water coil. The default is `Electric`.

#### 2.2.5.1.24 Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of 1.0 indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period.

#### 2.2.5.1.25 Field: Heating Coil Capacity

Enter `autosize` to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts. The default is `autosize`.

#### 2.2.5.1.26 Field: Gas Heating Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the heating coil type is gas.

#### 2.2.5.1.27 Field: Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W. This field applies only if the heating coil type is gas.

#### 2.2.5.1.28 Field: Dedicated Outdoor Air System Name

Enter the name of an `HVACTemplate:System:DedicatedOutdoorAir` object if this zone is served by a dedicated outdoor air system (DOAS). When a Dedicated Outdoor Air System Name is entered, the outdoor air flow rate for this zone equipment object (ref. `ZoneHVAC:PackagedTerminalAirConditioner`) will be set to zero and the DOAS will provide the ventilation air to the zone based on the outdoor air specifications in this object. If this field is blank, then the zone served by this PTAC system will not be served by a DOAS.

#### 2.2.5.1.29 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

#### 2.2.5.1.30 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 14°C.

**2.2.5.1.31 Field: Zone Cooling Design Supply Air Temperature Difference**

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

**2.2.5.1.32 Field: Zone Heating Design Supply Air Temperature Input Method**

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Heating Coil Design Setpoint will be used for sizing the zone heating design air flow rate and the heating coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

**2.2.5.1.33 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

**2.2.5.1.34 Field: Zone Heating Design Supply Air Temperature Difference**

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

**2.2.5.1.35 Field: Design Specification Outdoor Air Object Name**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

**2.2.5.1.36 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

**2.2.5.1.37 Field: Baseboard Heating Type**

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

**2.2.5.1.38 Field: Baseboard Heating Availability Schedule Name**

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

### 2.2.5.1.39 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the PTAC system. The baseboard heating will be set to heating sequence 2, which means it will meet any remaining heating load not met by the PTAC system.

### 2.2.5.1.40 Field: Capacity Control Method

This input denotes how the unit's output is controlled in order to meet zone heating or cooling requirement. The choices are *None* or *SingleZoneVAV*. For *None*, the unit varies the fan and/or coil speed to meet the load. If constant fan operating mode is selected the fan operates at the design cooling or heating air flow rate while the coil modulates to meet the load. If cycling fan operating mode is selected the fan and coil modulate in unison to meet the load. For *SingleZoneVAV*, the fan air flow rate is reduced to the no load supply air flow rate when the zone sensible load is low such that the maximum supply air temperature limit is not exceeded. If the unit cannot meet the load at this lower air flow rate, the fan speed increases while maintaining the maximum supply air temperature. If the unit still cannot meet the load the unit will operate at the maximum supply air flow rate and the maximum supply air temperature limit can be exceeded. Supply air temperature limits are identified in the **ZoneHVAC:PackagedTerminalAirConditioner** input fields for Minimum Supply Air Temperature in Cooling Mode and Maximum Supply Air Temperature in Heating Mode. Additionally, specific coil types are required for the SingleZoneVAV capacity control method. The cooling coil type is **Coil:Cooling:DX:SingleSpeed** while the heating coil types are **Coil:Heating:Water**, **Coil:Heating:Fuel** and **Coil:Heating:Electric**. If alternate coil types are used they are modeled using the load based control method.

## 2.2.6 HVACTemplate:Zone:PTHP

This object simulates a packaged terminal air-to-air heat pump (PTHP) with a DX cooling coil, a DX air-to-air heat pump heating coil, a supplemental heating coil (electric or gas), and an outdoor air mixer. No HVACTemplate:System object is required. Reference [ZoneHVAC:PackagedTerminalHeatPump](#) for more details about the PTHP model.

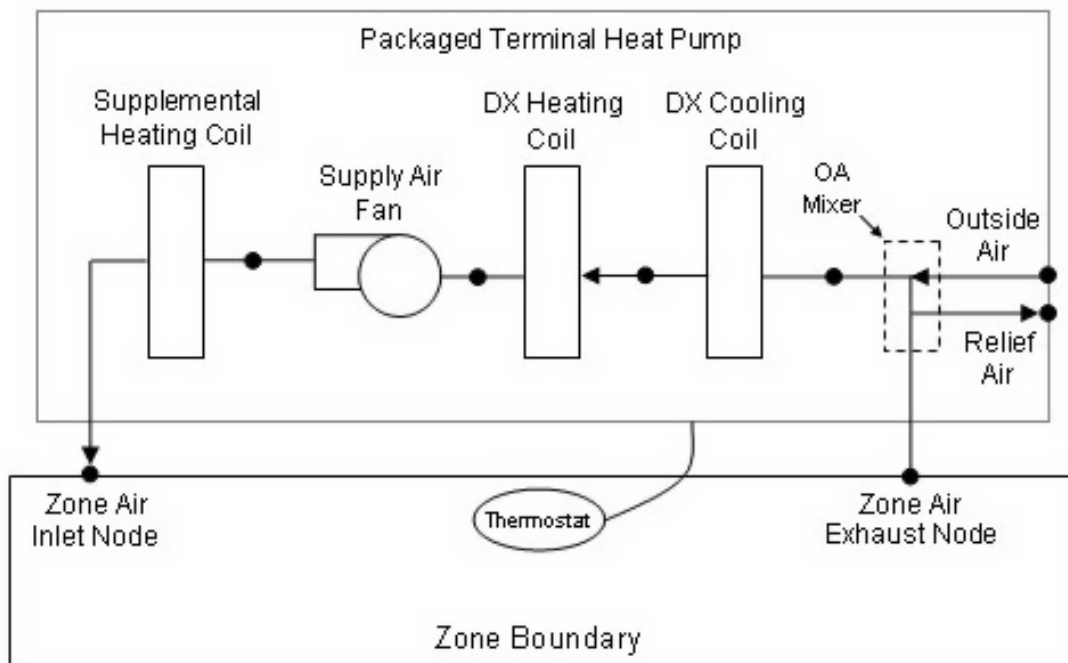

Figure 2.2: Schematic of a packaged terminal heat pump (draw through fan placement)

### 2.2.6.1 Inputs

#### 2.2.6.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.6.1.2 Field: Template Thermostat Name

Enter the name of a [HVACTemplate:Thermostat](#) object. Multiple HVACTemplate:Zone:\* objects can reference the same [HVACTemplate:Thermostat](#) object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of [HVACTemplate:Thermostat](#).

### 2.2.6.1.3 Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the DX cooling coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

### 2.2.6.1.4 Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

### 2.2.6.1.5 Field: No Load Supply Air Flow Rate

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. A value entered in this field will *not* be multiplied by the sizing factor or by zone multipliers. It is best to autosize or leave blank when using zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

### 2.2.6.1.6 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Heating Supply Air Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from **Sizing:Parameters** will be used.

### 2.2.6.1.7 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Cooling Supply Air Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from **Sizing:Parameters** will be used.

### 2.2.6.1.8 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are

referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

#### 2.2.6.1.9 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.6.1.10 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.6.1.11 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.6.1.12 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. When the fan operating mode schedule indicates continuous fan operation, the fan will operate whenever this schedule is 1.0. If the fan operating schedule indicates cycling fan operation, then fan will only cycle on as needed to meet a load.

#### 2.2.6.1.13 Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, a schedule of always zero (cycling fan) will be used.

#### 2.2.6.1.14 Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

#### 2.2.6.1.15 Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.6.1.16 Field: Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 75.

**2.2.6.1.17 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. The default is 0.9.

**2.2.6.1.18 Field: Cooling Coil Type**

Enter the type of cooling coil. There is currently only one choices for this field, SingleSpeedDX.

**2.2.6.1.19 Field: Cooling Coil Availability Schedule Name**

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.6.1.20 Field: Cooling Coil Gross Rated Total Capacity**

Enter autosize to let the automatic sizing algorithm determine the gross cooling coil total capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is autosize.

**2.2.6.1.21 Field: Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the gross sensible heat ratio based on the gross rated capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by the gross total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for. The default is autosize.

**2.2.6.1.22 Field: Cooling Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 3.0. The gross COP should not account for the supply air fan.

**2.2.6.1.23 Field: Heat Pump Heating Coil Type**

Enter the type of heat pump heating coil. There is currently only one choices for this field, SingleSpeedDXHeatPump.

**2.2.6.1.24 Field: Heat Pump Heating Coil Availability Schedule Name**

Usually set to blank, which allows the heat pump heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. A schedule value of 1.0 indicates that the heat pump heating coil can be on during a given time period. A value of zero denotes that the heat pump heating coil cannot be used during that time period.

**2.2.6.1.25 Field: Heat Pump Heating Coil Gross Rated Capacity**

Enter autosize to let the automatic sizing algorithm determine the heat pump heating coil gross rated capacity based on the maximum heating loads during the heating design day. If a value is entered, it represents the full load gross heating capacity, in watts of the DX heat pump unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is autosize.

**2.2.6.1.26 Field: Heat Pump Heating Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross heating coil capacity in watts divided by electrical power input in watts of the DX heating coil unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 2.75.

**2.2.6.1.27 Field: Heat Pump Heating Minimum Outdoor Dry-Bulb Temperature**

This numeric field defines the minimum outdoor dry-bulb temperature in degrees Celsius for PTHP compressor operation. The compressor will not operate (for DX heating or DX cooling) when outdoor dry-bulb temperatures fall below this value. The minimum value must be greater than or equal to -20 °C. The default value is -8°C.

**2.2.6.1.28 Field: Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

**2.2.6.1.29 Field: Heat Pump Defrost Strategy**

This alpha field has two choices: *ReverseCycle* or *Resistive*. If the *ReverseCycle* strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a *Resistive* defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is *ReverseCycle*.

**2.2.6.1.30 Field: Heat Pump Defrost Control**

This alpha field has two choices: *Timed* or *OnDemand*. If *Timed* control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For *Timed* defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If *OnDemand* defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature

entered in the input field “Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature” described above. If this input field is left blank, the default defrost control is *Timed*.

#### **2.2.6.1.31 Field: Heat Pump Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Heat Pump Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

#### **2.2.6.1.32 Field: Supplemental Heating Coil Type**

Enter the type of supplemental heating coil. The choices for this field are

- Electric
- Gas
- HotWater

The default is Electric.

#### **2.2.6.1.33 Field: Supplemental Heating Coil Availability Schedule Name**

Usually set to blank, which allows the supplemental heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when supplemental heating is only available seasonally. The schedule values denote whether the supplemental heating coil can run during a given time period. A schedule value of 1.0 indicates that the supplemental heating coil can be on during a given time period. A value of zero denotes that the supplemental heating coil cannot be used during that time period

#### **2.2.6.1.34 Field: Supplemental Heating Coil Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the supplemental heating coil can deliver in Watts. The default is autosize.

#### **2.2.6.1.35 Field: Supplemental Heating Coil Maximum Outdoor Dry-Bulb Temperature**

This numeric field defines the outdoor air dry-bulb temperature above which the supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

#### **2.2.6.1.36 Field: Supplemental Gas Heating Coil Efficiency**

Enter supplemental heating coil gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the supplemental heating coil type is gas.

#### **2.2.6.1.37 Field: Supplemental Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas supplemental heating coil operation, such as a combustion fan. The units are in W. The default is 0.0. This field applies only if the supplemental heating coil type is gas.

#### 2.2.6.1.38 Field: Dedicated Outdoor Air System Name

Enter the name of an **HVACTemplate:System:DedicatedOutdoorAir** object if this zone is served by a dedicated outdoor air system (DOAS). When a Dedicated Outdoor Air System Name is entered, the outdoor air flow rate for this zone equipment object (ref. **ZoneHVAC:PackagedTerminalHeatPump**) will be set to zero and the DOAS will provide the ventilation air to the zone based on the outdoor air specifications in this object. If this field is blank, then the zone served by this PTHP system will not be served by a DOAS.

#### 2.2.6.1.39 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

#### 2.2.6.1.40 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 14°C.

#### 2.2.6.1.41 Field: Zone Cooling Design Supply Air Temperature Difference

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

#### 2.2.6.1.42 Field: Zone Heating Design Supply Air Temperature Input Method

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Heating Coil Design Setpoint will be used for sizing the zone heating design air flow rate and the heating coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

#### 2.2.6.1.43 Field: Zone Heating Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

#### 2.2.6.1.44 Field: Zone Heating Design Supply Air Temperature Difference

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

#### 2.2.6.1.45 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

**2.2.6.1.46 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

**2.2.6.1.47 Field: Baseboard Heating Type**

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

**2.2.6.1.48 Field: Baseboard Heating Availability Schedule Name**

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

**2.2.6.1.49 Field: Baseboard Heating Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the PTHP system. The baseboard heating will be set to heating sequence 2, which means it will meet any remaining heating load not met by the PTHP system.

**2.2.6.1.50 Field: Capacity Control Method**

This input denotes how the unit's output is controlled in order to meet zone heating or cooling requirement. The choices are **None** or **SingleZoneVAV**. For **None**, the unit varies the fan and/or coil speed to meet the load. If constant fan operating mode is selected the fan operates at the design cooling or heating air flow rate while the coil modulates to meet the load. If cycling fan operating mode is selected the fan and coil modulate in unison to meet the load. For **SingleZoneVAV**, the fan air flow rate is reduced to the no load supply air flow rate when the zone sensible load is low such that the maximum supply air temperature limit is not exceeded. If the unit cannot meet the load at this lower air flow rate, the fan speed increases while maintaining the maximum supply air temperature. If the unit still cannot meet the load the unit will operate at the maximum supply air flow rate and the maximum supply air temperature limit can be exceeded. Supply air temperature limits are identified in the **Zone-HVAC:PackagedTerminalHeatPump** input fields for Minimum Supply Air Temperature in Cooling Mode and Maximum Supply Air Temperature in Heating Mode. Additionally, specific coil types are required for the SingleZoneVAV capacity control method. The cooling coil type is **Coil:Cooling:DX:SingleSpeed** while the heating coil type is **Coil:Heating:DX:SingleSpeed**.

As shown in an IDF:

## 2.2.7 HVACTemplate:Zone:WaterToAirHeatPump

This object simulates the zone portion of a water source heat pump system. Often many HVACTemplate:Zone:WaterToAirHeatPump objects will be used in a building along with a single HVACTemplate:Plant:MixedWaterLoop that contains a cooling tower and boiler.

### 2.2.7.1 Inputs

#### 2.2.7.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

**2.2.7.1.2 Field: Template Thermostat Name**

Enter the name of a **HVACTemplate:Thermostat** object. Multiple HVACTemplate:Zone:\* objects can reference the same **HVACTemplate:Thermostat** object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of **HVACTemplate:Thermostat**.

**2.2.7.1.3 Field: Cooling Supply Air Flow Rate**

This field specifies the supply air flow rate when the unit is operating in cooling mode. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m3/s. The default is autosize.

**2.2.7.1.4 Field: Heating Supply Air Flow Rate**

This field specifies the supply air flow rate when the unit is operating in heating mode. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m3/s. The default is autosize.

**2.2.7.1.5 Field: No Load Supply Air Flow Rate**

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., the coil is off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. A value entered in this field will *not* be multiplied by the sizing factor or by zone multipliers. It is best to autosize or leave blank when using zone multipliers. The units are in m3/s. The default is autosize.

**2.2.7.1.6 Field: Zone Heating Sizing Factor**

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Heating Supply Air Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from **Sizing:Parameters** will be used.

**2.2.7.1.7 Field: Zone Cooling Sizing Factor**

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Cooling Supply Air Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from **Sizing:Parameters** will be used.

**2.2.7.1.8 Field: Outdoor Air Method**

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow*

*per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

#### 2.2.7.1.9 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.7.1.10 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.7.1.11 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.7.1.12 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. When the fan operating mode schedule indicates continuous fan operation, the fan will operate whenever this schedule is 1.0. If the fan operating schedule indicates cycling fan operation, then fan will only cycle on as needed to meet a load.

#### 2.2.7.1.13 Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, a schedule of always zero (cycling fan) will be used.

#### 2.2.7.1.14 Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

**2.2.7.1.15 Field: Supply Fan Total Efficiency**

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.7.1.16 Field: Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 75.

**2.2.7.1.17 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. The default is 0.9.

**2.2.7.1.18 Field: Cooling Coil Type**

Enter the type of cooling coil. There is currently only one choices for this field, `Coil:Cooling:WaterToAirHeatPump:`

**2.2.7.1.19 Field: Cooling Coil Gross Rated Total Capacity**

Enter autosize to let the automatic sizing algorithm determine the cooling coil gross rated total capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross total cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions (26.7C (80F) entering air dry-bulb temperature, 19.4C (67F) entering air wet-bulb temperature, and 29.4C (85F) entering water temperature). Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is autosize. If a value is specified for this field, it is recommended that the Cooling Coil Rated Sensible Heat Ratio also be specified (see below for more details).

**2.2.7.1.20 Field: Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by gross total cooling capacity of the DX cooling coil at rated conditions (26.7C (80F) entering air dry-bulb temperature, 19.4C (67F) entering air wet-bulb temperature, and 29.4C (85F) entering water temperature). Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for. The default is autosize. If the Cooling Coil Rated Capacity is autosized, this field should also be autosized (any value specified for Cooling Coil Rate Sensible Heat Ratio will be ignored). If the Cooling Coil Rated Capacity has a specified value, then this field should also have a specified value. This is because the `Coil:Cooling:WaterToAirHeatPump:EquationFit` object has fields for Rated Total Cooling Capacity and Rated Sensible Cooling Capacity. If this field is autosized, a specified value for Cooling Coil Rated Capacity will not be used when the coil object sensible capacity is autosized.

**2.2.7.1.21 Field: Cooling Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions (26.7C (80F) entering air dry-bulb temperature, 19.4C (67F) entering air wet-bulb temperature, and 29.4C (85F) entering water temperature). The input power includes electric power for the compressor and condenser fan but does not

include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 3.5.

#### **2.2.7.1.22 Field: Heat Pump Heating Coil Type**

Enter the type of heat pump heating coil. There is currently only one choices for this field, `Coil:Heating:WaterToAirHeatPump:EquationFit`.

#### **2.2.7.1.23 Field: Heat Pump Heating Coil Gross Rated Capacity**

Enter autosize to let the automatic sizing algorithm determine the heat pump heating coil gross capacity based on the maximum heating loads during the heating design day. If a value is entered, it represents the full load heating capacity, in watts of the DX heat pump unit at rated conditions (21.11C (70F) entering air dry-bulb temperature and 21.11C (70F) entering water temperature). Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is autosize.

#### **2.2.7.1.24 Field: Heat Pump Heating Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross heating coil capacity in watts divided by electrical power input in watts of the DX heating coil unit at rated conditions (21.11C (70F) entering air dry-bulb temperature and 21.11C (70F) entering water temperature). The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 4.2.

#### **2.2.7.1.25 Field: Supplemental Heating Coil Availability Schedule Name**

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when supplemental heating is only available seasonally. The schedule values denote whether the supplemental heating coil can run during a given time period. A schedule value of 1.0 indicates that the supplemental heating coil can be on during a given time period. A value of zero denotes that the supplemental heating coil cannot be used during that time period

#### **2.2.7.1.26 Field: Supplemental Heating Coil Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the supplemental heating coil can deliver in Watts. The default is autosize.

#### **2.2.7.1.27 Field: Maximum Cycling Rate**

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown below (Henderson et al. 1999):

#### **2.2.7.1.28 Field: Heat Pump Time Constant**

This numeric field contains the time constant for the cooling coil’s capacity to reach steady state after startup. Suggested values are shown below (Henderson et al. 1999):

#### **2.2.7.1.29 Field: Fraction of On-Cycle Power Use**

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Figure 2.3:

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Figure 2.4:

Heat Pump Condition	Recommended Values
Typical	0.01
Good	0.01
Poor	0.03

Figure 2.5:

### 2.2.7.1.30 Field: Heat Pump Fan Delay Time

This numeric field contains the time delay in seconds for the heat pump supply air fan to shut off after compressor cycle off. This value can be obtained from the manufacturer or the heat pump catalog. Suggested value is 60 seconds. This value is disregarded at times when the WaterToAirHeatPump's fan operating mode schedule value is greater than 0 (i.e., continuous fan mode).

### 2.2.7.1.31 Field: Dedicated Outdoor Air System Name

Enter the name of an **HVACTemplate:System:DedicatedOutdoorAir** object if this zone is served by a dedicated outdoor air system (DOAS). When a Dedicated Outdoor Air System Name is entered, the outdoor air flow rate for this zone equipment object (ref. **ZoneHVAC:WaterToAirHeatPump**) will be set to zero and the DOAS will provide the ventilation air to the zone based on the outdoor air specifications in this object. If this field is blank, then the zone served by this water-to-air heat pump system will not be served by a DOAS.

### 2.2.7.1.32 Field: Supplemental Heating Coil Type

Enter the type of supplemental heating coil. The choices for this field are

- Electric
- HotWater

The default is Electric.

### 2.2.7.1.33 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

### 2.2.7.1.34 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 14°C.

### 2.2.7.1.35 Field: Zone Cooling Design Supply Air Temperature Difference

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

### 2.2.7.1.36 Field: Zone Heating Design Supply Air Temperature Input Method

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Heating Coil Design Setpoint will be used for sizing the zone heating design air flow rate and the heating coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

### 2.2.7.1.37 Field: Zone Heating Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

**2.2.7.1.38 Field: Zone Heating Design Supply Air Temperature Difference**

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

**2.2.7.1.39 Field: Heat Pump Coil Water Flow Mode**

This field specifies the way in which water flow through the heat pump coils will be modeled. For this template, WatertoAirHeatPump:EquationFit coil objects are generated and, therefore, there are three options:

- Cycling
- Constant
- ConstantOnDemand

**Cycling** varies water flow through the coil based on the heat pump Part Load Ratio. This control method is appropriate for modeling heat pumps that are outfitted with a solenoid valve which allows water to flow through the coil only when the compressor is active. This is the **default** for EnergyPlus V8 and later.

**Constant** provides a constant water flow regardless of heat pump operation. Remember that EnergyPlus has two coils (a heating coil and a cooling coil) to approximate the operation of one coil that can operate in either heating mode or cooling mode. Therefore, when the water flow mode is constant, there will be full flow through either the heating coil or the cooling coil, but not both at the same time.

**ConstantOnDemand** provides full flow through the coil whenever there is a load. When there is no load, there is zero flow through the coil. This control strategy represents the way EnergyPlus modeled heat pump water flow prior to Version 8.

**2.2.7.1.40 Field: Design Specification Outdoor Air Object Name**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

**2.2.7.1.41 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

**2.2.7.1.42 Field: Baseboard Heating Type**

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

### 2.2.7.1.43 Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

### 2.2.7.1.44 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the heat pump system. The baseboard heating will be set to heating sequence 2, which means it will meet any remaining heating load not met by the heat pump system.

As shown in an IDF:

## 2.2.8 HVACTemplate:Zone:VRF

This object simulates a variable refrigerant flow (VRF) zone terminal unit which is served by an **HVACTemplate:System:VRF** condenser unit. Reference **ZoneHVAC:TerminalUnit:VariableRefrigerantFlow** for more details about the VRF terminal unit model.

### 2.2.8.1 Inputs

#### 2.2.8.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.8.1.2 Field: Template Thermostat Name

Enter the name of a **HVACTemplate:Thermostat** object. Multiple HVACTemplate:Zone:\* objects can reference the same **HVACTemplate:Thermostat** object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of **HVACTemplate:Thermostat**.

#### 2.2.8.1.3 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Heating Supply Air Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from **Sizing:Parameters** will be used.

#### 2.2.8.1.4 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Cooling Supply Air Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from **Sizing:Parameters** will be used.

#### 2.2.8.1.5 Field: Rated Total Heating Capacity Sizing Ratio

This numeric field defines the ratio of the heating coil to cooling coil size when autosizing is used. The model assumes that when used, this value will be greater than 1. This field supersedes the Rated Total Heating Capacity Sizing Ratio entered in the **AirConditioner:VariableRefrigerantFlow** object. If this field is left blank, the value entered in the parent object is used for sizing. If neither field is used, the sizing ratio is assumed to be 1.

#### 2.2.8.1.6 Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the terminal unit is operating in cooling mode. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

#### 2.2.8.1.7 Field: No Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the terminal unit's cooling coil is not operating and the previous mode was cooling.. This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will

be sized to match the smaller of the Cooling and Heating flow rates. A value entered in this field will *not* be multiplied by the sizing factor or by zone multipliers. It is best to autosize or leave blank when using zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

#### 2.2.8.1.8 Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating **SizingPeriod:DesignDay**. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

#### 2.2.8.1.9 Field: No Heating Supply Air Flow Rate

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. A value entered in this field will *not* be multiplied by the sizing factor or by zone multipliers. It is best to autosize or leave blank when using zone multipliers. The units are in m<sup>3</sup>/s. The default is autosize.

#### 2.2.8.1.10 Field: Cooling Outdoor Air Flow Rate

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in cooling mode. If this field is set to autosize it will be sized based on the outdoor air inputs below, unless a dedicated outdoor air system is specified for this zone and then it will be set to zero.

#### 2.2.8.1.11 Field: Heating Outdoor Air Flow Rate

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in heating mode. If this field is set to autosize it will be sized based on the outdoor air inputs below, unless a dedicated outdoor air system is specified for this zone and then it will be set to zero.

#### 2.2.8.1.12 Field: No Load Outdoor Air Flow Rate

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is not operating in cooling or heating mode. If this field is set to autosize it will be sized based on the outdoor air inputs below, unless a dedicated outdoor air system is specified for this zone and then it will be set to zero.

#### 2.2.8.1.13 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone

design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

#### 2.2.8.1.14 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.8.1.15 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.8.1.16 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.8.1.17 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

#### 2.2.8.1.18 Field: Design Specification Zone Air Distribution Object Name

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

#### 2.2.8.1.19 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. When the fan operating mode schedule indicates continuous fan operation, the fan will operate whenever this schedule is 1.0. If the fan operating schedule indicates cycling fan operation, then fan will only cycle on as needed to meet a load.

#### 2.2.8.1.20 Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, a schedule of always zero (cycling fan) will be used.

**2.2.8.1.21 Field: Supply Fan Placement**

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

**2.2.8.1.22 Field: Supply Fan Total Efficiency**

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1. The default is 0.7.

**2.2.8.1.23 Field: Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 75.

**2.2.8.1.24 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. The default is 0.9.

**2.2.8.1.25 Field: Cooling Coil Type**

Enter the type of cooling coil. The options are *VariableRefrigerantFlowDX* or *None*. The default is *VariableRefrigerantFlowDX*.

**2.2.8.1.26 Field: Cooling Coil Availability Schedule Name**

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.8.1.27 Field: Cooling Coil Gross Rated Total Capacity**

Enter autosize to let the automatic sizing algorithm determine the gross cooling coil total capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is autosize.

**2.2.8.1.28 Field: Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the gross sensible heat ratio based on the gross rated capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by the gross total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities

used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for. The default is autosize.

#### 2.2.8.1.29 Field: Heat Pump Heating Coil Type

Enter the type of heat pump heating coil. The options are *VariableRefrigerantFlowDX* or *None*. The default is *VariableRefrigerantFlowDX*.

#### 2.2.8.1.30 Field: Heat Pump Heating Coil Availability Schedule Name

Usually set to blank, which allows the heat pump heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. A schedule value of 1.0 indicates that the heat pump heating coil can be on during a given time period. A value of zero denotes that the heat pump heating coil cannot be used during that time period.

#### 2.2.8.1.31 Field: Heat Pump Heating Coil Gross Rated Capacity

Enter autosize to let the automatic sizing algorithm determine the heat pump heating coil gross rated capacity based on the maximum heating loads during the heating design day. If a value is entered, it represents the full load gross heating capacity, in watts of the DX heat pump unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is autosize.

#### 2.2.8.1.32 Field: Zone Terminal Unit On Parasitic Electricity Energy Use

This numeric field defines the parasitic electrical energy use of the zone terminal unit when either terminal unit coil is operating. When in cooling mode, this electric energy use is reported in a zone terminal unit cooling electric consumption output variable. When in heating mode, this electric energy use is reported in a zone terminal unit heating electric consumption output variable.

#### 2.2.8.1.33 Field: Zone Terminal Unit Off Parasitic Electricity Energy Use

This numeric field defines the parasitic electrical energy use of the zone terminal unit when the terminal unit coil(s) is not operating. When the previous mode was cooling, this electric energy use is reported in a zone terminal unit cooling electric consumption output variable. When the previous mode was heating, this electric energy use is reported in a zone terminal unit heating electric consumption output variable.

#### 2.2.8.1.34 Field: Dedicated Outdoor Air System Name

Enter the name of an *HVACTemplate:System:DedicatedOutdoorAir* object if this zone is served by a dedicated outdoor air system (DOAS). When a Dedicated Outdoor Air System Name is entered, the outdoor air flow rate for this zone equipment object (ref. *ZoneHVAC:TerminalUnit:VariableRefrigerantFlow*) will be set to zero and the DOAS will provide the ventilation air to the zone based on the outdoor air specifications in this object. If this field is blank, then the zone served by this VRF terminal unit will not be served by a DOAS.

#### 2.2.8.1.35 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

**2.2.8.1.36 Field: Zone Cooling Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 14°C.

**2.2.8.1.37 Field: Zone Cooling Design Supply Air Temperature Difference**

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

**2.2.8.1.38 Field: Zone Heating Design Supply Air Temperature Input Method**

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Heating Coil Design Setpoint will be used for sizing the zone heating design air flow rate and the heating coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

**2.2.8.1.39 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

**2.2.8.1.40 Field: Zone Heating Design Supply Air Temperature Difference**

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

**2.2.8.1.41 Field: Baseboard Heating Type**

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

**2.2.8.1.42 Field: Baseboard Heating Availability Schedule Name**

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

### 2.2.8.1.43 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the PTHP system. The baseboard heating will be set to heating sequence 2, which means it will meet any remaining heating load not met by the PTHP system.

## 2.2.9 HVACTemplate:Zone:Unitary

This object simulates the zone portion of a constant volume direct-expansion based HVAC configuration with several different heating options. Often a single HVACTemplate:Zone:Unitary object will be used with a single HVACTemplate:System:Unitary (or HVACTemplate:System:UnitaryHeatPump:AirToAir, or HVACTemplate:System:UnitarySystem) object to simulate single zone direct-expansion based air conditioning systems. In addition, multiple HVACTemplate:Zone:Unitary objects may appear

that all reference the same HVACTemplate:System object in a multiple zone version. For a multizone system, only one zone is specified as the control zone (see HVACTemplate:System:Unitary, HVACTemplate:System:UnitaryHeatPump:AirToAir, or HVACTemplate:System:UnitarySystem for more information). Direct expansion includes single packaged rooftop systems commonly seen in commercial applications and split systems commonly seen in residential applications.

### 2.2.9.1 Inputs

#### 2.2.9.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.9.1.2 Field: Template Unitary System Name

Enter the name of the HVACTemplate:System:Unitary, HVACTemplate:System:UnitaryHeatPump:AirToAir, or HVACTemplate:System:UnitarySystem object serving this zone.

#### 2.2.9.1.3 Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple HVACTemplate:Zone:\* objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

#### 2.2.9.1.4 Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay and cooling SizingPeriod:DesignDay. Note that the zone must have a thermostat specified in order to autosize the flow rate, even if it is not the control zone in a multiple zone unitary system. If a value is entered it is used as the maximum supply air flow rate into the zone. It will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The template unitary system object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it will scale the zone values to match. The units are in m<sup>3</sup>/s.

#### 2.2.9.1.5 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from Sizing:Parameters will be used.

#### 2.2.9.1.6 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from Sizing:Parameters will be used.

#### 2.2.9.1.7 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a

zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

If the air handler serving this zone serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system.

#### 2.2.9.1.8 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.9.1.9 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m<sup>3</sup>/s-m<sup>2</sup>). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.9.1.10 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.9.1.11 Field: Supply Plenum Name

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### 2.2.9.1.12 Field: Return Plenum Name

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### 2.2.9.1.13 Field: Baseboard Heating Type

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric

- None

The default choice is None.

#### 2.2.9.1.14 Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

#### 2.2.9.1.15 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the unitary air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the unitary system. Prior to v7.1, the capacity was only applied to electric baseboard. Starting with v7.1, the capacity will be used for both hot water and electric baseboard.

#### 2.2.9.1.16 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Cooling Design Supply Air Temperature from the template unitary system serving this zone will be used. The default is *SystemSupplyAirTemperature*.

#### 2.2.9.1.17 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 12.8°C.

#### 2.2.9.1.18 Field: Zone Cooling Design Supply Air Temperature Difference

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

#### 2.2.9.1.19 Field: Zone Heating Design Supply Air Temperature Input Method

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Zone Heating Design Supply Air Temperature will be used for sizing the zone heating design air flow rate. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Heating Design Supply Air Temperature from the template unitary system serving this zone will be used. The default is *SystemSupplyAirTemperature*.

**2.2.9.1.20 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

**2.2.9.1.21 Field: Zone Heating Design Supply Air Temperature Difference**

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

**2.2.9.1.22 Field: Design Specification Outdoor Air Object Name**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

**2.2.9.1.23 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

**2.2.10 HVACTemplate:Zone:VAV**

This object simulates the zone portion of a variable air volume HVAC configuration with several different heating options. When heating is required, this terminal unit will activate the reheat coil first, and then increase airflow if reverse action is specified. Multiple **HVACTemplate:Zone:VAV**, **HVACTemplate:Zone:VAV:FanPowered** or **HVACTemplate:Zone:VAV:HeatAndCool** objects are usually specified for each **HVACTemplate:System:VAV** or **HVACTemplate:System:PackagedVAV** object. Reheat is specified at the zone level. Reference **AirTerminal:SingleDuct:VAV:Reheat** and **AirTerminal:SingleDuct:VAV:NoReheat** for more details about VAV terminal units.

### 2.2.10.1 Inputs

#### 2.2.10.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.10.1.2 Field: Template VAV System Name

Enter the name of the `HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV` object serving this zone.

#### 2.2.10.1.3 Field: Template Thermostat Name

Enter the name of a `HVACTemplate:Thermostat` object. Multiple `HVACTemplate:Zone:*` objects can reference the same `HVACTemplate:Thermostat` object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of `HVACTemplate:Thermostat`.

#### 2.2.10.1.4 Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating `SizingPeriod:DesignDay` and cooling `SizingPeriod:DesignDay`. If a value is entered it is used as the maximum supply air flow rate into the zone. It will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The `HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV` object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it will scale the zone values to match. The units are in m<sup>3</sup>/s.

#### 2.2.10.1.5 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from `Sizing:Parameters` will be used.

#### 2.2.10.1.6 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from `Sizing:Parameters` will be used.

#### 2.2.10.1.7 Field: Zone Minimum Air Flow Method

This field is used to select how the program will determine the minimum flow rate to the zone while the system is operating. There are three choices for selecting how the minimum flow rate is specified: Constant, `FixedFlowRate`, and `Scheduled`. If `Constant` is entered, then the program will use the value for the constant minimum air flow fraction entered in the following field. If `FixedFlowRate` is entered, then the program will use the value entered in the field below called Fixed Minimum Air Flow Rate. If `Scheduled` is entered, then the program will obtain the value for minimum flow fraction from the schedule named in the field below called Minimum Air Flow Fraction Schedule Name.

#### 2.2.10.1.8 Field: Constant Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow

rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Constant. If the previous field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils. If this field and the following field have values, the greater of the two is used for sizing.

#### 2.2.10.1.9 Field: Fixed Minimum Air Flow Rate

The minimum flow rate to the zone while the system is operating, specified as a fixed minimum air flow rate in meters cubed per second. The minimum air flow rate is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the Zone Minimum Air Flow Method field is set to FixedFlowRate. If the Zone Minimum Air Flow Method field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils. Only one of these two minimum air flow fields (i.e., this field and the previous field) should be used at any time. If this field and the previous field have values, the greater of the two is used for sizing.

#### 2.2.10.1.10 Field: Minimum Air Flow Fraction Schedule Name

The name of a schedule that determines the value of the minimum air flow fraction. The schedule should contain fractions from 0.0 to 1.0. These values will define the minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Scheduled. If the previous field is left blank (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then the air flow rate used for sizing normal-action reheat coils is the average of the minimum and maximum values in this schedule. The air flow rate used for reheat coil sizing is reported with other component sizing information as “Reheat Coil Sizing Air Volume Flow Rate.”

#### 2.2.10.1.11 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name for Sizing and Design Specification Zone Air Distribution Object Name fields below.

If the air handler serving this zone serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system.

**2.2.10.1.12 Field: Outdoor Air Flow Rate per Person**

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

**2.2.10.1.13 Field: Outdoor Air Flow Rate per Zone Floor Area**

The design outdoor air volumetric flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

**2.2.10.1.14 Field: Outdoor Air Flow Rate per Zone**

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

**2.2.10.1.15 Field: Reheat Coil Type**

A reheat coil may be added to the VAV box with this field. The choices are:

- HotWater
- Electric
- Gas
- None

The default choice is None.

**2.2.10.1.16 Field: Reheat Coil Availability Schedule Name**

Leave this field blank if you want the reheat coil to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the coil is available should be specified as 1.0. Those times that the coil is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the coil is providing heat but a schedule of when it can provide heat.

**2.2.10.1.17 Field: Damper Heating Action**

The VAV box flow rate can be controlled in one of two ways during heating operation:

- Normal
- Reverse

Under “Normal” operation, the supply air flow into the zone is the minimum air flow rate of the VAV system during heating, essentially acting like a constant volume system during heating. Under “Reverse” the air flow rate through the VAV box may increase above the minimum air flow when the heating demand cannot be satisfied unless greater air flow is provided. The default value is Normal. Reverse action only applies when Reheat Coil Type is HotWater. For electric reheat coils, Normal and Reverse behave the same. For more details, please see the section for **AirTerminal:SingleDuct:VAV:Reheat**.

**2.2.10.1.18 Control Fields for Maximum Flow During Reheat:**

The following two fields are used only when Reheat Coil Object Type = **Coil:Heating:Water** and Damper Heating Action = Reverse. Maximum Flow per Zone Floor Area During Reheat and Maximum Flow Fraction During Reheat are two optional methods to calculate the maximum allowable air flow rate during reheat operation. If both are entered, the greater resulting flow rate is used. If Design Specification Outdoor Air Object Name is also specified, it may increase this limit to meet the outdoor air flow rate requirement. At no time will the maximum flow rate calculated here exceed the value for Maximum Air Flow Rate. This limit is active only when the zone thermostat requests heating and the VAV box damper is reverse acting.

**2.2.10.1.19 Field: Maximum Flow per Zone Floor Area During Reheat**

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is multiplied by the zone area, to determine the maximum volume flow rate ( $\text{m}^3/\text{s}$ ) allowed during reheat operation (see detailed explanation above). This field is autocalculatable. If autocalculate is selected, the value is set to  $0.002032 \text{ m}^3/\text{s}\cdot\text{m}^2$  ( $0.4 \text{ cfm}/\text{ft}^2$ ). If this field and the following field are entered, the greater of the two inputs is used. If this field and the following field are left blank, the maximum flow will not be limited.

**2.2.10.1.20 Field: Maximum Flow Fraction During Reheat**

This fraction is multiplied by the Maximum Air Flow Rate to determine the maximum volume flow rate ( $\text{m}^3/\text{s}$ ) allowed during reheat operation (see detailed explanation above). This field is autocalculatable. If autocalculate is selected, the value is set to  $0.002032 \text{ m}^3/\text{s}\cdot\text{m}^2$  ( $0.4 \text{ cfm}/\text{ft}^2$ ) multiplied by the zone floor area divided by the Maximum Air Flow Rate. If this field and the previous field are entered, the greater of the two inputs is used. If this field and the previous field are left blank, the maximum flow will not be limited.

**2.2.10.1.21 Field: Maximum Reheat Air Temperature**

This field specifies the maximum allowable supply air temperature ( $^{\circ}\text{C}$ ) leaving the reheat coil in a VAV terminal unit during heating operation. If left blank, there is no limit, and the supply air temperature to the space may become unrealistically high during heating operation. If unknown, a value of  $35^{\circ}\text{C}$  ( $95^{\circ}\text{F}$ ) is recommended. There is no default in order to maintain consistency with prior results.

**2.2.10.1.22 Field: Design Specification Outdoor Air Object Name for Control**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person is non-zero (in the specified **DesignSpecification:OutdoorAir** object), then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref **DesignSpecification:OutdoorAir** object).

Note that this field is used only for specifying the design outdoor air flow rate used for controlling the terminal unit air flow rate. The field *Design Specification Outdoor Air Object Name for Sizing* (see below) is used to specify the design outdoor air flow rate.

**2.2.10.1.23 Field: Supply Plenum Name**

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### 2.2.10.1.24 Field: Return Plenum Name

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### 2.2.10.1.25 Field: Baseboard Heating Type

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

#### 2.2.10.1.26 Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

#### 2.2.10.1.27 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the VAV air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the VAV system. Prior to v7.1, the capacity was only applied to electric baseboard. Starting with v7.1, the capacity will be used for both hot water and electric baseboard.

#### 2.2.10.1.28 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Cooling Design Supply Air Temperature from the template VAV system serving this zone will be used (Ref. **HVACTemplate:System:VAV** or **HVACTemplate:System:PackagedVAV**). The default is *SystemSupplyAirTemperature*.

#### 2.2.10.1.29 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 12.8°C.

**2.2.10.1.30 Field: Zone Cooling Design Supply Air Temperature Difference**

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

**2.2.10.1.31 Field: Zone Heating Design Supply Air Temperature Input Method**

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Zone Heating Design Supply Air Temperature will be used for sizing the zone heating design air flow rate and the heating or reheat coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

**2.2.10.1.32 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

**2.2.10.1.33 Field: Zone Heating Design Supply Air Temperature Difference**

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

**2.2.10.1.34 Field: Design Specification Outdoor Air Object Name for Sizing**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*. Note that this field is used only for specifying the design outdoor air flow rate used for sizing. The field *Design Specification Outdoor Air Object Name for Sizing* (see above) is used to actively control the VAV terminal air flow rate.

**2.2.10.1.35 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

### 2.2.11 HVACTemplate:Zone:VAV:FanPowered

This object simulates the zone portion of a variable air volume HVAC configuration with a series or parallel fan powered terminal unit (also know as a powered induction unit or PIU) and several different heating options. Multiple `HVACTemplate:Zone:VAV`, `HVACTemplate:Zone:VAV:FanPowered` or `HVACTemplate:Zone:VAV:HeatAndCool` objects are usually specified for each `HVACTemplate:System:VAV` or `HVACTemplate:System:PackedVAV` object. Reheat is specified at the zone level.

The series powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a fixed flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The fan runs at a constant volume flow rate whenever the unit is on (and the fan's availability schedule is on or it is activated by an availability manager). With `HVACTemplate:Zone:VAV:FanPowered`, the secondary fan will operate according to the Zone PIU Fan Schedule and any Night Cycle Control specified in the system it is served by.) The fan is downstream of the primary and secondary air inlets. The variable mixing is accomplished by a damper in the unit's primary air supply inlet duct. This damper can move from fully open (100% primary air, 0% secondary air) to a minimum stop that is specified in the input description. At full cooling the damper will be fully open. At minimum cooling and for heating the damper will be at the minimum stop and the secondary air flow will be at its maximum. Reference object `AirTerminal:SingleDuct:SeriesPIU:Reheat` for more details.

Figure 2.6: Series PIU Terminal Unit

The parallel powered induction unit is an air system terminal unit that mixes varying amounts of

secondary (recirculated) air and primary (conditioned supply) air to produce a variable total flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The secondary and primary air streams enter the unit in parallel. The fan sits in the secondary air stream and runs only when the primary air flow is below the Parallel Fan On Flow Fraction and the fan's availability schedule is on or it is activated by an availability manager. With `HVACTemplate:Zone:VAV:FanPowered`, the secondary fan will operate according to the Zone PIU Fan Schedule and any Night Cycle Control specified in the system it is served by.). The primary air inlet contains a damper that can move from fully open (maximum primary air) to a minimum stop (minimum primary air). At full cooling load the primary air damper is fully open and the fan is off. The primary air flow is at maximum and there is little or no secondary air flow. As the cooling load decreases, the primary air damper gradually closes and the secondary air flow remains close to zero. At some point, usually when the primary air flow has reached the minimum, the fan switches on and secondary air is induced. The heating coil will switch on as needed to meet any heating demand. Reference object `AirTerminal:SingleDuct:ParallelPIU:Reheat` for more details.

Figure 2.7: Parallel PIU Terminal Unit

### 2.2.11.1 Inputs

#### 2.2.11.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.11.1.2 Field: Template VAV System Name

Enter the name of the `HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV` object serving this zone.

#### 2.2.11.1.3 Field: Template Thermostat Name

Enter the name of a `HVACTemplate:Thermostat` object. Multiple `HVACTemplate:Zone:*` objects can reference the same `HVACTemplate:Thermostat` object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of `HVACTemplate:Thermostat`.

#### 2.2.11.1.4 Field: Primary Supply Air Maximum Flow Rate

In a fan powered VAV terminal unit, the primary air flow is the air supplied by the central air handler. By entering Autosize, the maximum primary supply air flow rate is automatically determined for the zone

based on the loads experienced by the zone during the specified and cooling `SizingPeriod:DesignDay`. If a value is entered it is used as the maximum supply air flow rate into the zone. It will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The `HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV` object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it will scale the zone values to match. The units are in m<sup>3</sup>/s.

#### 2.2.11.1.5 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Primary Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from `Sizing:Parameters` will be used.

#### 2.2.11.1.6 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Primary Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from `Sizing:Parameters` will be used.

#### 2.2.11.1.7 Field: Primary Supply Air Minimum Flow Fraction

Enter the fraction that the VAV box can reduce to based on the primary supply air maximum flow rate. This field may be sized automatically by entering Autosize.

#### 2.2.11.1.8 Field: Secondary Supply Air Maximum Flow Rate

In a fan powered VAV terminal unit, the secondary air flow is the air taken from the zone by the terminal unit fan. By entering Autosize, the maximum secondary supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating `SizingPeriod:DesignDay`. If a value is entered, it will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The units are in m<sup>3</sup>/s.

#### 2.2.11.1.9 Field: Flow Type

This field specifies the type of fan powered unit (PIU). The choices for this field are:

- Series – Series configuration with recirculation directly from the zone
- Parallel – Parallel configuration with recirculation directly from the zone
- SeriesFromPlenum – Series configuration with recirculation from the return plenum
- ParallelFromPlenum – Parallel configuration with recirculation from the return plenum

See descriptions of these configurations in the general description for this object, above. For all types, the secondary fan will run according to the Zone PIU Fan Schedule (see below) and any Night Cycle Control specified in the system which serves this terminal unit (see Template VAV System Name above). For Parallel PIU, there is an additional secondary fan control based on the primary air flow fraction (see Parallel Fan On Flow Fraction below). For recirculation from plenum, a Return Plenum Name must be specified in this object or in the system object (`HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV`) which serves this terminal unit. The default is Parallel.

**2.2.11.1.10 Field: Parallel Fan On Flow Fraction**

For parallel PIUs, this field specifies the fraction of the primary air flow at which fan turns on. In the parallel PIU the fan operation is intermittent. If the primary air flow is above this fraction of the maximum, the fan is off. Otherwise the secondary fan will run according to the System Availability Schedule and Night Cycle Control specified in the **HVACTemplate:System:VAV** or **HVACTemplate:System:PackagedVAV** which serves this terminal unit. This field does not apply to series PIUs.

**2.2.11.1.11 Field: Outdoor Air Method**

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

If the air handler serving this zone serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system.

**2.2.11.1.12 Field: Outdoor Air Flow Rate per Person**

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

**2.2.11.1.13 Field: Outdoor Air Flow Rate per Zone Floor Area**

The design outdoor air volumetric flow rate per square meter of floor area (units are m<sup>3</sup>/s-m<sup>2</sup>). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

**2.2.11.1.14 Field: Outdoor Air Flow Rate per Zone**

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

**2.2.11.1.15 Field: Reheat Coil Type**

A reheat coil may be added to the VAV box with this field. The choices are:

- HotWater
- Electric

- Gas

The default choice is Electric.

#### **2.2.11.1.16 Field: Reheat Coil Availability Schedule Name**

Leave this field blank if you want the reheat coil to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the coil is available should be specified as 1.0. Those times that the coil is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the coil is providing heat but a schedule of when it can provide heat.

#### **2.2.11.1.17 Field: Fan Total Efficiency**

Enter the total efficiency of the zone induction fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

#### **2.2.11.1.18 Field: Fan Delta Pressure**

Enter the pressure rise of the zone induction fan in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa.

#### **2.2.11.1.19 Field: Fan Motor Efficiency**

Enter the shaft power of the zone induction fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. Note that the zone fan motor is assumed to be 100% in the air stream.

#### **2.2.11.1.20 Field: Supply Plenum Name**

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### **2.2.11.1.21 Field: Return Plenum Name**

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### **2.2.11.1.22 Field: Baseboard Heating Type**

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

**2.2.11.1.23 Field: Baseboard Heating Availability Schedule Name**

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

**2.2.11.1.24 Field: Baseboard Heating Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the VAV air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the VAV system. Prior to v7.1, the capacity was only applied to electric baseboard. Starting with v7.1, the capacity will be used for both hot water and electric baseboard.

**2.2.11.1.25 Field: Zone Cooling Design Supply Air Temperature Input Method**

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Cooling Design Supply Air Temperature from the template VAV system serving this zone will be used (Ref. **HVACTemplate:System:VAV** or **HVACTemplate:System:PackagedVAV**). The default is *SystemSupplyAirTemperature*.

**2.2.11.1.26 Field: Zone Cooling Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 12.8°C.

**2.2.11.1.27 Field: Zone Cooling Design Supply Air Temperature Difference**

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

**2.2.11.1.28 Field: Zone Heating Design Supply Air Temperature Input Method**

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Zone Heating Design Supply Air Temperature will be used for sizing the zone heating design air flow rate and the heating or reheat coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

**2.2.11.1.29 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

### 2.2.11.1.30 Field: Zone Heating Design Supply Air Temperature Difference

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

### 2.2.11.1.31 Field: Zone PIU Fan Schedule Name

This is the operating schedule for the zone PIU fan. For a parallel PIU, the zone fan operates only when the primary air flow is below the Parallel Fan On Flow Fraction and the Zone PIU Fan Schedule is on, or when it is activated by an availability manager. For a series PIU, the zone fan operates whenever the Zone PIU Fan Schedule is on, or it is activated by an availability manager. If this field is left blank, the System Availability Schedule for the HVACTemplate:System serving this zone will be used.

### 2.2.11.1.32 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

### 2.2.11.1.33 Field: Design Specification Zone Air Distribution Object Name

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

## 2.2.12 HVACTemplate:Zone:VAV:HeatAndCool

This object simulates the zone portion of a variable air volume HVAC configuration with several different heating options. When heating is required, this terminal unit will increase airflow first and then activate the optional reheat coil. Multiple `HVACTemplate:Zone:VAV`, `HVACTemplate:Zone:VAV:FanPowered`, or `HVACTemplate:Zone:VAV:HeatAndCool` objects are usually specified for each `HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV` object. Reheat is specified at the zone level. Reference `AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat` and `AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat` for more details about these VAV terminal units.

### 2.2.12.1 Inputs

#### 2.2.12.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.12.1.2 Field: Template VAV System Name

Enter the name of the `HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV` object serving this zone.

#### 2.2.12.1.3 Field: Template Thermostat Name

Enter the name of a `HVACTemplate:Thermostat` object. Multiple `HVACTemplate:Zone:*` objects can reference the same `HVACTemplate:Thermostat` object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of `HVACTemplate:Thermostat`.

#### 2.2.12.1.4 Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating `SizingPeriod:DesignDay` and cooling `SizingPeriod:DesignDay`. If a value is entered it is used as the maximum supply air flow rate into the zone. It will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The `HVACTemplate:System:VAV` or `HVACTemplate:System:PackagedVAV` object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it will scale the zone values to match. The units are in m<sup>3</sup>/s.

#### 2.2.12.1.5 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from `Sizing:Parameters` will be used.

#### 2.2.12.1.6 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from `Sizing:Parameters` will be used.

#### 2.2.12.1.7 Field: Constant Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow

rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Constant. If the previous field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils. If this field and the following field have values, the greater of the two is used for sizing.

#### 2.2.12.1.8 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name for Sizing and Design Specification Zone Air Distribution Object Name fields below.

If the air handler serving this zone serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system.

#### 2.2.12.1.9 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.12.1.10 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.12.1.11 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.12.1.12 Field: Design Specification Outdoor Air Object Name for Sizing

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*. Note that this field is used only for specifying the design outdoor air flow rate used for sizing. The field *Design Specification Outdoor Air Object Name for Sizing* (see above) is used to actively control the VAV terminal air flow rate.

**2.2.12.1.13 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

**2.2.12.1.14 Field: Reheat Coil Type**

A reheat coil may be added to the VAV box with this field. The choices are:

- HotWater
- Electric
- Gas
- None

The default choice is None.

**2.2.12.1.15 Field: Reheat Coil Availability Schedule Name**

Leave this field blank if you want the reheat coil to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the coil is available should be specified as 1.0. Those times that the coil is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the coil is providing heat but a schedule of when it can provide heat.

**2.2.12.1.16 Field: Maximum Reheat Air Temperature**

This field specifies the maximum allowable supply air temperature (°C) leaving the reheat coil in a VAV terminal unit during heating operation. If left blank, there is no limit, and the supply air temperature to the space may become unrealistically high during heating operation. If unknown, a value of 35C (95F) is recommended. There is no default in order to maintain consistency with prior results.

**2.2.12.1.17 Field: Supply Plenum Name**

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

**2.2.12.1.18 Field: Return Plenum Name**

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

**2.2.12.1.19 Field: Baseboard Heating Type**

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric

- None

The default choice is None.

#### 2.2.12.1.20 Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

#### 2.2.12.1.21 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the VAV air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the VAV system. Prior to v7.1, the capacity was only applied to electric baseboard. Starting with v7.1, the capacity will be used for both hot water and electric baseboard.

#### 2.2.12.1.22 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Cooling Design Supply Air Temperature from the template VAV system serving this zone will be used (Ref. *HVACTemplate:System:VAV* or *HVACTemplate:System:PackagedVAV*). The default is *SystemSupplyAirTemperature*.

#### 2.2.12.1.23 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 12.8°C.

#### 2.2.12.1.24 Field: Zone Cooling Design Supply Air Temperature Difference

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

#### 2.2.12.1.25 Field: Zone Heating Design Supply Air Temperature Input Method

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Zone Heating Design Supply Air Temperature will be used for sizing the zone heating design air flow rate and the heating or reheat coil. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. The default is *SupplyAirTemperature*.

### 2.2.12.1.26 Field: Zone Heating Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

### 2.2.12.1.27 Field: Zone Heating Design Supply Air Temperature Difference

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

## 2.2.13 HVACTemplate:Zone:ConstantVolume

This object simulates the zone portion of a constant volume HVAC configuration with or without reheat. One or more HVACTemplate:Zone:ConstantVolume objects will be used with a single HVACTemplate:System:ConstantVolume which has optional chilled water cooling and several types of heating. Reference AirTerminal:SingleDuct:ConstantVolume:NoReheat and AirTerminal:SingleDuct:ConstantVolume:Reheat for more details about the terminal units.

### 2.2.13.1 Inputs

#### 2.2.13.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.13.1.2 Field: Template Constant Volume System Name

Enter the name of the HVACTemplate:System:ConstantVolume object serving this zone.

### 2.2.13.1.3 Field: Template Thermostat Name

Enter the name of a **HVACTemplate:Thermostat** object. Multiple HVACTemplate:Zone:\* objects can reference the same **HVACTemplate:Thermostat** object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of **HVACTemplate:Thermostat**.

### 2.2.13.1.4 Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating **SizingPeriod:DesignDay** and cooling **SizingPeriod:DesignDay**. Note that the zone must have a thermostat specified in order to autosize the flow rate, even if it is not the control zone in a multiple zone unitary system. If a value is entered it is used as the maximum supply air flow rate into the zone. It will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The **HVACTemplate:System:ConstantVolume** object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it will scale the zone values to match. The units are in m<sup>3</sup>/s.

### 2.2.13.1.5 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from **Sizing:Parameters** will be used.

### 2.2.13.1.6 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from **Sizing:Parameters** will be used.

### 2.2.13.1.7 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

If the air handler serving this zone serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system.

**2.2.13.1.8 Field: Outdoor Air Flow Rate per Person**

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

**2.2.13.1.9 Field: Outdoor Air Flow Rate per Zone Floor Area**

The design outdoor air volumetric flow rate per square meter of floor area (units are m<sup>3</sup>/s-m<sup>2</sup>). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

**2.2.13.1.10 Field: Outdoor Air Flow Rate per Zone**

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

**2.2.13.1.11 Field: Design Specification Outdoor Air Object Name**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

**2.2.13.1.12 Field: Design Specification Zone Air Distribution Object Name**

This alpha field specifies the name of a **DesignSpecification:ZoneAirDistribution** object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*.

**2.2.13.1.13 Field: Reheat Coil Type**

A reheat coil may be added to the terminal unit with this field. The choices are:

- HotWater
- Electric
- Gas
- None

The default choice is None.

**2.2.13.1.14 Field: Reheat Coil Availability Schedule Name**

Leave this field blank if you want the reheat coil to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the coil is available should be specified as 1.0. Those times that the coil is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the coil is providing heat but a schedule of when it can provide heat.

**2.2.13.1.15 Field: Maximum Reheat Air Temperature**

This field specifies the maximum allowable supply air temperature (°C) leaving the reheat coil during heating operation. If left blank, there is no limit, and the supply air temperature to the space may become unrealistically high during heating operation. If unknown, a value of 35C (95F) is recommended. There is no default in order to maintain consistency with prior results.

### 2.2.13.1.16 Field: Supply Plenum Name

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

### 2.2.13.1.17 Field: Return Plenum Name

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

### 2.2.13.1.18 Field: Baseboard Heating Type

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

### 2.2.13.1.19 Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

### 2.2.13.1.20 Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the air handling system. The baseboard heating will be set to heating sequence 2, which means it will meet any remaining heating load not met by the air handling system.

### 2.2.13.1.21 Field: Zone Cooling Design Supply Air Temperature Input Method

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Cooling Coil Design Setpoint Temperature from the template system serving this zone will be used (Ref. [HVACTemplate:System:ConstantVolume](#)). The default is *SystemSupplyAirTemperature*.

**2.2.13.1.22 Field: Zone Cooling Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 12.8°C.

**2.2.13.1.23 Field: Zone Cooling Design Supply Air Temperature Difference**

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

**2.2.13.1.24 Field: Zone Heating Design Supply Air Temperature Input Method**

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Zone Heating Design Supply Air Temperature will be used for sizing the zone heating design air flow rate. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Heating Coil Design Setpoint Temperature from the template system serving this zone will be used (Ref. [HVACTemplate:System:ConstantVolume](#)). The default is *SystemSupplyAirTemperature*.

**2.2.13.1.25 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

**2.2.13.1.26 Field: Zone Heating Design Supply Air Temperature Difference**

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

## 2.2.14 HVACTemplate:Zone:DualDuct

This object simulates the zone portion of a constant volume or variable volume dual-duct HVAC system. One or more HVACTemplate:Zone:DualDuct objects may be used with a single HVACTemplate:System:DualDuct object which has optional chilled water cooling and several types of heating. A constant air volume dual duct system is simulated by setting the Zone Minimum Air Flow Fraction = 1.0. A variable air volume duct duct system is simulated by setting the Zone Minimum Air Flow Fraction <1.0. . Reference AirTerminal:DualDuct:ConstantVolume and AirTerminal:DualDuct:VAV for more details about the terminal units.

### 2.2.14.1 Inputs

#### 2.2.14.1.1 Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

#### 2.2.14.1.2 Field: Template Dual Duct System Name

Enter the name of the HVACTemplate:System:DualDuct object serving this zone.

#### 2.2.14.1.3 Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple HVACTemplate:Zone:\* objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

#### 2.2.14.1.4 Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay and cooling SizingPeriod:DesignDay. Note that the zone must have a thermostat specified in order to autosize the flow rate, even if it is not the control zone in a multiple zone unitary system. If a value is entered it is used as the maximum supply air flow rate into the zone. It will be multiplied by the Supply Air Sizing Factor and by zone multipliers. The HVACTemplate:System:DualDuct object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it will scale the zone values to match. The units are in m3/s.

#### 2.2.14.1.5 Field: Zone Heating Sizing Factor

This input is the zone level heating sizing ratio. The zone design heating air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Heating Sizing Factor from Sizing:Parameters will be used.

#### 2.2.14.1.6 Field: Zone Cooling Sizing Factor

This input is the zone level cooling sizing ratio. The zone design cooling air flow rate and load will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the Cooling Sizing Factor from Sizing:Parameters will be used.

#### 2.2.14.1.7 Field: Zone Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. This field is ignored if the system serving this zone is constant volume.

#### 2.2.14.1.8 Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, *Maximum* or *DetailedSpecification*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

*DetailedSpecification* means that the outdoor air specifications will be taken from a **DesignSpecification:OutdoorAir** object and optional **DesignSpecification:ZoneAirDistribution** object. These objects are referenced in the Design Specification Outdoor Air Object Name and Design Specification Zone Air Distribution Object Name fields below.

If the air handler serving this zone serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system.

#### 2.2.14.1.9 Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 2.2.14.1.10 Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m<sup>3</sup>/s-m<sup>2</sup>). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

#### 2.2.14.1.11 Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

#### 2.2.14.1.12 Field: Design Specification Outdoor Air Object Name for Sizing

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone. This field is used only when *Outdoor Air Method* = *DetailedSpecification*. Note that this field is used only for specifying the design outdoor air flow rate used for sizing. The field *Design Specification Outdoor Air Object Name for Control* (see below) is used to actively control the VAV terminal air flow rate.

#### 2.2.14.1.13 Field: Design Specification Zone Air Distribution Object Name

This alpha field specifies the name of a `DesignSpecification:ZoneAirDistribution` object which specifies the air distribution effectiveness for the zone. This field is used only when *Outdoor Air Method = DetailedSpecification*.

#### 2.2.14.1.14 Field: Design Specification Outdoor Air Object Name for Control

This alpha field specifies the name of a `DesignSpecification:OutdoorAir` object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person (in the specified `DesignSpecification:OutdoorAir` object) is non-zero, then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref `DesignSpecification:OutdoorAir` object).

Note that this field is used only for specifying the design outdoor air flow rate used for controlling the terminal unit air flow rate. The field *Design Specification Outdoor Air Object Name for Sizing* (see above) is used to specify the design outdoor air flow rate.

#### 2.2.14.1.15 Field: Cold Supply Plenum Name

This field allows the user to specify a cold supply plenum zone which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### 2.2.14.1.16 Field: Hot Supply Plenum Name

This field allows the user to specify a hot supply plenum zone which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### 2.2.14.1.17 Field: Return Plenum Name

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

#### 2.2.14.1.18 Field: Baseboard Heating Type

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

**2.2.14.1.19 Field: Baseboard Heating Availability Schedule Name**

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

**2.2.14.1.20 Field: Baseboard Heating Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the VAV air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the VAV system. Prior to v7.1, the capacity was only applied to electric baseboard. Starting with v7.1, the capacity will be used for both hot water and electric baseboard.

**2.2.14.1.21 Field: Zone Cooling Design Supply Air Temperature Input Method**

This field selects the method for specifying the cooling design supply air temperature. *SupplyAirTemperature* means that the field Zone Cooling Design Supply Air Temperature will be used for sizing the zone cooling design air flow rate and the cooling coil. *TemperatureDifference* means that the field Zone Cooling Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Cooling Design Supply Air Temperature from the template system serving this zone will be used (Ref. [HVACTemplate:System:DualDuct](#)). The default is *SystemSupplyAirTemperature*.

**2.2.14.1.22 Field: Zone Cooling Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 12.8°C.

**2.2.14.1.23 Field: Zone Cooling Design Supply Air Temperature Difference**

The temperature difference between the cooling design supply air temperature and the zone air temperature in degrees Celsius for the zone cooling design air flow rate calculation and cooling coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Cooling Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 11.11 deltaC.

**2.2.14.1.24 Field: Zone Heating Design Supply Air Temperature Input Method**

This field selects the method for specifying the heating design supply air temperature. *SupplyAirTemperature* means that the field Zone Heating Design Supply Air Temperature will be used for sizing the zone heating design air flow rate. *TemperatureDifference* means that the field Zone Heating Design Supply Air Temperature Difference will be used. *SystemSupplyAirTemperature* means that the Heating Coil Design Setpoint Temperature from the template system serving this zone will be used (Ref. [HVACTemplate:System:DualDuct](#)). The default is *SystemSupplyAirTemperature*.

**2.2.14.1.25 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *SupplyAirTemperature*. The default is 50°C.

### 2.2.14.1.26 Field: Zone Heating Design Supply Air Temperature Difference

The temperature difference between heating design supply air temperature and zone air temperature in degrees Celsius for the zone heating design air flow rate calculation and heating coil sizing. The absolute value is used, so the sign may be positive or negative. This field is used only when Zone Heating Design Supply Air Temperature Input Method is *TemperatureDifference*. The default is 30 deltaC.

## 2.2.15 HVACTemplate:System:VRF

This model simulates a variable-refrigerant-flow (or variable-refrigerant-volume) air-conditioning system. This system type models direct-expansion cooling and/or heating coils configured in a zone terminal unit (ref. [HVACTemplate:Zone:VRF](#)). For more details about this system type see [AirConditioner:VariableRefrigerantFlow](#).

### 2.2.15.1 Inputs

#### 2.2.15.1.1 Field: Name

Enter a name for the HVACTemplate:System:VRF object. This name is used in the [HVACTemplate:Zone:VRF](#) object to reference this system.

#### 2.2.15.1.2 Field: System Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value other than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (and all of its terminal units) as required. If this field is blank, the unit is enabled the entire simulation.

**2.2.15.1.3 Field: Gross Rated Total Cooling Capacity**

This numeric field defines the gross rated total cooling capacity of the DX cooling coil in watts. The total cooling capacity should be a “gross”, i.e., the effect of supply air fan heat NOT accounted for.

**2.2.15.1.4 Field: Gross Rated Cooling COP**

This numeric field defines the cooling coefficient of performance at rated conditions. The cooling coefficient of performance includes compressor power and condenser fan power. This COP value does not account for impacts due to the supply air fan. The nominal heat pump cooling COP must be greater than 0. If this field is left blank, a default coefficient of performance of 3.3 is assumed.

**2.2.15.1.5 Field: Minimum Outdoor Temperature in Cooling Mode**

This numeric field defines the minimum outdoor dry-bulb temperature allowed for cooling operation. Below this temperature, cooling is disabled. If this field is left blank, the default value is -6°C.

**2.2.15.1.6 Field: Maximum Outdoor Temperature in Cooling Mode**

This numeric field defines the maximum outdoor dry-bulb temperature allowed for cooling operation. Above this temperature, cooling is disabled. If this field is left blank, the default value is 43°C.

**2.2.15.1.7 Field: Gross Rated Heating Capacity**

This numeric field defines the gross total heat pump heating capacity at rated conditions in watts. The nominal heat pump heating capacity must be greater than 0 or set to autosize.

**2.2.15.1.8 Field: Rated Heating Capacity Sizing Ratio**

This numeric field defines the ratio of gross heating to gross cooling capacity. The model assumes that when used, this value will be greater than 1. A similar input is available in the **Zone-HVAC:TerminalUnit:VariableRefrigerantFlow** object. When the heating capacity is autosized, if this field is non-blank, this ratio is used to scale the heating capacity to the gross rated total cooling capacity regardless of the value entered in the terminal unit objects. When the heating capacity is not autosized, the gross rated heating capacity will be equal to the sum of the terminal unit heating coil size. If this field is blank and the terminal unit sizing ratio input is also blank, then the heating capacity sizing ratio is assumed to be 1. If this field is not blank and the heating capacity sizing ratio in the terminal unit object(s) is blank, then this ratio also applies to each heating coil. If this field is not blank and the heating capacity sizing ratio in the terminal units is also not blank, then the terminal unit heating coil capacity sizing ratio input applies to each heating coil.

**2.2.15.1.9 Field: Gross Rated Heating COP**

This numeric field defines the heating coefficient of performance at rated conditions. The heating coefficient of performance includes compressor power and condenser fan power. This gross COP value does NOT account for the supply air fan. The nominal heat pump heating COP must be greater than 0. If this field is left blank, a coefficient of performance of 3.4 is assumed.

**2.2.15.1.10 Field: Minimum Outdoor Temperature in Heating Mode**

This numeric field defines the minimum outdoor temperature allowed for heating operation. Below this temperature, heating is disabled. If this field is left blank, the default value is -20°C.

**2.2.15.1.11 Field: Maximum Outdoor Temperature in Heating Mode**

This numeric field defines the maximum outdoor temperature allowed for heating operation. Above this temperature, heating is disabled. If this field is left blank, the default value is 16°C.

**2.2.15.1.12 Field: Minimum Heat Pump Part-Load Ratio**

This numeric field specifies the minimum operating part-load ratio (PLR) of the heat pump. When the heat pump operates at a PLR below this value, the heat pump's compressor will cycle to meet the cooling or heating demand. Above this value, the heat pump's compressor operates the entire time step to meet the cooling or heating demand. The minimum value for this field is 0. If this field is left blank, the default value is 0.15. When the heat pump compressor cycles, the previous field is used to determine cycling losses.

**2.2.15.1.13 Field: Zone Name for Master Thermostat Location**

This alpha field defines the name of the zone where the “master” thermostat is located. When the heat pump is connected to multiple zone terminal units, one terminal unit must be selected as the master thermostat. The remaining thermostats are slaves and can operate only in the same mode as the master thermostat.

**2.2.15.1.14 Field: Master Thermostat Priority Control Type**

This choice field determines the logic used to simulate the “master” thermostat. Valid choices are LoadPriority, ZonePriority, ThermostatOffsetPriority, MasterThermostatPriority, and Scheduled. The default value is MasterThermostatPriority. When LoadPriority is selected, the total zone load is used to choose the operating mode as either cooling or heating. When ZonePriority is selected, the number of zones requiring cooling or heating determines the operating mode. When ThermostatOffsetPriority is selected, the zone farthest from the thermostat set point determines the operating mode. The MasterThermostatPriority choice operates the system according the zone load where the master thermostat is located. The heat pump can also be scheduled to operate in either cooling or heating mode. For scheduled operation, a schedule name is entered in the following field.

**2.2.15.1.15 Field: Thermostat Priority Schedule Name**

This alpha field identifies the schedule used when the previous field is set to Scheduled. Schedule values of 0 denote cooling mode while values of 1 denote heating mode. Any other values will force the system off.

**2.2.15.1.16 Field: Heat Pump Waste Heat Recovery**

This choice field defines the configuration of the heat pump refrigeration system. Valid choices are **Yes** and **No**. If Yes is selected, heat recovery is enabled and the heat pump can independently cool and heat different zones. If No is selected, the heat pump is only able to cool or heat for any given time step.

**2.2.15.1.17 Field: Equivalent Piping Length used for Piping Correction Factor in Cooling Mode**

This numeric field defines the equivalent pipe length in meters between the farthest terminal unit and the heat pump condenser. This value includes the gas refrigerant line length (for both horizontal and vertical distances), fitting losses, pipe bends, and other connections that contribute to piping losses. This field is used to calculate the piping correction factor in cooling mode. This value defines the head losses due to the pipe length between the farthest terminal unit and the heat pump condenser and impacts the maximum available capacity in cooling mode.

**2.2.15.1.18 Field: Vertical Height used for Piping Correction Factor**

This numeric field defines the vertical pipe height in meters between the highest or lowest terminal unit and the heat pump condenser. This value defines the gravitational losses due to a change in height between the highest (positive value), or lowest (negative value) terminal unit and the heat pump condenser. The

distance specified here is applied to the piping correction factor calculation for both cooling and heating. If the distance between the highest terminal unit above the heat pump condenser is greater than the distance between the lowest terminal unit below the condenser enter the difference between the highest and lowest terminal units as a positive distance, otherwise enter this difference as a negative distance. Example: if the distance from the heat pump condenser to the highest terminal unit above the condenser is 10 m and the distance from the heat pump condenser to the lowest terminal unit below the condenser is -15 m, then enter a value of -5 m in this field. This head loss impacts the maximum available capacity in cooling mode.

#### **2.2.15.1.19 Field: Equivalent Piping Length used for Piping Correction Factor in Heating Mode**

This numeric field defines the equivalent pipe length in meters between the farthest terminal unit and the heat pump condenser. This value includes the liquid refrigerant line length (for both horizontal and vertical distances), fitting losses, pipe bends, and other connections that contribute to piping losses. This field is used to calculate the piping correction factor in heating mode. This value defines the head losses due to the pipe length between the farthest terminal unit and the heat pump condenser and impacts the maximum available capacity in heating mode.

#### **2.2.15.1.20 Field: Crankcase Heater Power per Compressor**

This numeric field defines the electrical power consumed by the crankcase heater in watts for *each* compressor. This crankcase heater power is consumed when the outdoor temperature is below the maximum outdoor dry-bulb temperature for crankcase heater operation. The minimum value for this field is 0. If this field is left blank, the default value is 33 watts. Crankcase heater electrical consumption is applied only when the compressor is off or is applied during the off cycle when the compressor is cycling below the Minimum Heat Pump Part-Load Ratio. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

#### **2.2.15.1.21 Field: Number of Compressors**

This numeric field defines the number of compressors in the heat pump condensing unit and is used exclusively to determine the operating characteristics of the crankcase heater. For example, if the number of compressors is 3, one crankcase heater will operate when the heat pump condensing unit's part-load ratio is less than or equal to 0.67 (when the ratio of compressor size to total compressor capacity input is 0.33) and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. Similarly, two crankcase heaters will operate when the heat pump condensing unit's PLR is less than or equal to 0.33 and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. If the heat pump condensing unit is off, all 3 crankcase heaters will operate if the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. The minimum value for this field is 1. If this field is left blank, the default value is 2. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

#### **2.2.15.1.22 Field: Ratio of Compressor Size to Total Compressor Capacity**

This numeric field defines the size of the first stage compressor to the total compressor capacity and is used exclusively for calculating crankcase heater energy. If this field and the previous field are left blank, the default value is 0.5. If this field is left blank and the previous field is not blank, the compressors are assumed to be equally sized. When the number of compressors is greater than 2, the 2<sup>nd</sup> stage compressor and all additional compressors are assumed to be equally sized. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

#### 2.2.15.1.23 Field: Maximum Outdoor Dry-bulb Temperature for Crankcase Heater

This numeric field defines the maximum outdoor temperature, in degrees Celsius, below which the crankcase heater will operate. If this field is left blank, the default value is 0°C. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

#### 2.2.15.1.24 Field: Defrost Strategy

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle. Defrost can be disabled by entering a resistive defrost strategy using a timed defrost control, a 0 defrost time period fraction and a 0 resistive defrost heater capacity in the following inputs fields. This method is used when the Maximum Outdoor Dry-Bulb Temperature for Defrost Operation field value is greater than the expected minimum outdoor dry-bulb temperature simulated in the weather file.

#### 2.2.15.1.25 Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value of compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

#### 2.2.15.1.26 Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active. For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

#### 2.2.15.1.27 Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0 and it is autosizable. If this input field is left blank, the default is autosize.

#### 2.2.15.1.28 Field: Maximum Outdoor Dry-bulb Temperature for Defrost Operation

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. If this input field is left blank, the default value is 5 C. Defrost can be completely eliminated by selecting a temperature lower than the minimum expected outdoor temperature found in the weather file.

#### 2.2.15.1.29 Field: Condenser Type

This choice field defines the configuration of the heat pump condenser. Valid choices are **AirCooled**, **EvaporativelyCooled**, and **WaterCooled**. If WaterCooled is specified, then this unit will be served by an **HVACTemplate:Plant:MixedWaterLoop**.

**2.2.15.1.30 Field: Water Condenser Volume Flow Rate**

This numeric field defines the condenser water volume flow rate in cubic meters per second. This field is autosizable and only used for water-cooled systems.

**2.2.15.1.31 Field: Evaporative Condenser Effectiveness**

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{condinlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o}) \quad (2.1)$$

where

$T_{condinlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled and the simulation is calculating heating performance.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = EvapCooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = EvapCooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Cooling Capacity and Cooling EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

**2.2.15.1.32 Field: Evaporative Condenser Air Flow Rate**

The air volume flow rate, in m<sup>3</sup> per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m<sup>3</sup>/s per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = AirCooled.

**2.2.15.1.33 Field: Evaporative Condenser Pump Rated Power Consumption**

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value

for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = AirCooled.

#### **2.2.15.1.34 Field: Basin Heater Capacity**

This numeric field contains the capacity of the heat pump's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the heat pump compressor(s) is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **2.2.15.1.35 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the heat pump is off. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

#### **2.2.15.1.36 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the heat pump is off.

#### **2.2.15.1.37 Field: Fuel Type**

This alpha field determines the type of fuel that this variable refrigerant flow system uses. This field has seven choices: Electricity, NaturalGas, Propane, Diesel, Gasoline, FuelOilNo1, FuelOilNo2, OtherFuel1, and OtherFuel2. The default is Electricity. The use of alternate fuel types assumes an engine drives the variable speed compression system and also accounts for condenser air flow (i.e., a fan attached to the engine provides air flow through the outdoor condenser).

#### **2.2.15.1.38 Field: Minimum Outdoor Temperature in Heat Recovery Mode**

This numeric field defines the minimum outdoor dry-bulb temperature allowed for heat recovery operation. Below this temperature, heat recovery is disabled. This input must be greater than the larger of the minimum outdoor temperature in cooling or heating mode. If this field is left blank, the default value is the higher of the Minimum Outdoor Temperature in Cooling Mode or Minimum Outdoor Temperature in Heating Mode inputs. This system may still operate in cooling or heating only mode when outdoor temperatures are below the minimum outdoor temperature in heat recovery mode. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes.

#### **2.2.15.1.39 Field: Maximum Outdoor Temperature in Heat Recovery Mode**

This numeric field defines the maximum outdoor dry-bulb temperature allowed for heat recovery operation. Above this temperature, heat recovery is disabled. This input must be less than the smaller of the maximum outdoor temperature in cooling or heating mode. If this field is left blank, the default value

is the lower of the Maximum Outdoor Temperature in Cooling Mode or Maximum Outdoor Temperature in Heating Mode inputs.. This system may still operate in cooling or heating only mode when outdoor temperatures are above the maximum outdoor temperature in heat recovery mode. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes.

Following is an example input for a **AirConditioner:VariableRefrigerantFlow** system.

```

## 2.2.16 HVACTemplate:System:Unitary

This object simulates the system portion of a constant volume air handler with electric, gas, or hot water heating and optional direct-expansion (DX) cooling. This system may serve one or more **HVACTemplate:Zone:Unitary** objects. If this system serves more than one zone, only one zone is specified as the control zone. Common names for this sytem type include packaged rooftop systems commonly seen in commercial buildings and split systems (furnace with air conditioner) commonly seen in residential buildings.

### 2.2.16.1 Inputs

#### 2.2.16.1.1 Field: Name

Enter a name for the HVACTemplate:System:Unitary object. This name is used in the **HVACTemplate:Zone:Unitary** object to reference this system.

#### 2.2.16.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. If the “Supply Fan Operating Mode” (see below) is set to Cycling, then this is the supply fan operating schedule. If the fan mode is Cycling this is not a schedule of when the system is providing heating, cooling or air flow but a schedule of when it can provide either heating, cooling, or air flow.

#### 2.2.16.1.3 Field: Control Zone or Thermostat Location Name

Enter the name of the **HVACTemplate:Zone:Unitary** object that contains the thermostat. While multiple **HVACTemplate:Zone:Unitary** objects can be part of a HVACTemplate:System:Unitary system, only one of the zones contains a thermostat that controls heating and cooling operation. For a single zone system, this field should contain the name of that zone.

#### 2.2.16.1.4 Field: Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are m<sup>3</sup>/s.

#### 2.2.16.1.5 Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, a schedule of always zero (cycling fan) will be used.

#### 2.2.16.1.6 Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

#### 2.2.16.1.7 Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa.

#### 2.2.16.1.8 Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

**2.2.16.1.9 Field: Supply Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

**2.2.16.1.10 Field: Cooling Coil Type**

Enter the type of cooling coil. The choices for this field are:

- None
- SingleSpeedDX

Set this value to “SingleSpeedDX” if you want to simulate a system that provides cooling. You may set this value to “None” if no cooling is desired. The default value is SingleSpeedDX. Future versions may have additional cooling coil types.

**2.2.16.1.11 Field: Cooling Coil Availability Schedule Name**

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.16.1.12 Field: Cooling Design Supply Air Temperature**

Enter the cooling supply air temperature in °C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8°C.

**2.2.16.1.13 Field: Cooling Coil Gross Rated Total Capacity**

Enter autosize to let the automatic sizing algorithm determine the cooling coil gross capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross total cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W.

**2.2.16.1.14 Field: Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the gross rated capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by the gross total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for.

**2.2.16.1.15 Field: Cooling Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan.

**2.2.16.1.16 Field: Heating Coil Type**

Enter the type of heating used in the unitary system. The choices for this field are

- Electric
- Gas
- HotWater

**2.2.16.1.17 Field: Heating Coil Availability Schedule Name**

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of 1.0 indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

**2.2.16.1.18 Field: Heating Design Supply Air Temperature**

Enter the heating supply air temperature in °C to be used for sizing the heating coil and zone supply air flow rates. The default is 50°C.

**2.2.16.1.19 Field: Heating Coil Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts.

**2.2.16.1.20 Field: Gas Heating Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

**2.2.16.1.21 Field: Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W.

**2.2.16.1.22 Field: Maximum Outdoor Air Flow Rate**

Enter autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m<sup>3</sup>/s. That is, the entered value is used to define the Maximum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.16.1.23 Field: Minimum Outdoor Air Flow Rate**

Enter autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m<sup>3</sup>/s. The default is Autosize. The entered value is used to define the Minimum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.16.1.24 Field: Minimum Outdoor Air Schedule Name**

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

**2.2.16.1.25 Field: Economizer Type**

The options for this field are

- ‘FixedDryBulb’
- ‘DifferentialDryBulb’
- ‘FixedEnthalpy’
- ‘DifferentialEnthalpy’
- ‘ElectronicEnthalpy’ (i.e., humidity ratio curve strategy)
- ‘FixedDewPointAndDryBulb’
- ‘DifferentialDryBulbAndEnthalpy’
- ‘NoEconomizer’

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

**2.2.16.1.26 Field: Economizer Lockout**

Enter one of the following choices for this field:

- NoLockout
- LockoutWithHeating
- LockoutWithCompressor

The default value is **NoLockout**. The **LockoutWithHeating** means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. **LockoutWithCompressor** means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is on. In other words, when the DX coil is off, the economizer must meet the entire cooling load – it isn't allowed to operate in conjunction with the DX cooling coil. Similarly, when the DX coil is operating, the economizer is not allowed to operate. The **LockoutWithCompressor** option is sometimes called a “nonintegrated” economizer.

**2.2.16.1.27 Field: Economizer Upper Temperature Limit**

Enter the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature high limit control.

**2.2.16.1.28 Field: Economizer Lower Temperature Limit**

Enter the outdoor air temperature low limit (°C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

**2.2.16.1.29 Field: Economizer Upper Enthalpy Limit**

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

**2.2.16.1.30 Field: Economizer Maximum Limit Dewpoint Temperature**

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

**2.2.16.1.31 Field: Supply Plenum Name**

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any supply plenums have been specified, the outlet from the system supply plenum will flow through the supply plenum to the zone terminal unit.

**2.2.16.1.32 Field: Return Plenum Name**

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

**2.2.16.1.33 Field: Supply Fan Placement**

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *BlowThrough*.

**2.2.16.1.34 Field: Night Cycle Control**

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, or *CycleOnControlZone*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. The default is *StayOff*.

**2.2.16.1.35 Field: Night Cycle Control Zone Name**

For the Night Cycle Control option *CycleOnControlZone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

**2.2.16.1.36 Field: Heat Recovery Type**

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is **None**.

**2.2.16.1.37 Field: Sensible Heat Recovery Effectiveness**

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

**2.2.16.1.38 Field: Latent Heat Recovery Effectiveness**

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

**2.2.16.1.39 Field: Dehumidification Control Type**

There are three dehumidification control type options available:

- None
- CoolReheatHeatingCoil
- CoolReheatDesuperheater

The *CoolReheatHeatingCoil* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the heating coil. In the simulation, two instances of the heating coil are modeled, one for heating, and one for reheat. The two coil objects represent the same physical coil and never operate simultaneously.

The *CoolReheatDesuperheater* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided by a desuperheater coil (see object [Coil:Heating:Desuperheater](#)).

The default is *None* which meets the sensible cooling load only. The humidistat is located in the same zone that is specified above as the Control Zone or Thermostat Location Name.

**2.2.16.1.40 Field: Dehumidification Setpoint**

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%.

**2.2.16.1.41 Field: Humidifier Type**

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the [Humidifier:Steam:Electric](#) object. The default is *None*.

**2.2.16.1.42 Field: Humidifier Availability Schedule Name**

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period.

**2.2.16.1.43 Field: Humidifier Rated Capacity**

Enter the rated moisture output rate in m<sup>3</sup>/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m<sup>3</sup>/s.

**2.2.16.1.44 Field: Humidifier Rated Electric Power**

Enter the electric power input at the rated capacity moisture output. This field can be autosized. When it is autosized, it is calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20°C to saturated steam at 100°C.

**2.2.16.1.45 Field: Humidifier Control Zone Name**

This field specifies the zone name where the humidistat is located for controlling humidification.

**2.2.16.1.46 Field: Humidifier Setpoint**

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

**2.2.16.1.47 Field: Return Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 300 Pa.

**2.2.16.1.48 Field: Return Fan Motor efficiency**

Enter the shaft power of the return fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. Default is 0.9.

**2.2.16.1.49 Field: Return Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. Default is 1.0.

As shown in an IDF:

```
HVACTemplate:System:Unitary,

## 2.2.17 HVACTemplate:System:UnitaryHeatPump:AirToAir

This object simulates the system portion of a constant volume air handler with a direct-expansion (DX) air-to-air heat pump and supplemental heating (electric, gas, or hot water). This system may serve one or more **HVACTemplate:Zone:Unitary** objects. If this system serves more than one zone, only one zone is specified as the control zone. Common names for this sytem type include packaged rooftop heat pumps commonly seen in commercial buildings and split system heat pumps commonly seen in residential buildings.

### 2.2.17.1 Inputs

#### 2.2.17.1.1 Field: Name

Enter a name for the **HVACTemplate:System:UnitaryHeatPump:AirToAir** object. This name is used in the **HVACTemplate:Zone:Unitary** object to reference this system.

#### 2.2.17.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. During times when the system is available, the supply fan operating mode controls fan operation. (See “Supply Fan Operating Mode Schedule Name” below)

#### 2.2.17.1.3 Field: Control Zone or Thermostat Location Name

Enter the name of the **HVACTemplate:Zone:Unitary** object that contains the thermostat. While multiple **HVACTemplate:Zone:Unitary** objects can be part of a **HVACTemplate:System:UnitaryHeatPump:AirToAir** system, only one of the zones contains a thermostat that controls heating and cooling operation. For a single zone system, this field should contain the name of that zone.

#### 2.2.17.1.4 Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the DX cooling coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling **SizingPeriod:DesignDay**. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are in m3/s. The default is Autosize.

#### 2.2.17.1.5 Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating **SizingPeriod:DesignDay**. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are in m3/s. The default is Autosize.

**2.2.17.1.6 Field: No Load Supply Air Flow Rate**

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. A value entered in this field will *not* be multiplied by the sizing factor or by zone multipliers. It is best to autosize or leave blank when using zone multipliers. The units are in m<sup>3</sup>/s. The default is Autosize.

**2.2.17.1.7 Field: Supply Fan Operating Mode Schedule Name**

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, a schedule of always zero (cycling fan) will be used.

**2.2.17.1.8 Field: Supply Fan Placement**

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the dx cooling/heating coil and before the supplemental heating coil. *BlowThrough* models a system where the supply air fan is before the dx cooling/heating coil and the supplemental heating coil. The default is *BlowThrough*.

**2.2.17.1.9 Field: Supply Fan Total Efficiency**

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.17.1.10 Field: Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20 C at sea level, 101325 Pa. The default is 600 Pa.

**2.2.17.1.11 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater or equal to the Supply Fan Total Efficiency and less than or equal to 1. The default is 0.9.

**2.2.17.1.12 Field: Supply Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

**2.2.17.1.13 Field: Cooling Coil Type**

Enter the type of cooling coil. There is currently only one choices for this field, SingleSpeedDX. Future versions may have additional cooling coil types.

**2.2.17.1.14 Field: Cooling Coil Availability Schedule Name**

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.17.1.15 Field: Cooling Design Supply Air Temperature**

Enter the cooling supply air temperature in °C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8°C.

**2.2.17.1.16 Field: Cooling Coil Gross Rated Total Capacity**

Enter Autosize to let the automatic sizing algorithm determine the cooling coil capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross total cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross” capacity where the effect of supply air fan heat is not accounted for. The units are in W. The default is Autosize.

**2.2.17.1.17 Field: Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by the gross total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross” capacity where the effect of supply air fan heat is not accounted for. The default is Autosize.

**2.2.17.1.18 Field: Cooling Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 3.0.

**2.2.17.1.19 Field: Heat Pump Heating Coil Type**

Enter the type of heat pump heating coil. There is currently only one choice for this field, SingleSpeed-DXHeatPump.

**2.2.17.1.20 Field: Heating Design Supply Air Temperature**

Enter the heating supply air temperature in °C to be used for sizing the heating coil and zone supply air flow rates. The default is 50°C.

**2.2.17.1.21 Field: Heat Pump Heating Coil Availability Schedule Name**

Usually set to blank, which allows the heat pump heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. A schedule value of 1.0 indicates that the heat pump heating coil can be on during a given time period. A value of zero denotes that the heat pump heating coil cannot be used during that time period.

**2.2.17.1.22 Field: Heat Pump Heating Coil Gross Rated Capacity**

Enter Autosize to let the automatic sizing algorithm determine the heat pump heating coil gross capacity based on the maximum heating loads during the heating design day. If a value is entered, it represents the full load gross heating capacity, in watts of the DX heat pump unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. Capacity should be the “gross” capacity where the effect of supply air fan heat is not accounted for. The units are in W. The default is Autosize.

**2.2.17.1.23 Field: Heat Pump Heating Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross heating coil capacity in watts divided by electrical power input in watts of the DX heating coil unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 2.75.

**2.2.17.1.24 Field: Heat Pump Heating Minimum Outdoor Dry-Bulb Temperature**

This numeric field defines the minimum outdoor dry-bulb temperature in degrees Celsius for compressor operation. The compressor will not operate (for DX heating or DX cooling) when outdoor dry-bulb temperatures fall below this value. The minimum value must be greater than or equal to -20 °C. The default value is -8°C.

**2.2.17.1.25 Field: Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

**2.2.17.1.26 Field: Heat Pump Defrost Strategy**

This alpha field has two choices: *ReverseCycle* or *Resistive*. If the *ReverseCycle* strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a *Resistive* defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is *ReverseCycle*.

**2.2.17.1.27 Field: Heat Pump Defrost Control**

This alpha field has two choices: *Timed* or *OnDemand*. If *Timed* control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For *Timed* defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If *OnDemand* defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature

entered in the input field “Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature” described above. If this input field is left blank, the default defrost control is *Timed*.

#### **2.2.17.1.28 Field: Heat Pump Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Heat Pump Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

#### **2.2.17.1.29 Field: Supplemental Heating Coil Type**

Enter the type of supplemental heating coil. The choices for this field are

- Electric
- Gas
- HotWater

The default is Electric.

#### **2.2.17.1.30 Field: Supplemental Heating Coil Availability Schedule Name**

Usually set to blank, which allows the supplemental heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when supplemental heating is only available seasonally. The schedule values denote whether the supplemental heating coil can run during a given time period. A schedule value of 1.0 indicates that the supplemental heating coil can be on during a given time period. A value of zero denotes that the supplemental heating coil cannot be used during that time period

#### **2.2.17.1.31 Field: Supplemental Heating Coil Capacity**

Enter Autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the supplemental heating coil can deliver in Watts. The default is Autosize.

#### **2.2.17.1.32 Field: Supplemental Heating Coil Maximum Outdoor Dry-Bulb Temperature**

This numeric field defines the outdoor air dry-bulb temperature above which the supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

#### **2.2.17.1.33 Field: Supplemental Gas Heating Coil Efficiency**

Enter supplemental heating coil gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the supplemental heating coil type is gas.

#### **2.2.17.1.34 Field: Supplemental Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas supplemental heating coil operation, such as a combustion fan. The units are in W. The default is 0.0. This field applies only if the supplemental heating coil type is gas.

**2.2.17.1.35 Field: Maximum Outdoor Air Flow Rate**

Enter Autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. The units are in m<sup>3</sup>/s. That is, the entered value is used to define the Maximum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.17.1.36 Field: Minimum Outdoor Air Flow Rate**

Enter Autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m<sup>3</sup>/s. The default is Autosize. The entered value is used to define the Minimum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.17.1.37 Field: Minimum Outdoor Air Schedule Name**

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate during unoccupied or start up hours.

**2.2.17.1.38 Field: Economizer Type**

The options for this field are

- ‘FixedDryBulb’
- ‘DifferentialDryBulb’
- ‘FixedEnthalpy’
- ‘DifferentialEnthalpy’
- ‘ElectronicEnthalpy’ (i.e., humidity ratio curve strategy)
- ‘FixedDewPointAndDryBulb’
- ‘DifferentialDryBulbAndEnthalpy’
- ‘NoEconomizer’

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to

the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**

#### 2.2.17.1.39 Field: Economizer Lockout

Enter one of the following choices for this field:

- NoLockout
- LockoutWithHeating
- LockoutWithCompressor

The default value is **NoLockout**. The **LockoutWithHeating** means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. **LockoutWithCompressor** means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is on. In other words, when the DX coil is off, the economizer must meet the entire cooling load – it isn't allowed to operate in conjunction with the DX cooling coil. Similarly, when the DX coil is operating, the economizer is not allowed to operate. The **LockoutWithCompressor** option is sometimes called a “nonintegrated” economizer.

#### 2.2.17.1.40 Field: Economizer Maximum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type ‘FixedDryBulb’ or ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air temperature high limit control.

#### 2.2.17.1.41 Field: Economizer Maximum Limit Enthalpy

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

#### 2.2.17.1.42 Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

**2.2.17.1.43 Field: Economizer Minimum Limit Dry-Bulb Temperature**

Enter the outdoor air temperature low limit (C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

**2.2.17.1.44 Field: Supply Plenum Name**

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any zone supply plenums have been specified, the outlet from the system supply plenum will flow through the zone supply plenum to the zone terminal unit.

**2.2.17.1.45 Field: Return Plenum Name**

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

**2.2.17.1.46 Field: Night Cycle Control**

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, or *CycleOnControlZone*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. The default is *StayOff*.

**2.2.17.1.47 Field: Night Cycle Control Zone Name**

For the Night Cycle Control option *CycleOnControlZone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

**2.2.17.1.48 Field: Heat Recovery Type**

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is **None**.

**2.2.17.1.49 Field: Sensible Heat Recovery Effectiveness**

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

**2.2.17.1.50 Field: Latent Heat Recovery Effectiveness**

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

**2.2.17.1.51 Field: Humidifier Type**

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the **Humidifier:Steam:Electric** object. The default is *None*.

**2.2.17.1.52 Field: Humidifier Availability Schedule Name**

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

**2.2.17.1.53 Field: Humidifier Rated Capacity**

Enter the rated moisture output rate in m<sup>3</sup>/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m<sup>3</sup>/s.

**2.2.17.1.54 Field: Humidifier Rated Electric Power**

Enter the electric power input at the rated capacity moisture output. This field can be autosized. When it is autosized, it is calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20°C to saturated steam at 100°C.

**2.2.17.1.55 Field: Humidifier Control Zone Name**

This field specifies the zone name where the humidistat is located for controlling humidification.

**2.2.17.1.56 Field: Humidifier Setpoint**

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

**2.2.17.1.57 Field: Return Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 300 Pa.

**2.2.17.1.58 Field: Return Fan Motor efficiency**

Enter the shaft power of the return fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. Default is 0.9.

**2.2.17.1.59 Field: Return Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. Default is 1.0.

As shown in an IDF:

### 2.2.18 HVACTemplate:System:UnitarySystem

This object simulates a unitary system with option cooling coil (air-cooled DX, water-cooled DX, and chilled water), options heating coil (gas, electric, hot water, air-to-air heat pump, and water-to-air heat pump) with cycling or continuous fan controls. Often a single [HVACTemplate:Zone:Unitary](#) object will be used with a single [HVACTemplate:System:UnitarySystem](#) object to simulate single zone system. In addition, multiple [HVACTemplate:Zone:Unitary](#) objects may reference the same [HVACTemplate:System:UnitarySystem](#)

object in a multiple zone version. For a multiple zone system, only one zone is specified as the control zone. The model can simulate chilled water or heat pump systems seen in commercial buildings and split systems commonly seen in residential buildings. `HVACTemplate:System:UnitarySystem` is similar to `HVACTemplate:System:Unitary` and `HVACTemplate:System:UnitaryHeatPump:AirToAir`, but it offers more flexibility by using the more general `AirLoopHVAC:UnitarySystem` object instead of the more specific unitary furnace and heat pump objects.

### 2.2.18.1 Inputs

#### 2.2.18.1.1 Field: Name

Enter a name for the `HVACTemplate:System:UnitarySystem` object. This name is used in the `HVACTemplate:Zone:Unitary` object to reference this system.

#### 2.2.18.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. During times when the system is available, the supply fan operating mode controls fan operation. (See “Supply Fan Operating Mode Schedule Name” below)

#### 2.2.18.1.3 Field: Control Type

This alpha field contains control type i.e. load based or setpoint based for the unitary system. Valid choices are *Load* and *SetPoint*. *Load* control requires a Controlling Zone name and *SetPoint* control is an advanced option which requires set points at each coil outlet node. A single set point at the outlet of the system is allowed but not recommended. The user must add the desired setpoint managers to the idf file. The default is *Load*.

#### 2.2.18.1.4 Field: Control Zone or Thermostat Location Name

Enter the name of the `HVACTemplate:Zone:Unitary` object that contains the thermostat. While multiple `HVACTemplate:Zone:Unitary` objects can be part of a `HVACTemplate:System:UnitarySystem` system, only one of the zones contains a thermostat that controls heating and cooling operation. For a single zone system, this field should contain the name of that zone.

#### 2.2.18.1.5 Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the cooling coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling `SizingPeriod:DesignDay`. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are in m<sup>3</sup>/s. The default is Autosize.

#### 2.2.18.1.6 Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating `SizingPeriod:DesignDay`. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are in m<sup>3</sup>/s. The default is Autosize.

**2.2.18.1.7 Field: No Load Supply Air Flow Rate**

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. A value entered in this field will *not* be multiplied by the sizing factor or by zone multipliers. It is best to autosize or leave blank when using zone multipliers. The units are in m<sup>3</sup>/s. The default is Autosize.

**2.2.18.1.8 Field: Supply Fan Operating Mode Schedule Name**

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, a schedule of always zero (cycling fan) will be used.

**2.2.18.1.9 Field: Supply Fan Placement**

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils and before the supplemental heating (or reheat) coil. *BlowThrough* models a system where the supply air fan is before all of the coils. The default is *BlowThrough*.

**2.2.18.1.10 Field: Supply Fan Total Efficiency**

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.18.1.11 Field: Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20 C at sea level, 101325 Pa. The default is 600 Pa.

**2.2.18.1.12 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater or equal to the Supply Fan Total Efficiency and less than or equal to 1. The default is 0.9.

**2.2.18.1.13 Field: Supply Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

### 2.2.18.1.14 Field: Cooling Coil Type

There are seven coil types available:

- SingleSpeedDX (the default)
- TwoSpeedDX
- MultiSpeedDX
- TwoStageDX
- TwoStageHumidityControlDX
- HeatExchangerAssistedDX
- SingleSpeedDXWaterCooled
- ChilledWater
- ChilledWaterDetailedFlatModel
- HeatExchangerAssistedChilledWater
- None

*SingleSpeedDX* uses the `Coil:Cooling:DX:SingleSpeed` object.

*TwoSpeedDX* uses the `Coil:Cooling:DX:TwoSpeed` object.

*MultiSpeedDX* uses the `Coil:Cooling:DX:MultiSpeed` object.

*TwoStageDX* and *TwoStageHumidityControlDX* use the `Coil:Cooling:DX:TwoStageWithHumidityControlMode` object.

*HeatExchangerAssistedDX* uses the `CoilSystem:Cooling:DX:HeatExchangerAssisted`, `HeatExchanger:AirToAir:SensibleAndLatent`, and `Coil:Cooling:DX:SingleSpeed` objects.

*SingleSpeedDXWaterCooled* uses the `Coil:Cooling:WaterToAirHeatPump:EquationFit` object. This option requires an `HVACTemplate:Plant:MixedWaterLoop` to serve as the water source.

The default type is *SingleSpeedDX*

*ChilledWater* uses the `Coil:Cooling:Water` object with the DetailedAnalysis option. This is the preferred coil model for most chilled water applications.

*ChilledWaterDetailedFlatModel* uses the `Coil:Cooling:Water:DetailedGeometry` object. This option is available for special applications.

*HeatExchangerAssistedChilledWater* uses the `CoilSystem:Cooling:DX:HeatExchangerAssisted`, `HeatExchanger:AirToAir:SensibleAndLatent`, and `Coil:Cooling:Water` objects.

### 2.2.18.1.15 Field: Number of Speeds for Cooling

This field defines the number of cooling speeds is a multi-speed cooling coil is specified. The default is 1, and the maximum allowed is 10. This field only applies if Cooling Coil Type is MultiSpeedDX.

### 2.2.18.1.16 Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.18.1.17 Field: Cooling Design Supply Air Temperature**

Enter the cooling supply air temperature in °C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8°C.

**2.2.18.1.18 Field: DX Cooling Coil Gross Rated Total Capacity**

Enter Autosize to let the automatic sizing algorithm determine the cooling coil gross total cooling capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross total cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor air-cooled condenser coil at 35°C drybulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is Autosize. This field is only used when the cooling coil type is set to one of the DX options. For two-speed DX coils, the low-speed capacity is assumed to be 0.33 times this value. For two-stage DX coils, the stage 1 capacity is assumed to be 0.5 times this value.

**2.2.18.1.19 Field: DX Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the gross rated cooling total capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by gross total cooling capacity of the DX cooling coil at rated conditions. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for. This field is only used when the cooling coil type is set to one of the DX options. The default is Autosize.

For air-cooled DX coils the rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor air-cooled condenser coil at 35°C drybulb.

For water-cooled DX coils the rated conditions are 26.7°C (80°F) entering air dry-bulb temperature, 19.4°C (67°F) entering air wet-bulb temperature, and 29.4°C (85°F) entering water temperature.

For two-speed DX coils, the low-speed SHR is assumed to be equal to this value. For two-stage DX coils, the stage 1 SHR is assumed to be equal to this value. For two-stage DX coil with humidity control, the humidity control mode SHR is assumed to be 0.9 times this value (for both stage 1 and stage 2).

**2.2.18.1.20 Field: DX Cooling Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross cooling coil total capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor air-cooled condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 3.0. This field is only used when the cooling coil type is set to one of the DX options. For two-speed DX coils, the low-speed COP is assumed to be 1.5 times this value. For two-stage DX coils, the stage 1 COP is assumed to be this value. For two-stage DX coil with humidity control, the humidity control mode COP is assumed to be 0.9 times this value (for both stage 1 and stage 2). The gross COP should not account for the supply air fan.

**2.2.18.1.21 Field: Heating Coil Type**

The heating coil is located in the supply air stream, downstream of the cooling coil. The choices for this field are

- Electric

- Gas
- HotWater
- SingleSpeedDXHeatPumpAirSource (air-to-air heat pump)
- MultiSpeedDXHeatPumpAirSource (air-to-air heat pump)
- SingleSpeedDXHeatPumpWaterSource (water-to-air heat pump). This option requires an **HVACTemplate:Plant:MixedWaterLoop** to serve as the water source.
- MultiStageElectric (uses coil object type **Coil:Heating:Electric:MultiStage**)
- MultiStageGas (uses coil object type **Coil:Heating:Gas:MultiStage**)
- None

The default value is Gas.

#### 2.2.18.1.22 Field: Number of Speeds or Stages for Heating

This field defines the number of heating speeds or stages if a multi-speed heatpump or multi-stage heating coil is specified. The default is 1. For heating coil type MultiSpeedDXHeatPumpAirSource, the maximum number of speeds allowed is 10. For heating coil types MultiStageElectric and MultiStageGas, the maximum number of stages allowed is 4. For other heating coil types, this field is ignored.

#### 2.2.18.1.23 Field: Heating Coil Availability Schedule Name

Usually left blank, which allows the heating coil to be available as needed anytime the system is operating. If a schedule name is specified, it defines when the heating coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period.

#### 2.2.18.1.24 Field: Heating Design Supply Air Temperature

Enter the heating supply air temperature in °C to be used for sizing the heating coil and zone supply air flow rates. The default is 50°C.

#### 2.2.18.1.25 Field: Heating Coil Gross Rated Capacity

Enter Autosize to let the automatic sizing algorithm determine the heating coil gross capacity based on the maximum heating loads during the heating design day. The units are in W. The default is Autosize.

If the Heating Coil Type is Electric or Gas, this field is the rated output of the heating coil not including any effect of the supply air fan.

If the Heating Coil Type is HotWater, this field is the rated output of the heating coil not including any effect of the supply air fan at the following conditions: inlet water temperature is 82.2 degrees C (180 degrees F), output water temperature is 71.1 degrees C (160 degrees F), inlet air temperature is 16.6 degrees C (60 degrees F), and outlet air temperature is 32.2 degrees C (90 degrees F).

If the Heating Coil Type is SingleSpeedDXHeatPumpAir this field represents the full load gross heating capacity, in watts of the DX heat pump unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11°C wetbulb. Capacity should be the “gross” capacity where the effect of supply air fan heat is not accounted for.

If the Heating Coil Type is *SingleSpeedDXHeatPumpWater* this field represents the full load heating capacity, in watts of the DX heat pump unit at rated conditions (21.11C (70F) entering air dry-bulb temperature and 21.11C (70F) entering water temperature). Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for.

#### 2.2.18.1.26 Field: Gas Heating Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the heating coil type is gas.

#### 2.2.18.1.27 Field: Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W. This field applies only if the heating coil type is gas.

#### 2.2.18.1.28 Field: Heat Pump Heating Coil Gross Rated COP

Enter the coefficient of performance defined as the gross heating coil capacity in watts divided by electrical power input in watts of the DX heat pump heating coil unit at rated conditions. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 2.75 which is appropriate for an air-to-air heat pump. This value should be changed for a water-to-air heat pump. The rated conditions are described above under Heating Coil Gross Rated Capacity.

#### 2.2.18.1.29 Field: Heat Pump Heating Minimum Outdoor Dry-Bulb Temperature

This numeric field defines the minimum outdoor dry-bulb temperature in degrees Celsius for compressor operation. The compressor will not operate (for DX heating or DX cooling) when outdoor dry-bulb temperatures fall below this value. The minimum value must be greater than or equal to -20 °C. The default value is -8°C.

#### 2.2.18.1.30 Field: Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

#### 2.2.18.1.31 Field: Heat Pump Defrost Strategy

This alpha field has two choices: *ReverseCycle* or *Resistive*. If the *ReverseCycle* strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a *Resistive* defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is *ReverseCycle*.

#### 2.2.18.1.32 Field: Heat Pump Defrost Control

This alpha field has two choices: *Timed* or *OnDemand*. If *Timed* control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For *Timed* defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If *OnDemand* defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature” described above. If this input field is left blank, the default defrost control is *Timed*.

**2.2.18.1.33 Field: Heat Pump Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Heat Pump Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

**2.2.18.1.34 Field: Supplemental Heating or Reheat Coil Type**

Enter the type of supplemental heating coil or reheat coil. The choices for this field are

- Electric
- Gas
- HotWater
- DesuperHeater (applicable only if cooling coil type is air-cooled DX)
- None

The default is None.

**2.2.18.1.35 Field: Supplemental Heating or Reheat Coil Availability Schedule Name**

Usually set to blank, which allows the supplemental heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when supplemental heating is only available seasonally. The schedule values denote whether the supplemental heating coil can run during a given time period. A schedule value of 1.0 indicates that the supplemental heating coil can be on during a given time period. A value of zero denotes that the supplemental heating coil cannot be used during that time period

**2.2.18.1.36 Field: Supplemental Heating or Reheat Coil Capacity**

Enter Autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the supplemental heating coil can deliver in Watts. The default is Autosize.

**2.2.18.1.37 Field: Supplemental Heating or Reheat Coil Maximum Outdoor Dry-Bulb Temperature**

This numeric field defines the outdoor air dry-bulb temperature above which the supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

**2.2.18.1.38 Field: Supplemental Gas Heating Coil Efficiency**

Enter supplemental heating coil gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the supplemental heating coil type is gas.

**2.2.18.1.39 Field: Supplemental Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas supplemental heating coil operation, such as a combustion fan. The units are in W. The default is 0.0. This field applies only if the supplemental heating coil type is gas.

**2.2.18.1.40 Field: Maximum Outdoor Air Flow Rate**

Enter Autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. The units are in m<sup>3</sup>/s. That is, the entered value is used to define the Maximum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template. The default is Autosize.

**2.2.18.1.41 Field: Minimum Outdoor Air Flow Rate**

Enter Autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m<sup>3</sup>/s. The default is Autosize. The entered value is used to define the Minimum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.18.1.42 Field: Minimum Outdoor Air Schedule Name**

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate during unoccupied or start up hours.

**2.2.18.1.43 Field: Economizer Type**

The options for this field are

- ‘FixedDryBulb’
- ‘DifferentialDryBulb’
- ‘FixedEnthalpy’
- ‘DifferentialEnthalpy’
- ‘ElectronicEnthalpy’ (i.e., humidity ratio curve strategy)
- ‘FixedDewPointAndDryBulb’
- ‘DifferentialDryBulbAndEnthalpy’
- ‘NoEconomizer’

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to

the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**

#### 2.2.18.1.44 Field: Economizer Lockout

Enter one of the following choices for this field:

- NoLockout
- LockoutWithHeating
- LockoutWithCompressor

The default value is **NoLockout**. The **LockoutWithHeating** means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. **LockoutWithCompressor** means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is on. In other words, when the DX coil is off, the economizer must meet the entire cooling load – it isn’t allowed to operate in conjunction with the DX cooling coil. Similarly, when the DX coil is operating, the economizer is not allowed to operate. The **LockoutWithCompressor** option is sometimes called a “nonintegrated” economizer.

#### 2.2.18.1.45 Field: Economizer Maximum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type ‘FixedDryBulb’ or ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air temperature high limit control.

#### 2.2.18.1.46 Field: Economizer Maximum Limit Enthalpy

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

#### 2.2.18.1.47 Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

**2.2.18.1.48 Field: Economizer Minimum Limit Dry-Bulb Temperature**

Enter the outdoor air temperature low limit (C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

**2.2.18.1.49 Field: Supply Plenum Name**

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any zone supply plenums have been specified, the outlet from the system supply plenum will flow through the zone supply plenum to the zone terminal unit.

**2.2.18.1.50 Field: Return Plenum Name**

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

**2.2.18.1.51 Field: Heat Recovery Type**

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is **None**.

**2.2.18.1.52 Field: Sensible Heat Recovery Effectiveness**

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

**2.2.18.1.53 Field: Latent Heat Recovery Effectiveness**

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

**2.2.18.1.54 Field: Heat Recovery Heat Exchanger Type**

This alpha field denotes the type of heat exchanger being modeled: Plate (e.g., fixed plate) or Rotary (e.g., rotating cylinder or wheel). The default choice for this field is “Plate”. The heat exchanger type affects the modeling of frost control options and supply air outlet temperature control. For rotary heat exchangers, rotational speed is varied to control frost formation or the supply air outlet temperature. For plate exchangers, air bypass around the heat exchanger is used to obtain the desired effect.

### 2.2.18.1.55 Field: Heat Recovery Frost Control Type

This alpha field has four choices: None, ExhaustAirRecirculation, ExhaustOnly and MinimumExhaustTemperature. If this field is left blank, the default frost control type is “None”. For modeling preheat frost control, specify “None” for this input field and insert a separate heating coil object in the supply inlet air stream to keep the air temperature above the desired frost threshold temperature.

*ExhaustAirRecirculation*: dampers are used to direct exhaust air back into the zone through the supply side of the heat exchanger when the supply (outdoor) air inlet temperature falls below a threshold temperature. The fraction of time that exhaust air is circulated through the supply side of the heat exchanger is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When exhaust air is being recirculated, no supply (outdoor ventilation) air is being provided through the heat exchanger unit (which may or may not be acceptable regarding ventilation for occupants).

*ExhaustOnly (supply air bypass)*: this control cycles off the supply air flow through the heat exchanger for a certain period of time while the exhaust air continues to flow through the exhaust side of the heat exchanger. The fraction of time that the supply flow through the heat exchanger is cycled off is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When implemented in real applications, provisions are usually made to avoid building depressurization when this frost control is operating (automatic or pressure-operated dampers, or a bypass air damper around the supply side of the heat exchanger). For this frost control type, it is assumed that the supply air is bypassed around the heat exchanger during frost control operation (i.e., the total supply flow is not reduced during defrost, but merely bypassed around the heat exchanger).

*MinimumExhaustTemperature*: the temperature of the exhaust air leaving the heat exchanger is monitored and the heat exchanger effectiveness is decreased (by slowing heat exchanger rotation or bypassing supply air around the plate exchanger) to keep the exhaust air from falling below the threshold temperature.

### 2.2.18.1.56 Field: Dehumidification Control Type

There are three dehumidification control type options available:

- None
- CoolReheat
- Multimode

The *CoolReheat* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the reheat coil. In the simulation, two instances of the heating coil are modeled, even if the main heating coil acts as the reheat coil in the actual system.

*Multimode* is only applicable for cooling coil type *TwoStageHumidityControlDX*. In this case, the enhanced dehumidification mode is activated as needed, but the system operates to meet the sensible dry-bulb temperature cooling setpoint.

The default is *None* which meets the sensible cooling load only. The humidistat is located in the same zone that is specified above as the Control Zone or Thermostat Location Name.

### 2.2.18.1.57 Field: Dehumidification Relative Humidity Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%. This field is ignored if a Dehumidification Relative Humidity Setpoint Schedule Name is specified.

**2.2.18.1.58 Field: Dehumidification Relative Humidity Setpoint Schedule Name**

Enter the name of the dehumidification setpoint schedule. If this field is left blank, the setpoint will be constant at the Dehumidification Relative Humidity Setpoint, The values in the schedule are in percent (0 to 100).

**2.2.18.1.59 Field: Humidifier Type**

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the **Humidifier:Steam:Electric** object. The default is *None*.

**2.2.18.1.60 Field: Humidifier Availability Schedule Name**

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

**2.2.18.1.61 Field: Humidifier Rated Capacity**

Enter the rated moisture output rate in m3/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m3/s.

**2.2.18.1.62 Field: Humidifier Rated Electric Power**

Enter the electric power input at the rated capacity moisture output. This field can be autosized. When it is autosized, it is calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20°C to saturated steam at 100°C.

**2.2.18.1.63 Field: Humidifier Control Zone Name**

This field specifies the zone name where the humidistat is located for controlling humidification.

**2.2.18.1.64 Field: Humidifier Relative Humidity Setpoint**

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%. This field is ignored if a Humidifier Relative Humidity Setpoint Schedule Name is specified.

**2.2.18.1.65 Field: Humidifier Relative Humidity Setpoint Schedule Name**

Enter the name of the dehumidification setpoint schedule. If this field is left blank, the setpoint will be constant at the Dehumidification Relative Humidity Setpoint, The values in the schedule are in percent (0 to 100).

**2.2.18.1.66 Field: Sizing Option**

This field specifies the sizing method for the system supply air flow rate. *Coincident* sizes on the sum of the coincident zone supply air flow rates. *NonCoincident* sizes on sum of the noncoincident zone design supply air flow rates. The default is *NonCoincident*.

**2.2.18.1.67 Field: Return Fan**

Enter *Yes* if the system has a return fan. The default is *No*.

**2.2.18.1.68 Field: Return Fan Total Efficiency**

Enter the total efficiency of the return fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1. Default is 0.7.

**2.2.18.1.69 Field: Return Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 300 Pa.

**2.2.18.1.70 Field: Return Fan Motor efficiency**

Enter the shaft power of the return fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. Default is 0.9.

**2.2.18.1.71 Field: Return Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. Default is 1.0.

As shown in an IDF:

## 2.2.19 HVACTemplate:System:VAV

This object simulates the system portion of a variable air volume HVAC configuration with chilled water cooling and several different heating options. Multiple **HVACTemplate:Zone:VAV** objects are usually specified for each **HVACTemplate:System:VAV** object.

### 2.2.19.1 Inputs

#### 2.2.19.1.1 Field: Name

Enter a name for the **HVACTemplate:System:VAV** object. This name is used in the **HVACTemplate:Zone:VAV** object to reference this system.

#### 2.2.19.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Please note that for this system type, this is a schedule of when the system is providing air flow.

#### 2.2.19.1.3 Field: Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. This flow rate will *not* be multiplied by a sizing factor or by zone

multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are  $\text{m}^3/\text{s}$ .

#### 2.2.19.1.4 Field: Supply Fan Minimum Flow Rate

Enter the minimum supply air volume that may be provided. This field may be set to autosize. The units are in  $\text{m}^3/\text{s}$ .

#### 2.2.19.1.5 Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

#### 2.2.19.1.6 Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered  $20^\circ\text{C}$  at sea level, 101325 Pa. The default is 1000 Pa.

#### 2.2.19.1.7 Field: Supply Fan Motor efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

#### 2.2.19.1.8 Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

#### 2.2.19.1.9 Field: Cooling Coil Type

There are two coil types available:

- ChilledWater
- ChilledWaterDetailedFlatModel

*ChilledWater* uses the COIL:Cooling:Water object with the DetailedAnalysis option. This is the preferred coil model for most applications. *ChilledWaterDetailedFlatModel* uses the **Coil:Cooling:Water:DetailedGeometry** object. This option is available for special applications. The default is *ChilledWater*.

#### 2.2.19.1.10 Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of one indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.19.1.11 Field: Cooling Coil Setpoint Schedule Name**

If a constant setpoint for the cooling coil is to be specified, leave this field blank, and the Cooling Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the cooling coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the cooling coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Cooling Coil Setpoint Reset Type is something other than None (see below).

**2.2.19.1.12 Field: Cooling Coil Design Setpoint**

Enter the cooling supply air temperature in C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8C. If no Cooling Coil Setpoint Schedule or Cooling Coil Setpoint Reset Type is specified, this value is used as a constant cooling supply air setpoint temperature.

**2.2.19.1.13 Field: Heating Coil Type**

The heating coil is located in the supply air stream, upstream of the cooling coil and after the outdoor air mixing box. If no central heating coil is used in the VAV system, then the option “none” should be specified here. Otherwise this indicates the type of heating coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is None. Note that the configuration of HVACTemplate:System:VAV assumes that there will be reheat coils or baseboard heating to provide heating control at the zone level. If a heating coil is specified, the heating and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

**2.2.19.1.14 Field: Heating Coil Availability Schedule Name**

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

**2.2.19.1.15 Field: Heating Coil Setpoint Schedule Name**

If a constant setpoint for the heating coil is to be specified, leave this field blank, and the Heating Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the heating coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the heating coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Heating Coil Setpoint Reset Type is something other than None (see below).

**2.2.19.1.16 Field: Heating Coil Design Setpoint**

Enter the heating supply air temperature in C to be used for sizing the heating coil and zone supply air flow rates. If no Heating Coil Setpoint Schedule or Heating Coil Setpoint Reset Type is specified, this value is used as a constant heating supply air setpoint temperature. The default is 10.0C.

**2.2.19.1.17 Field: Gas Heating Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

**2.2.19.1.18 Field: Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating operation, such as a combustion fan. The units are in W.

**2.2.19.1.19 Field: Preheat Coil Type**

The preheat coil is located in the outdoor air stream, upstream of the outdoor air mixing box and tempers the outdoor air. If no preheat coil is used in the VAV system, then the option “none” should be specified here. Otherwise this indicates the type of preheat coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is None. If a preheat coil is specified, the preheat and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

**2.2.19.1.20 Field: Preheat Coil Availability Schedule Name**

Usually set to blank, which allows the preheat coil to be available anytime the system is operating. If a schedule name is specified, it defines when the preheat coil is available. This is most often used when preheat is only available seasonally. The schedule values denote whether the preheat coil can run during a given time period. A schedule value of 1.0 indicates that the preheat coil can be on during a given time period. A value of zero denotes that the preheat coil cannot be used during that time period

**2.2.19.1.21 Field: Preheat Coil Setpoint Schedule Name**

If a constant setpoint for the preheat coil is to be specified, leave this field blank, and the Preheat Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the preheat coil specify the schedule name here. The schedule should control the leaving air temperature from the preheat coil. The values in the schedule are in degrees C.

**2.2.19.1.22 Field: Preheat Coil Design Setpoint**

Enter the preheat supply air temperature in C to be used for sizing the preheat coil. If no Preheat Coil Setpoint Schedule is specified, this value is used as a constant preheat supply air setpoint temperature. The default is 7.2C.

**2.2.19.1.23 Field: Gas Preheat Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

**2.2.19.1.24 Field: Gas Preheat Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating operation, such as an combustion fan. The units are in W.

**2.2.19.1.25 Field: Maximum Outdoor Air Flow Rate**

Enter autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m3/s. That is, the entered value is used to define the Maximum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.19.1.26 Field: Minimum Outdoor Air Flow Rate**

Enter autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m3/s. The default is Autosize. The entered value is used to define the Minimum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.19.1.27 Field: Minimum Outdoor Air Control Type**

Choices for this field are **FixedMinimum** or **ProportionalMinimum**. FixedMinimum means that the minimum outdoor air flow rate is fixed no matter what the actual system flow rate is. ProportionalMinimum means the minimum outdoor air flow rate varies in proportion to the total system air flow rate. The default is ProportionalMinimum.

**2.2.19.1.28 Field: Minimum Outdoor Air Schedule Name**

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

**2.2.19.1.29 Field: Economizer Type**

The options for this field are

- ‘FixedDryBulb’
- ‘DifferentialDryBulb’
- ‘FixedEnthalpy’
- ‘DifferentialEnthalpy’
- ‘ElectronicEnthalpy’ (i.e., humidity ratio curve strategy)
- ‘FixedDewPointAndDryBulb’
- ‘DifferentialDryBulbAndEnthalpy’

- ‘NoEconomizer’

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

#### 2.2.19.1.30 Field: Economizer Lockout

The only choice for this field is

- NoLockout

The default value is NoLockout. Future versions may have additional options.

#### 2.2.19.1.31 Field: Economizer Upper Temperature Limit

Enter the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature high limit control.

#### 2.2.19.1.32 Field: Economizer Lower Temperature Limit

Enter the outdoor air temperature low limit (°C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

**2.2.19.1.33 Field: Economizer Upper Enthalpy Limit**

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

**2.2.19.1.34 Field: Economizer Maximum Limit Dewpoint Temperature**

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

**2.2.19.1.35 Field: Supply Plenum Name**

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any supply plenums have been specified, the outlet from the system supply plenum will flow through the supply plenum to the zone terminal unit.

**2.2.19.1.36 Field: Return Plenum Name**

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

**2.2.19.1.37 Field: Supply Fan Placement**

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

**2.2.19.1.38 Field: Supply Fan Part-Load Power Coefficients**

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers
- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.8. VAV Supply Fan Part-Load Power Coefficient Options below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotorPressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources’: *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

Figure 2.8: VAV Supply Fan Part-Load Power Coefficient Options

**2.2.19.1.39 Field: Night Cycle Control**

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, *CycleOnControl Zone* or *CycleOnAnyZoneFansOnly*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. *CycleOnAnyZoneFansOnly* is the same as *CycleOnAny* except that only the zone fans are cycled on and the central air handler fan is left off (applicable only if using **HVACTemplate:Zone:VAV:FanPowered** in one or more zones). The default is *StayOff*.

**2.2.19.1.40 Field: Night Cycle Control Zone Name**

For the Night Cycle Control option *Cycle On Control Zone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

**2.2.19.1.41 Field: Heat Recovery Type**

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is **None**.

**2.2.19.1.42 Field: Sensible Heat Recovery Effectiveness**

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

**2.2.19.1.43 Field: Latent Heat Recovery Effectiveness**

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

**2.2.19.1.44 Field: Cooling Coil Setpoint Reset Type**

Select the type of automatic reset control for the cooling supply air temperature. The choices are:

- None – no reset, use the Cooling Coil Setpoint Schedule or Cooling Coil Design Setpoint.
- Warmest – reset the cooling supply air temperature to the highest supply air temperature that will meet the cooling requirements of all the zones at the maximum supply air flow rate. The minimum setpoint allowed is the Cooling Coil Design Setpoint. The maximum setpoint allowed is defaulted to the greater of 18C or the Heating Coil Design Setpoint plus 1.0C. (Reference **SetpointManager:Warmest**)
- OutdoorAirTemperatureReset – reset the cooling supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below 15.6C the setpoint is the Cooling Coil Design Setpoint plus 5.2C. When the ODB is at or above 26.7C the setpoint is the Cooling Coil Design Setpoint. In between, the setpoint is varied linearly. (Reference **SetpointManager:OutdoorAirReset**)

- **WarmestTemperatureFirst** – find the highest setpoint temperature that will satisfy all the zone cooling loads at minimum supply air flow rate. If this setpoint temperature is less than the Cooling Coil Design Setpoint, the setpoint temperature is set to the minimum, and the supply air flow rate is increased to meet the loads. This option is appropriate when modeling a single-zone VAV system. The maximum setpoint allowed is defaulted to the greater of 18C or the Heating Coil Design Setpoint plus 1.0C. (Reference [SetpointManager:WarmestTemperatureFlow](#))

The default is *None*.

#### 2.2.19.1.45 Field: Heating Coil Setpoint Reset Type

Select the type of automatic reset control for the central heating supply air temperature. The choices are:

- **None** – no reset, use the Heating Coil Setpoint Schedule or Heating Coil Design Setpoint.
- **OutdoorAirTemperatureReset** – reset the heating supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below –6.7C the setpoint is the Heating Coil Design Setpoint. When the ODB is at or above 10.0C the setpoint is the Heating Coil Design Setpoint minus 5.2C. In between, the setpoint is varied linearly. (Reference [SetpointManager:OutdoorAirReset](#)).

The default is *None*.

#### 2.2.19.1.46 Field: Dehumidification Control Type

There are two dehumidification control type options available:

- **None**
- **CoolReheat**

The *CoolReheat* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the terminal unit reheat coils if available.

The default is *None* which meets the sensible cooling setpoint only.

#### 2.2.19.1.47 Field: Dehumidification Control Zone Name

This field specifies the zone name where the humidistat is located for controlling dehumidification.

#### 2.2.19.1.48 Field: Dehumidification Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%.

#### 2.2.19.1.49 Field: Humidifier Type

There are two humidifier type options available:

- **None**
- **ElectricSteam**

The *ElectricSteam* humidifier option uses the [Humidifier:Steam:Electric](#) object. The default is *None*.

**2.2.19.1.50 Field: Humidifier Availability Schedule Name**

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

**2.2.19.1.51 Field: Humidifier Rated Capacity**

Enter the rated moisture output rate in m<sup>3</sup>/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m<sup>3</sup>/s.

**2.2.19.1.52 Field: Humidifier Rated Electric Power**

Enter the electric power input at the rated capacity moisture output. This field can be autosized. When it is autosized, it is calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20°C to saturated steam at 100°C.

**2.2.19.1.53 Field: Humidifier Control Zone Name**

This field specifies the zone name where the humidistat is located for controlling humidification.

**2.2.19.1.54 Field: Humidifier Setpoint**

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

**2.2.19.1.55 Field: Sizing Option**

This field specifies the sizing method for the system supply air flow rate. *Coincident* sizes on the sum of the coincident zone supply air flow rates. *NonCoincident* sizes on sum of the noncoincident zone design supply air flow rates. The default is *NonCoincident*.

**2.2.19.1.56 Field: Return Fan**

Enter *Yes* if the system has a return fan. The default is *No*.

**2.2.19.1.57 Field: Return Fan Total Efficiency**

Enter the total efficiency of the return fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1.

**2.2.19.1.58 Field: Return Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 500 Pa.

**2.2.19.1.59 Field: Return Fan Motor efficiency**

Enter the shaft power of the return fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

### 2.2.19.1.60 Field: Return Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

### 2.2.19.1.61 Field: Return Fan Part-Load Power Coefficients

Select the set of generic pre-defined coefficients to use for the return fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers
- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.8. VAV Supply Fan Part-Load Power Coefficient Options (see Supply Fan Part-Load Power Coefficients above). The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotor-PressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources': *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

As shown in an IDF:

## 2.2.20 HVACTemplate:System:PackagedVAV

This object simulates the system portion of a packaged direct-expansion based variable air volume HVAC configuration with several different heating options. Multiple **HVACTemplate:Zone:VAV** objects are usually specified for each **HVACTemplate:System:PackagedVAV** object.

### 2.2.20.1 Inputs

#### 2.2.20.1.1 Field: Name

Enter a name for the **HVACTemplate:System:PackagedVAV** object. This name is used in the **HVACTemplate:Zone:VAV** object to reference this system.

#### 2.2.20.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Please note that for this system type, this is a schedule of when the system is providing air flow.

#### 2.2.20.1.3 Field: Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are m<sup>3</sup>/s. The default is Autosize.

#### 2.2.20.1.4 Field: Supply Fan Minimum Flow Rate

Enter the minimum supply air volume that may be provided. This field may be set to autosize. The units are in  $\text{m}^3/\text{s}$ .

#### 2.2.20.1.5 Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

#### 2.2.20.1.6 Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

#### 2.2.20.1.7 Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered  $20^\circ\text{C}$  at sea level, 101325 Pa. The default is 1000 Pa.

#### 2.2.20.1.8 Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater or equal to the Supply Fan Total Efficiency and less than or equal to 1. The default is 0.9.

#### 2.2.20.1.9 Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

#### 2.2.20.1.10 Field: Cooling Coil Type

The coil types available:

- TwoSpeedDX
- TwoSpeedHumidControlDX

*TwoSpeedDX* uses the **Coil:Cooling:DX:TwoSpeed** object. This is the preferred coil model for most applications. The *TwoSpeedHumidControlDX* option uses the **Coil:Cooling:DX:TwoStageWithHumidityControlMode** object.

#### 2.2.20.1.11 Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of one indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

**2.2.20.1.12 Field: Cooling Coil Setpoint Schedule Name**

If a constant setpoint for the cooling coil is to be specified, leave this field blank, and the Cooling Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the cooling coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the cooling coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Cooling Coil Setpoint Reset Type is something other than None (see below). The default is None.

**2.2.20.1.13 Field: Cooling Coil Design Setpoint**

Enter the cooling supply air temperature in degrees C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8C. If no Cooling Coil Setpoint Schedule or Cooling Coil Setpoint Reset Type is specified, this value is used as a constant cooling supply air setpoint temperature.

**2.2.20.1.14 Field: Cooling Coil Gross Rated Total Capacity**

Enter Autosize to let the automatic sizing algorithm determine the cooling coil gross rated total capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross total cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. For Cooling Coil Type = TwoSpeedDX, the low-speed capacity is assumed to be 0.33 times this value. For Cooling Coil Type = TwoSpeedHumidControlDX, the stage 1 capacity is assumed to be 0.5 times this value. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is Autosize.

**2.2.20.1.15 Field: Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by the gross total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for. The default is Autosize.

**2.2.20.1.16 Field: Cooling Coil Gross Rated COP**

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The gross COP should not account for the supply air fan. The default is 3.0.

**2.2.20.1.17 Field: Heating Coil Type**

Enter the type of heating used in the unitary system. The choices for this field are

- Electric
- Gas
- HotWater

**2.2.20.1.18 Field: Heating Coil Availability Schedule Name**

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of 1.0 indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

**2.2.20.1.19 Field: Heating Coil Setpoint Schedule Name**

If a constant setpoint for the heating coil is to be specified, leave this field blank, and the Heating Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the heating coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the heating coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Heating Coil Setpoint Reset Type is something other than None (see below).

**2.2.20.1.20 Field: Heating Coil Design Setpoint**

Enter the heating supply air temperature in degrees C to be used for sizing the heating coil and zone supply air flow rates. If no Heating Coil Setpoint Schedule or Heating Coil Setpoint Reset Type is specified, this value is used as a constant heating supply air setpoint temperature. The default is 10.0C.

**2.2.20.1.21 Field: Heating Coil Capacity**

Enter Autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts.

**2.2.20.1.22 Field: Gas Heating Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

**2.2.20.1.23 Field: Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W. The default is 0.0 W.

**2.2.20.1.24 Field: Maximum Outdoor Air Flow Rate**

Enter Autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m3/s. That is, the entered value is used to define the Maximum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template. The default is Autosize.

**2.2.20.1.25 Field: Minimum Outdoor Air Flow Rate**

Enter Autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m3/s. The default is Autosize. The entered value is used to define the Minimum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.20.1.26 Field: Minimum Outdoor Air Control Type**

Choices for this field are **FixedMinimum** or **ProportionalMinimum**. **FixedMinimum** means that the minimum outdoor air flow rate is fixed no matter what the actual system flow rate is. **ProportionalMinimum** means the minimum outdoor air flow rate varies in proportion to the total system air flow rate. The default is **ProportionalMinimum**.

**2.2.20.1.27 Field: Minimum Outdoor Air Schedule Name**

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

**2.2.20.1.28 Field: Economizer Type**

The options for this field are

- ‘FixedDryBulb’
- ‘DifferentialDryBulb’
- ‘FixedEnthalpy’
- ‘DifferentialEnthalpy’
- ‘ElectronicEnthalpy’ (i.e., humidity ratio curve strategy)
- ‘FixedDewPointAndDryBulb’
- ‘DifferentialDryBulbAndEnthalpy’
- ‘NoEconomizer’

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

#### 2.2.20.1.29 Field: Economizer Lockout

Enter one of the following choices for this field:

- NoLockout
- LockoutWithHeating
- LockoutWithCompressor

The default value is **NoLockout**. The **LockoutWithHeating** means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. **LockoutWithCompressor** means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is on. In other words, when the DX coil is off, the economizer must meet the entire cooling load – it isn’t allowed to operate in conjunction with the DX cooling coil. Similarly, when the DX coil is operating, the economizer is not allowed to operate. The **LockoutWithCompressor** option is sometimes called a “nonintegrated” economizer.

#### 2.2.20.1.30 Field: Economizer Maximum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type ‘FixedDryBulb’ or ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air temperature high limit control.

#### 2.2.20.1.31 Field: Economizer Maximum Limit Enthalpy

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

#### 2.2.20.1.32 Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

#### 2.2.20.1.33 Field: Economizer Minimum Limit Dry-Bulb Temperature

Enter the outdoor air temperature low limit (C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

**2.2.20.1.34 Field: Supply Plenum Name**

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any zone supply plenums have been specified, the outlet from the system supply plenum will flow through the zone supply plenum to the zone terminal unit.

**2.2.20.1.35 Field: Return Plenum Name**

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

**2.2.20.1.36 Field: Supply Fan Part-Load Power Coefficients**

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers
- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.9 below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotorPressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources': *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

**2.2.20.1.37 Field: Night Cycle Control**

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, *CycleOnControl Zone* or *CycleOnAnyZoneFansOnly*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. *CycleOnAnyZoneFansOnly* is the same as *CycleOnAny* except that only the zone fans are cycled on and the central air handler fan is left off (applicable only if using **HVACTemplate:Zone:VAV:FanPowered** in one or more zones). The default is *StayOff*.

**2.2.20.1.38 Field: Night Cycle Control Zone Name**

For the Night Cycle Control option *Cycle On Control Zone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

Figure 2.9: VAV Supply Fan Part-Load Power Coefficient Options

**2.2.20.1.39 Field: Heat Recovery Type**

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is **None**.

**2.2.20.1.40 Field: Sensible Heat Recovery Effectiveness**

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

**2.2.20.1.41 Field: Latent Heat Recovery Effectiveness**

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

**2.2.20.1.42 Field: Cooling Coil Setpoint Reset Type**

Select the type of automatic reset control for the cooling supply air temperature. The choices are:

- None – no reset, use the Cooling Coil Setpoint Schedule or Cooling Coil Design Setpoint.
- Warmest – reset the cooling supply air temperature to the highest supply air temperature that will meet the cooling requirements of all the zones at the maximum supply air flow rate. The minimum setpoint allowed is the Cooling Coil Design Setpoint. The maximum setpoint allowed is defaulted to the greater of 18C or the Heating Coil Design Setpoint plus 1.0C. (Reference [SetpointManager:Warmest](#))
- OutdoorAirTemperatureReset – reset the cooling supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below 15.6C the setpoint is the Cooling Coil Design Setpoint plus 5.2C. When the ODB is at or above 26.7C the setpoint is the Cooling Coil Design Setpoint. In between, the setpoint is varied linearly. (Reference [SetpointManager:OutdoorAirReset](#))
- WarmestTemperatureFirst – find the highest setpoint temperature that will satisfy all the zone cooling loads at minimum supply air flow rate. If this setpoint temperature is less than the Cooling Coil Design Setpoint, the setpoint temperature is set to the minimum, and the supply air flow rate is increased to meet the loads. This option is appropriate when modeling a single-zone VAV system. The maximum setpoint allowed is defaulted to the greater of 18C or the Heating Coil Design Setpoint plus 1.0C. (Reference [SetpointManager:WarmestTemperatureFlow](#))

The default is *None*.

#### 2.2.20.1.43 Field: Heating Coil Setpoint Reset Type

Select the type of automatic reset control for the central heating supply air temperature. The choices are:

- None – no reset, use the Heating Coil Setpoint Schedule or Heating Coil Design Setpoint.
- OutdoorAirTemperatureReset – reset the heating supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below  $-6.7^{\circ}\text{C}$  the setpoint is the Heating Coil Design Setpoint. When the ODB is at or above  $10.0^{\circ}\text{C}$  the setpoint is the Heating Coil Design Setpoint minus  $5.2^{\circ}\text{C}$ . In between, the setpoint is varied linearly. (Reference [Setpoint-Manager:OutdoorAirReset](#)).

The default is *None*.

#### 2.2.20.1.44 Field: Dehumidification Control Type

There are two dehumidification control type options available:

- None
- CoolReheat

The *CoolReheat* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the terminal unit reheat coils if available.

The default is *None* which meets the sensible cooling setpoint only.

#### 2.2.20.1.45 Field: Dehumidification Control Zone Name

This field specifies the zone name where the humidistat is located for controlling dehumidification.

#### 2.2.20.1.46 Field: Dehumidification Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%.

#### 2.2.20.1.47 Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the [Humidifier:Steam:Electric](#) object. The default is *None*.

#### 2.2.20.1.48 Field: Humidifier Availability Schedule Name

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period.

#### 2.2.20.1.49 Field: Humidifier Rated Capacity

Enter the rated moisture output rate in  $\text{m}^3/\text{s}$ . The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is  $0.000001 \text{ m}^3/\text{s}$ .

**2.2.20.1.50 Field: Humidifier Rated Electric Power**

Enter the electric power input at the rated capacity moisture output. This field can be autosized. When it is autosized, it is calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20°C to saturated steam at 100°C.

**2.2.20.1.51 Field: Humidifier Control Zone Name**

This field specifies the zone name where the humidistat is located for controlling humidification.

**2.2.20.1.52 Field: Humidifier Setpoint**

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

**2.2.20.1.53 Field: Sizing Option**

This field specifies the sizing method for the system supply air flow rate. *Coincident* sizes on the sum of the coincident zone supply air flow rates. *NonCoincident* sizes on sum of the noncoincident zone design supply air flow rates. The default is *NonCoincident*.

**2.2.20.1.54 Field: Return Fan**

Enter *Yes* if the system has a return fan. The default is *No*.

**2.2.20.1.55 Field: Return Fan Total Efficiency**

Enter the total efficiency of the return fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1.

**2.2.20.1.56 Field: Return Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 500 Pa.

**2.2.20.1.57 Field: Return Fan Motor efficiency**

Enter the shaft power of the return fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

**2.2.20.1.58 Field: Return Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

**2.2.20.1.59 Field: Return Fan Part-Load Power Coefficients**

Select the set of generic pre-defined coefficients to use for the return fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers

- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.8. VAV Supply Fan Part-Load Power Coefficient Options (see Supply Fan Part-Load Power Coefficients above). The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotorPressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources': *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

As shown in an IDF:

### 2.2.21 HVACTemplate:System:ConstantVolume

This object simulates the system portion of a constant air volume HVAC configuration with option chilled water cooling and several different heating options. One or more **HVACTemplate:Zone:ConstantVolume** objects are specified for each zone served by the HVACTemplate:System:ConstantVolume object.

#### 2.2.21.1 Inputs

##### 2.2.21.1.1 Field: Name

Enter a name for the HVACTemplate:System:ConstantVolume object. This name is used in the **HVACTemplate:Zone:ConstantVolume** object to reference this system.

##### 2.2.21.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Please note that for this system type, this is a schedule of when the system is providing air flow.

##### 2.2.21.1.3 Field: Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are m<sup>3</sup>/s.

##### 2.2.21.1.4 Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

##### 2.2.21.1.5 Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 600 Pa.

##### 2.2.21.1.6 Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

#### 2.2.21.1.7 Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

#### 2.2.21.1.8 Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

#### 2.2.21.1.9 Field: Cooling Coil Type

There are two coil types available:

- ChilledWater
- ChilledWaterDetailedFlatModel
- HeatExchangerAssistedChilledWater
- None

*ChilledWater* uses the COIL:Cooling:Water object with the DetailedAnalysis option. This is the preferred coil model for most applications. *ChilledWaterDetailedFlatModel* uses the **Coil:Cooling:Water:DetailedGeometry** object. This option is available for special applications. *HeatExchangerAssistedChilledWater* uses the **CoilSystem:Cooling:Water:HeatExchangerAssisted**, **HeatExchanger:AirToAir:SensibleAndLatent**, and **Coil:Cooling:Water** objects. The default is *ChilledWater*.

#### 2.2.21.1.10 Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1 indicates that the cooling coil can be on during a given time period. A value of 0 denotes that the cooling coil cannot be used during that time period.

#### 2.2.21.1.11 Field: Cooling Coil Setpoint Control Type

Specifies the cooling coil setpoint control type:

- FixedSetpoint - uses the Cooling Coil Design Setpoint as the supply air setpoint.
- Scheduled - uses the Cooling Coil Design Setpoint as the supply air setpoint.
- OutdoorAirTemperatureReset - varies the supply air setpoint based on the values entered for Cooling Coil Setpoint at Outdoor Dry-Bulb Low, Cooling Coil Reset Outdoor Dry-Bulb Low, Cooling Coil Setpoint at Outdoor Dry-Bulb High, and Cooling Coil Reset Outdoor Dry-Bulb High.
- Warmest – resets the cooling supply air temperature to the highest supply air temperature that will meet the cooling requirements of all the zones. The minimum setpoint allowed is the Cooling Coil Design Setpoint. The maximum setpoint allowed is defaulted to the greater of 18C or the Heating Coil Design Setpoint plus 1.0C. (Reference **SetpointManager:Warmest**)

- **ControlZone** – controls the supply air temperature to meet the current cooling load for the zone specified as the Cooling Coil Control Zone Name (below). The minimum setpoint is the Cooling Coil Design Setpoint. The maximum setpoint allowed is defaulted to the greater of 18C or the Heating Coil Design Setpoint plus 1.0C. (Reference [SetpointManager:SingleZone:Cooling](#))

The default is *FixedSetpoint*.

NOTE: The user must ensure that the cooling coil and heating coil setpoints do not overlap to avoid unwanted simultaneous heating and cooling. The simulation will not check this automatically. It is recommended that the cooling setpoint always be at least 0.1C higher than the heating coil setpoint.

#### 2.2.21.1.12 Field: Cooling Coil Control Zone Name

If the Cooling Coil Setpoint Control Type is ControlZone, enter the name of the [HVACTemplate:Zone:ConstantVolume](#) object that contains the cooling thermostat.

#### 2.2.21.1.13 Field: Cooling Coil Design Setpoint Temperature

Enter the cooling supply air temperature in C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8C. If no Cooling Coil Setpoint Schedule or Cooling Coil Setpoint Reset Type is specified, this value is used as a constant cooling supply air setpoint temperature.

#### 2.2.21.1.14 Field: Cooling Coil Setpoint Schedule Name

If a constant setpoint for the cooling coil is to be specified, leave this field blank, and the Cooling Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the cooling coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the cooling coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Cooling Coil Setpoint Reset Type is something other than None (see above).

#### 2.2.21.1.15 Field: Cooling Coil Setpoint at Outdoor Dry-Bulb Low

The cooling coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or below the low limit (Cooling Coil Reset Outdoor Dry-Bulb Low). Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.6C.

#### 2.2.21.1.16 Field: Cooling Coil Reset Outdoor Dry-Bulb Low

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Cooling Coil Setpoint at Outdoor Dry-Bulb Low. Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.6C.

#### 2.2.21.1.17 Field: Cooling Coil Setpoint at Outdoor Dry-Bulb High

The cooling coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or above the high limit (Cooling Coil Reset Outdoor Dry-Bulb High). Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.8C.

#### 2.2.21.1.18 Field: Cooling Coil Reset Outdoor Dry-Bulb High

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Cooling Coil Setpoint at Outdoor Dry-Bulb High. Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 23.3C.

### 2.2.21.1.19 Field: Heating Coil Type

The heating coil is located in the supply air stream, upstream of the cooling coil and after the outdoor air mixing box. If no central heating coil is used in the Constant Volume system, then the option “none” should be specified here. Otherwise this indicates the type of heating coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is *HotWater*. Note that the configuration of `HVACTemplate:System:ConstantVolume` assumes that there will be reheat coils or baseboard heating to provide heating control at the zone level. If a heating coil is specified, the heating and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

### 2.2.21.1.20 Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period.

### 2.2.21.1.21 Field: Heating Coil Setpoint Control Type

Specifies the heating coil setpoint control type:

- FixedSetpoint - uses the Heating Coil Design Setpoint as the supply air setpoint.
- Scheduled - uses the Heating Coil Setpoint Schedule to set the supply air setpoint.
- OutdoorAirTemperatureReset - varies the supply air setpoint based on the values entered for Heating Coil Setpoint at Outdoor Dry-Bulb Low, Heating Coil Reset Outdoor Dry-Bulb Low, Heating Coil Setpoint at Outdoor Dry-Bulb High, and Heating Coil Reset Outdoor Dry-Bulb High.
- ControlZone - controls the supply air temperature to meet the current heating load for the zone specified as the Heating Coil Control Zone Name (below). The maximum setpoint is the Heating Coil Design Setpoint. The minimum setpoint allowed is defaulted to the lesser of the Heating Coil Design Setpoint minus 5.2C or the Cooling Coil Design Setpoint minus 1.0C. (Reference [Setpoint-Manager:SingleZone:Heating](#))

The default is FixedSetpoint.

NOTE: The user must ensure that the cooling coil and heating coil setpoints do not overlap to avoid unwanted simultaneous heating and cooling. The simulation will not check this automatically. It is recommended that the cooling setpoint always be at least 0.1C higher than the heating coil setpoint.

### 2.2.21.1.22 Field: Heating Coil Control Zone Name

Enter the name of the `HVACTemplate:Zone:ConstantVolume` object that contains the heating thermostat. While multiple `HVACTemplate:Zone:ConstantVolume` objects can be part of a `HVACTemplate:System:ConstantVolume` system, only one of the zones contains a thermostat that controls heating operation. For a single zone system, this field should contain the name of that zone.

**2.2.21.1.23 Field: Heating Coil Design Setpoint**

Enter the heating supply air temperature in C to be used for sizing the heating coil and zone supply air flow rates. If no Heating Coil Setpoint Schedule or Heating Coil Setpoint Reset Type is specified, this value is used as a constant heating supply air setpoint temperature. The default is 10.0C.

**2.2.21.1.24 Field: Heating Coil Setpoint Schedule Name**

If a constant setpoint for the heating coil is to be specified, leave this field blank, and the Heating Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the heating coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the heating coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Heating Coil Setpoint Reset Type is something other than None (see above).

**2.2.21.1.25 Field: Heating Coil Setpoint at Outdoor Dry-Bulb Low**

The heating coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or below the low limit (Heating Coil Reset Outdoor Dry-Bulb Low). Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.0C.

**2.2.21.1.26 Field: Heating Coil Reset Outdoor Dry-Bulb Low**

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Heating Coil Setpoint at Outdoor Dry-Bulb Low. Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 7.8C.

**2.2.21.1.27 Field: Heating Coil Setpoint at Outdoor Dry-Bulb High**

The heating coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or above the high limit (Heating Coil Reset Outdoor Dry-Bulb High). Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.2C.

**2.2.21.1.28 Field: Heating Coil Reset Outdoor Dry-Bulb High**

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Heating Coil Setpoint at Outdoor Dry-Bulb High. Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.2C.

**2.2.21.1.29 Field: Heating Coil Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts.

**2.2.21.1.30 Field: Gas Heating Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

**2.2.21.1.31 Field: Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating operation, such as a combustion fan. The units are in W.

### 2.2.21.1.32 Field: Preheat Coil Type

The preheat coil is located in the outdoor air stream, upstream of the outdoor air mixing box and tempers the outdoor air. If no preheat coil is used in the constant volume system, then the option “none” should be specified here. Otherwise this indicates the type of preheat coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is None. If a preheat coil is specified, the preheat and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

### 2.2.21.1.33 Field: Preheat Coil Availability Schedule Name

Usually set to blank, which allows the preheat coil to be available anytime the system is operating. If a schedule name is specified, it defines when the preheat coil is available. This is most often used when preheat is only available seasonally. The schedule values denote whether the preheat coil can run during a given time period. A schedule value of 1.0 indicates that the preheat coil can be on during a given time period. A value of zero denotes that the preheat coil cannot be used during that time period

### 2.2.21.1.34 Field: Preheat Coil Design Setpoint

Enter the preheat supply air temperature in C to be used for sizing the preheat coil. If no Preheat Coil Setpoint Schedule is specified, this value is used as a constant preheat supply air setpoint temperature. The default is 7.2C.

### 2.2.21.1.35 Field: Preheat Coil Setpoint Schedule Name

If a constant setpoint for the preheat coil is to be specified, leave this field blank, and the Preheat Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the preheat coil specify the schedule name here. The schedule should control the leaving air temperature from the preheat coil. The values in the schedule are in degrees C.

### 2.2.21.1.36 Field: Gas Preheat Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

### 2.2.21.1.37 Field: Gas Preheat Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating operation, such as an combustion fan. The units are in W.

### 2.2.21.1.38 Field: Maximum Outdoor Air Flow Rate

Enter autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m3/s. That is, the entered value is used to define the Maximum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.21.1.39 Field: Minimum Outdoor Air Flow Rate**

Enter autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m<sup>3</sup>/s. The default is Autosize. The entered value is used to define the Minimum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.21.1.40 Field: Minimum Outdoor Air Schedule Name**

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

**2.2.21.1.41 Field: Economizer Type**

The options for this field are

- ‘FixedDryBulb’
- ‘DifferentialDryBulb’
- ‘FixedEnthalpy’
- ‘DifferentialEnthalpy’
- ‘ElectronicEnthalpy’ (i.e., humidity ratio curve strategy)
- ‘FixedDewPointAndDryBulb’
- ‘DifferentialDryBulbAndEnthalpy’
- ‘NoEconomizer’

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

#### 2.2.21.1.42 Field: Economizer Upper Temperature Limit

Enter the outdoor air temperature high limit ( $^{\circ}\text{C}$ ) for economizer operation. If the outdoor air temperature is above this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature high limit control.

#### 2.2.21.1.43 Field: Economizer Lower Temperature Limit

Enter the outdoor air temperature low limit ( $^{\circ}\text{C}$ ) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

#### 2.2.21.1.44 Field: Economizer Upper Enthalpy Limit

Enter the outdoor air upper enthalpy limit (in  $\text{J/kg}$ ) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

#### 2.2.21.1.45 Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit ( $^{\circ}\text{C}$ ) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

#### 2.2.21.1.46 Field: Supply Plenum Name

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any supply plenums have been specified, the outlet from the system supply plenum will flow through the supply plenum to the zone terminal unit.

#### 2.2.21.1.47 Field: Return Plenum Name

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

#### 2.2.21.1.48 Field: Night Cycle Control

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, *CycleOnControlZone* or *CycleOnAnyZoneFansOnly*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan

will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. *CycleOnAnyZoneFansOnly* is the same as *CycleOnAny* except that only the zone fans are cycled on and the central air handler fan is left off (applicable only if using *HVACTemplate:Zone:VAV:FanPowered* in one or more zones). The default is *StayOff*.

#### 2.2.21.1.49 Field: Night Cycle Control Zone Name

For the Night Cycle Control option *Cycle On Control Zone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

#### 2.2.21.1.50 Field: Heat Recovery Type

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is **None**.

#### 2.2.21.1.51 Field: Sensible Heat Recovery Effectiveness

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

#### 2.2.21.1.52 Field: Latent Heat Recovery Effectiveness

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

#### 2.2.21.1.53 Field: Heat Recovery Heat Exchanger Type

This alpha field denotes the type of heat exchanger being modeled: Plate (e.g., fixed plate) or Rotary (e.g., rotating cylinder or wheel). The default choice for this field is “Plate”. The heat exchanger type affects the modeling of frost control options and supply air outlet temperature control. For rotary heat exchangers, rotational speed is varied to control frost formation or the supply air outlet temperature. For plate exchangers, air bypass around the heat exchanger is used to obtain the desired effect.

#### 2.2.21.1.54 Field: Heat Recovery Frost Control Type

This alpha field has four choices: None, ExhaustAirRecirculation, ExhaustOnly and MinimumExhaust-Temperature. If this field is left blank, the default frost control type is “None”. For modeling preheat frost control, specify “None” for this input field and insert a separate heating coil object in the supply inlet air stream to keep the air temperature above the desired frost threshold temperature.

*ExhaustAirRecirculation*: dampers are used to direct exhaust air back into the zone through the supply side of the heat exchanger when the supply (outdoor) air inlet temperature falls below a threshold temperature. The fraction of time that exhaust air is circulated through the supply side of the heat exchanger is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When exhaust air is being recirculated, no supply (outdoor ventilation) air is being provided through the heat exchanger unit (which may or may not be acceptable regarding ventilation for occupants).

*ExhaustOnly (supply air bypass)*: this control cycles off the supply air flow through the heat exchanger for a certain period of time while the exhaust air continues to flow through the exhaust side of the heat exchanger. The fraction of time that the supply flow through the heat exchanger is cycled off is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When implemented in real applications, provisions are usually made to avoid building depressurization when this frost control is operating (automatic or pressure-operated dampers, or a bypass air damper around the supply side of the heat exchanger). For this frost control type, it is assumed that the supply air is bypassed around the heat exchanger during frost control operation (i.e., the total supply flow is not reduced during defrost, but merely bypassed around the heat exchanger).

*MinimumExhaustTemperature*: the temperature of the exhaust air leaving the heat exchanger is monitored and the heat exchanger effectiveness is decreased (by slowing heat exchanger rotation or bypassing supply air around the plate exchanger) to keep the exhaust air from falling below the threshold temperature.

#### 2.2.21.1.55 Field: Dehumidification Control Type

There are two dehumidification control type options available:

- None
- CoolReheat

The *CoolReheat* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the central heating coil if available or the terminal unit reheat coils if available.

The default is *None* which meets the sensible cooling setpoint only.

#### 2.2.21.1.56 Field: Dehumidification Control Zone Name

This field specifies the zone name where the humidistat is located for controlling dehumidification.

#### 2.2.21.1.57 Field: Dehumidification Relative Humidity Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%. This field is ignored if a Dehumidification Relative Humidity Setpoint Schedule Name is specified.

#### 2.2.21.1.58 Field: Dehumidification Relative Humidity Setpoint Schedule Name

Enter the name of the dehumidification setpoint schedule. If this field is left blank, the setpoint will be constant at the Dehumidification Relative Humidity Setpoint, The values in the schedule are in percent (0 to 100).

#### 2.2.21.1.59 Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the `Humidifier:Steam:Electric` object. The default is *None*.

**2.2.21.1.60 Field: Humidifier Availability Schedule Name**

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

**2.2.21.1.61 Field: Humidifier Rated Capacity**

Enter the rated moisture output rate in m<sup>3</sup>/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m<sup>3</sup>/s.

**2.2.21.1.62 Field: Humidifier Rated Electric Power**

Enter the electric power input at the rated capacity moisture output. This field can be autosized. When it is autosized, it is calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20°C to saturated steam at 100°C.

**2.2.21.1.63 Field: Humidifier Control Zone Name**

This field specifies the zone name where the humidistat is located for controlling humidification.

**2.2.21.1.64 Field: Humidifier Relative Humidity Setpoint**

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%. This field is ignored if a Humidifier Relative Humidity Setpoint Schedule Name is specified.

**2.2.21.1.65 Field: Humidifier Relative Humidity Setpoint Schedule Name**

Enter the name of the dehumidification setpoint schedule. If this field is left blank, the setpoint will be constant at the Dehumidification Relative Humidity Setpoint, The values in the schedule are in percent (0 to 100).

**2.2.21.1.66 Field: Return Fan**

Enter *Yes* if the system has a return fan. The default is *No*.

**2.2.21.1.67 Field: Return Fan Total Efficiency**

Enter the total efficiency of the return fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1. Default is 0.7.

**2.2.21.1.68 Field: Return Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 300 Pa.

**2.2.21.1.69 Field: Return Fan Motor efficiency**

Enter the shaft power of the return fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. Default is 0.9.

### 2.2.21.1.70 Field: Return Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. Default is 1.0.

As shown in an IDF:

## 2.2.22 HVACTemplate:System:DualDuct

This object simulates the system portion of a constant air volume or variable air volume dual-duct HVAC configuration with optional chilled water cooling and several different heating options. One or more [HVACTemplate:Zone:DualDuct](#) objects may be specified for each zone served by the HVACTemplate:System:DualDuct object. The system will be constant volume if all of the [HVACTemplate:Zone:DualDuct](#) objects served by this system have Zone Minimum Air Flow Fraction = 1.0.

### 2.2.22.1 Inputs

#### 2.2.22.1.1 Field: Name

Enter a name for the HVACTemplate:System:DualDuct object. This name is used in the [HVACTemplate:Zone:DualDuct](#) object to reference this system.

#### 2.2.22.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Please note that for this system type, this is a schedule of when the system is providing air flow.

#### 2.2.22.1.3 Field: Supply Fan Configuration Type

This field specifies the supply fan configuration. \* *SingleConstantVolume*\* and *SingleVariableVolume* specify one supply fan located in the main supply air duct before the split into a cold supply air duct and a hot supply air duct. This configuration uses the ‘Main Supply Fan’ input fields which follow immediately below. *DualConstantVolume* and *DualVariableVolume* specify two supply fans, one located in the cold supply air duct and one located in the hot supply air duct. *Dual* uses the ‘Cold Duct Supply Fan’ and Hot Duct Supply Fan’ inputs which follow below. The default is *SingleConstantVolume*.

#### 2.2.22.1.4 Field: Main Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are m<sup>3</sup>/s.

#### 2.2.22.1.5 Field: Main Supply Fan Minimum Flow Fraction

Enter the minimum supply air flow fraction that may be provided. This field is ignored if the system is constant volume.

#### 2.2.22.1.6 Field: Main Supply Fan Total Efficiency

Enter the total efficiency of the main supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7..

#### 2.2.22.1.7 Field: Main Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 1000 Pa.

#### 2.2.22.1.8 Field: Main Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

#### 2.2.22.1.9 Field: Main Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

#### 2.2.22.1.10 Field: Main Supply Fan Part-Load Power Coefficients

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers
- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.8. VAV Supply Fan Part-Load Power Coefficient Options below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotorPressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources': *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

#### 2.2.22.1.11 Field: Cold Duct Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum cold duct air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are m<sup>3</sup>/s.

Figure 2.10: VAV Supply Fan Part-Load Power Coefficient Options

**2.2.22.1.12 Field: Cold Duct Supply Fan Minimum Flow Fraction**

Enter the minimum cold duct air flow fraction that may be provided. This field is ignored if the system is constant volume.

**2.2.22.1.13 Field: Cold Duct Supply Fan Total Efficiency**

Enter the total efficiency of the cold duct supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.22.1.14 Field: Cold Duct Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 1000 Pa.

**2.2.22.1.15 Field: Cold Duct Supply Fan Motor efficiency**

Enter the shaft power of the cold duct supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

**2.2.22.1.16 Field: Cold Duct Supply Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the cold duct air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

**2.2.22.1.17 Field: Cold Duct Supply Fan Part-Load Power Coefficients**

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers
- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.8. VAV Supply Fan Part-Load Power Coefficient Options below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotorPressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources': *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

**2.2.22.1.18 Field: Cold Duct Supply Fan Placement**

Enter the cold duct supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *Draw Through*.

**2.2.22.1.19 Field: Hot Duct Supply Fan Maximum Flow Rate**

Enter Autosize to set the system maximum hot duct air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. This flow rate will *not* be multiplied by a sizing factor or by zone multipliers. If using zone multipliers a value entered here must be large enough to serve the multiplied zones. The units are  $\text{m}^3/\text{s}$ .

**2.2.22.1.20 Field: Hot Duct Supply Fan Minimum Flow Fraction**

Enter the minimum hot duct air flow fraction that may be provided. This field is ignored if the system is constant volume.

**2.2.22.1.21 Field: Hot Duct Supply Fan Total Efficiency**

Enter the total efficiency of the hot duct supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.22.1.22 Field: Hot Duct Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 1000 Pa.

**2.2.22.1.23 Field: Hot Duct Supply Fan Motor efficiency**

Enter the shaft power of the hot duct supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

**2.2.22.1.24 Field: Hot Duct Supply Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the hot duct air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

**2.2.22.1.25 Field: Hot Duct Supply Fan Part-Load Power Coefficients**

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers
- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.8. VAV Supply Fan Part-Load Power Coefficient Options below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotorPressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources': *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

### 2.2.22.1.26 Field: Hot Duct Supply Fan Placement

Enter the hot duct supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *Draw Through*.

### 2.2.22.1.27 Field: Cooling Coil Type

There are two coil types available:

- ChilledWater
- ChilledWaterDetailedFlatModel
- None

*ChilledWater* uses the COIL:Cooling:Water object with the DetailedAnalysis option. This is the preferred coil model for most applications. *ChilledWaterDetailedFlatModel* uses the **Coil:Cooling:Water:DetailedGeometry** object. This option is available for special applications. The default is *ChilledWater*.

### 2.2.22.1.28 Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1 indicates that the cooling coil can be on during a given time period. A value of 0 denotes that the cooling coil cannot be used during that time period.

### 2.2.22.1.29 Field: Cooling Coil Setpoint Control Type

Specifies the cooling coil setpoint control type:

- FixedSetpoint
- Scheduled
- OutdoorAirTemperatureReset
- Warmest – reset the cooling supply air temperature to the highest supply air temperature that will meet the cooling requirements of all the zones. The minimum setpoint allowed is the Cooling Coil Design Setpoint. The maximum setpoint allowed is defaulted to 18C or the Cooling Design Setpoint + 5.2C whichever is greater.. (Reference **SetpointManager:Warmest**)

FixedSetpoint uses the Cooling Coil Design Setpoint as the supply air setpoint. Scheduled uses the Cooling Coil Setpoint Schedule to set the supply air setpoint. OutdoorAirTemperatureReset varies the supply air setpoint based on the values entered for Cooling Coil Setpoint at Outdoor Dry-Bulb Low, Cooling Coil Reset Outdoor Dry-Bulb Low, Cooling Coil Setpoint at Outdoor Dry-Bulb High, and Cooling Coil Reset Outdoor Dry-Bulb High. The default is FixedSetpoint.

### 2.2.22.1.30 Field: Cooling Coil Design Setpoint Temperature

Enter the cooling supply air temperature in C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8C. If no Cooling Coil Setpoint Schedule or Cooling Coil Setpoint Reset Type is specified, this value is used as a constant cooling supply air setpoint temperature.

**2.2.22.1.31 Field: Cooling Coil Setpoint Schedule Name**

If a constant setpoint for the cooling coil is to be specified, leave this field blank, and the Cooling Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the cooling coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the cooling coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Cooling Coil Setpoint Reset Type is something other than None (see above).

**2.2.22.1.32 Field: Cooling Coil Setpoint at Outdoor Dry-Bulb Low**

The cooling coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or below the low limit (Cooling Coil Reset Outdoor Dry-Bulb Low). Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.6C.

**2.2.22.1.33 Field: Cooling Coil Reset Outdoor Dry-Bulb Low**

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Cooling Coil Setpoint at Outdoor Dry-Bulb Low. Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.6C.

**2.2.22.1.34 Field: Cooling Coil Setpoint at Outdoor Dry-Bulb High**

The cooling coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or above the high limit (Cooling Coil Reset Outdoor Dry-Bulb High). Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.8C.

**2.2.22.1.35 Field: Cooling Coil Reset Outdoor Dry-Bulb High**

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Cooling Coil Setpoint at Outdoor Dry-Bulb High. Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 23.3C.

**2.2.22.1.36 Field: Heating Coil Type**

The heating coil is located in the supply air stream, upstream of the cooling coil and after the outdoor air mixing box. If no central heating coil is used in the Constant Volume system, then the option “none” should be specified here. Otherwise this indicates the type of heating coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is HotWater. Note that the configuration of **HVACTemplate:System:ConstantVolume** assumes that there will be reheat coils or baseboard heating to provide heating control at the zone level. If a heating coil is specified, the heating and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

**2.2.22.1.37 Field: Heating Coil Availability Schedule Name**

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period.

**2.2.22.1.38 Field: Heating Coil Setpoint Control Type**

Specifies the heating coil setpoint control type:

- FixedSetpoint
- Scheduled
- OutdoorAirTemperatureReset
- Warmest – reset the heating supply air temperature to the coldest supply air temperature that will meet the heating requirements of all the zones. The maximum setpoint allowed is the Heating Coil Design Setpoint. The minimum setpoint allowed is defaulted to 20C or the Heating Coil Design Setpoint – 5.2C whichever is lower.. (Reference [SetpointManager:Coldest](#))

FixedSetpoint uses the Heating Coil Design Setpoint as the supply air setpoint. Scheduled uses the Heating Coil Setpoint Schedule to set the supply air setpoint. OutdoorAirTemperatureReset varies the supply air setpoint based on the values entered for Heating Coil Setpoint at Outdoor Dry-Bulb Low, Heating Coil Reset Outdoor Dry-Bulb Low, Heating Coil Setpoint at Outdoor Dry-Bulb High, and Heating Coil Reset Outdoor Dry-Bulb High. The default is FixedSetpoint.

**2.2.22.1.39 Field: Heating Coil Design Setpoint**

Enter the heating supply air temperature in C to be used for sizing the heating coil and zone supply air flow rates. If no Heating Coil Setpoint Schedule or Heating Coil Setpoint Reset Type is specified, this value is used as a constant heating supply air setpoint temperature. The default is 50.0C.

**2.2.22.1.40 Field: Heating Coil Setpoint Schedule Name**

If a constant setpoint for the heating coil is to be specified, leave this field blank, and the Heating Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the heating coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the heating coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Heating Coil Setpoint Reset Type is something other than None (see above).

**2.2.22.1.41 Field: Heating Coil Setpoint at Outdoor Dry-Bulb Low**

The heating coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or below the low limit (Heating Coil Reset Outdoor Dry-Bulb Low). Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 50.0C.

**2.2.22.1.42 Field: Heating Coil Reset Outdoor Dry-Bulb Low**

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Heating Coil Setpoint at Outdoor Dry-Bulb Low. Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 7.8C.

**2.2.22.1.43 Field: Heating Coil Setpoint at Outdoor Dry-Bulb High**

The heating coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or above the high limit (Heating Coil Reset Outdoor Dry-Bulb High). Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 20.0C.

**2.2.22.1.44 Field: Heating Coil Reset Outdoor Dry-Bulb High**

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Heating Coil Setpoint at Outdoor Dry-Bulb High. Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.2C.

**2.2.22.1.45 Field: Heating Coil Capacity**

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts.

**2.2.22.1.46 Field: Gas Heating Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

**2.2.22.1.47 Field: Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating operation, such as a combustion fan. The units are in W.

**2.2.22.1.48 Field: Preheat Coil Type**

The preheat coil is located in the outdoor air stream, upstream of the outdoor air mixing box and tempers the outdoor air. If no preheat coil is used in the constant volume system, then the option “none” should be specified here. Otherwise this indicates the type of preheat coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is None. If a preheat coil is specified, the preheat and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

**2.2.22.1.49 Field: Preheat Coil Availability Schedule Name**

Usually set to blank, which allows the preheat coil to be available anytime the system is operating. If a schedule name is specified, it defines when the preheat coil is available. This is most often used when preheat is only available seasonally. The schedule values denote whether the preheat coil can run during a given time period. A schedule value of 1.0 indicates that the preheat coil can be on during a given time period. A value of zero denotes that the preheat coil cannot be used during that time period

**2.2.22.1.50 Field: Preheat Coil Design Setpoint**

Enter the preheat supply air temperature in C to be used for sizing the preheat coil. If no Preheat Coil Setpoint Schedule is specified, this value is used as a constant preheat supply air setpoint temperature. The default is 7.2C.

**2.2.22.1.51 Field: Preheat Coil Setpoint Schedule Name**

If a constant setpoint for the preheat coil is to be specified, leave this field blank, and the Preheat Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the preheat coil specify the schedule name here. The schedule should control the leaving air temperature from the preheat coil. The values in the schedule are in degrees C.

**2.2.22.1.52 Field: Gas Preheat Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

**2.2.22.1.53 Field: Gas Preheat Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating operation, such as an combustion fan. The units are in W.

**2.2.22.1.54 Field: Maximum Outdoor Air Flow Rate**

Enter autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m3/s. That is, the entered value is used to define the Maximum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.22.1.55 Field: Minimum Outdoor Air Flow Rate**

Enter autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m3/s. The default is Autosize. The entered value is used to define the Minimum Outdoor Air Flow Rate for the **Controller:OutdoorAir** object that will be generated by this template.

**2.2.22.1.56 Field: Minimum Outdoor Air Control Type**

Choices for this field are **FixedMinimum** or **ProportionalMinimum**. FixedMinimum means that the minimum outdoor air flow rate is fixed no matter what the actual system flow rate is. ProportionalMinimum means the minimum outdoor air flow rate varies in proportion to the total system air flow rate. The default is ProportionalMinimum.

**2.2.22.1.57 Field: Minimum Outdoor Air Schedule Name Name**

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

### 2.2.22.1.58 Field: Economizer Type

The options for this field are

- ‘FixedDryBulb’
- ‘DifferentialDryBulb’
- ‘FixedEnthalpy’
- ‘DifferentialEnthalpy’
- ‘ElectronicEnthalpy’ (i.e., humidity ratio curve strategy)
- ‘FixedDewPointAndDryBulb’
- ‘DifferentialDryBulbAndEnthalpy’
- ‘NoEconomizer’

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

**FixedEnthalpy** checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

**DifferentialEnthalpy** does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

### 2.2.22.1.59 Field: Economizer Lockout

The only choice for this field is

- NoLockout

The default value is NoLockout. Future versions may have additional options.

**2.2.22.1.60 Field: Economizer Upper Temperature Limit**

Enter the outdoor air temperature high limit ( $^{\circ}\text{C}$ ) for economizer operation. If the outdoor air temperature is above this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature high limit control.

**2.2.22.1.61 Field: Economizer Lower Temperature Limit**

Enter the outdoor air temperature low limit ( $^{\circ}\text{C}$ ) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

**2.2.22.1.62 Field: Economizer Upper Enthalpy Limit**

Enter the outdoor air upper enthalpy limit (in  $\text{J/kg}$ ) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

**2.2.22.1.63 Field: Economizer Maximum Limit Dewpoint Temperature**

Input for this field is the outdoor air dewpoint limit ( $^{\circ}\text{C}$ ) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type ‘FixedDewPointAndDryBulb’ has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

**2.2.22.1.64 Field: Cold Supply Plenum Name**

Set to blank if no cold supply plenum is to be modeled. If a cold supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves the cold inlets of all zones on this system. If any zone supply plenums have been specified, the outlet from the system supply plenum will flow through the zone supply plenum to the zone terminal unit.

**2.2.22.1.65 Field: Hot Supply Plenum Name**

Set to blank if no hot supply plenum is to be modeled. If a hot supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves hot inlets of all zones on this system. If any zone supply plenums have been specified, the outlet from the system supply plenum will flow through the zone supply plenum to the zone terminal unit.

**2.2.22.1.66 Field: Return Plenum Name**

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

**2.2.22.1.67 Field: Night Cycle Control**

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, or *CycleOnControlZone*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even

though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. The default is *StayOff*.

#### 2.2.22.1.68 Field: Night Cycle Control Zone Name

For the Night Cycle Control option *Cycle On Control Zone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

#### 2.2.22.1.69 Field: Heat Recovery Type

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is **None**.

#### 2.2.22.1.70 Field: Sensible Heat Recovery Effectiveness

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

#### 2.2.22.1.71 Field: Latent Heat Recovery Effectiveness

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

#### 2.2.22.1.72 Field: Heat Recovery Heat Exchanger Type

This alpha field denotes the type of heat exchanger being modeled: Plate (e.g., fixed plate) or Rotary (e.g., rotating cylinder or wheel). The default choice for this field is “Plate”. The heat exchanger type affects the modeling of frost control options and supply air outlet temperature control. For rotary heat exchangers, rotational speed is varied to control frost formation or the supply air outlet temperature. For plate exchangers, air bypass around the heat exchanger is used to obtain the desired effect.

#### 2.2.22.1.73 Field: Heat Recovery Frost Control Type

This alpha field has four choices: None, ExhaustAirRecirculation, ExhaustOnly and MinimumExhaust-Temperature. If this field is left blank, the default frost control type is “None”. For modeling preheat frost control, specify “None” for this input field and insert a separate heating coil object in the supply inlet air stream to keep the air temperature above the desired frost threshold temperature.

*ExhaustAirRecirculation*: dampers are used to direct exhaust air back into the zone through the supply side of the heat exchanger when the supply (outdoor) air inlet temperature falls below a threshold temperature. The fraction of time that exhaust air is circulated through the supply side of the heat exchanger is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When exhaust air is being recirculated, no supply (outdoor ventilation) air is being provided through the heat exchanger unit (which may or may not be acceptable regarding ventilation for occupants).

*ExhaustOnly (supply air bypass)*: this control cycles off the supply air flow through the heat exchanger for a certain period of time while the exhaust air continues to flow through the exhaust side of the heat

exchanger. The fraction of time that the supply flow through the heat exchanger is cycled off is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When implemented in real applications, provisions are usually made to avoid building depressurization when this frost control is operating (automatic or pressure-operated dampers, or a bypass air damper around the supply side of the heat exchanger). For this frost control type, it is assumed that the supply air is bypassed around the heat exchanger during frost control operation (i.e., the total supply flow is not reduced during defrost, but merely bypassed around the heat exchanger).

*MinimumExhaustTemperature*: the temperature of the exhaust air leaving the heat exchanger is monitored and the heat exchanger effectiveness is decreased (by slowing heat exchanger rotation or bypassing supply air around the plate exchanger) to keep the exhaust air from falling below the threshold temperature.

#### 2.2.22.1.74 Field: Dehumidification Control Type

There are two dehumidification control type options available:

- None
- CoolReheat

The *CoolReheat* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the terminal unit reheat coils if available.

The default is *None* which meets the sensible cooling setpoint only.

#### 2.2.22.1.75 Field: Dehumidification Control Zone Name

This field specifies the zone name where the humidistat is located for controlling dehumidification.

#### 2.2.22.1.76 Field: Dehumidification Relative Humidity Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%. This field is ignored if a Dehumidification Relative Humidity Setpoint Schedule Name is specified.

#### 2.2.22.1.77 Field: Dehumidification Relative Humidity Setpoint Schedule Name

Enter the name of the dehumidification setpoint schedule. If this field is left blank, the setpoint will be constant at the Dehumidification Relative Humidity Setpoint, The values in the schedule are in percent (0 to 100).

#### 2.2.22.1.78 Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the **Humidifier:Steam:Electric** object. The default is *None*.

#### 2.2.22.1.79 Field: Humidifier Availability Schedule Name

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period.

**2.2.22.1.80 Field: Humidifier Rated Capacity**

Enter the rated moisture output rate in m<sup>3</sup>/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m<sup>3</sup>/s.

**2.2.22.1.81 Field: Humidifier Rated Electric Power**

Enter the electric power input at the rated capacity moisture output. This field can be autosized. When it is autosized, it is calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20°C to saturated steam at 100°C.

**2.2.22.1.82 Field: Humidifier Control Zone Name**

This field specifies the zone name where the humidistat is located for controlling humidification.

**2.2.22.1.83 Field: Humidifier Relative Humidity Setpoint**

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%. This field is ignored if a Humidifier Relative Humidity Setpoint Schedule Name is specified.

**2.2.22.1.84 Field: Humidifier Relative Humidity Setpoint Schedule Name**

Enter the name of the dehumidification setpoint schedule. If this field is left blank, the setpoint will be constant at the Dehumidification Relative Humidity Setpoint, The values in the schedule are in percent (0 to 100).

**2.2.22.1.85 Field: Sizing Option**

This field specifies the sizing method for the system supply air flow rate when the system type is variable volume. *Coincident* sizes on the sum of the coincident zone supply air flow rates. *NonCoincident* sizes on sum of the noncoincident zone design supply air flow rates. The default is *NonCoincident*.

**2.2.22.1.86 Field: Return Fan**

Enter *Yes* if the system has a return fan. The default is *No*.

**2.2.22.1.87 Field: Return Fan Total Efficiency**

Enter the total efficiency of the return fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1.

**2.2.22.1.88 Field: Return Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 500 Pa.

**2.2.22.1.89 Field: Return Fan Motor efficiency**

Enter the shaft power of the return fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

### 2.2.22.1.90 Field: Return Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

### 2.2.22.1.91 Field: Return Fan Part-Load Power Coefficients

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- InletVaneDampers
- OutletDampers
- VariableSpeedMotor
- ASHRAE90.1-2004Appendix G
- VariableSpeedMotorPressureReset

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 2.8. VAV Supply Fan Part-Load Power Coefficient Options below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table. The *VariableSpeedMotorPressureReset* option is based on Good Static Pressure Reset VSD Fan from Energy Design Resources': *Design Guidelines: Advanced Variable Air Volume (VAV) Systems* (EDR\_DesignGuidelines\_VAV.pdf).

As shown in an IDF:

### 2.2.23 HVACTemplate:System:DedicatedOutdoorAir

The HVACTemplate:System:DedicatedOutdoorAir creates a dedicated outdoor air system which must be used in conjunction with one or more of the following objects:

HVACTemplate:Zone:BaseboardHeat  
 HVACTemplate:Zone:FanCoil  
 HVACTemplate:Zone:PTAC

HVACTemplate:Zone:PTHP

HVACTemplate:Zone:WaterToAirHeatPump

HVACTemplate:Zone:VRF

It is a constant volume dedicated outdoor air system which can serve multiple zones. It may have any combination of heating coil, cooling coil, and heat recovery. It may have dehumidification and humidification controls as well as several supply temperature control types. It supplies 100% outdoor air when the system is available, and assumes an equal volume of return air is available for heat recovery. If the system to be modeled does not have actual return ducts, but collects flow from exhaust fans to a central heat recovery point, then this approach should be equivalent. If the system does not have heat recovery and the air is exhausted or leaves by exfiltration, then the return path of this system will simply be a path to dump the flow as relief air with no impact on energy use.

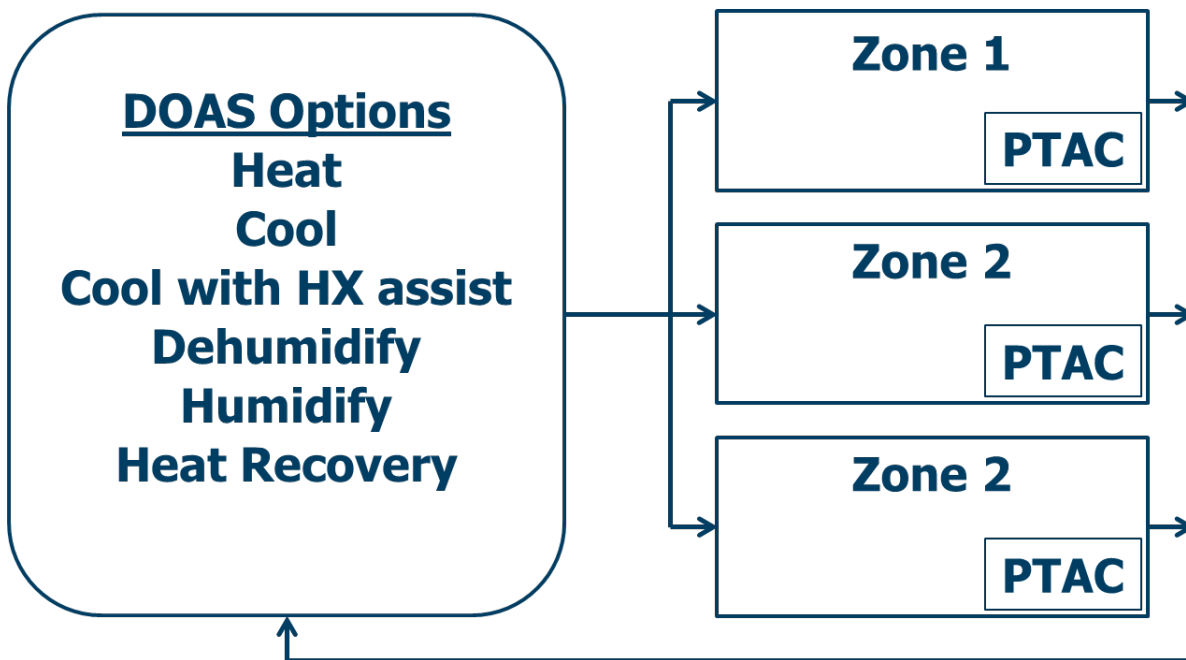

Figure 2.11: DOAS serving three zones with PTACs.

There may be more than one HVACTemplate:System:DedicatedOutdoorAir object in an idf file. If a zone is to be served by one of these systems, this is specified in the HVACTemplate:Zone:\* object using the field “Dedicated Outdoor Air System Name”. For zones which are served by one of these DOAS systems, the outdoor air flow rate in the zone equipment (fan coil, PTAC, etc.) will be set to zero.

### 2.2.23.1 Inputs

#### 2.2.23.1.1 Field: Name

This field is a unique name which the user assigns to this system. This name can then be referred to in an HVACTemplate:Zone:\* object to specify that this system provides outdoor air to that zone.

#### 2.2.23.1.2 Field: System Availability Schedule Name

Leave this field blank if you want the system to operate at all times. If a schedule name is specified, those times that the system is operating should be specified as 1.0. Those times that the system is not operating should have a zero value in the schedule specified. Please note that for this system type, this is a schedule of when the system is providing air flow.

**2.2.23.1.3 Field: Air Outlet Type**

This field indicates if the air is delivered directly into the zone(s) or into the other system(s) that serve the zone(s) (e.g. fan coil system). For now, only one option is available for this field: `DirectIntoZone`.

**2.2.23.1.4 Field: Supply Fan Flow Rate**

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone air flow inputs sum to a greater value. The units are  $\text{m}^3/\text{s}$ .

**2.2.23.1.5 Field: Supply Fan Total Efficiency**

Enter the total efficiency of the supply fan. This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

**2.2.23.1.6 Field: Supply Fan Delta Pressure**

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered to be 20° C at sea level, 101325 Pa.

**2.2.23.1.7 Field: Supply Fan Motor Efficiency**

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

**2.2.23.1.8 Field: Supply Fan Motor in Air Stream Fraction**

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

**2.2.23.1.9 Field: Supply Fan Placement**

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

**2.2.23.1.10 Field: Cooling Coil Type**

There are seven coil types available:

- ChilledWater
- ChilledWaterDetailedFlatModel
- TwoSpeedDX
- TwoStageDX
- TwoStageHumidityControlDX
- HeatExchangerAssistedChilledWater

- HeatExchangerAssistedDX
- None

*ChilledWater* uses the **Coil:Cooling:Water** object with the DetailedAnalysis option. This is the preferred coil model for most chilled water applications.

*ChilledWaterDetailedFlatModel* uses the **Coil:Cooling:Water:DetailedGeometry** object. This option is available for special applications.

*TwoSpeedDX* uses the **Coil:Cooling:DX:TwoSpeed** object.

*TwoStageDX* and *TwoStageHumidityControlDX* use the **Coil:Cooling:DX:TwoStageWithHumidityControlMode** object.

*HeatExchangerAssistedChilledWater* uses the **CoilSystem:Cooling:Water:HeatExchangerAssisted**, **HeatExchanger:AirToAir:SensibleAndLatent**, and **Coil:Cooling:Water** objects.

*HeatExchangerAssistedDX* uses the **CoilSystem:Cooling:DX:HeatExchangerAssisted**, **HeatExchanger:AirToAir:SensibleAndLatent**, and **Coil:Cooling:DX:SingleSpeed** objects.

The default type is *ChilledWater*.

#### 2.2.23.1.11 Field: Cooling Coil Availability Schedule Name

Usually left blank, which allows the cooling coil to be available as needed anytime the system is operating. If a schedule name is specified, it defines when the cooling coil is available. This is most often used when cooling is only available seasonally. A schedule value of one indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

#### 2.2.23.1.12 Field: Cooling Coil Setpoint Control Type

Specifies the cooling coil setpoint control type:

- FixedSetpoint
- Scheduled
- OutdoorAirTemperatureReset

FixedSetpoint uses the Cooling Coil Design Setpoint as the supply air setpoint. Scheduled uses the Cooling Coil Setpoint Schedule to set the supply air setpoint. OutdoorAirTemperatureReset varies the supply air setpoint based on the values entered for Cooling Coil Setpoint at Outdoor Dry-Bulb Low, Cooling Coil Reset Outdoor Dry-Bulb Low, Cooling Coil Setpoint at Outdoor Dry-Bulb High, and Cooling Coil Reset Outdoor Dry-Bulb High. The default is FixedSetpoint.

NOTE: The user must ensure that the cooling coil and heating coil setpoints do not overlap to avoid unwanted simultaneous heating and cooling. The simulation will not check this automatically. It is recommended that the cooling setpoint always be at least 0.1C higher than the heating coil setpoint.

#### 2.2.23.1.13 Field: Cooling Coil Design Setpoint

Enter the cooling supply air temperature in C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8C. If Cooling Coil Setpoint Control Type = FixedSetpoint, then this value is also used as the constant cooling supply air setpoint temperature.

**2.2.23.1.14 Field: Cooling Coil Setpoint Schedule Name**

This field is used when Cooling Coil Setpoint Control Type = Scheduled. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the cooling coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Cooling Coil Setpoint Reset Type is something other than Scheduled (see above).

**2.2.23.1.15 Field: Cooling Coil Setpoint at Outdoor Dry-Bulb Low**

The cooling coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or below the low limit (Cooling Coil Reset Outdoor Dry-Bulb Low). Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.6C.

**2.2.23.1.16 Field: Cooling Coil Reset Outdoor Dry-Bulb Low**

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Cooling Coil Setpoint at Outdoor Dry-Bulb Low. Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.6C.

**2.2.23.1.17 Field: Cooling Coil Setpoint at Outdoor Dry-Bulb High**

The cooling coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or above the high limit (Cooling Coil Reset Outdoor Dry-Bulb High). Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.8C.

**2.2.23.1.18 Field: Cooling Coil Reset Outdoor Dry-Bulb High**

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Cooling Coil Setpoint at Outdoor Dry-Bulb High. Used only when Cooling Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 23.3C.

**2.2.23.1.19 Field: DX Cooling Coil Gross Rated Total Capacity**

Enter Autosize to let the automatic sizing algorithm determine the cooling coil gross total cooling capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load gross total cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor air-cooled condenser coil at 35°C drybulb. Capacity should be the “gross”, i.e., the effect of supply air fan heat is not accounted for. The units are in W. The default is Autosize. This field is only used when the cooling coil type is set to one of the DX options. For two-speed DX coils, the low-speed capacity is assumed to be 0.33 times this value. For two-stage DX coils, the stage 1 capacity is assumed to be 0.5 times this value.

**2.2.23.1.20 Field: DX Cooling Coil Gross Rated Sensible Heat Ratio**

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the gross rated cooling total capacity and air flow rate. Otherwise, enter the value of the ratio of the gross sensible capacity divided by gross total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor air-cooled condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross”, i.e., the effect of supply air fan heat is not accounted for. The default is Autosize. This field is only used when the cooling coil

type is set to one of the DX options. For two-speed DX coils, the low-speed SHR is assumed to be equal to this value. For two-stage DX coils, the stage 1 SHR is assumed to be equal to this value. For two-stage DX coil with humidity control, the humidity control mode SHR is assumed to be 0.9 times this value (for both stage 1 and stage 2).

#### 2.2.23.1.21 Field: DX Cooling Coil Gross Rated COP

Enter the coefficient of performance defined as the gross cooling coil total capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor air-cooled condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 3.0. This field is only used when the cooling coil type is set to one of the DX options. For two-speed DX coils, the low-speed COP is assumed to be 1.5 times this value. For two-stage DX coils, the stage 1 COP is assumed to be this value. For two-stage DX coil with humidity control, the humidity control mode COP is assumed to be 0.9 times this value (for both stage 1 and stage 2). The gross COP should not account for the supply air fan.

#### 2.2.23.1.22 Field: Heating Coil Type

The heating coil is located in the supply air stream, downstream of the cooling coil. If no central heating coil is used in the dedicated outdoor air system, then the option “none” should be specified here. Otherwise this indicates the type of heating coil. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is HotWater. If a heating coil is specified, the heating and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other. When the dehumidification control type is set to *CoolReheatHeatingCoil*, the heating coil is used for reheat.

#### 2.2.23.1.23 Field: Heating Coil Availability Schedule Name

Usually left blank, which allows the heating coil to be available as needed anytime the system is operating. If a schedule name is specified, it defines when the heating coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period.

#### 2.2.23.1.24 Field: Heating Coil Setpoint Control Type

Specifies the cooling coil setpoint control type:

- FixedSetpoint
- Scheduled
- OutdoorAirTemperatureReset

FixedSetpoint uses the Heating Coil Design Setpoint as the supply air setpoint. Scheduled uses the Heating Coil Setpoint Schedule to set the supply air setpoint. OutdoorAirTemperatureReset varies the supply air setpoint based on the values entered for Heating Coil Setpoint at Outdoor Dry-Bulb Low, Heating Coil Reset Outdoor Dry-Bulb Low, Heating Coil Setpoint at Outdoor Dry-Bulb High, and Heating Coil Reset Outdoor Dry-Bulb High. The default is FixedSetpoint.

NOTE: The user must ensure that the cooling coil and heating coil setpoints do not overlap to avoid unwanted simultaneous heating and cooling. The simulation will not check this automatically. It is recommended that the cooling setpoint always be at least 0.1C higher than the heating coil setpoint.

#### **2.2.23.1.25 Field: Heating Coil Design Setpoint**

Enter the heating supply air temperature in C to be used for sizing the heating coil and zone supply air flow rates. If Heating Coil Setpoint Control Type = FixedSetpoint, then this value is also used as the constant heating supply air setpoint temperature. The default is 12.2C.

#### **2.2.23.1.26 Field: Heating Coil Setpoint Schedule Name**

This field is used when Heating Coil Setpoint Control Type = Scheduled. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the heating coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C.

#### **2.2.23.1.27 Field: Heating Coil Setpoint at Outdoor Dry-Bulb Low**

The heating coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or below the low limit (Heating Coil Reset Outdoor Dry-Bulb Low). Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 15.0C.

#### **2.2.23.1.28 Field: Heating Coil Reset Outdoor Dry-Bulb Low**

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Heating Coil Setpoint at Outdoor Dry-Bulb Low. Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 7.8C.

#### **2.2.23.1.29 Field: Heating Coil Setpoint at Outdoor Dry-Bulb High**

The heating coil supply air setpoint temperature in C when the outdoor dry-bulb temperature is at or above the high limit (Heating Coil Reset Outdoor Dry-Bulb High). Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.2C.

#### **2.2.23.1.30 Field: Heating Coil Reset Outdoor Dry-Bulb High**

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Heating Coil Setpoint at Outdoor Dry-Bulb High. Used only when Heating Coil Setpoint Control Type = OutdoorAirTemperatureReset. The default is 12.2C.

#### **2.2.23.1.31 Field: Gas Heating Coil Efficiency**

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field is only used when the heating coil type is set to gas.

**2.2.23.1.32 Field: Gas Heating Coil Parasitic Electric Load**

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W. This field is only used when the heating coil type is set to gas.

**2.2.23.1.33 Field: Heat Recovery Type**

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- None
- Sensible
- Enthalpy

The default is None.

**2.2.23.1.34 Field: Heat Recovery Sensible Effectiveness []**

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

**2.2.23.1.35 Field: Heat Recovery Latent Effectiveness []**

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

**2.2.23.1.36 Field: Heat Recovery Heat Exchanger Type**

This alpha field denotes the type of heat exchanger being modeled: Plate (e.g., fixed plate) or Rotary (e.g., rotating cylinder or wheel). The default choice for this field is “Plate”. The heat exchanger type affects the modeling of frost control options and supply air outlet temperature control. For rotary heat exchangers, rotational speed is varied to control frost formation or the supply air outlet temperature. For plate exchangers, air bypass around the heat exchanger is used to obtain the desired effect.

**2.2.23.1.37 Field: Heat Recovery Frost Control Type**

This alpha field has four choices: None, ExhaustAirRecirculation, ExhaustOnly and MinimumExhaust-Temperature. If this field is left blank, the default frost control type is “None”. For modeling preheat frost control, specify “None” for this input field and insert a separate heating coil object in the supply inlet air stream to keep the air temperature above the desired frost threshold temperature.

*ExhaustAirRecirculation*: dampers are used to direct exhaust air back into the zone through the supply side of the heat exchanger when the supply (outdoor) air inlet temperature falls below a threshold temperature. The fraction of time that exhaust air is circulated through the supply side of the heat exchanger is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When exhaust air is being recirculated, no supply (outdoor ventilation) air is being provided through the heat exchanger unit (which may or may not be acceptable regarding ventilation for occupants).

*ExhaustOnly (supply air bypass)*: this control cycles off the supply air flow through the heat exchanger for a certain period of time while the exhaust air continues to flow through the exhaust side of the heat exchanger. The fraction of time that the supply flow through the heat exchanger is cycled off is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time. When implemented in real applications, provisions are usually made to avoid building depressurization when this frost control is operating (automatic or

pressure-operated dampers, or a bypass air damper around the supply side of the heat exchanger). For this frost control type, it is assumed that the supply air is bypassed around the heat exchanger during frost control operation (i.e., the total supply flow is not reduced during defrost, but merely bypassed around the heat exchanger).

*MinimumExhaustTemperature*: the temperature of the exhaust air leaving the heat exchanger is monitored and the heat exchanger effectiveness is decreased (by slowing heat exchanger rotation or bypassing supply air around the plate exchanger) to keep the exhaust air from falling below the threshold temperature.

### 2.2.23.1.38 Field: Dehumidification Control Type

There are three dehumidification control type options available:

- None
- CoolReheatHeatingCoil
- CoolReheatDesuperheater
- Multimode

The *CoolReheatHeatingCoil* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the heating coil, if available.

The *CoolReheatDesuperheater* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided by a desuperheater coil (Ref. object **Coil:Heating:Desuperheater**). The desuperheater coil setpoint is set to the cooling setpoint and the desuperheater Heat Reclaim Recovery Efficiency is set to 0.3. *CoolReheatDesuperheater* is only applicable for Cooling Coil Type *TwoSpeedDX*, *TwoStageDX*, *TwoStageHumidityControlDX*, or *HeatExchangerAssistedDX*.

*Multimode* is only applicable for cooling coil type *TwoStageHumidityControlDX*. In this case, the enhanced dehumidification mode is activated as needed, but the system operates to meet the sensible dry-bulb temperature cooling setpoint.

The default is *None* which meets the sensible dry-bulb temperature cooling setpoint only.

### 2.2.23.1.39 Field: Dehumidification Setpoint

This field specifies the supply air humidity ratio setpoint for dehumidification. The default is 0.00924 kgWater/kgDryAir (12.8C or 55F dewpoint). This value is also used as the Central Cooling Design Supply Air Humidity Ratio in the **Sizing:System** object. If a Dehumidification Setpoint Schedule Name is specified, the schedule will be used for control.

### 2.2.23.1.40 Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the **Humidifier:Steam:Electric** object. The default is *None*.

### 2.2.23.1.41 Field: Humidifier Availability Schedule Name

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period.

## 2.2.24 HVACTemplate:Plant:ChilledWaterLoop

The piping systems that connect the chilled water coils in the HVAC template objects with the chillers and the cooling towers (if present) are described with this object. The piping systems are called loops and this object describes the controls and pumps on the loops. Only one of these objects may be defined in an input file and all chilled water coils from HVAC template objects are served with this object.

### 2.2.24.1 Inputs

#### 2.2.24.1.1 Field: Name

The name used to designate the HVACTemplate:Plant:ChilledWaterLoop.

#### 2.2.24.1.2 Field: Pump Schedule Name

Leave this field blank if the chilled water and condenser water pumps are always available. If a schedule name is specified, those times that the pumps are available should be specified as 1.0. Those times that the pumps are not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the system is providing chilled water to the coils but a schedule of when it can provide chilled water to the coils.

#### 2.2.24.1.3 Field: Pump Control Type

Applies to both chilled water and condenser loop pumps. The choices for this field are:

- Intermittent
- Continuous

The default value is Intermittent.

If the pump control type is **Continuous**, the pump will run according to the Pump Schedule (see above) regardless of whether or not there is a load. If the pump control type is **Intermittent**, the pump will run if a load is sensed and will shut off if there is no load on the loop.

#### 2.2.24.1.4 Field: Chiller Plant Operation Scheme Type

The choices for this field are:

- Default
- UserDefined

Default operation type makes all equipment available at all times operating in order of Priority specified in **HVACTemplate:Plant:Chiller** objects. If a different scheme is to be used to sequence the chillers, then this entry should be set to User Defined. If the User Defined option is chosen, then additional EnergyPlus objects must be included and completely defined in the IDF file such as shown below depending on the type of plant operation control scheme chosen:

- **PlantEquipmentOperationSchemes**
- **PlantEquipmentOperation:CoolingLoad**
- **PlantEquipmentList** (refer to **HVACTemplate:Plant:Chiller** object description for chiller key name required in this object).

The default value is Default.

#### 2.2.24.1.5 Field: Chiller Plant Equipment Operation Schemes Name

This field should contain the name of a **PlantEquipmentOperationSchemes** object only when the previous field is set to UserDefined. It is ignored if Chiller Plant Operation Scheme Type is Default.

#### 2.2.24.1.6 Field: Chilled Water Setpoint Schedule Name

Enter the name of a chilled water setpoint schedule that has values that change at different times of the year. If a constant set point is needed simply leave this field blank and the value in the next field will be used at all times. The values in the schedule are in degrees C. This field is ignored if the Chilled Water Setpoint Reset Type is something other than None.

#### 2.2.24.1.7 Field: Chilled Water Design Setpoint

Enter the chilled water setpoint temperature to be used for sizing the chilled water loop and associated equipment in degrees C. If the Chilled Water Setpoint Schedule is blank and the Chilled Water Setpoint Reset Type is *None*, then this value will be used as the setpoint at all times.

#### 2.2.24.1.8 Field: Chilled Water Pump Configuration

The choices for this field are

- VariablePrimaryNoSecondary – variable flow to chillers and coils
- ConstantPrimaryNoSecondary – constant flow to chillers and coils with bypass
- ConstantPrimaryVariableSecondary – constant flow to chillers with bypass, variable flow to coils
- VariablePrimaryConstantSecondary – variable flow to chillers, constant flow to coils with bypass

The default value is ConstantPrimaryNoSecondary.

The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop.

A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components.

**2.2.24.1.9 Field: Primary Chilled Water Pump Rated Head**

The rated head of the primary chilled water pump in Pa. The default value is 179352 Pa which is equivalent to 60 feet H<sub>2</sub>O.

**2.2.24.1.10 Field: Secondary Chilled Water Pump Rated Head**

The rated head of the secondary chilled water pump in Pa. The default value is 179352 Pa which is equivalent to 60 feet H<sub>2</sub>O. This field is applicable only if the “Chilled Water Pump Configuration” is *Constant Primary Variable Secondary* or *Variable Primary Constant Secondary*.

**2.2.24.1.11 Field: Condenser Plant Operation Scheme Type**

The choices for this field are:

- Default
- UserDefined

Default operation type makes all equipment available at all times operating in order of Priority specified in **HVACTemplate:Plant:Tower** objects. If a different scheme is to be used to sequence the towers, then this entry should be set to User Defined. May be left blank if not serving any water cooled chillers.

If User Defined option is chosen, then additional EnergyPlus objects must be included and completely defined in the IDF file such as shown below depending on the type of condenser operation control scheme chosen:

- **CondenserEquipmentOperationSchemes**
- **PlantEquipmentOperation:CoolingLoad**
- **PlantEquipmentList** (refer to the **HVACTemplate:Plant:Tower** object description for key name required for this object.

The default value is Default.

**2.2.24.1.12 Field: Condenser Equipment Operation Schemes Name**

This field should contain the name of a **CondenserEquipmentOperationSchemes** object only when the previous field is set to UserDefined. It is ignored if Condenser Plant Operation Scheme Type is Default. May be left blank if not serving any water cooled chillers.

**2.2.24.1.13 Field: Condenser Water Temperature Control Type**

If water cooled chillers are present the condenser water temperature control can be one of the following options:

- OutdoorWetBulbTemperature
- SpecifiedSetpoint

If a specified set point is used then the towers are operated to deliver that condenser water set point. If outdoor wet-bulb is used then the condenser water temperature decreases with decreasing outdoor wet-bulb temperature. May be left blank if not serving any water cooled chillers.

**2.2.24.1.14 Field: Condenser Water Setpoint Schedule Name**

Used when Condenser Water Temperature Control Type is set to Specified Setpoint. Ignored if Condenser Water Temperature Control Type is set to Outdoor Wet-bulb. The field may be left blank if constant setpoint temperature is used for the condenser water temperature. If may also be left blank if not serving any water cooled chillers. If specified, the schedule should contain the set point temperatures in degrees C for the condenser water loop.

**2.2.24.1.15 Field: Condenser Water Design Setpoint**

- Enter the condenser water temperature to be used for sizing the condenser loop and associated equipment. If a constant setpoint control is used for the condenser water, this value will be used as the setpoint at all times. May be left blank if not serving any water cooled chillers. Used when Condenser Water Temperature Control Type is set to Specified Setpoint. Ignored if Condenser Water Temperature Control Type is set to OutdoorWetBulbTemperature. The units are in C.

**2.2.24.1.16 Field: Condenser Water Pump Rated Head**

The rated head of the condenser water pumps in Pa. May be left blank if not serving any water cooled chillers. The default value is 179352 Pa which is equivalent to 60 feet H<sub>2</sub>O.

**2.2.24.1.17 Field: Chilled Water Setpoint Reset Type**

Select the type of automatic reset control for the chilled water supply temperature. The choices are:

- None – no reset, use the Chilled Water Setpoint Schedule or Chilled Water Design Setpoint.
- OutdoorAirTemperatureReset – reset the chilled water supply temperature based on the following default rules. The temperature limits and setpoints are specified using the fields below. If the default values are used, when the outdoor dry-bulb temperature (ODB) is at or below 15.6C the setpoint is 12.2C. When the ODB is at or above 26.7C the setpoint is 6.7C. In between, the setpoint is varied linearly. (Reference [SetpointManager:OutdoorAirReset](#))

The default is *None*.

**2.2.24.1.18 Field: Chilled Water Setpoint at Outdoor Dry-Bulb Low**

The chilled water setpoint temperature in C when the outdoor dry-bulb is at or below the low limit (Chilled Water Reset Outdoor Dry Bulb Low). The default is 12.2C.

**2.2.24.1.19 Field: Chilled Water Reset Outdoor Dry-Bulb Low**

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Chilled Water Setpoint at Outdoor Dry Bulb Low. The default is 15.6C.

**2.2.24.1.20 Field: Chilled Water Setpoint at Outdoor Dry-Bulb High**

The chilled water setpoint temperature in C when the outdoor dry-bulb is at or above the high limit (Chilled Water Reset Outdoor Dry Bulb Low). The default is 6.7C.

**2.2.24.1.21 Field: Chilled Water Reset Outdoor Dry-Bulb High**

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Chilled Water Setpoint at Outdoor Dry Bulb High. The default is 26.7C.

**2.2.24.1.22 Field: Chilled Water Primary Pump Type**

Describes the type of pump configuration used for the primary portion of the chilled water loop. The options include:

- SinglePump
- PumpPerChiller
- TwoHeaderedPumps
- ThreeHeaderedPumps
- FourHeaderedPumps
- FiveHeaderedPumps

**2.2.24.1.23 Field: Chilled Water Secondary Pump Type**

Describes the type of pump configuration used for the secondary portion of the chilled water loop. The options include:

- SinglePump
- TwoHeaderedPumps
- ThreeHeaderedPumps
- FourHeaderedPumps
- FiveHeaderedPumps

**2.2.24.1.24 Field: Condenser Water Pump Type**

Describes the type of pump configuration used for the condenser water loop. The options include:

- SinglePump
- PumpPerTower
- TwoHeaderedPumps
- ThreeHeaderedPumps
- FourHeaderedPumps
- FiveHeaderedPumps

**2.2.24.1.25 Field: Chilled Water Supply Side Bypass Pipe**

The field determines if a supply side bypass pipe is present in the chilled water loop. The choices for this field are

- Yes
- No.

**2.2.24.1.26 Field: Chilled Water Demand Side Bypass Pipe**

The field determines if a demand side bypass pipe is present in the chilled water loop. The choices for this field are

- Yes
- No.

**2.2.24.1.27 Field: Condenser Water Supply Side Bypass Pipe**

The field determines if a supply side bypass pipe is present in the condenser water loop. The choices for this field are

- Yes
- No.

**2.2.24.1.28 Field: Condenser Water Demand Side Bypass Pipe**

The field determines if a demand side bypass pipe is present in the condenser water loop. The choices for this field are

- Yes
- No.

**2.2.24.1.29 Field: Fluid Type**

This field determines the type of fluid used for the boiler loop. The following options are available:

- Water
- EthyleneGlycol30
- EthyleneGlycol40
- EthyleneGlycol50
- EthyleneGlycol60
- PropyleneGlycol30
- PropyleneGlycol40
- PropyleneGlycol50
- PropyleneGlycol60

**2.2.24.1.30 Field: Loop Design Delta Temperature**

The temperature difference used in sizing the loop flow rate. The default is 6.67C.

**2.2.24.1.31 Field: Minimum Outdoor Dry Bulb Temperature**

The minimum outdoor dry bulb temperature that the chilled water loops operate.

## 2.2.25 HVACTemplate:Plant:Chiller

A chiller or purchased cooling source is described with this object. To define multiple chillers, use multiple HVACTemplate:Plant:Chiller objects and use the Sizing Factor field to apportion the total capacity if autosizing.

### 2.2.25.1 Inputs

#### 2.2.25.1.1 Field: Name

The name used to reference the HVACTemplate:Plant:Chiller object.

#### 2.2.25.1.2 Field: Chiller Type

While EnergyPlus has a variety of chiller options, the only choices currently for this field are:

- DistrictChilledWater
- ElectricCentrifugalChiller
- ElectricScrewChiller
- ElectricReciprocatingChiller

The EnergyPlus equipment object types which are used are **DistrictCooling** or **Chiller:Electric:EIR**. These equipment type keys must be used if setting up a user-defined chiller plant operation scheme.

#### 2.2.25.1.3 Field: Capacity

This field may be set to autosize, which means that the capacity is based on the peak loads during the design days. This numeric field contains the design cooling capacity of the chiller. This capacity should be at the design temperatures and water flow rates. The units are in W.

#### 2.2.25.1.4 Field: Nominal COP

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps, evap-cooled or air-cooled condenser fans, or cooling tower fans. This Nominal COP should be at the design temperatures and water flow rates. Not applicable if Chiller Type is DistrictChilledWater.

#### 2.2.25.1.5 Field: Condenser Type

The choices for this field are

- AirCooled
- WaterCooled
- EvaporativelyCooled

The default value is WaterCooled. If WaterCooled, then at least one **HVACTemplate:Plant:Tower** object should be defined. Not applicable if Chiller Type is Purchased Chilled Water.

#### 2.2.25.1.6 Field: Priority

Enter the priority number of the chiller where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Chiller Plant Operation Scheme Type is set to Default in **HVACTemplate:Plant:ChilledWaterLoop**. Equipment is operated in order of the priority number. This allows multiple chillers to be sequenced.

#### 2.2.25.1.7 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the chiller object inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

#### 2.2.25.1.8 Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. Below this part-load ratio, the compressor cycles on and off to meet the cooling load. The Minimum Part Load Ratio must be less than or equal to the Maximum Part Load Ratio. The default value is 0.0.

#### 2.2.25.1.9 Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0.0 and 1.0. The Maximum Part Load Ratio must be greater than or equal to the Minimum Part Load Ratio. The default value is 1.0.

#### 2.2.25.1.10 Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 1.0.

### 2.2.25.1.11 Field: Minimum Unloading Ratio

This numeric field contains the chiller's minimum unloading ratio. The expected range is between 0 and 1. The minimum unloading ratio is where the chiller capacity can no longer be reduced by unloading and must be false loaded to meet smaller cooling loads. A typical false loading strategy is hot-gas bypass. The minimum unloading ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 0.25.

### 2.2.25.1.12 Field: Leaving Chilled Water Lower Temperature Limit

This numeric field contains the lower limit for the leaving chilled water temperature in Celsius. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold. The default value is 5 °C.

As shown in an IDF:

```
HVACTemplate:Plant:Chiller,
  District Cooling,          !- Chiller Name
  ElectricCentrifugalChiller, !- Chiller Type
  autosize,                  !- Capacity {W}
  3.2,                       !- COP

  0.2,                       !- Minimum Unloading Ratio
  2;                          !- Leaving Chilled Water Lower Temperature Limit {C}
```

## 2.2.26 HVACTemplate:Plant:Chiller:ObjectReference

This object references a detailed chiller object and adds it to an **HVACTemplate:Plant:ChilledWaterLoop**. The user must create a complete detailed chiller object with all required curve or performance objects. The detailed chiller object is referenced by object type and name and the chiller will be automatically to the chilled water loop branches and equipment list.

### 2.2.26.1 Inputs

#### 2.2.26.1.1 Field: Name

The name of this object.

#### 2.2.26.1.2 Field: Chiller Object Type

The object type of the referenced chiller. Select from one of the following supported chiller object types:

- **Chiller:Electric:EIR**
- **Chiller:Electric:ReformulatedEIR**

#### 2.2.26.1.3 Field: Chiller Name

The object name of the referenced chiller.

#### 2.2.26.1.4 Field: Priority

Enter the priority number of the chiller where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Chiller Plant Operation Scheme Type is set to Default in **HVACTemplate:Plant:ChilledWaterLoop**. Equipment is operated in order of the priority number. This allows multiple chillers to be sequenced.

An example in an IDF:

```
HVACTemplate:Plant:Chiller:ObjectReference,
Main Chiller Connection, !- Name
Chiller:Electric:EIR,    !- Chiller Object Type
Main Chiller,           !- Chiller Name
1;                      !- Priority
```

---

### 2.2.27 HVACTemplate:Plant:Tower

A cooling tower is described with this object. To define multiple cooling towers, use multiple HVACTemplate:Plant:Tower objects and use the Sizing Factor field to apportion the total capacity if autosizing.

#### 2.2.27.1 Inputs

##### 2.2.27.1.1 Field: Name

The name used to reference the HVACTemplate:Plant:Tower object.

##### 2.2.27.1.2 Field: Tower Type

The choices for this field are

- SingleSpeed
- TwoSpeed

The EnergyPlus equipment object types which are used are **CoolingTower:SingleSpeed** or **CoolingTower:TwoSpeed**. These equipment type keys must be used if setting up a user-defined condenser plant operation scheme.

##### 2.2.27.1.3 Field: High-Speed Nominal Capacity

Applicable for Tower Type Single Speed and Two Speed. This field may be set to autosize. If this field is set to autosize, then the Low-Speed Nominal Capacity and the Free Convection Capacity must also be autosized. The units are W. This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under high-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be 5.382E-8 m<sup>3</sup>/s per watt of high-speed nominal capacity (3 gpm/ton). 125% of this nominal tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator).

##### 2.2.27.1.4 Field: High-Speed Fan Power

The tower fan electric consumption when at high speed. Applicable for Tower Type Single Speed and Two Speed. This field may be set to autosize. The units are W.

### 2.2.27.1.5 Field: Low-Speed Nominal Capacity

Applicable only for Tower Type Two Speed. This field may be set to autosize. If this field is set to autosize, then the High-Speed Nominal Capacity and the Free Convection Capacity must also be autosized. The units are W. This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under low-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be  $5.382\text{E-}8 \text{ m}^3/\text{s}$  per watt of high-speed nominal tower capacity (input field above). 125% of this nominal tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). The value specified for this field must be greater than zero but less than the value specified for the field “Tower High-Speed Nominal Capacity”.

### 2.2.27.1.6 Field: Low-Speed Fan Power

The tower fan electric consumption when at low speed. Applicable only for Tower Type Two Speed. This field may be set to autosize. The units are W.

### 2.2.27.1.7 Field: Free Convection Capacity

Applicable for Tower Type Single Speed and Two Speed. This field may be set to autosize. If this field is set to autosize, then the High-Speed Nominal Capacity and the Low-Speed Nominal Capacity must also be autosized. The units are W. This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts when the tower is in the “free convection” regime (water flow exists but tower fan is turned off), with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be  $5.382\text{E-}8 \text{ m}^3/\text{s}$  per watt of high-speed nominal tower capacity (input field above). 125% of this free convection tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). If the user does not wish to model “free convection”, then this field should be set to 0.0.

### 2.2.27.1.8 Field: Priority

Enter the priority number of the tower where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Condenser Plant Operation Scheme Type is set to Default in **HVACTemplate:Plant:ChilledWaterLoop** or **HVACTemplate:Plant:MixedWaterLoop**. Equipment is operated in order of the priority number. This allows multiple towers to be sequenced.

#### **Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the tower object inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Air Flow Rate at High Fan Speed;
3. Fan Power at High Fan Speed;
4. U-Factor Times Area Value at High Fan Speed;
5. Air Flow Rate at Low Fan Speed (for two-speed tower);
6. Fan Power at Low Fan Speed (for two-speed tower);

7. U-Factor Times Area Value at Low Fan Speed (for two-speed tower);
8. Air Flow Rate in Free Convection Regime;
9. U-Factor Times Area Value at Free Convection Air Flow Rate.

Note that the U-Factor Times Area Value at High Fan Speed is not *multiplied* by the Sizing Factor. Instead the design tower load is multiplied by the sizing factor and the design UA then calculated as usual. The U-Factor Times Area Value at Low Fan Speed is set to 60% of the full load design UA. The U-Factor Times Area Value at Free Convection Air Flow Rate is set to 10% of the design Tower UA.

#### 2.2.27.1.9 Field: Template Plant Loop Type

This field specifies whether this tower will serve a *ChilledWaterLoop* (ref. [HVACTemplate:Plant:ChilledWaterLoop](#)) or a *MixedWaterLoop* (ref. [HVACTemplate:Plant:MixedWaterLoop](#)). If this field is left blank, this tower will serve a ChilledWaterLoop if present or a MixedWaterLoop (if no ChilledWaterLoop is present).

An example in an IDF:

```
HVACTemplate:Plant:Tower,
  Main Tower,           !- Name
  SingleSpeed,          !- Tower Type
  autosize,             !- High Speed Nominal Capacity {W}
  autosize,             !- High Speed Fan Power {W}
  autosize,             !- Low Speed Nominal Capacity {W}
  autosize,             !- Low Speed Fan Power {W}
  autosize,             !- Free Convection Capacity {W}
  1,                   !- Priority
  ;                     !- Sizing Factor
```

### 2.2.28 HVACTemplate:Plant:Tower:ObjectReference

This object references a detailed cooling tower object and adds it to an [HVACTemplate:Plant:ChilledWaterLoop](#) or *MixedWaterLoop*. The user must create a complete detailed cooling tower object with all required curve or performance objects. The detailed cooling tower object is referenced by object type and name and the tower will be automatically to the chilled water loop or mixed water loop branches and equipment list.

#### 2.2.28.1 Inputs

##### 2.2.28.1.1 Field: Name

The name of this object.

##### 2.2.28.1.2 Field: Cooling Tower Object Type

The object type of the referenced tower. Select from one of the following supported tower object types:

- [CoolingTower:SingleSpeed](#)
- [CoolingTower:TwoSpeed](#)
- [CoolingTower:VariableSpeed](#)

##### 2.2.28.1.3 Field: Cooling Tower Name

The object name of the referenced tower.

#### 2.2.28.1.4 Field: Priority

Enter the priority number of the tower where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Condenser Plant Operation Scheme Type is set to Default in **HVACTemplate:Plant:ChilledWaterLoop** or **MixedWaterLoop**. Equipment is operated in order of the priority number. This allows multiple towers to be sequenced.

#### 2.2.28.1.5 Field: Template Plant Loop Type

This field specifies whether this tower will serve a *ChilledWaterLoop* (ref. **HVACTemplate:Plant:ChilledWaterLoop**) or a *MixedWaterLoop* (ref. **HVACTemplate:Plant:MixedWaterLoop**). If this field is left blank, this tower will serve a ChilledWaterLoop if present or a MixedWaterLoop (if no ChilledWaterLoop is present).

An example in an IDF:

```
HVACTemplate:Plant:Tower:ObjectReference,
Main Tower Connection,      !- Name
CoolingTower:TwoSpeed,      !- Cooling Tower Object Type
Main Tower,                 !- Cooling Tower Name
1;                           !- Priority
```

### 2.2.29 HVACTemplate:Plant:HotWaterLoop

The piping systems that connect the hot water coils in the HVAC template objects with the boilers are described with this object. The piping systems are called loops and this object describes the controls and pumps on the loops. Only one of these objects should be defined in an input file and all hot water coils from HVAC template objects are served with this object.

#### 2.2.29.1 Inputs

##### 2.2.29.1.1 Field: Name

The name used to designate the HVACTemplate:Plant:HotWaterLoop.

##### 2.2.29.1.2 Field: Pump Schedule Name

Leave this field blank if the hot water pump is always available. If a schedule name is specified, those times that the pump is available should be specified as 1.0. Those times that the pump is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the system is providing hot water to the coils but a schedule of when it can provide hot water to the coils.

##### 2.2.29.1.3 Field: Pump Control Type

The choices for this field are

- Intermittent
- Continuous

The default value is Intermittent.

If the pump control type is **Continuous**, the pump will run according to the Pump Schedule (see above) regardless of whether or not there is a load. If the pump control type is **Intermittent**, the pump will run if a load is sensed and will shut off if there is no load on the loop.

#### 2.2.29.1.4 Field: Hot Water Plant Operation Scheme Type

The choices for this field are:

- Default
- UserDefined

Default operation type makes all equipment available at all times operating in order of Priority specified in **HVACTemplate:Plant:Boiler** objects. If a different scheme is to be used to sequence the boilers, then this entry should be set to User Defined.

If User Defined option is chosen, then additional EnergyPlus objects must be defined in the IDF file such as shown below depending on the type of plant operation control scheme chosen:

- **PlantEquipmentOperationSchemes**
- **PlantEquipmentOperation:HeatingLoad**
- **PlantEquipmentList** (refer to **HVACTemplate:Plant:Boiler** object description for key name required in this object)

The default value is Default.

#### 2.2.29.1.5 Field: Hot Water Plant Equipment Operation Schemes Name

This field should contain the name of a **PlantEquipmentOperationSchemes** object only when the previous field is set to User Defined. It is ignored if Hot Water Plant Operation Scheme Type is Default.

#### 2.2.29.1.6 Field: Hot Water Setpoint Schedule Name

Enter the name of a hot water setpoint schedule that has values that change at different times of the year. If a constant set point is needed simply leave this field blank and the value in the next field will be used at all times. The values in the schedule are in degrees C. This field is ignored if the Hot Water Setpoint Reset Type is something other than None.

#### 2.2.29.1.7 Field: Hot Water Design Setpoint

Enter the hot water setpoint temperature to be used for sizing the hot water loop and associated equipment in degrees C. If the Hot Water Setpoint Schedule is blank and the Hot Water Setpoint Reset Type is *None*, then this value will be used as the setpoint at all times.

#### 2.2.29.1.8 Field: Hot Water Pump Configuration

The choices for this field are

- VariableFlow
- ConstantFlow

The default value is ConstantFlow. The variable flow option simulates a pump with variable flow to boilers and coils, excess bypassed. The constant flow option simulates constant flow to boilers and coils, excess bypassed.

The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is

constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop.

A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components.

#### **2.2.29.1.9 Field: Hot Water Pump Rated Head**

The rated head of the hot water pump in Pa. The default value is 179352 Pa which is equivalent to 60 feet H<sub>2</sub>O.

#### **2.2.29.1.10 Field: Hot Water Setpoint Reset Type**

Select the type of automatic reset control for the Hot Water supply temperature. The choices are:

- None – no reset, use the Hot Water Setpoint Schedule or Hot Water Design Setpoint.
- OutdoorAirTemperatureReset – reset the Hot Water supply temperature based on the following default rules. The temperature limits and setpoints are specified using the fields below. If the default values are used, when the outdoor dry-bulb temperature (ODB) is at or below  $-6.7^{\circ}\text{C}$  the setpoint is  $82.2^{\circ}\text{C}$ . When the ODB is at or above  $10.0^{\circ}\text{C}$  the setpoint is  $65.6^{\circ}\text{C}$ . In between, the setpoint is varied linearly. (Reference [SetpointManager:OutdoorAirReset](#))

The default is *None*.

#### **2.2.29.1.11 Field: Hot Water Setpoint at Outdoor Dry Bulb Low**

The Hot Water setpoint temperature in  $^{\circ}\text{C}$  when the outdoor dry-bulb is at or below the low limit (Hot Water Reset Outdoor Dry Bulb Low). The default is  $-6.7^{\circ}\text{C}$ .

#### **2.2.29.1.12 Field: Hot Water Reset Outdoor Dry Bulb Low**

The low limit of outdoor dry-bulb temperature in  $^{\circ}\text{C}$  for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Hot Water Setpoint at Outdoor Dry Bulb Low. The default is  $82.2^{\circ}\text{C}$ .

#### **2.2.29.1.13 Field: Hot Water Setpoint at Outdoor Dry Bulb High**

The Hot Water setpoint temperature in  $^{\circ}\text{C}$  when the outdoor dry-bulb is at or above the high limit (Hot Water Reset Outdoor Dry Bulb Low). The default is  $10.0^{\circ}\text{C}$ .

#### **2.2.29.1.14 Field: Hot Water Reset Outdoor Dry Bulb High**

The high limit of outdoor dry-bulb temperature in  $^{\circ}\text{C}$  for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Hot Water Setpoint at Outdoor Dry Bulb High. The default is  $65.6^{\circ}\text{C}$ .

#### **2.2.29.1.15 Field: Hot Water Pump Type**

Describes the type of pump configuration used for the hot water loop. The options include:

- SinglePump

- PumpPerBoiler
- TwoHeaderedPumps
- ThreeHeaderedPumps
- FourHeaderedPumps
- FiveHeaderedPumps

**2.2.29.1.16 Field: Supply Side Bypass Pipe**

The field determines if a supply side bypass pipe is present in the hot water loop. The choices for this field are

- Yes
- No.

**2.2.29.1.17 Field: Demand Side Bypass Pipe**

The field determines if a demand side bypass pipe is present in the hot water loop. The choices for this field are

- Yes
- No.

**2.2.29.1.18 Field: Fluid Type**

This field determines the type of fluid used for the chilled water loop. The following options are available:

- Water
- EthyleneGlycol30
- EthyleneGlycol40
- EthyleneGlycol50
- EthyleneGlycol60
- PropyleneGlycol30
- PropyleneGlycol40
- PropyleneGlycol50
- PropyleneGlycol60

**2.2.29.1.19 Field: Loop Design Delta Temperature**

The temperature difference used in sizing the loop flow rate. The default is 11C.

**2.2.29.1.20 Field: Maximum Outdoor Dry Bulb Temperature**

The maximum outdoor dry bulb temperature that the hot water loops operate.

### 2.2.29.1.21 Field: Load Distribution Scheme

This alpha field contains the Load Distribution Scheme Keyword. The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, five schemes are functional. **Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand. **SequentialLoad** loads each piece of equipment sequentially in the order specified in the **PlantEquipmentList** to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand. **UniformLoad** evenly distributes the loop demand among all available components on the equipment list for a given load range. **SequentialUniformPLR** loads all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). Components are loaded sequentially based on the order specified in the **PlantEquipmentList** until each component is fully loaded, at which point the next subsequent component is added and the load is distributed uniformly based on PLR between the components. **UniformPLR** will load all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). No equipment will be loaded below its minimum PLR. If the total load is less than the sum of all equipment on the **PlantEquipmentList** operating at their respective minimum PLRs, then the last item in the equipment list is dropped and the load is distributed based on a uniform PLR for the remaining plant equipment.

Note: For all schemes, if the load for any individual component is less than the component load at the minimum PLR, the individual component model will false load or reduce duty cycle while operating at the minimum part load ratio until the load is met.

As shown in an IDF:

```
HVACTemplate:Plant:HotWaterLoop,

## 2.2.30 HVACTemplate:Plant:Boiler

A boiler or purchased heating source is described with this object. To define multiple boilers, use multiple HVACTemplate:Plant:Boiler objects and use the Sizing Factor field to apportion the total capacity if autosizing.

### 2.2.30.1 Inputs

#### 2.2.30.1.1 Field: Name

The name used to reference the HVACTemplate:Plant:Boiler object.

### 2.2.30.1.2 Field: Boiler Type

While EnergyPlus has a variety of boiler options, the choices for this field are:

- DistrictHotWater – District heating
- HotWaterBoiler – Hot water boiler (non-condensing)
- CondensingHotWaterBoiler – Hot water boiler (condensing)

The EnergyPlus equipment object types which are used are **DistrictHeating** or **Boiler:HotWater**. These equipment type keys must be used if setting up a user-defined boiler plant operation scheme.

### 2.2.30.1.3 Field: Capacity

This field may be set to autosize, which means that the capacity is based on the peak loads during the design days. This numeric field contains the design heating capacity of the boiler. This capacity should be at the design water flow rates. The units are in W.

### 2.2.30.1.4 Field: Efficiency

This numeric field contains the heating efficiency (as a fraction between 0 and 1) of the boiler's burner. Not applicable if Boiler Type is DistrictHotWater.

### 2.2.30.1.5 Field: Fuel Type

The choices for this field are

- Electricity
- NaturalGas
- Propane
- FuelOilNo1
- FuelOilNo2
- Coal
- Diesel
- Gasoline
- OtherFuel1
- OtherFuel2

Not applicable if Boiler Type is DistrictHotWater

### 2.2.30.1.6 Field: Priority

Enter the priority number of the boiler where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Boiler Plant Operation Scheme Type is set to Default in **HVACTemplate:Plant:HotWaterLoop**. Equipment is operated in order of the priority number. This allows multiple boilers to be sequenced.

### 2.2.30.1.7 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the boiler object inputs that would be altered by the sizing factor are: Nominal Capacity and Design Water Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

### 2.2.30.1.8 Field: Minimum Part Load Ratio

This numeric field contains the minimum part load ratio. If the ratio of demand to boiler nominal capacity is less than the minimum part load ratio, then the Min PLR will determine the operating PLR. The expected range is between 0 and 1. If this field is left blank, the default value is 0.0.

### 2.2.30.1.9 Field: Maximum Part Load Ratio

This numeric field contains the maximum part load ratio. If the ratio of demand to boiler nominal capacity is greater than the maximum part load ratio, then the Max PLR will determine the operating PLR. This value may exceed 1, but the normal range is between 0 and 1.1. If this field is left blank, the default value is 1.1.

### 2.2.30.1.10 Field: Optimum Part Load Ratio

This numeric field contains the optimum part load ratio. This is the part load ratio at which the boiler performs at its maximum efficiency. If this field is left blank, the default value is 1.0.

### 2.2.30.1.11 Field: Water Outlet Upper Temperature Limit

This numeric field contains the outlet temperature upper limit. If this field is left blank, the default value is 100.0°C.

### 2.2.30.1.12 Field: Template Plant Loop Type

This field specifies whether this boiler will serve a *HotWaterLoop* (ref. [HVACTemplate:Plant:HotWaterLoop](#)) or a *MixedWaterLoop* (ref. [HVACTemplate:Plant:MixedWaterLoop](#)). If this field is left blank, this tower will serve a *HotWaterLoop* if present or a *MixedWaterLoop* (if no *HotWaterLoop* is present).

An example in an IDF:

```
HVACTemplate:Plant:Boiler,
  Main Boiler,          !- Name
  HotWaterBoiler,       !- Boiler Type
  autosize,             !- Capacity {W}
  0.8,                  !- Efficiency
  NaturalGas,           !- Fuel Type
  1,                    !- Priority
  1,                    !- Sizing Factor
  0.1,                  !- Minimum Part Load Ratio
  1.1,                  !- Maximum Part Load Ratio
  0.9,                  !- Optimum Part Load Ratio
  99.9;                 !- Water Outlet Upper Temperature Limit {C}
```

## 2.2.31 HVACTemplate:Plant:Boiler:ObjectReference

This object references a detailed boiler object and adds it to an [HVACTemplate:Plant:HotWaterLoop](#) or *MixedWaterLoop*. The user must create a complete detailed boiler object with all required curve or performance objects. The detailed boiler object is referenced by object type and name and the boiler will be automatically to the hot water or mixed water loop branches and equipment list.

### 2.2.31.1 Inputs

#### 2.2.31.1.1 Field: Name

The name of this object.

#### 2.2.31.1.2 Field: Boiler Object Type

The object type of the referenced boiler. Select from one of the following supported boiler object types:

- **Boiler:HotWater**

#### 2.2.31.1.3 Field: Boiler Name

The object name of the referenced boiler.

#### 2.2.31.1.4 Field: Priority

Enter the priority number of the boiler where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Hot Water Plant Operation Scheme Type is set to Default in **HVACTemplate:Plant:HotWaterLoop** or **MixedWaterLoop**. Equipment is operated in order of the priority number. This allows multiple boilers to be sequenced.

#### 2.2.31.1.5 Field: Template Plant Loop Type

This field specifies whether this boiler will serve a *HotWaterLoop* (ref. **HVACTemplate:Plant:HotWaterLoop**) or a *MixedWaterLoop* (ref. **HVACTemplate:Plant:MixedWaterLoop**). If this field is left blank, this tower will serve a *HotWaterLoop* if present or a *MixedWaterLoop* (if no *HotWaterLoop* is present).

An example in an IDF:

```
HVACTemplate:Plant:Boiler:ObjectReference,
Main Boiler Connection,  !- Name
Boiler:HotWater,        !- Boiler Object Type
Main Boiler,            !- Boiler Name
1;                      !- Priority
```

## 2.2.32 HVACTemplate:Plant:MixedWaterLoop

This object simulates the central plant loop portion of a water source heat pump system. Often many **HVACTemplate:Zone:WaterToAirHeatPump** objects will be used in a building along with a single **HVACTemplate:Plant:MixedWaterLoop** that contains one or more cooling towers and boilers. The piping systems are called loops and this object describes the controls and pumps on the loops. Only one of these objects should be defined in an input file.

### 2.2.32.1 Inputs

#### 2.2.32.1.1 Field: Name

The name used to designate the **HVACTemplate:Plant:MixedWaterLoop**.

#### 2.2.32.1.2 Field: Pump Schedule Name

Leave this field blank if the water pump is always available. If a schedule name is specified, those times that the pump is available should be specified as 1.0. Those times that the pump is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the system is providing water to the water-to-air heat pumps but a schedule of when it can provide water to the water-to-air heat pumps.

### 2.2.32.1.3 Field: Pump Control Type

The choices for this field are

- Intermittent
- Continuous

The default value is Intermittent.

If the pump control type is **Continuous**, the pump will run according to the Pump Schedule (see above) regardless of whether or not there is a load. If the pump control type is **Intermittent**, the pump will run if a load is sensed and will shut off if there is no load on the loop.

### 2.2.32.1.4 Field: Operation Scheme Type

The choices for this field are:

- Default
- UserDefined

Default operation type makes all equipment available at all times operating in order of Priority specified in **HVACTemplate:Plant:Boiler** objects. If a different scheme is to be used to sequence the boilers, then this entry should be set to User Defined.

If User Defined option is chosen, then additional EnergyPlus objects must be defined in the IDF file such as shown below depending on the type of plant operation control scheme chosen:

- **PlantEquipmentOperationSchemes**
- **PlantEquipmentOperation:CoolingLoad**
- **PlantEquipmentOperation:HeatingLoad**
- **PlantEquipmentList** (refer to **HVACTemplate:Plant:Boiler** object description for key name required in this object)

The default value is Default.

### 2.2.32.1.5 Field: Equipment Operation Schemes Name

This field should contain the name of a **PlantEquipmentOperationSchemes** object only when the previous field is set to User Defined. It is ignored if Hot Water Plant Operation Scheme Type is Default.

### 2.2.32.1.6 Field: High Temperature Setpoint Schedule Name

Enter the name of a high temperature setpoint schedule that has values that change at different times of the year. If a constant set point is needed simply leave this field blank and the value in the next field will be used at all times. The values in the schedule are in degrees C.

### 2.2.32.1.7 Field: High Temperature Design Setpoint

Enter the high temperature setpoint temperature to be used for sizing the water loop and associated equipment in degrees C. If the High Temperature Setpoint Schedule is blank, then this value will be used as the setpoint at all times. The default is 33C.

**2.2.32.1.8 Field: Low Temperature Setpoint Schedule Name**

Enter the name of a low temperature setpoint schedule that has values that change at different times of the year. If a constant set point is needed simply leave this field blank and the value in the next field will be used at all times. The values in the schedule are in degrees C.

**2.2.32.1.9 Field: Low Temperature Design Setpoint**

Enter the low temperature setpoint temperature to be used for sizing the water loop and associated equipment in degrees C. If the Low Temperature Setpoint Schedule is blank, then this value will be used as the setpoint at all times. The default is 20C.

**2.2.32.1.10 Field: Water Pump Configuration**

The choices for this field are

- VariableFlow
- ConstantFlow

The default value is ConstantFlow. The variable flow option simulates a pump with variable flow to boilers, cooling towers, and water to air heat pump, excess bypassed. The constant flow option simulates constant flow to boilers, cooling towers, and water to air heat pumps, excess bypassed.

The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop.

A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components.

**2.2.32.1.11 Field: Water Pump Rated Head**

The rated head of the hot water pump in Pa. The default value is 179352 Pa which is equivalent to 60 feet H<sub>2</sub>O.

**2.2.32.1.12 Field: Water Pump Type**

Describes the type of pump configuration used for mixed water loop. The options include:

- SinglePump
- PumpPerTowerOrBoiler
- TwoHeaderedPumps
- ThreeHeaderedPumps
- FourHeaderedPumps
- FiveHeaderedPumps

**2.2.32.1.13 Field: Supply Side Bypass Pipe**

The field determines if a supply side bypass pipe is present in the mixed water loop. The choices for this field are

- Yes
- No

**2.2.32.1.14 Field: Demand Side Bypass Pipe**

The field determines if a demand side bypass pipe is present in the mixed water loop. The choices for this field are

- Yes
- No

**2.2.32.1.15 Field: Fluid Type**

This field determines the type of fluid used for the mixed water loop. The following options are available:

- Water
- EthyleneGlycol30
- EthyleneGlycol40
- EthyleneGlycol50
- EthyleneGlycol60
- PropyleneGlycol30
- PropyleneGlycol40
- PropyleneGlycol50
- PropyleneGlycol60

**2.2.32.1.16 Field: Loop Design Delta Temperature**

The temperature difference used in sizing the loop flow rate. The default is 5.6C.

**2.2.32.1.17 Field: Load Distribution Scheme**

This alpha field contains the Load Distribution Scheme Keyword. The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, five schemes are functional. **Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand. **SequentialLoad** loads each piece of equipment sequentially in the order specified in the **PlantEquipmentList** to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand. **UniformLoad** evenly distributes the loop demand among all available components on the equipment list for a given load range. **SequentialUniformPLR** loads all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). Components are loaded sequentially based on the order specified in the **PlantEquipmentList** until each component is fully loaded, at which point the next subsequent component is added and the load

is distributed uniformly based on PLR between the components. **UniformPLR** will load all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). No equipment will be loaded below its minimum PLR. If the total load is less than the sum of all equipment on the **PlantEquipmentList** operating at their respective minimum PLRs, then the last item in the equipment list is dropped and the load is distributed based on a uniform PLR for the remaining plant equipment.

Note: For all schemes, if the load for any individual component is less than the component load at the minimum PLR, the individual component model will false load or reduce duty cycle while operating at the minimum part load ratio until the load is met.

As shown in an IDF:

```
HVACTemplate:Plant:MixedWaterLoop,
  Only Water Loop,           !- Name
  ,                           !- Pump Schedule Name

```

---

# Chapter 3

## EnergyPlus Economics

### 3.1 Group – Economics

EnergyPlus contains a number of objects to model construction cost and utility bill calculations.

The objects used by EnergyPlus for construction cost calculations are as follows:

- `ComponentCost:Adjustments`
- `ComponentCost:Reference`
- `ComponentCost:LineItem`

The objects used by EnergyPlus for utility bill calculations are as follows:

- `UtilityCost:Tariff`
- `UtilityCost:Qualify`
- `UtilityCost:Charge:Simple`
- `UtilityCost:Charge:Block`
- `UtilityCost:Ratchet`
- `UtilityCost:Variable`
- `UtilityCost:Computation`

The objects used for performing a life-cycle cost analysis are:

- `LifeCycleCost:Parameters`
- `LifeCycleCost:RecurringCosts`
- `LifeCycleCost:NonrecurringCost`
- `LifeCycleCost:UsePriceEscalation`
- `LifeCycleCost:UseAdjustment`

The object used for specifying the currency symbol of the monetary unit used is:

- `CurrencyType`

## 3.2 Introduction to Economics

While it is true that monthly utility bills are often directly related to monthly energy consumption and monthly peak demand, due to the elaborate regulatory environment and the changing value of the energy based on load factor, the calculations involved are often complicated. The EnergyPlus approach is to allow you to model the individual component charges that make up the utility bill and report the results on a monthly basis.

To show you how simple the specification of a rate can be here is a simple example for a flat charge of 8 cents for every kWh sold.

```
UtilityCost:Tariff,
  TariffExample1,          ! Name
  Electricity:Facility,    ! Output Meter Name
  kWh;                    ! Conversion Factor Choice

UtilityCost:Charge:Simple,
  ChargeExample1,         ! Charge Variable Name
  TariffExample1,         ! Tariff Name
  totalEnergy,            ! Source Variable
  Annual,                 ! Season
  EnergyCharges,          ! Category Variable Name
  0.08;                   ! Cost Per Unit Value or Variable Name
```

---

Overall, the goals of the economics section of EnergyPlus are to make simple tariffs easy to model and complex tariffs possible to model.

The cost implications of alternative, energy-related design options may be important in determining the whether or not a particular design is viable. Although the main purpose of EnergyPlus is to determine the energy performance of a building, component cost modeling is provided to allow estimating initial construction costs associated with the building and HVAC system being modeled. This is provided in order to ensure that cost estimates are consistent with the EnergyPlus model and it allows using results calculated during a simulation such as equipment sizes and surface areas. The cost estimating capabilities are not comprehensive and are not intended to duplicate all the types of analyses included in cost estimating software. Economics modeling is being implemented in stages.

The objects used by EnergyPlus for calculating first costs for construction projects are as follows:

- **ComponentCost:Adjustments**
- **ComponentCost:Reference**
- **ComponentCost:LineItem**

The results of the cost estimate are reported in a Construction Cost Estimate Summary table provided that the user requests the results using the object **Output:Table:SummaryReports** object with the Component Cost Economics Summary option selected. The style of this predefined report can be controlled using the **OutputControl:Table:Style** object. If the Annual Building Performance Report Summary is also requested, then cost estimate results will follow that data in the same output file.

EnergyPlus also implements other objects for life-cycle costing:

- **LifeCycleCost:Parameters**
- **LifeCycleCost:RecurringCosts**
- **LifeCycleCost:NonrecurringCost**
- **LifeCycleCost:UsePriceEscalation**

- LifeCycleCost:UseAdjustment

The rest of this Economics section is organized to first present reference material on tariff calculations followed by construction cost estimating, and finally life-cycle costing

### 3.3 Conceptual Framework – Variables and Hierarchy

To understand how to use the utility bill calculation portion of EnergyPlus you first need to understand some important concepts of variables and hierarchy. A variable, for the purposes of this section, is simply a named holder of a series of numbers. In most cases, the variable will be a named holder of 12 numbers, one number for each monthly utility bill. Here is a visualization of a variable called Electric Energy Use:

Table 3.1: Example Electric Energy Use (for Economics Calculation)

Month	Electric Energy Use
January	12143
February	13454
March	14178
April	14876
May	15343
June	16172
July	16105
August	15762
September	14543
October	13987
November	13287
December	12403

If you have ever done any computer programming, you can think of a variable as an array. Many of the names used in the utility bill calculation portion of EnergyPlus are names of variables. In the case of the UtilityCost:Charge objects, the name of the object is also used as a name of a variable.

In many of today’s utility rates, the charges for energy or demand are broken into distribution and supply charges. To allow for this, more than one charge may to be defined for a particular category. The variables assigned to the same category are added together.

The categories are combined in following hierarchy:

Any charges included in the EnergyCharges category are added together. The EnergyCharges, DemandCharges and ServiceCharges are added together to form the Basis. The Basis, Adjustments and Surcharges are added together to form the Subtotal. The Subtotal and Taxes are added together to be the Total. The total represents the total monthly charges on that tariff for the energy source used. The combining of categories together is performed automatically unless the user specifies the **UtilityCost:Computation**. In addition, each category, which is also a variable, may be used as a source. For example, a tax that is 5% of the subtotal would be shown as:

```
UtilityCost:Charge:Simple,
```

Figure 3.1: Hierarchy for Economics Charges

TaxOfFivePercent,	! Charge Variable Name
TariffExample1,	! Tariff Name
Subtotal,	! Source Variable
Annual,	! Season
Taxes,	! Category Variable Name
0.05;	! Cost Per Unit Value or Variable Name

As you can see, the **UtilityCost:Charge:Simple** and **UtilityCost:Charge:Block** objects do most of the “work” of computing the annual energy cost. The benefit of using this categorization is that totals of each category are shown in the output reports and it organizes the charges in the monthly calculations in a logical way that fits almost all tariffs. If no categorization is desired, theoretically, all charges could be assigned to the Total category. The categories themselves are simply variable names. Charges may also be assigned to the “NotIncluded” category if the result of the charge is used as an intermediate calculation and should not be included in the Total.

The rest of this section is divided into a reference of the objects and the fields, a set of examples, discussion of the reporting, and a description of Complex Tariff Modeling. For most tariffs, simply using a variety of **UtilityCost:Charge:Simple**’s and **UtilityCost:Charge:Block**’s will result in a good model but for some more complex tariffs, especially ones with complex block sizes, variables may be computed using a very simple programming language that may appear in the **UtilityCost:Computation** object. This will be described more in the Complex Tariff Modeling section.

### 3.4 UtilityCost:Tariff

Defines the name of the tariff, the type of tariff, and other details about the overall tariff. Each other object that is part of the tariff model references the tariff name including the **UtilityCost:Charge:Simple**, **UtilityCost:Charge:Block**, **UtilityCost:Ratchet**, **UtilityCost:Qualify**, **UtilityCost:Variable** and **UtilityCost:Computation** objects.

Multiple **UtilityCost:Tariff** objects can appear in the same IDF file. It is common that electric and gas utilities have more than one rate that may be used. Only one **UtilityCost:Tariff** for each **Output:Meter** object and Group Name is shown in the Economics Summary Report. The one that is shown in that report is chosen by first eliminating **UtilityCost:Tariff** objects that are not qualified due to their **UtilityCost:Qualify** objects. If more than one **UtilityCost:Tariff** object remains, the one that has the lowest cost for a combination of a Meter and Group Name will be selected. If the Group Name field is not used, then the lowest cost **UtilityCost:Tariff** is chosen for each Meter.

Part of the tariff description is used to transform the annual energy use of any fuel under any meter

into a group of named variables containing the values for each of the periods that the bills are calculated (usually monthly). The schedules create a variable for energy use and for demand. If specified it also creates a variable for energy and a variable for demand for the “on-peak”, “off-peak”, and “shoulder” periods for use in time-of-use tariffs. It performs this allocation prior to other calculations for the tariff. The variables that are always created are:

- totalEnergy
- totalDemand

### 3.4.1 Inputs

#### 3.4.1.0.1 Field: Name

The name of the tariff. Tariffs are sometimes called rates. The name is used in identifying the output results and in associating all of the charges and other objects that make up a tariff.

#### 3.4.1.0.2 Field: Output Meter Name

The name of any meter defined but usually set to either Electricity:Facility or NaturalGas:Facility.

#### 3.4.1.0.3 Field: Conversion Factor Choice

A choice that allows several different predefined conversion factors to be used; otherwise, user defined conversion factors are used as defined in the next two fields.

- UserDefined
- kWh
- Therm
- MMBtu
- MJ
- KBtu
- MCF
- CCF
- m3
- gal
- kgal

Not all choices will be accepted by EnergyPlus depending on the resource of the Output Meter of the tariff object, and the same Conversion Factor Choice will take different values depending on the resource type. EnergyPlus will differentiate between **Water Meters** and **Energy Meters**.

Energy Meters natively report energy in Joules (J) and demand in Joules/Sec (J/s) which is equivalent to Watts (W). If Conversion Factor Choice is omitted or not a valid conversion factor from the table below, the default is kWh and a warning is issued to the user. EnergyPlus will make a distinction between Electric, Gas, and 'Other' meters to determine the accepted options. If 'Therm' is used for an electric meter, the user is warned that this is an unusual choice for electricity. The following table shows the accepted options and the conversion factors for an Electric Meter.

Table 3.2: Built in UtilityCost:Tariff Conversion Factors for Electric Meters

Choice	Energy Conversion Factor	Demand Conversion Factor
kWh	0.0000002778	0.001
MJ	0.000001	0.0036
MMBtu	9.4781712E-10	0.000003412
KBtu	9.4781712E-07	0.003412
Therm	9.4781712E-09	0.00003412

The following table shows the accepted options and the conversion factors for a Gas Meter. Note that for volumetric units, the simplification for the heat content of natural gas is that 100 CCF = 1 therm. It is recommended to use actual values for the heat content of natural gas in your region/year by using "UserDefined" and manually entering the conversion factors for energy and demand.

Table 3.3: Built in UtilityCost:Tariff Conversion Factors for Gas Meters

Choice	Energy Conversion Factor	Demand Conversion Factor
kWh	0.0000002778	0.001
MJ	0.000001	0.0036
MMBtu	9.4781712E-10	0.000003412
KBtu	9.4781712E-07	0.003412
Therm	9.4781712E-09	0.00003412
MCF	9.4781712E-10	0.000003412
CCF	9.4781712E-09	0.00003412
m3	2.6839192e-10	9.6617081E-05

Water Meters natively report "energy" in cubic meters (m3). If Conversion Factor Choice is omitted or not a valid conversion factor from the table below, the default is m3 and a warning is issued to the user. The following table shows the accepted options and the conversion factors for a water meter.

Table 3.4: Built in UtilityCost:Tariff Conversion Factors for Water Meters

Choice	Energy Conversion Factor
CCF	0.353146667214885
gal	264.172052360252
kgal	0.264172052360252

The following table shows the accepted options and the conversion factors for all other Meters that aren't either Water, Electric, or gas.

Table 3.5: Built in UtilityCost:Tariff Conversion Factors for Other Meters

Choice	Energy Conversion Factor	Demand Conversion Factor
kWh	0.0000002778	0.001
MJ	0.000001	0.0036
MMBtu	9.4781712E-10	0.000003412
KBtu	9.4781712E-07	0.003412
Therm	9.4781712E-09	0.00003412

#### 3.4.1.0.4 Field: Energy Conversion Factor

Is a multiplier used to convert energy into the units specified by the utility in their tariff. If left blank, it defaults to 1 (no conversion). This field will be used only if Conversion Factor Choice is set to UserDefined. Within EnergyPlus energy always has units of J (joules), except for water meters that have units of m3. For conversion from J to kWh use the value of 0.0000002778. This is also used for all objects that reference the UtilityCost:Tariff.

#### 3.4.1.0.5 Field: Demand Conversion Factor

Is a multiplier used to convert demand into the units specified by the utility in their tariff. If left blank, it defaults to 1 (no conversion). This field will be used only if Conversion Factor Choice is set to UserDefined. Within EnergyPlus demand always has units of J/s (joules/sec) which equivalent to W (watts). For conversion from W to kW use the value of 0.001. This is also used for all objects that reference the UtilityCost:Tariff.

#### 3.4.1.0.6 Field: Time of Use Period Schedule Name

The name of the schedule that defines the time-of-use periods that occur each day. The period schedule is used to determine which variables are defined. The values for the different variables are:

- 1 is Peak
- 2 is Shoulder
- 3 is OffPeak
- 4 is MidPeak

The following variables are created automatically if these different periods are used in the schedule and include:

- peakEnergy
- peakDemand
- shoulderEnergy
- shoulderDemand
- offPeakEnergy
- offPeakDemand

- midPeakEnergy
- midPeakDemand

Some special variables are created that include only demand from one period that exceeds the demand from another period. For other months that do not exceed, the values are zero. These variables are seldom used but are available for the occasional rate that includes a clause looking at demands during one period that exceed another period.

- PeakExceedsOffPeak
- OffPeakExceedsPeak
- PeakExceedsMidPeak
- MidPeakExceedsPeak
- PeakExceedsShoulder
- ShoulderExceedsPeak

If no Period Schedule is specified then no peak, offPeak, midPeak or shoulder variables are defined.

#### **3.4.1.0.7 Field: Season Schedule Name**

The name of a schedule that defines the seasons. The seasons are

- 1 is Winter
- 2 is Spring
- 3 is Summer
- 4 is Autumn

The change in the season schedule must occur at the same time as the change in the Monthly Schedule. In other words, a season must end at the same time as a billing month. Variables are automatically created if a season schedule is used. These variables are set to 1 within the season and 0 for the months that are not in the season. The variables are:

- isWinter
- isNotWinter
- isSpring
- isNotSpring
- isSummer
- isNotSummer
- isAutumn
- isNotAutumn

#### 3.4.1.0.8 Field: Month Schedule Name

The name of the schedule that defines the billing periods of the year. Normally this entry is allowed to default and a schedule will be internally used that has the breaks between billing periods occurring at the same time as the breaks between months, i.e., at midnight prior to the first day of the month. If other billing periods are used such as two month cycles or a single bill for an entire season, such as some natural gas companies do in the summer, then the month schedule may be used to redefine it. Make sure that the month schedule and season schedule are consistent, otherwise an error will be issued.

- 1 is the first month, usually January
- 2 is the second month, usually February
- 3 is the third month, usually March
- 4 is the fourth month, usually April
- 5 is the fifth month, usually May
- 6 is the sixth month, usually June
- 7 is the seventh month, usually July
- 8 is the eighth month, usually August
- 9 is the ninth month, usually September
- 10 is the tenth month, usually October
- 11 is the eleventh month, usually November
- 12 is the twelfth month, usually December

Thus, the schedule that represents this would look like the following. If no schedule is specified the following Month Schedule is used which defines the months of the year as the normal calendar months.

```
Schedule:Compact, defaultMonths, number,
Through: 1/31, For: AllDays, Until: 24:00, 1,
Through: 2/28, For: AllDays, Until: 24:00, 2,
Through: 3/31, For: AllDays, Until: 24:00, 3,
Through: 4/30, For: AllDays, Until: 24:00, 4,
Through: 5/31, For: AllDays, Until: 24:00, 5,
Through: 6/30, For: AllDays, Until: 24:00, 6,
Through: 7/31, For: AllDays, Until: 24:00, 7,
Through: 8/31, For: AllDays, Until: 24:00, 8,
Through: 9/30, For: AllDays, Until: 24:00, 9,
Through: 10/31, For: AllDays, Until: 24:00, 10,
Through: 11/30, For: AllDays, Until: 24:00, 11,
Through: 12/31, For: AllDays, Until: 24:00, 12;
```

#### 3.4.1.0.9 Field: Demand Window Length

The determination of demand can vary by utility. Some utilities use the peak instantaneous demand measured but most use a fifteen minute average demand or a one hour average demand. Some gas utilities measure demand as the use during the peak day or peak week. The choices for demand window are:

- QuarterHour
- HalfHour

- FullHour
- Day
- Week

If no value is entered, QuarterHour is assumed. The choice may be overridden based on the value of **Timestep** so that they are consistent:

- If the **Timestep** is 6, i.e. 10 minute timesteps, then QuarterHour is not used and HalfHour is used instead.
- If **Timestep** is 3, i.e. 20 minute timesteps, then QuarterHour and HalfHour are not used and FullHour is used instead.

Day and Week are primarily used by fuel utilities.

#### 3.4.1.0.10 Field: Monthly Charge or Variable Name

The fixed monthly service charge that many utilities have. The entry may be numeric and gets added to the ServiceCharges variable or if a variable name is entered here, its values for each month are used.

#### 3.4.1.0.11 Field: Minimum Monthly Charge or Variable Name

The minimum total charge for the tariff or if a variable name is entered here, its values for each month are used. The sum of the subtotal and taxes usually equals the total unless you have specified the minimum monthly charge. If the minimum monthly charge does not apply to the entire bill, a **UtilityCost:Computation** object can be specified using a Minimum function for the appropriate variables.

#### 3.4.1.0.12 Field: Real Time Pricing Charge Schedule Name

Used with real time pricing rates. The name of a schedule that contains the cost of energy for that particular time period of the year. Real time rates can be modeled using a charge schedule with the actual real time prices entered in the schedule. The charges should be consistent with the conversion factor specified in the tariff.

#### 3.4.1.0.13 Field: Customer Baseline Load Schedule Name

Used with real time pricing rates and often described as the CBL or customer baseline load. The name of a schedule that contains the baseline energy use for the customer. Many real time rates apply the charges as a credit or debit only to the difference between the baseline use and the actual use. The baseline use is established between the customer and the utility using a contract. If this field is used the baseline use schedule will be used for establishing the totalEnergy and totalDemand instead of the metered value and the real time rate charge is added or subtracted to the rate calculation using the real time charge schedule. If this field is not used, the real time charge schedule applies to all energy from the meter and totalEnergy and totalDemand is based on metered value as usual.

#### 3.4.1.0.14 Field: Group Name

The group name of the tariff such as distribution, transmission, supplier, etc. If more than one tariff with the same group name is present and qualifies, only the lowest cost tariff is used. Usually the group name field is left blank which results in all tariffs using the same meter variable being compared and the lowest cost one being selected.

#### 3.4.1.0.15 Field: Buy Or Sell

Sets whether the tariff is used for buying, selling or both to the utility. This should be allowed to default to BuyFromUtility unless a power generation system is included in the building that may generate more power than the building needs during the year. The choices are:

- BuyFromUtility – The values from the metered variable are used and are shown as being purchases from the utility.
- SellToUtility – The values from the metered variable are used for a “sell back” rate to the utility. The charges in the rate should be expressed as negative values.
- NetMetering – Negative values are used to reduce any positive values during the specific period on the tariff when negative values occur.

A warning will be issued if the selection of this field does not match the type of meter.

### 3.5 UtilityCost:Qualify

Many utilities provide a large number of tariffs and separate their customers by the amount of energy use they have or by the amount of demand. The qualify object allows only certain tariffs that are modeled to be used. If the results of the simulation fall outside of the range of qualifications, that tariff is still calculated but the “Qualified” entry will say “No” and the UtilityCost:Qualify that caused its exclusion is shown. When multiple tariffs from the same utility are modeled and only one of them should be used, make sure that the qualifiers are consistent especially within the same GroupName (see **UtilityCost:Tariff**). Multiple UtilityCost:Qualify objects can appear for a specific rate and they can be based on any variable.

The energy used and demands for each month vary. Since it is possible that they vary across the minimum and maximum values defined by this object, a choice in how to treat the thresholds is necessary. Say that a utility has two tariffs, a small tariff that has a maximum demand requirement of 50kW and a large tariff that has a minimum demand requirement of 50kW. If the use for a building goes above the 50kW threshold during some summer months and the rest of the time is below 50kW, then how does the utility choose which rate would qualify. The utility probably has very specific requirements about which months or consecutive months can be above or below a threshold to qualify for the rate.

#### 3.5.1 Inputs

##### 3.5.1.0.1 Field: Name

The name used for the UtilityCost:Qualify and displayed if the tariff does not qualify. It is also treated as a variable and contains:

- 1 for each month that does qualify,
- 0 for months that do not qualify, and
- -1 for months that are not part of the season selected.

##### 3.5.1.0.2 Field: Tariff Name

The name of the **UtilityCost:Tariff** object that is associated with this UtilityCost:Qualify object.

##### 3.5.1.0.3 Field: Variable Name

The name of the variable used. For energy and demand, the automatically created variables, totalEnergy and totalDemand should be used, respectively.

#### 3.5.1.0.4 Field: Qualify Type

Enter either “Minimum” or “Maximum”.

#### 3.5.1.0.5 Field: Threshold Value or Variable Name

The minimum or maximum value for the qualify. If the variable has values that are less than this value when the qualify type is minimum then the tariff may be disqualified. If the variable has values that are greater than this value when the qualify type is maximum then the tariff may be disqualified. For demand, it is still the minimum of the demands set each month even though the demands are, by definition, the peak value for the month. Depending on the threshold test entry (see below) this minimum applies to all months, some of the months, or just a single month.

#### 3.5.1.0.6 Field: Season

If the UtilityCost:Qualify only applies to a season, enter the season name from the following list:

- Annual
- Winter
- Spring
- Summer
- Fall

If this field is left blank, it defaults to Annual.

#### 3.5.1.0.7 Field: Threshold Test

Enter either “Count” or “Consecutive”. Uses the number in Number of Months in one of two different ways depending on the Threshold Test. If the Threshold Test is set to “Count” then the qualification is based on the count of the total number of months per year. If the Threshold Test is set to “Consecutive” then the qualification is based on a consecutive number of months. If left blank this field defaults to count and it should be allowed to default for most cases.

#### 3.5.1.0.8 Field: Number of Months

A number from 1 to 12. If no value entered, 12 is assumed when the qualify type is minimum and 1 when the qualify type is maximum. This is the number of months that the threshold test applies to determine if the rate qualifies or not. If the season is less than 12 months (if it is not annual) then the value is automatically reduced to the number of months of the season.

## 3.6 UtilityCost:Charge:Simple

The UtilityCost:Charge:Simple is one of the most often used objects for tariff calculation. It is used to compute energy and demand charges that are very simple. It may also be used for taxes, surcharges and any other charges that occur on a utility bill. As many UtilityCost:Charge:Simple objects as needed may be defined for a single tariff and they will be added together.

### 3.6.1 Inputs

#### 3.6.1.0.1 Field: Charge Variable Name

This is the name associated with the `UtilityCost:Charge:Simple` object and will appear in the report. In addition, the results of the `UtilityCost:Charge:Simple` calculation are stored in a variable with the same name. That way, the results may be used for further calculation. Spaces are not significant in Charge Variable Names. They are removed during the utility bill calculation process.

#### 3.6.1.0.2 Field: Tariff Name

The name of the tariff that this `UtilityCost:Charge:Simple` is associated with.

#### 3.6.1.0.3 Field: Source Variable

The name of the source used by the `UtilityCost:Charge:Simple`. This is usually the name of the variable holding the energy or demand but may also be the name of any variable including the subtotal or basis if other charges are based on those.

#### 3.6.1.0.4 Field: Season

This is the name (or number) of a season for which the `UtilityCost:Charge:Simple` is calculated. If this is set to `Annual`, the calculations are performed for the `UtilityCost:Charge:Simple` for the entire year (all months) otherwise it is calculated only for those months in the season defined. The season is defined by the Season Schedule in the `UtilityCost:Tariff` object. The choices for seasons are the following names or numbers may be used:

- Annual
- Winter
- Spring
- Summer
- Fall

#### 3.6.1.0.5 Field: Category Variable Name

All charges get added somewhere in the hierarchy described in the introduction to EnergyPlus economics above. This field shows where the charge should be added. The reason to enter this field appropriately is so that the charge gets reported in a reasonable category. The charge automatically gets added to the variable that is the category. The choices for this field are limited to:

- EnergyCharges
- DemandCharges
- ServiceCharges
- Basis
- Adjustment
- Surcharge
- Subtotal

- Taxes
- Total
- NotIncluded

#### 3.6.1.0.6 Field: Cost per Unit Value or Variable Name

This field contains either a single number or the name of a variable. The number is multiplied with all of the energy or demand or other source that is specified in the source field. If a variable is used, then the monthly values of the variable are multiplied against the variable specified in the source field. This field makes it easy to include a simple charge without specifying block sizes. It is added to any of the block calculations (see later fields) but is most often used by itself. If no value or variable is entered, a zero is assumed. This is a good way to include a tax or cost adjustment. For SellToUtility tariffs, the values in this field are usually expressed as negative numbers.

## 3.7 UtilityCost:Charge:Block

The UtilityCost:Charge:Block objects is also used extensively for tariff calculation. It is used to compute energy and demand charges that are structured in blocks of charges. It may also be used for taxes, surcharges and any other charges that occur on a utility bill but those are more commonly simple flat charges so **UtilityCost:Charge:Simple** is more commonly used for those functions. As many UtilityCost:Charge:Block objects as needed may be defined for a single tariff and they will be added together. Blocks are a structure used by almost all utilities for calculating energy and demand charges and they allow the utility to charge more or less per unit of energy or demand if more units are used.

### 3.7.1 Inputs

#### 3.7.1.0.1 Field: Charge Variable Name

This is the name associated with the UtilityCost:Charge:Block object and will appear in the report. In addition, the results of the UtilityCost:Charge:Block are stored in a variable with the same name. That way, the results may be used for further calculation.

#### 3.7.1.0.2 Field: Tariff Name

The name of the tariff that this UtilityCost:Charge:Block is associated with.

#### 3.7.1.0.3 Field: Source Variable

The name of the source used by the UtilityCost:Charge:Block. This is usually the name of the variable holding the energy or demand but may also be the name of any variable including the subtotal or basis if other charges are based on those.

#### 3.7.1.0.4 Field: Season

This is the name (or number) of a season for which the UtilityCost:Charge:Block is calculated. If this is set to annual, the calculations are performed for the UtilityCost:Charge:Block for the entire year (all months) otherwise it is calculated only for those months in the season defined. The season is defined by the Season Schedule in the **UtilityCost:Tariff** object. The choices for seasons are the following names or numbers may be used:

- Annual

- Summer
- Winter
- Spring
- Fall

#### 3.7.1.0.5 Field: Category Variable Name

All charges get added somewhere in the hierarchy described in the introduction to EnergyPlus economics above. This field shows where the charge should be added. The reason to enter this field appropriately is so that the charge gets reported in a reasonable category. The charge automatically gets added to the variable that is the category. The choices for this field are limited to:

- EnergyCharges
- DemandCharges
- ServiceCharges
- Basis
- Adjustment
- Surcharge
- Subtotal
- Taxes
- Total
- NotIncluded

#### 3.7.1.0.6 Field: Remaining Into Variable

If the blocks do not use all of the energy or demand from the source, some energy and demand remains, then the remaining amount should be assigned to a variable. If no variable is assigned and some amount of energy or demand is not used in the block structure a warning will be issued.

#### 3.7.1.0.7 Field: Block Size Multiplier Value or Variable Name

The sizes of the blocks are usually used directly but if a value or a variable is entered here, the block sizes entered in the rest of the charge are first multiplied by the entered value prior to being used. This is common for rates that are kWh/kW rates and in that case the variable that holds the monthly total electric demand would be entered. If no value is entered, a default value of one is assumed so that the block sizes remain exactly as entered. This field is unusual for the EnergyPlus syntax because it can be either a number or a name of a variable.

#### 3.7.1.0.8 Field: Block Size 1 Value or Variable Name

The size of the first block of the charges is entered here. For most rates that use multiple blocks, this will be the value for the first block size. Additional block sizes are entered with every other field. A default variable named “remaining” contains a large value and this may be used when the remaining amount should be included in that block. This field and the next field may be repeated in groups of two for as many blocks as are defined. This field is unusual for the EnergyPlus syntax because it can be either a number or a name of a variable.

### 3.7.1.0.9 Field: Block 1 Cost per Unit Value or Variable Name

The cost of the first block. This value is also repeated for every other field in the charge. As many blocks may be entered as are needed. This field and the previous field may be repeated in groups of two for as many blocks as are defined. This field is unusual for the EnergyPlus syntax because it can be either a number or a name of a variable. For SellToUtility tariffs, the values in this field are usually expressed as negative numbers.

These last two fields may be repeated fifteen times. If more blocks are defined by the utility, the computation can be continued using another UtilityCost:Charge:Block and using the variable from Remaining Into Variable as the source variable.

## 3.8 UtilityCost:Ratchet

The UtilityCost:Ratchet command allows the modeling of tariffs that include some type of seasonal ratcheting. Ratchets are most common when used with electric demand charges. A ratchet is when a utility requires that the demand charge for a month with a low demand may be increased to be more consistent with a month that set a higher demand charge.

While the details of the UtilityCost:Ratchet command are described further in this section, an example is probably the easiest way to learn the basic functions.

Ratchet Example: A utility has a single ratchet that says that the billing demand for each month of the year is the higher value of the actual demand or 60% of the peak summer demand

```
UtilityCost:Ratchet,
  BillingDemand1,    ! Ratchet Variable Name
  ExampleTariff1,   ! Tariff Name
  TotalDemand,      ! Baseline Source Variable
  TotalDemand,      ! Adjustment Source Variable
  Summer,           ! Season From
  Annual,           ! Season To
  0.60,             ! Multiplier Value or Variable Name
  0;                ! Offset Value or Variable Name
```

The Ratchet Variable Name (the first field) should be used wherever the ratchet should be applied and is often the source variable for **UtilityCost:Charge:Simple** or **UtilityCost:Charge:Block**.

The detailed steps taken for the ratchet are the following:

- AdjSeasonal contains either:
  - When SeasonFrom is not set to Monthly, the maximum for all months in Season From in the Adjustment Source Variable. This is a single value.
  - When SeasonFrom is set to Monthly, the monthly values of the Adjustment Source Variable.
- $\text{AdjPeak} = (\text{AdjSeasonal} + \text{Offset}) * \text{Multiplier}$
- $\text{MaxAdjBase} = \text{maximum value of either AdjPeak or Baseline Source Variable}$
- The resulting Ratchet Variable contains:
  - For months not in SeasonTo, the values of Baseline Source Variable
  - For months in SeasonTo, the values of MaxAdjBase

If multiple ratchets occur in the same tariff, multiple `UtilityCost:Ratchet` commands should be “chained” together with the Baseline Source Variable subsequent ratchets referencing the Ratchet Variable Name of the previous `UtilityCost:Ratchet`.

Since the ratchet command can add together two variables, multiply two variables, or take the maximum value between two variables, it may be used for other difficult to model tariffs without needing to use `UtilityCost:Computation`. Clever use of `UtilityCost:Ratchet` should be well documented with comments.

### 3.8.1 Inputs

#### 3.8.1.0.1 Field: Ratchet Variable Name

The name of the ratchet and the name of the result of this single ratchet.

#### 3.8.1.0.2 Field: Tariff Name

The name of the tariff that this `UtilityCost:Ratchet` is associated with.

#### 3.8.1.0.3 Field: Baseline Source Variable

The name of the variable used as the baseline value. When the ratcheted value exceeds the baseline value for a month the ratcheted value is used but when the baseline value is greater then the ratcheted value the baseline value is used. Usually the electric demand charge is used. The baseline source variable can be the results of another ratchet object. This allows utility tariffs that have multiple ratchets to be modeled.

#### 3.8.1.0.4 Field: Adjustment Source Variable

The variable that the ratchet is calculated from. It is often but not always the same as the baseline source variable. The ratcheting calculations using offset and multiplier are using the values from the adjustment source variable. If left blank, the adjustment source variable is the same as the baseline source variable.

#### 3.8.1.0.5 Field: Season From

The name of the season that is being examined. The maximum value for all of the months in the named season is what is used with the multiplier and offset. This is most commonly Summer or Annual. When Monthly is used, the adjustment source variable is used directly for all months.

- Annual
- Winter
- Spring
- Summer
- Fall
- Monthly

#### 3.8.1.0.6 Field: Season To

The name of the season when the ratchet would be calculated. This is most commonly Winter. The ratchet only is applied to the months in the named season. The resulting variable for months not in the Season To selection will contain the values as appear in the baseline source variable.

- Annual

- Winter
- Spring
- Summer
- Fall

#### 3.8.1.0.7 Field: Multiplier Value or Variable Name

Often the ratchet has a clause such as “the current month demand or 90% of the summer month demand”. For this case a value of 0.9 would be entered here as the multiplier. This value may be left blank if no multiplier is needed and a value of one will be used as a default.

#### 3.8.1.0.8 Field: Offset Value or Variable Name

A less common strategy is to say that the ratchet must be all demand greater than a value, in this case an offset that is added to the demand may be entered here. If entered, it is common for the offset value to be negative representing that the demand be reduced. If no value is entered it is assumed to be zero and not affect the ratchet.

## 3.9 UtilityCost:Variable

The UtilityCost:Variable object allows for the direct entry of monthly values into a variable.

### 3.9.1 Inputs

#### 3.9.1.0.1 Field: Name

The name of the variable.

#### 3.9.1.0.2 Field: Tariff Name

The name of the tariff that is using the variable.

#### 3.9.1.0.3 Field: Variable Type

This field is used to indicate the kind of units that may be associated with the variable. It is used by IDF Editor to display the appropriate SI and IP units for the January through December values. The available options are shown below. If none of these options are appropriate, select **Dimensionless** which will have no unit conversion.

- Energy
- Demand
- Currency
- Dimensionless

#### 3.9.1.0.4 Field: January through December Values

An entry (up to 24 are available) of the monthly values of the variable. Normally 12 months are used for most utility rates and so 12 values should be entered. If any values are not entered, the value of the previous entry is used. This allows a variable that is constant for an entire year to be entered using only the first value.

## 3.10 UtilityCost:Computation

The UtilityCost:Computation object lists a series of computations that are used to perform the bill calculation. The object is only used for complex tariffs that cannot be modeled any other way. For 95% of the utility tariffs, using UtilityCost:Computation is unnecessary and should be avoided. If the UtilityCost:Computation object is used, it must contain references to all objects involved in the rate in the order that they should be computed.

### 3.10.1 Inputs

#### 3.10.1.0.1 Field: Name

The name of the UtilityCost:Computation.

#### 3.10.1.0.2 Field: Tariff Name

The name of the tariff that this **UtilityCost:Charge:Simple** is associated with.

#### 3.10.1.0.3 Field: Compute Step N

The Compute Step fields contain a simple language that describes the steps used in the computation process similar to a programming language. If no entry is made to any Compute Step fields (as usually the case) a default method of computing the rates shall be used. Compute Step is described later in this section under Complex Tariff Modeling.

Remember, this object should be omitted for almost all tariffs.

## 3.11 UtilityCost:Tariff Examples

One of the best ways to learn the details of EnergyPlus Economics is to see some example tariffs and how they translate into objects. To do this, several different rates of increasing complexity are shown in the following examples.

Another source of examples is the large set of tariff input objects provided with EnergyPlus in the macro data set file called “UtilityTariffObjects.imf” located in the “MacroDataSets” folder where EnergyPlus is installed. This file contains sets of objects that fully define tariffs for commercial customers from a collection of U.S. utility companies.

### 3.11.0.1 Example A – Flat Energy Charge

As an example of the simplest type of tariff.

Customer Charge: \$2.51 per month

Energy Charge: 5.5342 cents/kWh

This tariff would use a single **UtilityCost:Charge:Simple** object. The monthly charge is part of the **UtilityCost:Tariff** object.

```
UtilityCost:Tariff,
  ExampleA,           ! Name
  Electricity:Facility, ! Output Meter Name
  kWh,                ! Conversion Factor Choice
  ,                   ! Energy Conversion Factor
  ,                   ! Demand Conversion Factor
  ,                   ! Time of Use Period Schedule Name
  ,                   ! Season Schedule Name
  ,                   ! Month Schedule Name
  ,                   ! Demand Window Length
  2.51;               ! Monthly Charge or Variable Name
```

```

UtilityCost:Charge:Simple,
  FlatEnergyCharge,      ! Charge Variable Name
  ExampleA,              ! Tariff Name
  totalEnergy,           ! Source Variable
  Annual,                ! Season
  EnergyCharges,         ! Category Variable Name
  0.055342;              ! Cost Per Unit Value or Variable Name

```

---

### 3.11.0.2 Example B – Block Energy Charge

Another simple type of tariff is one where the energy charges vary by the amount of energy consumed each month.

Customer Charge:   \$5.75 per month  
 Energy Charge:     7.231 cents/kWh for first 200 kWh  
                       6.656 cents/kWh for next 1000 kWh  
                       5.876 cents/kWh for over 1200 kWh

This tariff would use a single **UtilityCost:Charge:Block** object. The monthly charge is part of the **UtilityCost:Tariff** object. Note that the block sizes are every other field at the bottom of the object and the that final block size references a built in variable called “remaining” that contains a very large number.

```

UtilityCost:Tariff,
  ExampleB,              ! Name
  Electricity:Facility,   ! Output Meter Name
  kWh,                  ! Conversion Factor Choice
  ,                     ! Energy Conversion Factor
  ,                     ! Demand Conversion Factor
  ,                     ! Time of Use Period Schedule Name
  ,                     ! Season Schedule Name
  ,                     ! Month Schedule Name
  ,                     ! Demand Window Length
  5.75;                 ! Monthly Charge or Variable Name

UtilityCost:Charge:Block,
  BlockEnergyCharge,     ! Charge Variable Name
  ExampleB,              ! Tariff Name
  totalEnergy,           ! Source Variable
  Annual,                ! Season
  EnergyCharges,         ! Category Variable Name
  ,                      ! Remaining Into Variable
  ,                      ! Block Size Multiplier Value or Variable Name
  200,                   ! Block Size 1 Value or Variable Name
  0.07231,               ! Block 1 Cost per Unit Value or Variable Name
  1000,                  ! Block Size 2 Value or Variable Name
  0.06656,               ! Block 2 Cost per Unit Value or Variable Name
  remaining,             ! Block Size 3 Value or Variable Name
  0.05876;              ! Block 3 Cost per Unit Value or Variable Name

```

---

### 3.11.0.3 Example C – Block Energy and Demand Charges

This example contains both a block for energy and a block for demand and is very similar to the previous example except it now includes demand charges as well. The energy and demand charges vary by the amount of energy and demand consumed each month.

Energy Charge:     4.74 cents/kWh for first 20,000 kWh  
                       4.24 cents/kWh for next 180,000 kWh  
                       3.83 cents/kWh for additional kWh  
 Demand Charge:    5.38 dollars per kW for first 20 kW

4.23 dollars per kW for next 80 kW

3.60 dollars per kW for additional kW

This tariff would use two **UtilityCost:Charge:Block** objects. No monthly charge is shown so the **UtilityCost:Tariff** object can include just the first four fields. Note that the block sizes are every other field at the bottom of the object and the that final block size references a built in variable called “remaining” that contains a very large number.

```
UtilityCost:Tariff,
  ExampleC,                ! Name
  Electricity:Facility,     ! Output Meter Name
  KWh;                     ! Conversion Factor Choice

UtilityCost:Charge:Block,
  BlockEnergyCharge,       ! Charge Variable Name
  ExampleC,                ! Tariff Name
  totalEnergy,             ! Source Variable
  Annual,                  ! Season
  EnergyCharges,           ! Category Variable Name
  ,                         ! Remaining Into Variable
  ,                         ! Block Size Multiplier Value or Variable Name
  20000,                   ! Block Size 1 Value or Variable Name
  0.0474,                  ! Block 1 Cost per Unit Value or Variable Name
  180000,                  ! Block Size 2 Value or Variable Name
  0.0424,                  ! Block 2 Cost per Unit Value or Variable Name
  remaining,               ! Block Size 3 Value or Variable Name
  0.0383;                  ! Block 3 Cost per Unit Value or Variable Name

UtilityCost:Charge:Block,
  BlockDemandCharge,       ! Charge Variable Name
  ExampleC,                ! Tariff Name
  totalDemand,             ! Source Variable
  Annual,                  ! Season
  DemandCharges,          ! Category Variable Name
  ,                         ! Remaining Into Variable
  ,                         ! Block Size Multiplier Value or Variable Name
  20,                      ! Block Size 1 Value or Variable Name
  5.38,                    ! Block 1 Cost per Unit Value or Variable Name
  80,                      ! Block Size 2 Value or Variable Name
  4.23,                    ! Block 2 Cost per Unit Value or Variable Name
  remaining,               ! Block Size 3 Value or Variable Name
  3.60;                    ! Block 3 Cost per Unit Value or Variable Name
```

#### 3.11.0.4 Example D - Seasonal Energy Charges with Minimum Charge

Another type of tariff is one where the energy charges vary by the amount of energy consumed each month and are different for the summer and winter. In addition, this example demonstrates the minimum charge field.

Minimum Charge:     \$7.00 per month

Winter – October through May

Energy Charge:     4.385 cents/kWh for first 650 kWh

3.763 cents/kWh for next 350 kWh

3.704 cents/kWh for over 1000 kWh

Summer – June through September

Energy Charge:     8.385 cents/kWh for first 650 kWh

7.588 cents/kWh for next 350 kWh

7.103 cents/kWh for over 1000 kWh

This tariff would use two **UtilityCost:Charge:Block** objects. The monthly charge is part of the **Utility-Cost:Tariff** object. Note that the block sizes are every other field at the bottom of the object and the that final block size references a built in variable called “remaining” that contains a very large number.

```
UtilityCost:Tariff,
  ExampleD,                ! Name
  Electricity:Facility,     ! Output Meter Name
  KWh,                     ! Conversion Factor Choice
  ,                         ! Energy Conversion Factor
  ,                         ! Demand Conversion Factor
  ,                         ! Time of Use Period Schedule Name
  TwoSeasonSchedule,       ! Season Schedule Name
  ,                         ! Month Schedule Name
  ,                         ! Demand Window Length
  ,                         ! Monthly Charge or Variable Name
  7.00;                     ! Minimum Monthly Charge or Variable Name

UtilityCost:Charge:Block,
  WinterEnergyCost,        ! Charge Variable Name
  ExampleD,                ! Tariff Name
  totalEnergy,             ! Source Variable
  Winter,                  ! Season
  EnergyCharges,           ! Category Variable Name
  ,                         ! Remaining Into Variable
  ,                         ! Block Size Multiplier Value or Variable Name
  650,                     ! Block Size 1 Value or Variable Name
  0.04385,                 ! Block 1 Cost per Unit Value or Variable Name
  350,                     ! Block Size 2 Value or Variable Name
  0.03763,                 ! Block 2 Cost per Unit Value or Variable Name
  remaining,               ! Block Size 3 Value or Variable Name
  0.03704;                 ! Block 3 Cost per Unit Value or Variable Name

UtilityCost:Charge:Block,
  SummerEnergyCost,        ! Charge Variable Name
  ExampleD,                ! Tariff Name
  totalEnergy,             ! Source Variable
  Summer,                  ! Season
  EnergyCharges,           ! Category Variable Name
  ,                         ! Remaining Into Variable
  ,                         ! Block Size Multiplier Value or Variable Name
  650,                     ! Block Size 1 Value or Variable Name
  0.08385,                 ! Block 1 Cost per Unit Value or Variable Name
  350,                     ! Block Size 2 Value or Variable Name
  0.07588,                 ! Block 2 Cost per Unit Value or Variable Name
  remaining,               ! Block Size 3 Value or Variable Name
  0.07103;                 ! Block 3 Cost per Unit Value or Variable Name

Schedule:Compact, TwoSeasonSchedule, number,
Through: 5/31, For: AllDays, Until: 24:00, 1,
Through: 9/30, For: AllDays, Until: 24:00, 3,
Through: 12/31, For: AllDays, Until: 24:00, 1;
```

### 3.11.0.5 Example E – kWh/kW Energy Charges

A more advanced rate varies the size of the blocks based on amount of demand for the month. This creates an effective demand charge if the blocks have declining values.

Customer Charge: \$14.00 per month

Energy Charge: 8.756 cents/kWh for all consumption not greater than 200 hours times the demand  
6.812 cents/kWh for all consumption in excess of 200 hours and not greater than  
400 hours times the demand

5.029 cents/kWh for all consumption in excess of 400 hours times the demand.

This tariff would use a single **UtilityCost:Charge:Block** object. The monthly charge is part of the **UtilityCost:Tariff** object. In this case the Block Size Multiplier Value (or Variable) is set to the totalDemand variable.

```
UtilityCost:Tariff,
  ExampleE,                ! Name
  Electricity:Facility,     ! Output Meter Name
  KWh,                     ! Conversion Factor Choice
  ,                         ! Energy Conversion Factor
  ,                         ! Demand Conversion Factor
  ,                         ! Time of Use Period Schedule Name
  ,                         ! Season Schedule Name
  ,                         ! Month Schedule Name
  ,                         ! Demand Window Length
  14;                      ! Monthly Charge or Variable Name

UtilityCost:Charge:Block,
  BlockEnergyCharge,       ! Charge Variable Name
  ExampleE,                ! Tariff Name
  totalEnergy,             ! Source Variable
  Annual,                  ! Season
  EnergyCharges,           ! Category Variable Name
  ,                         ! Remaining Into Variable
  totalDemand,             ! Block Size Multiplier Value or Variable Name
  200,                     ! Block Size 1 Value or Variable Name
  0.08756,                 ! Block 1 Cost per Unit Value or Variable Name
  200,                     ! Block Size 2 Value or Variable Name
  0.06812,                 ! Block 2 Cost per Unit Value or Variable Name
  remaining,               ! Block Size 3 Value or Variable Name
  0.05029;                 ! Block 3 Cost per Unit Value or Variable Name
```

### 3.11.0.6 Example F – Seasonal Time of Use Energy

Tariffs sometimes have higher costs for energy consumed during the daytime than at night. This example includes energy charges that vary by the time of day and by the season.

Monthly Charge:      \$37.75 per month  
 Winter – October through May  
 On Peak:              8.315 cents/kWh  
 Off-Peak:             2.420 cents/kWh  
 Summer – June through September  
 On Peak:              14.009 cents/kWh  
 Off-Peak:             6.312 cents/kWh

The on-peak period is defined as the hours starting at 10am and ending at 7pm, Monday through Friday for June through September and 3pm to 10pm Monday through Friday for October through May. All other hours are considered off-peak.

The tariff is only applicable for customers that use 50KW for at least one month of the year.

This tariff uses four different **UtilityCost:Charge:Simple** objects to capture the variation with time of the energy cost. The monthly charge is part of the **UtilityCost:Tariff** object.

```
UtilityCost:Tariff,
  ExampleF,                ! Name
  Electricity:Facility,     ! Output Meter Name
  kWh,                     ! Conversion Factor Choice
  ,                         ! Energy Conversion Factor
  ,                         ! Demand Conversion Factor
  TimeOfDaySchedule,      ! Time of Use Period Schedule Name
  TwoSeasonSchedule,      ! Season Schedule Name
  ,                         ! Month Schedule Name
```

```
Schedule: Compact, TimeOfDaySchedule, number,
Through: 5/31, For: AllDays, Until: 15:00, 3,
                                Until: 22:00, 1,
                                Until: 24:00, 3,
Through: 9/30, For: AllDays, Until: 10:00, 3,
                                Until: 19:00, 1,
                                Until: 24:00, 3,
Through: 12/31, For: AllDays, Until: 15:00, 3,
                                Until: 22:00, 1,
                                Until: 24:00, 3;
```

### 3.11.0.7 Example G – Blocks within Blocks

Utilities have come up with many different ways to encourage certain load factors and discourage other load factors. One method that has been used is blocks defined within other blocks. In the following example standard kWh blocks exist within the energy allocated for the first of several kWh/kW blocks.

Monthly Charge: \$35 per month

Energy Charge: For all consumption not greater than 200 hours times the demand use

10.32 cents/kWh for the first 1000 kWh

7.43 cents/kWh for the next 4000 kWh

6.23 cents/kWh for the next 5000 kWh

4.27 cents/kWh for the remaining kWh less than 200 hours times the demand

6.82 cents/kWh for all consumption in excess of 200 hours and not greater than

400 hours times the demand

5.03 cents/kWh for all consumption in excess of 400 hours times the demand.

To set up this “block within a block” a **UtilityCost:Charge:Block** is first used to separate out the first 200 kWh/kW. The “EnergyFirst200kWhPerkW” charge performs this. It uses demand to multiply the first block size by 200 and the “cost” for the block is simply 1 since it passes through the energy to the variable “EnergyFirst200kWhPerkW”. The remaining energy goes into the “restOfEnergy” variable as specified as the “Remaining Into Variable” field. After this is evaluated we have two new variables that hold energy. Each of these variables are then separately used in **UtilityCost:Charge:Block** objects to evaluate the different parts of the example tariff. By using the “Remaining Into Variable” along with the concept of variables, many very complex tariffs may be modeled.

```

### 3.11.0.8 Example H – Real Time Pricing

Some utilities have tariffs that can have different prices every hour of the year called Real Time Pricing tariffs. Often the utility will inform the customer of the prices for each hour of the day just one day in advance. To model this type of utility rate a normal schedule is used that contains the prices on an hourly basis. The “Charge Schedule” field is where the Schedule object containing the prices is referenced. In addition, the “Baseline Use Schedule” field is used to set the schedule for the customer baseline load. Not all utilities use a customer baseline load so the field can be left blank if none is needed. The Period, Season and Month Schedules are not needed for these tariffs unless UtilityCost:Charge’s are used. The [Schedule:File](#) object can be especially useful to input a complex schedule that changes throughout the year.

Example H, shown below, is an example of how to use the [UtilityCost:Tariff](#) object with a schedule to calculate a utility tariff using real time prices. The example real time pricing schedule results in the same energy cost as Example F – Seasonal Time of Use Energy. This is only an example and usually for real time pricing the schedule values would vary throughout the year.

! EXAMPLE H - Real Time Pricing (RTP)

```

### 3.11.0.9 Example I – Selling and Net-Metering

When the building contains a generator, photovoltaics, or other sources of electrical power, there is an opportunity for the building generator to produce more power than the building uses. The excess power can either be sold to the utility or offset the energy purchased.

When the excess power is sold, two utility rates need to be defined. The first can be defined just as in any of the previous examples. Since the “Buy or Sell” field of the **UtilityCost:Tariff** object defaults to “buyFromUtility” it does not even need to be specified. The meter specified in the “Output Meter” is usually set to “ElectricityPurchased:Facility.”

The second tariff needs to be defined with the “Buy or Sell” field set to “sellToUtility.” The “Output Meter” is usually set to “ElectricitySurplusSold:Facility.” It is important to set the appropriate meters that correspond with the “Buy or Sell” field. The example below shows an tariff that sells the excess electricity back to utility. The **UtilityCost:Charge:Simple** object contains a “Cost Per Value” with a negative number. A negative number is critical if a credit for selling this electricity is expected.

#### ! EXAMPLE I - Selling

```

UtilityCost:Charge:Simple,
  GeneratedElectricSold,    !- Charge Variable Name
  ExampleI-Sell,           !- Tariff Name
  totalEnergy,             !- Source Variable
  Annual,                  !- Season
  EnergyCharges,           !- Category Variable Name
  -0.02;                   !- Cost Per Unit Value (or Variable)

UtilityCost:Tariff,
  ExampleI-Sell,           !- Name
  ElectricitySurplusSold:Facility, !- Output Meter Name
  kWh,                    !- Conversion Factor Choice
  ,                        !- Energy Conversion Factor
  ,                        !- Demand Conversion Factor
  ,                        !- Time of Use Period Schedule Name
  ,                        !- Season Schedule Name
  ,                        !- Month Schedule Name
  ,                        !- Demand Window Length
  ,                        !- Monthly Charge or Variable Name
  ,                        !- Minimum Monthly Charge or Variable Name
  ,                        !- Real Time Pricing Charge Schedule Name
  ,                        !- Customer Baseline Load Schedule Name
  ,                        !- Group Name
  sellToUtility;           !- Buy Or Sell

```

```
UtilityCost:Charge:Simple,
```

---

```

GeneratedElectricSold,    !- Charge Variable Name
ExampleI-Sell,           !- Tariff Name
totalEnergy,             !- Source Variable
Annual,                  !- Season
EnergyCharges,           !- Category Variable Name
-0.02;                   !- Cost Per Unit Value or Variable Name

```

---

The next part of this example is a rate that uses net-metering. With net metering the meter conceptually turns backwards when the energy is being sold to the utility directly reducing the energy consumption being charged. Effectively, the rate charge for purchased electricity is the same as the rate credited for electricity sold to the utility. In this the “Buy or Sell” field should be set to “netMetering.” It is also important the “Output Meter” is set to a meter that represents net metering such as “ElectricityNet:Facility.” The following example shows a simple example tariff using net metering with a single UtilityCost:Charge:Simple:

```

!  EXAMPLE I - Net Metering

UtilityCost:Tariff,
  ExampleI-NetMeter,      !- Name
  ElectricityNet:Facility, !- Output Meter Name
  kWh,                   !- Conversion Factor Choice
  ,                       !- Energy Conversion Factor
  ,                       !- Demand Conversion Factor
  ,                       !- Time of Use Period Schedule Name
  ,                       !- Season Schedule Name
  ,                       !- Month Schedule Name
  ,                       !- Demand Window Length
  30.00,                  !- Monthly Charge or Variable Name
  ,                       !- Minimum Monthly Charge or Variable Name
  ,                       !- Real Time Pricing Charge Schedule Name
  ,                       !- Customer Baseline Load Schedule Name
  ,                       !- Group Name
  netMetering;           !- Buy Or Sell

UtilityCost:Charge:Simple,
  NetMeteredCharge,      !- Charge Variable Name
  ExampleI-NetMeter,     !- Tariff Name
  totalEnergy,           !- Source Variable
  Annual,                 !- Season
  EnergyCharges,         !- Category Variable Name
  0.065;                  !- Cost Per Unit Value or Variable Name

```

---

## 3.12 UtilityCost:Tariff Reporting

A standardized tabular output report is created which shows all components of all categories in the calculation sequence on a variable basis (usually 12 numbers, one for each month). The economics reports may be requested by specifying TariffReport and EconomicResultSummary in the **Output:Table:SummaryReports** object. They are also generated with any of the AllSummary options. The values reported are in the units specified in the **UtilityCost:Tariff** object. The report includes:

## 3.13 Economic Results Summary Report

- Annual Cost – Shows the annual cost for qualified and selected electric and gas tariffs and the total cost

- **Tariff Summary** – For each tariff included shows if that tariff was selected, if it was qualified, what meter it was connected to, what group it was part of, and the annual cost. The qualified tariff with the lowest annual cost for each of the meters is indicated as “selected” and shown in the Annual Cost section of the report. If multiple groups are defined, a tariff is selected from each group.

### **Tariff Summary**

- **Summary table** – Shows the if that tariff was selected, if it was qualified, which qualifier disqualified the tariff, what meter it was connected to, what group it was part of, if the computation was based on a user defined computation or was automatic.
- **Categories** – Shows the monthly results of all the category variables.
- **Charges** – Shows the monthly results for all of the simple and block charges.
- **Ratchets** – Shows the monthly results for all ratchets.
- **Qualifies** – Shows the monthly results for all qualifies.
- **Native Variables** – Shows the monthly values for the native variables such as TotalEnergy and TotalDemand.
- **Other Variables** – Shows the monthly values for any other variables not appearing in the other tables.
- **Computation** – Shows the computational steps used including those generated automatically.

The report is part of the tabular report and is created using the same style as specified for the tabular reports.

## **3.14 Complex Tariff Modeling**

Much can be accomplished with the **UtilityCost:Charge:Simple** and **UtilityCost:Charge:Block** objects. In almost all cases, these structures are flexible enough to model the tariff. At times the built in approach is not sufficient to model a particular rate. In those cases, the rate may be modeled by using the **UtilityCost:Computation** object. For most rates this object can be omitted but for difficult to model rates, they may be used to modify the normal way the rate computation is performed.

Each **ComputeStep** is performed in order and can be either a variable followed by an expression or simply a variable.

- demandMod SUM demand1 demand2
- chargeSummer1

The normal calculations associated with the **UtilityCost:Qualify**, **UtilityCost:Charge:Simple**, **UtilityCost:Charge:Block**, or **UtilityCost:Ratchet** are performed the first time that object is called. Subsequent times are not recomputed but use the value stored in the appropriate variable. The result of the computation for those objects is available in the expression for further computation. The expressions allow the manipulation of variables directly using simple mathematical functions. Only variable names may be entered along with operators. Numbers may not be entered and should be entered with **UtilityCost:Variable**. Multiple operators are allowed per step. Variables names do not include spaces. If spaces are found in a variable name then an error is shown. Unused variables are flagged with a warning. All expressions are in the form:

- assignedToVariable OPERATOR variable1 variable2

Each step is performed for each of the months before the next step is taken. The same operation is performed for each step as specified.

The actual evaluation of the expression is performed from the end of the line to the beginning using stack based operations. Some operators pull all values from the stack (SUM, MAXIMUM, MINIMUM) while most use just one or two values from the stack. All operations return a single value to the stack. This stack based approach to expressions is sometimes called Polish Notation. While multiple operators are allowed per line, it reduces confusion if each line has only a single operator.

When the **UtilityCost:Computation** object is used, it must contain references to all objects involved in the rate in the order that they should be computed. No checking is performed for objects that should or should not be included; instead, the computational process is driven completely by the input of this object.

A typical rate will have a simple series of steps. For example F the following steps would be created automatically by the software:

```
UtilityCost:Computation,
  SpecialStepsForF,           !- Name
  ExampleF,                   !- Tariff Name
  EnergyCharges SUM SummerOnPeak SummerOffPeak WinterOnPeak WinterOffPeak, Compute Step 1
  Basis SUM EnergyCharges DemandCharges ServiceCharges, Compute Step 2
  SubTotal SUM Basis Adjustments Surcharges, Compute Step 3
  Total SUM SubTotal Taxes, Compute Step 4
  MinDemand; Compute Step 5
```

This example does not have any dependency of different charges that are summed on the same line but if it did the charges could appear by themselves on lines and this would indicate the order that they should be computed. Here is the same example again showing that form.

```
UtilityCost:Computation,
  SpecialStepsForF,           !- Name
  ExampleF,                   !- Tariff Name
  SummerOnPeak,               !- Compute Step 1
  SummerOffPeak,              !- Compute Step 2
  WinterOnPeak,               !- Compute Step 3
  WinterOffPeak,              !- Compute Step 4
  EnergyCharges SUM SummerOnPeak SummerOffPeak WinterOnPeak WinterOffPeak, !- Compute Step 5
  Basis SUM EnergyCharges DemandCharges ServiceCharges, !- Compute Step 6
  SubTotal SUM Basis Adjustments Surcharges, !- Compute Step 7
  Total SUM SubTotal Taxes, !- Compute Step 8
  MinDemand; !- Compute Step 9
```

This second expanded format is generated automatically when no **UtilityCost:Computation** object is provided.

The functions built in are (number of arguments in parentheses):

#### 3.14.0.1 Operator: SUM (unlimited)

Adds together all of the variable values for each month for as many variables that are used.

#### 3.14.0.2 Operator: ADD (2)

Adds together the first variable value with the second variable value.

#### 3.14.0.3 Operator: MULTIPLY (2)

Multiplies the first variable value with the second variable value. MULT may also be used.

**3.14.0.4 Operator: SUBTRACT (2)**

Subtracts the second variable value from the first variable value. SUBT may also be used.

**3.14.0.5 Operator: DIVIDE (2)**

Divides the first variable value by the second variable value. DIV may also be used.

**3.14.0.6 Operator: ABSOLUTE (1)**

Takes the absolute value of the variable value. This turns negative values into positive ones. ABS may also be used.

**3.14.0.7 Operator: INTEGER (1)**

Removes non-integer portions of the variable values. INT may also be used.

**3.14.0.8 Operator: SIGN (1)**

Returns a 1 for positive values, -1 for negative values and 0 for zero values.

**3.14.0.9 Operator: MAXIMUM (unlimited)**

Selects the maximum value across variables for each of the months. Two or more variables may be used. MAX may also be used.

**3.14.0.10 Operator: MINIMUM (unlimited)**

Selects the minimum value across variables for each of the months. Two or more variables may be used. MIN may also be used.

**3.14.0.11 Operator: EXCEEDS (2)**

Returns the difference between the first and second variable if the first variable is greater than the second. If the second variable is greater or equal to the first variable returns a zero.

**3.14.0.12 Operator: ANNUALMINIMUM (1)**

Returns the minimum value of the twelve months in the variable. Zero values are ignored (see also ANNUALMINZERO). If all values are zero then zero is returned. ANMIN may also be used.

**3.14.0.13 Operator: ANNUALMAXIMUM (1)**

Returns the maximum value of the twelve months in the variable. Zero values are ignored (see also ANNUALMAXZERO). If all values are zero then zero is returned. ANMAX may also be used.

**3.14.0.14 Operator: ANNUALSUM (1)**

Returns the sum of the twelve months in the variable. ANSUM may also be used.

**3.14.0.15 Operator: ANNUALAVERAGE (1)**

Returns the sum of the twelve monthly values divided by the number of non-zero monthly values. If all values are zero then zero is returned. If an average is desired that includes zero valued elements the SUM() function should be used divided by 12. ANAVG may also be used.

**3.14.0.16 Operator: ANNUALOR (1)**

Returns 1 for all monthly values if any of the monthly values are non-zero. ANOR may also be used.

**3.14.0.17 Operator: ANNUALAND (1)**

Returns 1 for all monthly values if all of the monthly values are non-zero. ANAND may also be used.

**3.14.0.18 Operator: ANNUALMAXIMUMZERO (1)**

Returns the maximum value of the twelve monthly values in x. Zeros are counted so if a zero is the largest value (the rest would be negative) a zero may be returned. ANMAXZ may also be used.

**3.14.0.19 Operator: ANNUALMINIMUMZERO (1)**

Returns the minimum value of the twelve monthly values in x. Zeros are counted. ANMINZ may also be used.

**3.14.0.20 Operator: IF (3)**

Returns the value of the second variable if the first variable is non-zero otherwise returns the value of the third variable. Usually used with GT, GE, LT, LE, EQ, NE operators.

**3.14.0.21 Operator: GREATERTHAN (2)**

1 if the first variable value is greater than the second variable value otherwise 0. GT may also be used.

**3.14.0.22 Operator: GREATEREQUAL (2)**

1 if the first variable value is greater than or equal to the second variable value otherwise 0. GE may also be used.

**3.14.0.23 Operator: LESSTHAN (2)**

1 if the first variable value is less than the second variable value otherwise 0. LT may also be used.

**3.14.0.24 Operator: LESSEQUAL (2)**

1 if the first variable value is less than or equal to the second variable value otherwise 0. LE may also be used.

**3.14.0.25 Operator: EQUAL (2)**

1 if the first variable value is equal to the second variable value otherwise 0. EQ may also be used.

**3.14.0.26 Operator: NOTEQUAL (2)**

1 if the first variable value is not equal to the second variable value otherwise 0. NE may also be used.

**3.14.0.27 Operator: AND (2)**

1 if the first variable value and second variable values are both not zero otherwise 0.

**3.14.0.28 Operator: OR (2)**

1 if the first variable value and second variable values are either not zero, otherwise 0 if both the first and second variable value are both zero.

**3.14.0.29 Operator: NOT (2)**

1 if the first variable value and only variable value is zero otherwise 0 if the first variable value is not zero.

**3.14.0.30 Operator: FROM (Unlimited)**

Indicates what variables a variable is dependant on (or derived from). No computation is performed. The algorithm that creates the automatic sequence of equations uses these to indicate when variables are dependant on other variables so that they can be sorted into the correct order.

## 3.15 Cost Estimating

In order to understand how to include cost estimates, it may be helpful to first define some terminology and provide an overview of the process used in EnergyPlus. There are three broad steps involved. The first involves determining *construction* costs by summing individual “line items.” The second involves determining *project* costs by adjusting construction costs to account for things like profit and design fees. The third involves comparing the current simulation to a reference case so that marginal increases can be calculated. Each of these steps involves using one of the three ‘ComponentCost’ objects described below.

### 3.15.1 ComponentCost:LineItem

Each instance of this object creates a cost line item and will contribute to the total for a cost estimate. Each line item is reported in table form in the tabular report file. The user must request that this report be generated by including a **Output:Table:SummaryReports** object with the Component Cost Economics Summary option selected. The style of a tabular report can be controlled using the **OutputControl:Table:Style** object.

Cost estimates are not currently general in that they cannot be performed for every type of component that could be included in an EnergyPlus model. Although a “General” option is available where all information needed for the cost line item is input by the user, the usefulness of cost modeling within EnergyPlus is expected to be enhanced when quantities are obtained from elsewhere in the input file or computed during a simulation. The cost computations are programmed in selected ways for selected objects. The objects available and the type of cost modeling that may be performed are discussed in detail in the discussion of Reference Object Type field. A particular instance of this object will always have many blank fields. Entering values in too many fields may cause an error because the program may determine how a particular cost is to be calculated based on the presence of non-zero values in particular fields. The input object includes fields that are reserved for future use in expanded cost estimate and investment analyses planned for future versions of EnergyPlus. If you would like to request additional

objects or different methods of modeling component costs, feel free to describe your needs and submit a request via email to [energyplus-support@gard.com](mailto:energyplus-support@gard.com).

### 3.15.1.1 Inputs

#### 3.15.1.1.1 Field: Name

This field is a user-selected name that will appear in the line item description of the cost report. It is not used in the calculation but allows identifying a line item in the subsequent report.

#### 3.15.1.1.2 Field: Type

This field is not yet used and may be left blank.

#### 3.15.1.1.3 Field: Line Item Type

The cost estimate line item calculation will be controlled by the name entered in this field. The requirements for the remaining input, and the cost calculations performed, will vary depending on the object referenced here. Only selected objects can be entered here. The objects available for cost estimating are listed in the following table showing the active fields and options available for each.

Table 3.6: Cost Line Item Types (ref Objects)

Object Types available (choice keys)	Cost per each	Cost per m <sup>2</sup>	Cost per kW	Cost per kW*COP	Cost per m <sup>3</sup>	Cost per m <sup>3</sup> /s	Cost per W/K	Qty	Wildcard for Name
General	X							X	
Construction		X							
Coil:DX Coil:Cooling:DX: SingleSpeed	X		X	X					X
Coil:Heating:Fuel	X		X	X					X
Chiller:Electric	X		X	X					
Daylighting:Controls	X								X
Shading:Zone:Detailed		X							
Lights	X		X						
Generator:Photovoltaic			X						

#### General

This choice of object is used to calculate costs in a general way. No quantities from internal calculations are used. All information needed for the cost line item is input by the user. The Cost per Each and the Quantity fields that follow need to have values.

#### Construction

This choice of object type is used to calculate the costs associated with surfaces based on the type of **Construction** used for the surface. Costs are entered on a per-square-meter basis. The program finds all the surfaces that have the type of **Construction** named in the Reference Object Name field that follows and determines the total area. If the model includes duplicate surfaces, as for interior partitions or floors,

these will be detected and not double-counted. The cost entered in **Cost per Area** field (\$/m<sup>2</sup>) is used for each surface. The line item subtotal is calculated by multiplying the number of units by **Cost per Area**. The **Cost per Area** should include all the material layers defined in the **Construction**.

### **Coil:DX or Coil:Cooling:DX:SingleSpeed**

This choice of object type is used to calculate the cost of direct expansion cooling equipment. Cost can be entered in three different ways, (1) per each, (2) per kW total cooling capacity, or (3) per kW total cooling capacity per COP (coefficient of performance). The program will determine which method to use by examining which input fields have non-zero values. It is an error to specify costs in more than one way. The per-each approach is most useful for discrete packages. The per-kW approach is useful for autosizing DX coils with the same COP. The per-kW-per-COP approach is convenient for modeling autosized DX coils with differing COPs as long as a linear relationship is sufficient.

The wildcard character “\*” may be used in the object name field that follows to allow a single line item to include all of the DX coils in the model.

### **Coil:Heating:Fuel**

This choice of object type is used to calculate the cost of gas-fired heating equipment. Cost can be entered in three different ways, (1) per each, (2) per kW of heating capacity, or (3) per kW total cooling capacity per nominal efficiency (actually uses the per kW per COP field). The program will determine which method to use by examining which input fields have non-zero values. It is an error to specify costs in more than one way. The per-each approach is most useful for discrete packages. The per-kW approach is useful for autosizing heating coils with the same efficiency. The per-kW-per-Eff approach is convenient for modeling autosized heating coils with differing efficiencies as long as a linear relationship is sufficient.

The wildcard character “\*” may be used in the object name field that follows to allow a single line item to include all of the gas heating coils in the model.

### **Chiller:Electric**

This choice of object type is used to calculate the cost of a central chiller. The object name entered in following field must correspond to a **Chiller:Electric** object name defined elsewhere in the input file. Cost can be entered in three different ways, (1) per each, (2) per kW total cooling capacity or (3) per kW total cooling capacity per COP (coefficient of performance). The program will determine which method to use by examining which input fields have non-zero values. It is an error to specify costs in more than one way. The per-each approach is most useful for discrete chillers. The per-kW approach is useful for autosizing chillers with the same COP. The per-kW-per-COP approach is convenient for modeling autosized chillers with differing COPs as long as a linear relationship is sufficient.

### **Daylighting:Controls**

These choices of object type are used to include the cost of controllers needed to control electric lighting in response to daylight. The only option for entering costs is “per each”. The wildcard character “\*” may be used in the following object name field to allow a single line item to include all of the simple and detailed daylighting controls in the cost model.

### **Shading:Zone:Detailed**

This choice of object type is used to calculate the costs associated with attached shading surfaces. Costs are entered on a per-square-meter basis. The cost calculations are similar to those for heat transfer surfaces but are handled separately because “Construction” is not defined for a shading surface. The object name entered in the following field must correspond to a **Shading:Zone:Detailed** object name defined elsewhere in the input file.

**Lights**

This choice of object is used to calculate the costs associated with electric lighting. Costs are entered on either a cost-per-each basis or as a cost-per-kilowatt-of-design-level. (This design level is an input in the **Lights** object.). The object name entered into the following field must match the name of a Zone object defined elsewhere in the input file.

**Generator:Photovoltaic**

This choice of object is used to calculate the costs associated with a photovoltaic system. Costs are entered on a cost-per-kilowatt-of-rated-capacity. The rated capacity of a photovoltaic generator is calculated for cost modeling by exposing the surface to a 1000 W/m<sup>2</sup> incident radiation using the area fraction and nominal fixed efficiency input by the user (from the **Generator:Photovoltaic** object). The object name entered into the following field must match the name of a **Generator:Photovoltaic** object defined elsewhere in the input file.

**3.15.1.1.4 Field: Item Name**

This field is used to refer to a specific instance of an object. The wildcard character “\*” is acceptable for some objects as described above for the previous field.

**3.15.1.1.5 Field: Object End Use Key**

This field is not yet used and may be left blank.

**3.15.1.1.6 Field: Cost per Each**

This field is used to enter cost information on a per-each basis. The units are dollars (\$).

**3.15.1.1.7 Field: Cost per Area**

This field is used to enter cost information on a per-area basis. The units are dollars per square meter (\$/m<sup>2</sup>).

**3.15.1.1.8 Field: Cost per Unit of Output Capacity**

This field is used to enter cost information on a per-kilowatt basis. The units are dollars per kilowatt (\$/kW).

**3.15.1.1.9 Field: Cost per Unit of Output Capacity per COP**

This field is used to enter cost information on a per-kilowatt-per-COP basis. The units are dollars per kilowatt per non-dimensional COP (\$/kW-COP). Note that this field can be used for **Coil:Heating:Fuel** cost modeling in which case the better terminology would be per-kilowatt-per-non-dimensional-efficiency.

**3.15.1.1.10 Field: Cost per Volume**

This field is not yet used but will be used to enter cost information on a per-cubic-meter basis. The units are dollars per cubic meter (\$/m<sup>3</sup>).

**3.15.1.1.11 Field: Cost per Volume Rate**

This field is not yet used but will be used to enter cost information on a per-cubic-meter-per-second basis. The units are dollars per cubic meter (\$/(m<sup>3</sup>/s)).

### 3.15.1.1.12 Field: Cost per Energy per Temperature Difference

This field is not yet used but will be used to enter cost information on a per-watt-per-Kelvin basis. These units will be used to represent a UA description of coils and the like. The units are dollars per watt per delta K (\$/(W/K)).

### 3.15.1.1.13 Field: Quantity

This field is used to directly enter the line item quantity. The units should correspond to what is used in the Per Each field.

Some examples of this object in an IDF:

```

ComponentCost:LineItem,

```

## 3.15.2 ComponentCost:Adjustments

This object can be used to perform various modifications to the construction costs to arrive at an estimate for total project costs. This object allows extending the line item model so that the overall costs of the project will reflect various profit and fees. Only one object of this type can be included in the input file. The results are included in the Construction Cost Estimate Summary table by request using the [Output:Table:SummaryReports](#) object with the Component Cost Economics Summary option selected.

### 3.15.2.1 Inputs

#### 3.15.2.1.1 Field: Miscellaneous Cost per Conditioned Area

This optional field can be used to enter a cost model for miscellaneous project costs that are not included in the line item modeling. Miscellaneous costs are entered in dollars per square meter of conditioned floor area. This field allows including the costs of project elements that go beyond what can be modeled using “[ComponentCost:LineItem](#)” input objects including such things as structural components, site preparation, finishes, etc. The value input in this field will be multiplied by the conditioned floor area and listed in the Construction Cost Estimate Summary table. The miscellaneous project costs are added to the line item

model total to determine the “modeled and miscellaneous Construction costs” that will be multiplied by the fractions in the following five fields.

#### 3.15.2.1.2 Field: Design and Engineering Fees

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for design and engineering fees. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.2.1.3 Field: Contractor Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for Contractor fees. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.2.1.4 Field: Contingency

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added for contingency. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.2.1.5 Field: Permits, Bonding and Insurance

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for permitting, bonding, and insurance costs to the project. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.2.1.6 Field: Commissioning Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for commissioning services. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.2.1.7 Field: Regional Adjustment Factor

This optional field can be used to enter an adjustment factor to account for regional differences in construction costs. The factor will be applied to the modeled and miscellaneous construction costs to determine an amount that should be added, or subtracted, to account for local variations in construction costs. The default factor is 1.0. The additive adjustment is calculated by subtracting 1.0 from the value entered in this field. This field is useful for using national average data in the line item and miscellaneous construction cost models and then altering the results based on regional differences.

An example of this object in an IDF is:

```
ComponentCost:Adjustments,
    467, !- Miscellaneous Cost per Conditioned Area
    0.07, !- Design and Engineering Fees
    0.07, !- Contractor Fee
    0.10, !- Contingency
    0.04, !- Permits, Bonding and Insurance
    0.015, !- Commissioning Fee
    1.136, !- Regional Adjustment Factor
```

### 3.15.3 ComponentCost:Reference

This object can be used to allow comparing the current cost estimate to the results of a previous estimate for a reference building. This object parallels the ComponentCost:Adjustment object but adds a field for entering the cost line item model result for the reference building. All the various adjustments to the project cost estimate are available here to allow using factors that differ between the current and

the reference building models. The factors entered in the field associated with this object are applied to the reference building while the factors listed in the `ComponentCost:Adjustment` object are applied to the current building model cost estimate. Only one object of this type can be included in the input file. The results are included in the Construction Cost Estimate Summary table by request using the `Output:Table:SummaryReports` object with the Component Cost Economics Summary option selected.

### 3.15.3.1 Inputs

#### 3.15.3.1.1 Field: Reference Building Line Item Costs

This field is used to enter a dollar amount representing the total for the reference building that the user would like to compare to the line item cost model for the current building model. A typical source of data for this would be the “Line Item Subtotal” from a previous EnergyPlus simulation.

#### 3.15.3.1.2 Field: Reference Building Miscellaneous Cost per Conditioned Area

This optional field can be used to enter a cost model for miscellaneous project costs that are not included in the line item modeling. Miscellaneous costs are entered in dollars per square meter of conditioned floor area. This field allows including the costs of project elements that go beyond what can be modeled using “`ComponentCost:LineItem`” input objects including such things as structural components, site preparation, finishes, etc. The value input in this field will be multiplied by the conditioned floor area and listed in the Construction Cost Estimate Summary table. The miscellaneous project costs are added to the reference building line item subtotal to determine the “modeled and miscellaneous construction costs” that will be multiplied by the fractions in the following five fields.

#### 3.15.3.1.3 Field: Reference Building Design and Engineering Fees

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for design and engineering fees. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.3.1.4 Field: Reference Building Contractor Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for Contractor fees. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.3.1.5 Field: Reference Building Contingency

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added for contingency. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.3.1.6 Field: Reference Building Permits, Bonding and Insurance

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for permitting, bonding, and insurance costs to the project. Note that is not the same as a fraction of the total cost estimate.

#### 3.15.3.1.7 Field: Reference Building Commissioning Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for commissioning services. Note that is not the same as a fraction of the total cost estimate.

### 3.15.3.1.8 Field: Reference Building Regional Adjustment Factor

This optional field can be used to enter an adjustment factor to account for regional differences in construction costs. The factor will be applied to the modeled and miscellaneous construction costs to determine an amount that should be added, or subtracted, to account for local variations in construction costs. The default factor is 1.0. The additive adjustment is calculated by subtracting 1.0 from the value entered in this field. This field is useful for using national average data in the line item and miscellaneous construction cost models and then altering the results based on regional differences.

An example of this object in an IDF is:

```
ComponentCost:Reference,
  683060.000, !- Reference Building Line Item Costs {$}
  467.0, !- Reference Building Miscellaneous Cost per Conditioned Area {$/m2}
  0.060, !- Reference Building Design and Engineering Fees {dimensionless}
  0.070, !- Reference Building Contractor Fee {dimensionless}
  0.100, !- Reference Building Contingency
  0.04, !- Reference Building Permits, Bonding and Insurance {dimensionless}
  0.0075, !- Reference Building Commissioning Fee {dimensionless}
  1.136; !- Reference Building Regional Adjustment Factor {dimensionless}
```

## 3.15.4 Economics Cost Estimate Reporting

Cost estimate results are only output to tabular reports; they are not available in the standard output file (.eso). The results are included in the Construction Cost Estimate Summary table by request using the object **Output:Table:SummaryReports** object with the Component Cost Economics Summary option selected. The figure below shows an example of summary output using html style for tabular reporting. A second table is produced that provides the line item details with one line for every line item object. Per-area cost modeling and cost normalization are based on total conditioned floor area which is also provided in the tabular report.

“Line Item Subtotal” is the sum of items explicitly modeled in the cost estimate. For the reference building, this value is input by the user. For the current building, this value is the sum of line items which are detailed in Cost Line Item Details table that follows.

“Misc. Cost” is the product of the user-defined Miscellaneous Cost Model (per Square Meter) and the conditioned floor area.

“Regional Adjustment” is the product of the user-defined Regional Adjustment Factor and the conditioned floor area.

“Design Fee” is the product of the user-defined Design and Engineering Fee Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Contractor Fee” is the product of the user-defined Contractor Fee Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Contingency” is the product of the user-defined Contingency Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Permits, Bonds, and Insurance” is the product of the Permits, Bonding, Insurance Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Commissioning” is the product of the user-defined Commissioning Fee Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Cost Estimate Total” is the sum of eight items above and represents the total project cost estimate.

“Cost per Conditioned Building Area” is the Cost Estimate Total divided by the total conditioned floor area. This represents a normalized cost intensity.

**Construction Cost Estimate Summary**

Reference Case  
information input by user  
(typ. from previous model)

Current information  
calculated for model

Sub total of  
line items

	Reference Bldg.	Current Bldg.	Model	Difference
Line Item SubTotal (\$)	665082.04	718282.97		53200.93
Misc. Costs (\$)	928979.09	928979.09		0.00
Regional Adjustment (\$)	216792.31	224027.64		7235.33

Figure 3.2: Economics Cost Modeling

## 3.16 Life-Cycle Costing

Life-cycle costing is used with building energy simulation in order to justify energy efficiency upgrades. Many alternative building technologies that result in energy savings cost more initially, or may cost more to maintain, than traditional solutions. In order to justify selecting these energy savings technologies, it is essential to combine both initial and future costs in the decision process. Using life-cycle costs provides a framework to combine initial costs and future costs into a single combined measure, called the “present value.” Present value is a metric that combines all costs and reduces (or discounts) those costs that occur in the future. Discounting future costs is based on the principal of the time value of money.

The calculations are based on discounting the future values according to normal life-cycle costing techniques as described in NIST Handbook 135 “Life-Cycle Costing Manual for the Federal Energy Management Program.”

The following is a list of life-cycle costing related objects that provide a way to describe the parameters and costs associated with the life-cycle of a building or building system:

- `LifeCycleCost:Parameters`
- `LifeCycleCost:RecurringCosts`
- `LifeCycleCost:NonrecurringCost`
- `LifeCycleCost:UsePriceEscalation`
- `LifeCycleCost:UseAdjustment`

The utility costs (see `UtilityCost:Tariff`) and first costs (see `ComponentCost:LineItem`) are calculated by EnergyPlus are used along with other current and future costs input using the `LifeCycleCost:RecurringCosts` and `LifeCycleCost:NonrecurringCost` objects and these are combined into the present value life-cycle cost metric. The `LifeCycleCost:Parameters` object establishes the set of assumptions for the analysis along with `LifeCycleCost:UsePriceEscalation` (often from a DataSet) and `LifeCycleCost:UseAdjustment`.

It is important to understand that the comparison of different simulation results and their present values is not performed by EnergyPlus. Instead, EnergyPlus provides the present value calculations for a specific simulation combining the energy costs, first costs, and future costs and you need to make the comparison between the results of multiple simulations.

The results of using the LifeCycleCost objects are included in the tabular report file when LifeCycleCostReport is specified in the `Output:Table:SummaryReports` object. It is also generated with any of the AllSummary options. The report appearing in the tabular report file is titled “Life Cycle Cost Report.” This report shows the costs and the timing of costs, often called “cash flows,” along with the present value in several different tables. The tabular results would show the present value of all current and future costs.

The datasets file “LCCUsePriceEscalationDataSetXXXX.idf” includes the energy escalation factors from the NIST Handbook 135 annual supplement for the year indicated. These are necessary to use because the expected change in price for electricity and various fuels does not change at the same rate as inflation.

Life-cycle costing should not be confused with life-cycle analysis. With life-cycle costing the result is an economic evaluation of current and future expenditures in order to make a decision on alternative investments. In life cycle analysis, the environmental impact such as equivalent CO<sub>2</sub> production involved in the materials, delivery, manufacturing, and construction are combined with environmental impacts of the building in operation and the eventual removal of the building and is used to understand the overall environmental impact or embodied energy.

## 3.17 LifeCycleCost:Parameters

Provides inputs related to the overall life-cycle analysis. It establishes many of the assumptions used in computing the present value. It is important that when comparing the results of multiple simulations that the fields in the LifeCycleCost:Parameters objects are the same for all the simulations. To aide in this comparison, the first table in the Life-Cycle Cost Report shows the inputs to this object. Only one LifeCycleCost:Parameters object is permitted for a file.

### 3.17.1 Inputs

#### 3.17.1.0.1 Field: Name

An identifying name used for the LifeCycleCost:Parameters object.

#### 3.17.1.0.2 Field: Discounting Convention

The field specifies if the discounting of future costs should be computed as occurring at the end of each year, the middle of each year, or the beginning of each year. The most common discounting convention uses the end of each year. Without a specific reason, the end of each year should be used. Some military projects may specifically require using the middle of each year. The year being used starts with the base year and month and repeats every full year. All costs assumed to occur during that duration are accumulated and shown as an expense either at the beginning, middle or end of the year. The options are:

- BeginningOfYear
- MidYear
- EndOfYear

#### 3.17.1.0.3 Field: Inflation Approach

This field is used to determine if the analysis should use constant dollars or current dollars which is related to how inflation is treated. The two options are:

- ConstantDollar
- CurrentDollar

The default option is ConstantDollars

If ConstantDollar is selected, then the Real Discount Rate input is used and it excludes the rate of inflation. If CurrentDollar is selected, then the Nominal Discount Rate input is used and it includes the rate of inflation. From NIST Handbook 135:

“The constant dollar approach has the advantage of avoiding the need to project future rates of inflation or deflation. The price of a good or service stated in constant dollars is not affected by the rate of general inflation. For example, if the price of a piece of equipment is \$1,000 today and \$1,050 at the end of a year in which prices in general have risen at an annual rate of 5 percent, the price stated in constant dollars is still \$1,000; no inflation adjustment is necessary. In contrast, if cash flows are stated in current dollars, future amounts include general inflation, and an adjustment is necessary to convert the current-dollar estimate to its constant-dollar equivalent. This adjustment is important because constant- and current-dollar amounts must not be combined in an LCCA [life cycle cost analysis].”

For most analyses, using the ConstantDollar option will be easier since the effect of inflation may be ignored.

**3.17.1.0.4 Field: Real Discount Rate**

Enter the real discount rate as a decimal. For a 3% rate, enter the value 0.03. This input is used when the Inflation Approach is ConstantDollar. The real discount rate reflects the interest rates needed to make current and future expenditures have comparable equivalent values when general inflation is ignored. When Inflation Approach is set to CurrentDollar this input is ignored. If this field is blank and Inflation Approach is ConstantDollar, a warning is issued.

**3.17.1.0.5 Field: Nominal Discount Rate**

Enter the nominal discount rate as a decimal. For a 5% rate, enter the value 0.05. This input is used when the Inflation Approach is CurrentDollar. The real discount rate reflects the interest rates needed to make current and future expenditures have comparable equivalent values when general inflation is included. When Inflation Approach is set to ConstantDollar this input is ignored. If this field is blank and Inflation Approach is CurrentDollar, a warning is issued.

**3.17.1.0.6 Field: Inflation Rate**

Enter the rate of inflation for general goods and services as a decimal. For a 2% rate, enter the value 0.02. If this field is not blank and Inflation Approach is ConstantDollar, a warning is issued.

**3.17.1.0.7 Field: Base Date Month**

Enter the month that is the beginning of study period, also known as the beginning of the base period. According to NIST 135 “the base date is the point in time to which all project-related costs are discounted in an LCCA [life cycle cost analysis]. The base date is usually the first day of the study period for the project, which in turn is usually the date that the LCCA is performed. In a constant dollar analysis, the base date usually defines the time reference for the constant dollars (e.g. 1995 constant dollars). It is essential that you use the same base data and constant-dollar year for all of the project alternatives to be compared. If you set the base date to the date that the LCCA is performed, then the constant dollar basis for the analysis will be the current date, and you can use actual costs as of that date without adjusting for general inflation.”

The choices are:

- January
- February
- March
- April
- May
- June
- July
- August
- September
- October
- November
- December

The default value is January.

This field could also be referred to as part of “the date of study.” It is used as the date for constant dollars.

#### **3.17.1.0.8 Field: Base Date Year**

Enter the four digit year that is the beginning of study period, such as a year expressed in four digits like “2013”. The study period is also known as the base period. See more details in the previous field.

#### **3.17.1.0.9 Field: Service Date Month**

Enter the month that is the beginning of building occupancy. Energy costs computed by EnergyPlus are assumed to occur during the year following the service date. The service date must be the same or later than the Base Date. The choices are:

- January
- February
- March
- April
- May
- June
- July
- August
- September
- October
- November
- December

The default value is January. According to NIST Handbook 135:

“The service date is the date on which the project is expected to be implemented; operating and maintenance costs (including energy- and water-related costs) are generally incurred after this date, not before.”

This field could also be referred to as part of “beneficial occupancy date.”

#### **3.17.1.0.10 Field: Service Date Year**

Enter the four digit year that is the beginning of occupancy, such as two years after the previously entered year expressed in four digits like “2013”. See more details in the previous field.

#### **3.17.1.0.11 Field: Length of Study Period in Years**

Enter the number of years of the study period. It is the number of years that the study continues based on the start at the base date. The default value is 25 years and the maximum study period is 100 years. Only integers may be used indicating whole years. According to NIST Handbook 135, “the study period for an LCCA is the time over which the costs and benefits related to a capital investment decision are of interest to the decision maker. Thus, the study period begins with the base date and includes both the [planning/construction] period (if any) and the relevant service period for the project. The service period begins with the service date and extends to the end of the study period.”

**3.17.1.0.12 Field: Tax rate**

Enter the overall marginal tax rate for the project costs. This does not include energy or water taxes. The single tax rate entered here is not intended to be a replacement of the complex calculations necessary to compute personal or corporate taxes; instead it is an approximate that may be used for a simple analysis assuming a constant tax rate is applied on all costs. The tax rate entered should be based on the marginal tax rate for the entity and not the average tax rate. Enter the tax rate results in present value calculations after taxes. Most analyses do not factor in the impact of taxes and assume that all options under consideration have roughly the same tax impact. Due to this, many times the tax rate can be left to default to zero and the present value results before taxes are used to make decisions. The value should be entered as a decimal value. For 15% enter 0.15. For an analysis that does not include tax impacts, enter 0.0. The default is 0.

**3.17.1.0.13 Field: Depreciation Method**

For an analysis that includes income tax impacts, this entry describes how capital costs are depreciated. According to IRS Publication 946 – How to Depreciate Property “Depreciation is an annual income tax deduction that allows you to recover the cost or other basis of certain property over the time you use the property. It is an allowance for Fair market value the wear and tear, deterioration, or obsolescence of the Intangible property.” Details on which depreciation method to choose depends on the property being depreciated and IRS Publication 946 and your accountant are the best sources of information in determining which depreciation method to choose. Only one depreciation method may be used for an analysis and is applied to all capital expenditures. Only analyses that include tax impacts need to select a depreciation method.

The options are:

- ModifiedAcceleratedCostRecoverySystem-3year
- ModifiedAcceleratedCostRecoverySystem-5year
- ModifiedAcceleratedCostRecoverySystem-7year
- ModifiedAcceleratedCostRecoverySystem-10year
- ModifiedAcceleratedCostRecoverySystem-15year
- ModifiedAcceleratedCostRecoverySystem-20year
- StraightLine-27year
- StraightLine-31year
- StraightLine-39year
- StraightLine-40year
- None

Depreciation allowances reduce the actual/nominal tax dollars paid by the owner. Thus, analyses using depreciation should be conducted in nominal dollars. For an analysis that does not include tax effects, None should be selected.

The default value is None.

An example of this object in an IDF:

```

LifeCycleCost:Parameters,

```

---

## 3.18 LifeCycleCost:RecurringCosts

Recurring costs are costs that repeat over time on a regular schedule during the study period. If costs associated with equipment do repeat but not on a regular schedule, use **LifeCycleCost:NonrecurringCost** objects instead. Costs related to energy usage are not included here. The **UtilityCost:Tariff** and other **UtilityCost** objects can be used to compute energy costs that are automatically included in the life-cycle cost calculations

### 3.18.1 Inputs

#### 3.18.1.0.1 Field: Name

The identifier used for the object. The name is used in identifying the cash flow equivalent in the output results in the Life-Cycle Cost Report.

#### 3.18.1.0.2 Field: Category

Enter the category of the recurring costs. Choose the closest category. The options include:

- Maintenance
- Repair
- Operation
- Replacement
- MinorOverhaul
- MajorOverhaul
- OtherOperational

The default value is Maintenance.

For recommendations on estimating other operational costs, see NIST 135 Section 4.6.3.

#### 3.18.1.0.3 Field: Cost

Enter the cost in dollars (or the appropriate monetary unit) for the recurring costs. Enter the cost for each time it occurs. For example, if the annual maintenance cost is \$500, enter 500 here.

**3.18.1.0.4 Field: Start of Costs**

Enter when the costs start. The First Year of Cost is based on the number of years past the Start of Costs. For most maintenance costs, the Start of Costs should be Service Period. The options are:

- ServicePeriod
- BasePeriod

The default value is ServicePeriod.

**3.18.1.0.5 Field: Years From Start**

This field and the Months From Start field together represent the time from either the start of the Service Period, on the service month and year, or start of the Base Period, on the base month and year (depending on the Start of Costs field) that the costs start to occur. Normally, for most maintenance costs that begin in the first year that the equipment is in service the Start of Costs is the Service Period and the Years from Start will be 0. Only integers should be entered representing whole years. The default value is 0.

**3.18.1.0.6 Field: Months From Start**

This field and the Years From Start field together represent the time from either the start of the Service Period, on the service month and year, or start of the Base Period, on the base month and year (depending on the Start of Costs field) that the costs start to occur. Normally, for most maintenance costs the Start of Costs is the Service Period and the Months from Start will be 0. Only integers should be entered representing whole months. The Years From Start (times 12) and Months From Start are added together. The default value is 0.

**3.18.1.0.7 Field: Repeat Period Years**

This field and the Repeat Period Months field indicate how much time elapses between reoccurrences of the cost. For costs that occur every year, such as annual maintenance costs, the Repeat Period Years should be 1 and Repeat Period Months should be 0. Only integers should be entered representing whole years. The default value is 1.

**3.18.1.0.8 Field: Repeat Period Months**

This field and the Repeat Period Years field indicate how much time elapses between reoccurrences of the cost. For costs that occur every year the Repeat Period Years should be 1 and Repeat Period Months should be 0. For, costs that occur every eighteen months, the Repeat Period Years should be 1 and the Repeat Period Months should be 6. Only integers should be entered representing whole years. The Repeat Period Years (times 12) and Repeat Period Months are added together. The default value is 0.

**3.18.1.0.9 Field: Annual Escalation Rate**

Enter the annual escalation rate as a decimal. For a 1% rate, enter the value 0.01. This input is used when the Inflation Approach is CurrentDollar. When Inflation Approach is set to ConstantDollar this input is ignored. The default value is 0.

An example of this object in an IDF:

```
LifeCycleCost:RecurringCosts,
    AnnualMaint,      !- Name
    Maintenance,      !- Category
    2000,              !- Cost
    ServicePeriod,     !- Start of Costs
    0,                 !- Years from Start
```

---

```

0,          !- Months from Start
1,          !- Repeat Period Years
0,          !- Repeat Period Months
0;          !- Annual escalation rate

```

---

## 3.19 LifeCycleCost:NonrecurringCost

A non-recurring cost happens only once during the study period. For costs that occur more than once during the study period on a regular schedule, use the LifeCycleCost:RecurringCost object.

### 3.19.1 Inputs

#### 3.19.1.0.1 Field: Name

The identifier used for the object. The name is used in identifying the cash flow equivalent in the output results in the Life-Cycle Cost Report.

#### 3.19.1.0.2 Field: Category

Enter the category of the non-recurring costs. Choose the closest category. The options include:

- Construction
- Salvage
- OtherCapital

The default is Construction.

For recommendations on estimating capital and salvage (residual) costs, see NIST 135 Section 4.5.

#### 3.19.1.0.3 Field: Cost

Enter the non-recurring cost value. For construction and other capital costs the value entered is typically a positive value. For salvage costs, the value entered is typically a negative value which represents the money paid to the investor for the equipment at the end of the study period.

#### 3.19.1.0.4 Field: Start of Costs

Enter when the costs start. The First Year of Cost is based on the number of years past the Start of Costs. For most non-recurring costs the Start of Costs should be Base Period which begins at the base month and year. The options are:

- ServicePeriod
- BasePeriod

The default value is BasePeriod

#### 3.19.1.0.5 Field: Years From Start

This field and the Months From Start field together represent the time from either the start of the Service Period, on the service month and year, or start of the Base Period, on the base month and year (depending on the Start of Cost field) that the costs start to occur. Normally, for most capital costs the Start of Costs is the Base Period and the Years from Start will be 0. These would be first costs for the building equipment or system. Salvage costs are usually shown as happening in the last year of the analysis. Only integers should be entered representing whole years. The default value is 0.

**3.19.1.0.6 Field: Months From Start**

This field and the Years From Start field together represent the time from either the start of the Service Period, on the service month and year, or start of the Base Period, on the base month and year (depending on the Start of Cost field) that the costs start to occur. Normally, for most capital costs the Start of Costs is the Base Period and the Months from Start will be 0. Only integers should be entered representing whole months. The Years From Start (times 12) and Months From Start are added together. The default value is 0.

An example of this object in an IDF:

```
LifeCycleCost:NonrecurringCost,
    EstimatedSalvage,      !- Name
    Salvage,              !- Category
    -2000,                !- Cost
    ServicePeriod,        !- Start of Costs
    20,                   !- Years from Start
    0;                    !- Months from Start
```

**3.20 LifeCycleCost:UsePriceEscalation**

The LifeCycleCost:UsePriceEscalation object will commonly be part of a dataset on life cycle costs. The values for this object may be found in the annual supplement to NIST Handbook 135 in Tables Ca-1 to Ca-5. A dataset file comes with EnergyPlus in the DataSet directory and includes the LCCUsePriceEscalationDataSetXXXX.idf file which includes the value for the supplement to NIST 135 from the year indicated. The object provides inputs for the escalations of energy and water costs assuming that they change differently than inflation. According to the NIST 135 supplement the values are “present projected fuel price indices for the four Census regions and for the United States. These indices, when multiplied by annual energy costs computed at base-date prices provide estimates of future-year costs in constant base-date dollars. Constant-dollar cost estimates are needed when discounting is performed with a real discount rate (i.e., a rate that does not include general price inflation).”

The LCCUsePriceEscalationDataSetXXXX.idf is periodically updated by the EnergyPlus development team using data available from NIST along with a spreadsheet to convert that data into an IDF dataset file. The NIST 135 annual supplement is available from NIST or through US DOE FEMP program.

<http://www1.eere.energy.gov/femp/program/lifecycle.html>

If requested, NIST personnel will provide a file called ENCOSTxx.TXT which contains the data used to create Table Ca-1 to Table Ca-5 in the supplement. To convert the data in the ENCOSTxx.TXT file to an IDF file, open the ENCOSTxx.TXT file in a text editor and copy the entire contents into the first tab called “Step 1” of the conversion spreadsheet. The conversion spreadsheet file named ConvertENCOSTtoEnergyPlusLifeCycleCost.xls is available upon request from the EnergyPlus development team. The “Step 2” tab separates the data into columns. The “Step 3” tab computes ratios that are the same as Table Ca-1 to Table C1-6 in the supplement. Checking these values against what appears in the printed supplement is recommended. The “Step 4” and “Step 5” tabs rearrange the data and the “Step 6” tab shows the data in a format that can be easily copied and pasted into a new idf dataset file. The final step requires using your text editor to replace the fuel names with those used by EnergyPlus. The replacement names are listed on the “FuelNameConversion” tab.

**3.20.1 Inputs****3.20.1.0.1 Field: Name**

The identifier used for the object. The name usually identifies the location (such as the state, region, country or census area) that the escalations apply to. In addition the name should identify the building

class such as residential, commercial, or industrial and the use type such as electricity, natural gas, or water.

#### **3.20.1.0.2 Field: Resource**

Enter the resource such as:

- Electricity
- ElectricityPurchased
- ElectricityProduced
- ElectricitySurplusSold
- ElectricityNet
- NaturalGas
- Propane
- FuelOilNo1
- FuelOilNo2
- Coal
- Steam
- Gasoline
- Diesel
- OtherFuel1
- OtherFuel2
- Water

#### **3.20.1.0.3 Field: Escalation Start Year**

This field and the Escalation Start Month define the time that corresponds to “Year 1 Escalation” such as a year expressed in four digits like “2013”, when the escalation rates are applied. This field and the Escalation Start Month define the time that escalation begins.

#### **3.20.1.0.4 Field: Escalation Start Month**

This field and the Escalation Start Year define the time that corresponds to “Year 1 Escalation” such as a year expressed in four digits such as “2013”, when the escalation rates are applied. This field and the Escalation Start Year define the time that escalation begins.

The choices are:

- January
- February
- March

- April
- May
- June
- July
- August
- September
- October
- November
- December

The default value is January. According to NIST Handbook 135:

#### 3.20.1.0.5 Field: Year 1 Escalation

The escalation in price of the energy or water use for the first year expressed as a decimal.

#### 3.20.1.0.6 Field: Year n Escalation

The escalation in price of the energy or water use for the n-th year expressed as a decimal. This object often includes 25 to 50 years of projected values. The maximum number of escalations used in a simulation is 100.

If the number of years in LifeCycleCost:UsePriceEscalation is less than the number of years in the analysis period as defined by the Length of Study Period in Years field in the LifeCycleCost:Parameters object, the remaining years will assume no escalation or an escalation of 1. Normal inflation will be the only affect for these years.

An example of this object in an IDF:

```
LifeCycleCost:UsePriceEscalation,
  NorthEast Residential-Electricity,  !- Name
  Electricity,                       !- Resource
  2010,                              !- Escalation Start Year
  January,                           !- Escalation Start Month
  0.9374,                             !- Year 1 Escalation
  0.9790,                             !- Year 2 Escalation
  1.0138,                             !- Year 3 Escalation
  1.0127,                             !- Year 4 Escalation
  1.0096,                             !- Year 5 Escalation
  1.0177,                             !- Year 6 Escalation
  1.0279,                             !- Year 7 Escalation
  1.0334,                             !- Year 8 Escalation
  1.0327,                             !- Year 9 Escalation
  1.0382,                             !- Year 10 Escalation
  1.0454,                             !- Year 11 Escalation
  1.0494,                             !- Year 12 Escalation
  1.0564,                             !- Year 13 Escalation
  1.0587,                             !- Year 14 Escalation
  1.0549,                             !- Year 15 Escalation
  1.0566,                             !- Year 16 Escalation
  1.0630,                             !- Year 17 Escalation
  1.0707,                             !- Year 18 Escalation
  1.0857,                             !- Year 19 Escalation
  1.0953,                             !- Year 20 Escalation
  1.1063,                             !- Year 21 Escalation
  1.1165,                             !- Year 22 Escalation
```

1.1227,	!- Year 23 Escalation
1.1292,	!- Year 24 Escalation
1.1349,	!- Year 25 Escalation
1.1414,	!- Year 26 Escalation
1.1480,	!- Year 27 Escalation
1.1550,	!- Year 28 Escalation
1.1617,	!- Year 29 Escalation
1.1686;	!- Year 30 Escalation

---

## 3.21 LifeCycleCost:UseAdjustment

Used by advanced users to adjust the energy or water use costs for future years. This should not be used for compensating for inflation but should only be used to increase the costs of energy or water based on assumed changes to the actual use of water or energy, such as due to changes in the future function of the building or the impact of future adjacent buildings on energy use. This object is not commonly used and should be used with caution. The adjustments begin at the start of the service period.

### 3.21.1 Inputs

#### 3.21.1.0.1 Field: Name

The identifier used for the object.

#### 3.21.1.0.2 Field: Resource

Enter the resource such as:

- Electricity
- ElectricityPurchased
- ElectricityProduced
- ElectricitySurplusSold
- ElectricityNet
- NaturalGas
- Propane
- FuelOilNo1
- FuelOilNo2
- Coal
- Steam
- Gasoline
- Diesel
- OtherFuel1
- OtherFuel2
- Water

**3.21.1.0.3 Field: Year 1 multiplier**

The multiplier to be applied to the end use cost for the first year in the service period. The total utility costs for the selected end use is multiplied by this value. For no change enter 1.0.

**3.21.1.0.4 Field: Year N multiplier**

The multiplier to be applied to the end use cost for each following year. The total utility costs for the selected end use is multiplied by this value. For no change enter 1.0. This object often includes 25 to 50 years of values. The maximum number of multipliers used in a simulation is 100.

An example of this object in an IDF:

```
LifeCycleCost:UseAdjustment,
  ElecAdjustment,      !- Name
  Electricity,          !- Resource
  1.0000,              !- Year 1 Multiplier
  1.0022,              !- Year 2 Multiplier
  1.0023,              !- Year 3 Multiplier
  1.0024,              !- Year 4 Multiplier
  1.0025,              !- Year 5 Multiplier
  1.0026,              !- Year 6 Multiplier
  1.0027;              !- Year 7 Multiplier
```

---

## 3.22 CurrencyType

By default, the predefined reports related to economics use the \$ symbol. If a different symbol should be shown in the predefined reports to represent the local currency this object can be used. If the object is not used, the \$ sign is used in the reports. Only one CurrencyType object is allowed in the input file.

### 3.22.1 Inputs

**3.22.1.0.1 Field: Monetary Unit**

The commonly used three letter currency code for the units of money for the country or region. Based on ISO 4217 currency codes. Common currency codes are USD for the U.S. Dollar represented with '\$' and EUR for Euros represented with '€'. The three letter currency codes can be seen at the following web sites (as of August 2015):

<https://www.currency-iso.org/en/home/tables/table-a1.html>

<http://www.xe.com/symbols.php>

When a three letter currency code is specified, the HTML file will use either an ASCII character if available or one or more UNICODE characters. Since not all browsers and all fonts used by browsers completely support UNICODE, not all currency symbols may be rendered correctly. If a box or a box with four small letters appears, this indicates that the browser and its fonts do not support a specific UNICODE character.

For text reports, an ASCII representation of the currency code will be used. Since ASCII is much more limited than UNICODE, many times the three letter currency code will be shown in the reports.

Since forms of currency change, please contact EnergyPlus support if a new currency code and symbol are needed.

# Chapter 4

## Parametric Objects

### 4.1 Group – Parametrics

In order to assess a group of alternatives, the Parametric objects can be used in a single file as an alternative of maintaining a group of files with small differences. Updating portions of the multiple files that do not change between permutations becomes tedious and error prone and may lead to incorrect conclusions concerning the energy savings of specific measures. The ParametricPreprocessor.exe program (described in the AuxiliaryPrograms document) interprets the following objects in a single file and creates the group of files automatically. The objects in the group are:

- Parametric:SetValueForRun
- Parametric:Logic
- Parametric:RunControl
- Parametric:FileNameSuffix

A simple example of part of an IDF file is shown below:

```
Parametric:SetValueForRun,
    $insDepth,           !- Parameter Name
    0.0508,              !- Value 1
    0.0762,              !- Value 2
    0.1016,              !- Value 3
    0.1270;              !- Value 4

Material,
    IN1,                 !- Name
    VeryRough,           !- Roughness
    = $insDepth,         !- Thickness {m}
    2.3000000E-02,       !- Conductivity {W/m-K}
    24.00000,            !- Density {kg/m3}
    1590.000,            !- Specific Heat {J/kg-K}
    0.9000000,           !- Thermal Absorptance
    0.5000000,           !- Solar Absorptance
    0.5000000;           !- Visible Absorptance
```

In this example, the parameter \$insDepth is used in the Parametric object to describe the thickness of the material, in this case insulation. For the first simulation, \$insDepth is set to 0.0508 (2 inches) shown as the first value in the Parametric:SetValueForRun object. This value is then substituted in where ever the \$insDepth is shown in the file, in this example, in the Material object. The simulation would use this

first value and produce a set of results based on this insulation thickness. The second simulation would use the second value of the **Parametric:SetValueForRun** object of 0.0762 (3 inches) for the thickness of the insulation described in the **Material** object. This would then be simulated with a second set of results. This would be repeated a third time with 0.1015 (4 inches) and 0.1270 (5 inches) of insulation.

A new IDF file is created for each of these simulations and is named the original name of the file plus either a number or a user defined suffix (if **Parametric:FileNameSuffix** is used). Looking at how these created IDF files show the substituted values can help understand problems that may occur.

The “ = \$insDepth ” is a simple substitution but could also be a more complex expression involving operators and predefined functions such as

$$= \$insDepth * 1.1 + 0.0004 * \text{SQRT}(12)$$

Many sets of simulations can be defined just using different **Parametric:SetValueForRun** objects but for more advanced sets of parametric runs, the **Parametric:Logic** object can be used to perform additional calculations, logical operations, and to exclude entire objects in the file. The **Parametric:RunControl** allows individual runs to be performed or not. The **Parametric:FileNameSuffix** object controls the naming of the resulting sets of output files.

### 4.1.1 Expressions

Expressions can occur anywhere in the IDF file as a field value if the expression begins with an equals sign ( = ) and can also occur in assignment statements in the **Parametric:Logic** object. The operators include: +, -, \*, /, ^ (exponent), && (and), || (or), =, >, <, <=, >=, <>, and //. These are computed using standard operator precedence rules. The parenthesis are used to execute sub-expressions with higher precedence. Some built in functions, such as ABS, ACOS, ASIN, ATAN, COS, EXP, INT, LEN, LOG, MOD, NOT, SIN, SQRT, TAN are supported in expressions. These built in functions all take a single argument.

### 4.1.2 Processing Order

The order that the parameters are processed is important to understand their values. Like other objects in EnergyPlus, the order that they occur in the file is not important. The order of evaluation is:

- 1) Parameter values are based on **Parametric:SetValueForRun**
- 2) All lines of the **Parametric:Logic** object are evaluated
- 3) All embedded expressions in the file are evaluated

### 4.1.3 Parametric:SetValueForRun

The core parametric object is **Parametric:SetValueForRun** which sets the parameters value to different values depending on which run is being simulated.

For example

```
Parametric:SetValueForRun
  $ConstructionToUse,  !- Parameter Name
  TiltUpConcreteWall,  !- Value for run 1
  BlockWall,          !- Value for run 2
  SteelFrameWall,     !- Value for run 3
  WoodFrameWall;      !- Value for run 4

Parametric:SetValueForRun
  $WallRValue,        !- Parameter Name
  5,                  !- Value for run 1
  8,                  !- Value for run 2
  11,                 !- Value for run 3
```

---

```
17;                !- Value for run 4
```

---

Using `Parametric:SetValueForRun`, the value is set based on the which run number is currently being simulated. Multiple objects can be used and a set of parameter values would be defined for a given simulation. For example, the 3rd simulation would assign the “Value 3” value, 11, to the parameter `$WallRValue` and the “Value 3” value, “SteelFrameWall” to `$ConstructionToUse`. Since many `Parametric:SetValueForRun` objects can be used at once, all of the 3rd values would be assigned to the appropriate parameters. In IDF Editor, this object will appear as a table of values with each row being all the parameter values for a specific simulation and each column belonging to a specific parameter.

### 4.1.3.1 Inputs

#### 4.1.3.1.1 Field: Parameter Name

The name of the parameter. It must begin with the dollar sign character, and the second character must be a letter. The parameter name, unlike a typical EnergyPlus name, cannot contain spaces or any characters other than letters and numerals.

#### 4.1.3.1.2 Field: Value for run n

The value that should be substituted for the parameter on the n-th simulation. If multiple `Parametric:SetValueForRun` objects exist and they have different number of fields, the last field value will be used for the remaining field values. This means that to set all values the same, only the first value needed to be entered.

## 4.1.4 Parametric:Logic

The approach of using parameters and expressions, by itself, is very flexible and allows for many possible parametric simulations but it does not allow for objects to be included for some parametric cases and not others. For example, you might want an overhang on a window in some parametric runs and not others. The `Parametric:Logic` object can help in that scenario.

A single `Parametric:Logic` object is allowed per file. It has a freeform syntax including `IF` and `SELECT` blocks with each field in the object representing a single “line” of code. Essentially, this logic object looks like simple programming code.

```
Parametric:Logic,
Main,                !- name
IF $insDepth < 0.1,   !- parametric logic line 1
    DISABLE "MaterialWallBoard, !- parametric logic line 2
    DISABLE "MaterialExtFinish, !- parametric logic line 3
ENDIF;               !- parametric logic line 4
```

---

In addition, lines could contain assignment statements in the form of  
parameter = expression such as the second control line in the following example.

```
Parametric:Logic,
Main,                !- name
PARAMETER $THICKNESS, !- parametric logic line 1
$THICKNESS = 0.01 * $CMDEPTH, !- parametric logic line 2
IF $THICKNESS > 0.5,  !- parametric logic line 3
    DISABLE "MaterialWallBoard, !- parametric logic line 4
    DISABLE "MaterialExtFinish, !- parametric logic line 5
ENDIF;               !- parametric logic line 6
```

---

The statements include `PARAMETER`, `IF`, `ELSE`, `ELSEIF`, `ENDIF`, `SELECT`, `CASE`, `DEFAULT`, `ENDSELECT`, `ENABLE`, `DISABLE`, and `REMARK`. Nested `IF` and `SELECT` statements are allowed. All

objects are enabled until they are specifically disabled using the DISABLE statement and could be later re-enabled with ENABLE. An object that is named with the DISABLE statement would not appear in that simulation run.

The PARAMETER statement declares the name of the parameter. It is necessary that every parameter used in the Parametric:Logic object be initialized using the PARAMETER statement unless the parameters are created using the **Parametric:SetValueForRun** object. Requiring explicit parameter declaration reduces errors in software programming. Parameter names would not be case sensitive.

The DISABLE and ENABLE commands can have one or two arguments. If a second argument is present it is the kind of object.

---

```
DISABLE ""MaterialWallBoard ""Material,      !- parametric control line 4
```

---

The following sections describe each type of statement in more detail.

#### 4.1.4.1 Inputs

##### 4.1.4.1.1 IF ENDIF Block

As previously shown, the simplest IF block is in the form of

---

```
IF <conditional-expression>
  <true-block-of-statements>
ENDIF
```

---

The <conditional-expression> usually contains a logical comparison operator such as:

- == equal
- > greater than
- < less than
- <= less than or equal to
- >= greater than or equal to
- <> not equal to

The <true-block-of-statements> can contain other statements including other lines of IF and ENDIF. These statements are only executed when the <conditional-expression> evaluates to true. If the <conditional-expression> is false, none of the statements before the ENDIF are executed and instead execution begins again with the statement after the ENDIF statement.

##### 4.1.4.1.2 IF ELSE ENDIF Block

Another form of the IF block can contain the ELSE statement:

---

```
IF <conditional-expression>
  <true-block-of-statements>
ELSE
  <false-block-of-statements>
ENDIF
```

---

Like the simpler IF ENDIF form the <conditional-expression> is computed and the <true-block-of-statements> are executed if it is true. The additional feature of this form is that if the <conditional-expression> is false, the <false-block-of-statements> is executed instead of the <true-block-of-statements>.

#### 4.1.4.1.3 IF ELSEIF ELSE ENDIF Block

The most complex form of the IF block contains both ELSEIF statement (or statements) and the ELSE statement:

```
IF <conditional-expression-1>
  <true-block-of-statements-1>
ELSEIF <conditional-expression-2>
  <true-block-of-statements-2>
ELSEIF <conditional-expression-2>
  <true-block-of-statements-2>
ELSE
  <false-block-of-statements>
ENDIF
```

This form allows more complex logic to be expressed. If the <conditional-expression-1> is true then <true-block-of-statements-1> executed and when that is complete, execution resumes after the ENDIF statement. If <conditional-expression-1> is false then the ELSEIF <conditional-expression-2> is evaluated and if that is true then <true-block-of-statement-2> is executed. On the other hand, if <conditional-expression-2> is false, then the next ELSEIF conditional expression is evaluated following the same pattern if another ELSEIF is present, otherwise, the <false-block-of-statements> after the ELSE are executed. Another way of thinking of this block is that the conditional expressions are evaluated from the top to the bottom until one is found to be true and then the associated block of statements are executed. If none of the conditional expressions is true, the <false-block-of-statements> are executed.

#### 4.1.4.1.4 SELECT CASE DEFAULT ENDSELECT Block

The SELECT block is related to the IF block but is for the specific case of trying to match a variable with several specific values. The form of the SELECT block is:

```
SELECT <expression>
CASE <constant-1>
  <case-block-of-statements-1>
CASE <constant-2>
  <case-block-of-statements-2>
CASE <constant-3>
  <case-block-of-statements-3>
DEFAULT
  <default-block-of-statements>
ENDSELECT
```

With any number of CASE statements. The <expression> is evaluated and compared to the constants with each CASE statement. If a match is found the corresponding <case-block-of-statements> are executed otherwise if no match is found the <default-block-of-statements> is executed. One one matching CASE statement for each SELECT block is executed. An example of how this works is shown below:

```
Parametric:SetValueForRun,
  $EndMonth,
  2;

Parametric:Logic,
  Main2,
  PARAMETER $EndDay,
  SELECT $EndMonth,
    CASE 1,
      $EndDay = 31,
    CASE 2,
      $EndDay = 28,
    CASE 3,
      $EndDay = 31,
    CASE 4,
```

```

    $EndDay = 30,
CASE 5,
    $EndDay = 31,
CASE 6,
    $EndDay = 30,
CASE 7,
    $EndDay = 31,
CASE 8,
    $EndDay = 31,
CASE 9,
    $EndDay = 30,
CASE 10,
    $EndDay = 31,
CASE 11,
    $EndDay = 30,
CASE 12,
    $EndDay = 31,
DEFAULT,
    $EndDay = 30,
ENDSELECT;

```

With this example the \$EndDay value would be set to 28.

#### 4.1.4.1.5 ENABLE DISABLE

The ENABLE and DISABLE statements specifically are for removing (and not removing) other objects that appear in the EnergyPlus IDF file. It has two syntaxes:

```
DISABLE <objectname>
```

and

```
DISABLE <objectname>, <kind-of-object>
```

The DISABLE statement removes the object identified with either <objectname> or the combination of <objectname> and <kind-of-object> if the <objectname> is not unique in the EnergyPlus input file. By default, all objects are enabled in the input file. Objects need to be specifically disabled using the DISABLE statement. After an object is disabled in can later be re-enabled with the ENABLE statement which has similar syntax.

```
DISABLE <objectname>
```

and

```
DISABLE <objectname>, <kind-of-object>
```

```

Parametric:Logic,
  Main,
  DISABLE  "SOUTH WALL OVERHANG";

Shading:Zone:Detailed,
  SOUTH WALL OVERHANG,      !- Name
  ZONE SURFACE SOUTH,      !- Base Surface Name
  SCH 2,                    !- Transmittance Schedule Name
  4,                        !- Number of Vertices
  0.0,-1.0,3.0,             !- X,Y,Z = = > Vertex 1 {m}
  0.0,0.0,3.0,             !- X,Y,Z = = > Vertex 2 {m}
  4.0,0.0,3.0,             !- X,Y,Z = = > Vertex 3 {m}
  4.0,-1.0,3.0;            !- X,Y,Z = = > Vertex 4 {m}

```

An object that is named with the DISABLE statement would not appear in that simulation run.

**4.1.4.1.6 REMARK**

The REMARK statement is simply a way to include a comment in the Parametric:Logic fields. The text that follows the REMARK statement is ignored.

**4.1.4.1.7 OBJECT DEFINITION**

The definition of the Parametric:Logic object is shown below:

**4.1.4.1.8 Field: Name**

The name of the Parametric:Logic object.

**4.1.4.1.9 Field: Parametric Logic Line n**

The line that contains one statement in one of the following forms:

- <parameter> = <expression>
- PARAMETER <parameter>
- IF <expression>
- ELSEIF <expression>
- ELSE
- ENDIF
- SELECT <expression>
- CASE <constant>
- DEFAULT
- ENDSELECT
- ENABLE <constant>
- ENABLE <constant> <constant>
- DISABLE <constant>
- DISABLE <constant> <constant>
- REMARK <text to ignore>

**4.1.5 Parametric:RunControl**

The following Parametric:RunControl object controls which runs are simulated. The series of entries indicate if the run should be performed or not. This object is optional and if it is not included all runs are performed.

**4.1.5.1 Inputs****4.1.5.1.1 Field: Name**

The name of the optional Parametric:RunControl object.

**4.1.5.1.2 Field: Perform run n**

The value of the field can be either a yes or no. It cannot contain a parameter.

**4.1.6 Parametric:FileNameSuffix**

The file name of the IDF files that are created for each run and the output files for each run are based on the name of the file plus a “suffix”. The suffixes can be defined using the Parametric:FileNameSuffix object or if the object is missing will default to the run number.

**4.1.6.1 Inputs****4.1.6.1.1 Field: Name**

The name of the optional Parametric:FileNameSuffix object.

**4.1.6.1.2 Field: Suffix for file name in run n**

The value of the field is added to the IDF file name to create the resulting IDF file and output files. It cannot contain a parameter.

# Chapter 5

## Input for Output

Several items are used to specify what will appear in the output file(s). The output is described in the next section of this document.

### 5.1 Group – Reports

#### 5.1.1 Variable Dictionary Reports

One of the most important outputs for EnergyPlus is the Variable Dictionary reports – these contain the key variable names for each simulation. This single input object is used to produce two important reports that are used to identify the specific output variables and meters available for a specific EnergyPlus model. Two output files are produced (**eplusout.rdd** & **eplusout.mdd**) that list the names of the output variables and meters for that simulation. You may need to run your simulation once and produce these files before you ask for specific output variables (**rdd**) or meters (**mdd**) (see **Output:Variable** and **Output:Meter** objects). Variables available, to some extent, depend on the simulation input. Variables are “set up” during the initial “get input” processing done within the modules. Therefore, an item that is specific to a certain type of coil would not be available if that coil were not used during the simulation. This command will produce a list of variables available for reporting.

#### 5.1.2 Output:VariableDictionary

##### 5.1.2.1 Inputs

###### 5.1.2.1.1 Field: Key Field

For this field there are two choices: **IDF** and **regular**. The regular option is the default and produces a listing that shows the type of variable: Zone or HVAC, Average or Sum. “**Zone**” variables are calculated and can be reported after each Zone/Heat Balance timestep (ref: Timesteps input object). “**HVAC**” variables are calculated and can be reported with each variable HVAC timestep. “**Average**” variables will be averaged over the time interval being reported whereas “**Sum**” variables are summed over that time interval. (Meter variables are always summed.) Units for the variable are shown in “[ ]”.

###### 5.1.2.1.2 Field: Sort Option

For this field there are two choices: **Name** and **Unsorted**. By default, the listing of available reporting variables are unsorted – listed in the streaming order that EnergyPlus generates them. Or, you can have them sorted by name.

Examples of the options for this object follow:

---

```
Output:VariableDictionary,regular;
```

---

Results of this are shown in the Output Details document under the **eplusout.rdd** (output variables) and **eplusout.mdd** (meter variables) files.

The eplusout.mdd file has a similar format for meters:

### 5.1.2.2 Variable Dictionary Report in IDF Format

The common workflow process of examining Variable Dictionary Reports and then adding reporting requests to an IDF file can be facilitated by using the following alternate form (Report Name = IDF) of the input object that requests the reports.

---

```
Output:VariableDictionary, IDF;
```

---

A sorted request would appear similarly:

---

```
Output:VariableDictionary, IDF, Name;
```

---

## 5.1.3 Surface Reports

There are two specific objects for surfaces: **Output:Surfaces:List** and **Output:Surfaces:Drawing** – as the names imply, the list reports are simple text reports that are contained in one of the output files whereas the drawing reports will create files that are used in other graphic tools.

These objects and their use is described in the following:

### 5.1.4 Output:Surfaces:List

Examples of using the Output:Surfaces:List object follow:

#### 5.1.4.1 Inputs

##### 5.1.4.1.1 Lines Data Report

An example input object for this report follows.

---

```
Output:Surfaces:List, Lines;
```

---

The above IDF line will produce a simple file of line segments that constitute the surfaces in the IDF file. This file is the “lines” report (**eplusout.sln**) and is described in more detail in the Output Details and Examples document.

##### 5.1.4.1.2 Field: Report Specifications

An extra option of entering “IDF” in this field directs the Lines report to produce coordinates transformed into Surface Geometry (Lower Left Corner, CounterClockwise, WorldCoordinates). An example of this follows.

---

```
Output:Surfaces:List, Lines, IDF;
```

---

The result is put on the **eplusout.sln** file and is nearly ready for putting into a IDF. Again, it is described in more detail in the Output Details and Examples document.

#### 5.1.4.1.3 Detailed Surface Data Report

An example input object for this report follows.

```
Output:Surfaces:List, Details;
```

---

This report (in **eplusout.eio**) contains details about each surface – including surface name, associated zone, area, approximate height and width, tilt, outward facing angle. Specific details on this report can be found in the Output Details and Examples document.

#### 5.1.4.1.4 Vertices Data Report

An example input object for this report follows.

```
Output:Surfaces:List, Vertices;
```

---

This report (in **eplusout.eio**) contains the vertices of each surface along with surface name and other information. Specific details on this report can be found in the Output Details and Examples document.

#### 5.1.4.1.5 Detailed Surface Data With Vertices Report

An example input object for this report follows.

```
Output:Surfaces:List, DetailsWithVertices;
```

---

This report (in **eplusout.eio**) is the combination of the two preceding reports (Details and Vertices). Specific details on this report can be found in the Output Details and Examples document.

#### 5.1.4.1.6 View Factor Information Report

An example input object for this report follows.

```
Output:Surfaces:List, ViewFactorInfo;
```

---

This report (in **eplusout.eio**) provides details about the thermal radiation exchange view factors and interchange factors. Specific details on this report can be found in the Output Details and Examples document.

#### 5.1.4.1.7 DecayCurvesFromComponentLoadsSummary

An example input object for this report follows.

```
Output:Surfaces:List, DecayCurvesFromComponentLoadsSummary;
```

---

This report (in **eplusout.eio**) provides an intermediate calculation used, called a decay curve, in the Zone Component Loads Summary report for the estimate of the sensible-delayed column values. A decay curve is created for each surface in a zone by introducing a radiant pulse. Each value in each row of the report corresponds to a zone time step from the time the pulse was introduced. See Zone Component Load Summary described in object [Output:Table:SummaryReports](#) for more detailed information.

### 5.1.5 Output:Surfaces:Drawing

Examples of using the Output:Surfaces:Drawing object follow:

#### 5.1.5.1 Inputs

##### 5.1.5.1.1 DXF Surface Report

Examples input objects follow.

```
Output:Surfaces:Drawing, DXF;
Output:Surfaces:Drawing, DXF, RegularPolyline;
Output:Surfaces:Drawing, DXF, Triangulate3DFace, mycolorscheme;
```

---

The above IDF specification will produce a DXF file (**eplusout.dxf**) of the surfaces in the IDF file. Only one DXF report can be produced. More specifics on this report can be found in the Output Details and Examples document.

#### 5.1.5.1.2 Field: Report Specifications 1

As indicated in the example, you can select among three different ways that surfaces with more than four sides will appear in the DXF file. These are:

- ThickPolyline – surface with >4 sides will be represented as a “thick” line in the appropriate surface color. It will look like a hole in the drawing with a thicker edge.
- RegularPolyline – surface with >4 sides will be represented as a regular line in the appropriate surface color. It will look like a hole in the drawing.
- Triangulate3DFace – surface with >4 sides will be “triangulated” internally within EnergyPlus. This is only for drawing purposes and does not affect the calculations in any way. In a line version of the DXF, it will appear that the surface is split into triangles. In a solid view, the surface will appear similar to surfaces with  $\leq 4$  sides. The triangulation algorithm is not perfect and warnings do result when the software cannot triangulate the surface.

#### 5.1.5.1.3 Field: Report Specifications 2

This field can be used to control the color scheme in the DXF file by entering the name of an **OutputControl:SurfaceColorScheme** object. Using **OutputControl:SurfaceColorScheme**, you can define color schemes for surface representation. This feature will let you align the colors with the software of your choice (colors don’t seem to be standard across DXF viewers).

Several software programs can render this file into something viewable and are described in more detail in the Output Details and Examples document under the file name (**eplusout.dxf**).

#### 5.1.5.1.4 DXF Wire Frame Report

An example input object for this report follows.

```
Output:Surfaces:Drawing, DXF:WireFrame;
```

---

The above IDF specification will produce a DXF (Drawing Exchange Format) file (**eplusout.dxf**) of the surfaces in the IDF file using the DXF “Lines” command – producing only a wire frame capable file. More specifics on this report can be found in the Output Details and Examples document. Only one DXF report can be produced.

#### 5.1.5.1.5 VRML Report

Examples input objects for this report follow.

```
Output:Surfaces:Drawing, VRML;
Output:Surfaces:Drawing, VRML, Triangulate3DFace;
```

---

The above IDF specification produces a VRML (Virtual Reality Modeling Language) file (**eplusout.wrl**) of the surfaces in the IDF file. Only one VRML report can be produced. VRML files can be viewed in many web browsers after adding a “plug-in” and there are some stand-alone viewers as well. More specifics on this report can be found in the Output Details and Examples document.

#### 5.1.5.1.6 Field: Report Specifications 1

As indicated in the example, you can select several figure types (for >4 sided surfaces) in the DXF report. These are:

- ThickPolyline – surface with >4 sides will be represented as a “thick” line in the appropriate surface color. It will look like a hole in the drawing with a thicker edge.
- RegularPolyline – surface with >4 sides will be represented as a regular line in the appropriate surface color. It will look like a hole in the drawing.
- Triangulate3DFace – surface with >4 sides will be “triangulated” internally within EnergyPlus. This is only for drawing purposes and does not affect the calculations in any way. In a line version of the VRML, it will appear that the surface is split into triangles. In a solid view, the surface will appear similar to surfaces with  $\leq 4$  sides. The triangulation algorithm is not perfect and warnings do result when the software cannot triangulate the surface.

#### 5.1.5.1.7 Field: Report Specifications 2

Color schemes are not applicable for VRML reports.

### 5.1.6 Output:Schedules

This is a condensed reporting that illustrates the full range of schedule values – in the style of input: DaySchedule, WeekSchedule, and Annual Schedule.

#### 5.1.6.1 Inputs

##### 5.1.6.1.1 Field: Key Field

This field should contain the word **Hourly** or **TimeStep** to obtain the respective reports.

```
Output:Schedules, Hourly;      ! values on hourly increments (day schedule resolution)
Output:Schedules, TimeStep; ! will give them at the timestep of the simulation
```

---

This report is placed on the **eplusout.eio** file. Details of this reporting are shown in the Output Details and Examples document. Schedule values over time can also be obtained in the EnergyPlus Standard Output (in eplusout.eso) using **Output:Variable** objects.

### 5.1.7 Output:Constructions

#### 5.1.7.1 Inputs

##### 5.1.7.1.1 Constructions Report

This report content is added to the “**eplusout.eio**” file. It shows the calculated results related to conduction transfer functions for each construction. It also includes similar details about the windows. Specific details on this report can be found in the Output Details and Examples document. The following input object is used to obtain the Construction report.

```
Output:Constructions,Constructions;
```

---

##### 5.1.7.1.2 Field: Details Type 1, Details Type 2

Either field can contain the word “**Constructions**” to get the constructions report.

Or either field can contain the word “**Materials**” to obtain the Materials report.

### 5.1.7.1.3 Materials Report

This report content is added to the “**eplusout.eio**” file. It provides a summary of the thermal properties and thickness of the construction and window materials in the model. Specific details on this report can be found in the Output Details and Examples document. The following input object is used to obtain the Materials report.

```
Output:Constructions,Materials;
```

---

## 5.1.8 Output:DaylightFactors

This report content is added to the **eplusout.dfs** file.

Daylight factors are ratios of interior illuminance at a specific location to exterior horizontal illuminance. In EnergyPlus, they are pre-calculated hourly for every shadow calculation day for every exterior window of a daylight zone. The pre-calculated daylight factors are interpolated between hours and for the actual sky conditions in the time-step calculation of the daylighting performance of daylight zones.

EnergyPlus reports the daylight factors for four CIE sky types (clear, turbid clear, intermediate, and overcast) at noon time (12:00pm) for each exterior windows (base window without shading) in the **eio** file when the daylight factors are first calculated. This new object can report all hourly pre-calculated daylight factors. Details of the report are shown in the Output Details document.

### 5.1.8.1 Inputs

#### 5.1.8.1.1 Field: Reporting Days

This field is used to select days to report the daylight factors. Two choices are “**SizingDays**” and “**AllShadowCalculationDays**”. The “**SizingDays**” choice will output the daylight factors for only the sizing calculation days, while the “**AllShadowCalculationDays**” choice will output daylight factors for all shadow calculation days.

An example of this object follows.

```
Output:DaylightFactors,
  SizingDays;      !- Reporting Days
```

---

## 5.1.9 Output:EnergyManagementSystem

This report content is added to the “**eplusout.edd**” file. It shows information useful for the Energy Management System. The user can select the level of detail reported to the file using the fields in this object. However, there must be some other EMS-related input objects in the input file before this report will be generated.

### 5.1.9.1 Inputs

#### 5.1.9.1.1 Field: Actuator Availability Dictionary Reporting

This field is used to control the level of output reporting related to the EMS actuators that are available for a particular model. When EnergyPlus runs with EMS, it sets up a wide array of possible actuators that the EMS could use. (To actually use them requires an **EnergyManagementSystem:Actuator** object). Actuator availability dictionary reporting is provided to show the user what actuators are available in a particular building model. Regardless of the level of reporting chosen here, the same set of actuators are actually available. There are three levels to choose from. The “None” choice means that no reporting of available actuators is done. The “NotByUniqueNames” level means that the output includes only the types of actuators and their control options but not the unique, user-defined names that identify a

specific actuator in the model. The “Verbose” level means that the output includes all combinations of actuator types, control types, and the unique names of specific actuators. The verbose level provides all the information needed for input in an `EnergyManagementSystem:Actuator` input object.

#### 5.1.9.1.2 Field: Internal Variable Availability Dictionary Reporting

This field is used to control the level of output reporting related to the EMS internal variables that are available for a particular model. When EnergyPlus runs with EMS, it sets up a wide array of possible internal data sources that the EMS could use. (To actually use them requires an `EnergyManagementSystem:InternalVariable` object). Internal variable availability dictionary reporting is provided to show the user what internal data are available. Regardless of the level of reporting chosen here, the same internal data are available. There are three levels to choose from. The “None” choice means that no reporting of available internal data is done. The “NotByUniqueNames” level means that the output includes only the types of internal data but not the unique names that identify a specific instances in the model. The “Verbose” level means that the output includes all combinations of internal variables and the unique names of specific instances. The verbose level provides all the information needed for an `EnergyManagementSystem:InternalVariable` input object.

#### 5.1.9.1.3 Field: EnergyPlus Runtime Language Debug Output Level

This field is used to control the level of output reporting related to the execution of EnergyPlus Runtime Language, or Erl. This reporting is valuable for debugging Erl programs. When Erl programs are run inside EnergyPlus they can report error situations (such as divide by zero) or a full trace of each Erl statement. There are three levels of reporting. The “None” choice means that no reporting of Erl debug information is done. The “ErrorsOnly” choice means that Erl debugging traces are only output if the statement produces an error situation. The “Verbose” choice means that Erl debugging traces are done for each line of each Erl program. The verbose setting needs to be used with care because a large model with a long runperiod can easily create an EDD file that is too large for most computer systems (e.g. many GBs of text).

An example of this object follows.

```
Output:EnergyManagementSystem,
  Verbose,      ! Actuator Availability Dictionary Reporting
  Verbose,      ! Internal Variable Availability Dictionary Reporting
  ErrorsOnly;   ! EnergyPlus Runtime Language Debug Output Level
```

### 5.1.10 OutputControl:SurfaceColorScheme

This object provides control over the colors that appear in the DXF report, by surface. In addition, the Datasets folder contains example objects, including the “original” color scheme (prior to the 2.1 release).

#### 5.1.10.1 Inputs

##### 5.1.10.1.1 Field: Name

This assigns a unique name to this colorscheme data set. This name is used in the DXF output objects.

##### 5.1.10.1.2 Field Set: Drawing Element Type and Colorr

This set of fields can range from none (accepting the default colors) up to 15 sets with individual types of building elements assigned a color number. (drawing element types not assigned a color number will use the default color numbers)

#### 5.1.10.1.3 Field: Drawing Element <#> Type

This field uses a choice of the drawing types (Text, Walls, Windows, GlassDoors, Doors, Roofs, Floors, DetachedBuildingShades, DetachedFixedShades, AttachedBuildingShades, Photovoltaics, TubularDaylightDomes, TubularDaylightDiffusers, DaylightReferencePoint1, DaylightReferencePoint2) for the color number assignment in the following field.

#### 5.1.10.1.4 Field: Color for Drawing Element <#>

This is a color “number” from 0 to 255. DXF display software is not standardized – you may need to play around with these numbers if you don’t like the supplied default color scheme.

### 5.1.11 OutputControl:ReportingTolerances

This input object is created to allow more user control over some aspects of output reporting. Specifically, the reporting of “Time setpoint not met” hours See thermostat reporting (ZoneControl Thermostat Outputs).

#### 5.1.11.1 Inputs

##### 5.1.11.1.1 Field: Tolerance for Time Heating Setpoint Not Met

This field allows the entry of a value for the tolerance away from the heating setpoint reporting. If the zone temperature is below the heating setpoint by more than this value, the following output variables will increment as appropriate

Zone Heating Setpoint Not Met Time

Zone Heating Setpoint Not Met While Occupied Time

This also impacts table report “Annual Building Utility Performance Summary” subtable “Comfort and Setpoint Not Met Summary”.

##### 5.1.11.1.2 Field: Tolerance for Time Cooling Setpoint Not Met

This field allows the entry of a value for the tolerance away from the cooling setpoint reporting. If the zone temperature is above the cooling setpoint by more than this value, the following output variables will increment as appropriate

Zone Cooling Setpoint Not Met Time

Zone Cooling Setpoint Not Met While Occupied Time

This also impacts table report “Annual Building Utility Performance Summary” subtable “Comfort and Setpoint Not Met Summary”.

As seen in an IDF:

```
OutputControl:ReportingTolerances,.21,.21;
```

### 5.1.12 Output:Variable

This input object is used request results reporting. As shown above in the Variable Dictionary Report section, there are many different output variables available for reporting results from EnergyPlus. The Output:Variable object is primarily used for reporting time series data at various frequencies.

Each Output:Variable object causes a specific number assignment for outputs. For example, you could request separate reporting for the outside temperature:

```
Output:Variable,*,Site Outdoor Air Drybulb Temperature,timestep;
Output:Variable,*,Site Outdoor Air Drybulb Temperature,hourly;
Output:Variable,*,Site Outdoor Air Drybulb Temperature,monthly;
```

### 5.1.12.1 Inputs

#### 5.1.12.1.1 Field: Key Value

This alpha field can be used to make a specific reference for reporting. In addition to the generic variable names listed in the Variable Dictionary Report for the input file, variables will also have a key designator (such as Zone name or Surface name). You can reference the standard output file (**eplusout.eso**) to see just how these look.

```
41,2,ZN001:WALL003,Surface Inside Temperature [C]
42,2,ZN001:WALL004,Surface Inside Temperature [C]
43,2,ZN002:WALL003,Surface Inside Temperature [C]
44,2,ZN002:WALL004,Surface Inside Temperature [C]
45,2,ZN001:WALL004,Surface Outside Temperature [C]
46,2,ZN001:WALL004,Surface Int Convection Coeff[W/m2-K]
47,2,ZN001:WALL004,Surface Ext Convection Coeff[W/m2-K]
48,2,ZONE ONE,Zone Mean Radiant Temperature [C]
49,2,ZONE ONE,Zone Total Internal Latent Gain Energy [J]
50,2,ZONE ONE,Zone Lights Electric Energy [J]
51,2,ZONE ONE,Zone Air Temperature [C]
```

For example, in the previous block, one key for the surface variables is **ZN001:WALL004** whereas the key for the zone variables is **ZONE ONE** (note that the space is required and significant for this key).

You can have all keys listed in the standard output file by putting a “\*” in this field, you can have specific items listed by putting in a key value, or you can use regular expressions to filter the key values. If this field is left blank, it will use a \* as the default (i.e., you will get all variables of Variable Name).

Using regular expressions allows for powerful filtering capabilities on the key value. For example, in the previous block, you can find the Surface Inside Temperature for all surfaces in only ZN001 with a single Output:Variable expression.

```
Output:Variable,ZN001:.*,Surface Inside Temperature,timestep;
```

Consult the following URL for more information about the regular expressions RE2 supports: <https://github.com/google/re2/wiki/Syntax>

Note that due to the functionality of the Input Processor, no regular expression can contain a “,” even if it is a valid regular expression. If a regular expression has a comma in it then the Input Processor will create a new, erroneous field. The most common occurrence of a comma in a regular expression is ranges, such as “[a-zA-Z]{3,5}”.

#### 5.1.12.1.2 Field: Variable Name

This alpha field is the variable name (you don’t have to put on the units) that is shown in the Variable Dictionary Report file (eplusout.rdd). This field is required.

#### 5.1.12.1.3 Field: Reporting Frequency

This field specifies how often the variable will be listed in the output file. “**Detailed**” will list the value each calculation step (i.e. Zone or HVAC). “**Timestep**” will be the same as “Detailed” for Zone valued variables and will be aggregated to the Zone timestep (i.e. Timestep in Hour value) for HVAC variables. “**Hourly**” will aggregate the value to the hour. “**Daily**” will aggregate to the day (i.e. one value per day). “**Monthly**” will aggregate to the month (i.e. one value per month). “**RunPeriod**” will aggregate to the runperiod specified (each Design Day is a runperiod as is each runperiod object). “**Annual**” will aggregate to the year (i.e. one value per year) when used with a RunPeriod:CustomRange object. Default for this field if left blank or omitted is **Hourly**.

#### 5.1.12.1.4 Field: Schedule Name

The final field is a schedule name. This can be used to limit the number of lines that appear in your output file. For example, a schedule such as “ON PEAK” or “OFF PEAK” could provide a slice of values.

Or, a seasonal schedule could be devised. The output variable will be active during any hour in which the schedule value is >0. For daily, monthly, and environment reporting frequencies, the aggregate value will be only for active schedule hours. Summed variables will report the sum for the active hours only. Averaged variables will report the average during the active hours only. If Schedule\_Name is omitted, the output variable will be active for all hours.

Other IDF examples:

```
Output:Variable, * , Zone Mean Air Temperature, hourly;
Output:Variable, * , Zone Mean Radiant Temperature, timestep;
Output:Variable, * , Zone Air System Sensible Heating Energy, hourly;
Output:Variable, * , Zone Air System Sensible Cooling Energy, hourly;
Output:Variable, * , Zone Air Temperature, hourly;
Output:Variable, * , Zone Air Temperature; ! same as previous line
```

### 5.1.13 Output:Meter and Output:Meter:MeterFileOnly

### 5.1.14 Output:Meter:Cumulative and Output:Meter:Cumulative:-MeterFileOnly

Appropriate variables are grouped into “meters” for reporting purposes. (The meters available are listed in the `eplusout.mdd` file, see Variable Dictionary Report section.) If the “**Output:Meter**” input object is used, these results written out to both the **eplusout.eso** and **eplusout.mtr** files. This allows easy graphing and comparison with “normal” values (such as Zone Temperature or Outdoor Temperature). If the “**Output:Meter:MeterFileOnly**” input object is used, then the values results written out to only the **eplusout.mtr** file. The **eplusout.mtr** file has the same structure as the **eplusout.eso** file. A companion file, the **eplusout.mtd** file, contains a detailed list and explanation of all meters for a given run and the component values that are accumulated on each meter.

The cumulative meter outputs (**Output:Meter:Cumulative** and **Output:Meter:Cumulative:MeterFileOnly**) use the same meter names but the output is cumulative for the reporting (for each environment). That is, if the reporting frequency for the cumulative meter output is hourly, then hour 1 value will be that for hour 1, hour 2 value will be hour1 + hour2, etc. In other words, the end value for a cumulative meter reporting should be identical if you reported the value of the meter at the **RunPeriod** frequency.

#### 5.1.14.1 Field: Name

Meter names applicable for the simulation are shown on the Variable Dictionary Report contained in the **eplusout.mdd** file described in the Output Details and Examples document.

Meter names are of three forms:

- <ResourceType>:<name>

Or

- <EndUseType>:<ResourceType>:<name>

Or

- <EndUseSubcategory>:<EndUseType>:<ResourceType>:<name>.

The user requests reporting by either specifying the full name above (without Units) or a “wildcard” representation of that name (to obtain all meters of a type). For example, entering “Electricity:\*” for the

meter name will report on all the Electricity: meters (Electricity:Facility, Electricity:Building, Electricity:Zone:Resistive Zone, Electricity:Zone:East Zone, Electricity:North Zone in the example above). Both the resource types and end-use types are set within the program by the developers. End-use subcategories are user-defined and are an input field for certain objects.

To summarize the previous paragraph, you could use:

```
Output:Meter,Electricity:*;
```

To get the same outputs as if you had entered:

```
Output:Meter,Electricity:Facility;
Output:Meter,Electricity:Building;
Output:Meter,Electricity:Zone:South Zone;
Output:Meter,Electricity:Zone:East Zone;
Output:Meter,Electricity:North Zone;
```

From a three zone file that had no HVAC electricity (i.e., had only electric equipment or lighting equipment in an uncontrolled three zone building).

Current resource types are shown in the table below:

Table 5.1: Table of Metered Resource Types

Utility/Fuel Types
Electricity
NaturalGas
Gasoline
Diesel
Coal
FuelOilNo1
FuelOilNo2
Propane
OtherFuel1
OtherFuel2
Water
Steam
DistrictCooling
DistrictHeating
ElectricityPurchased
ElectricitySurplusSold
ElectricityNet
Other Resource Types
EnergyTransfer

The end use types are shown in the following table (note that certain end use types apply only to the EnergyTransfer resource):

Table 5.3: End Use Category Types

Utility/Fuel End Use Types
InteriorLights
ExteriorLights
InteriorEquipment
ExteriorEquipment
Fans
Pumps
Heating
Cooling
HeatRejection
Humidifier
HeatRecovery
DHW
Cogeneration
Refrigeration
WaterSystems
Additional End Use Types Only Used for EnergyTransfer
HeatingCoils
CoolingCoils
Chillers
Boilers
Baseboard
HeatRecoveryForCooling
HeatRecoveryForHeating

Specific meter types are then used for grouping the fuel type meters:

Table 5.5: Overall Meter Types

Meters
Facility
Building
Zone
HVAC
Plant

Facility meters contain all the energy of a fuel type. Building meters contain the sum of each zone's energy. HVAC meters contain the energy from the air and zone HVAC system components. Plant meters contain the energy from the plant equipment.

Thus, the following relationships should be observed:

$$Facility = \sum (Building + HVAC + Plant + Exterior) \quad (5.1)$$

$$Building = \sum_{1}^{NumberOfZones} Zone \quad (5.2)$$

There are also some special purpose meters used to describe electricity resource flows in greater detail. Electricity metering is tracked in more detail to accommodate the complexities of onsite electricity generation. There are three variations on the electricity resource type including: (1) “ElectricityPurchased” which is the quantity of electricity purchased and is always positive, (2) “ElectricitySold” which is the quantity of electricity exported by the building, that which is typically “sold” back to the power company, and is always positive, and (3) “ElectricityNet” which is the net electricity demand considering all sources of onsite generation and demand and can be either positive or negative.

#### 5.1.14.2 Field: Reporting Frequency

Similar to the output variables, meters can be reported at different frequencies. Their resolution is the Zone Timestep interval (Number of Timesteps input). For this frequency, the elemental value of the meter will be reported. For more inclusive frequencies, the summed value along with the maximum and minimum values for the time interval will be reported. Default for this field if left blank or omitted is **Hourly**.

Examples of specifying the object in the IDF follow.

```
Output:Meter,Electricity:*,RunPeriod;
Output:Meter,ExteriorEquipment*,RunPeriod;
Output:Meter:Cumulative,Electricity:*,Monthly;
```

#### 5.1.14.3 Meter Details File (eplusout.mtd)

The meter details file illustrates what is on each meter and vice versa. It is described in the Output Details and Examples document under the file name.

### 5.1.15 Output:EnvironmentalImpactFactors

The Output:**EnvironmentalImpactFactors** object triggers the necessary Facility meters to be reported and the Pollutants resulting from these on and off-site energy consumptions. These values are put into the eplusout.mtr file. Facility meters contain all the energy of a fuel type. Thus, the following relationships should be observed:

$$Facility = \sum (Building + System + Plant + Exterior) \quad (5.3)$$

Information regarding how the coefficients are derived and applied can be found in the Engineering Document.

To turn on the reporting and the calculations for the environmental factors the user enters 3 objects:

**Output:EnvironmentalImpactFactors:** (with associated reporting frequency, more than one frequency can be requested)

**EnvironmentalImpactFactors:** (contains additional information necessary for the calculations not included in the Fuel Factors)

**FuelFactors:** (required for every fuel that is simulated and converted in this simulation input file)

Users will enter environmental impact factors for each Fuel Type or FuelFactor. This is the same for each Fuel Type: Natural Gas, Residual Oil, Distillate Oil, Coal, Off-Site Electricity, Gasoline, and Propane. For District Heating, District Cooling, and Steam there are additional fields in the **EnvironmentalImpactFactors** object that help in the conversion of their energy to Natural Gas and Electricity.

The energy is obtained internally from the following facility meters:

Electricity:Facility	Diesel:Facility
DistrictCooling:Facility	DistrictHeating:Facility
NaturalGas:Facility	Gasoline:Facility
Coal:Facility	FuelOilNo1:Facility
FuelOilNo2:Facility	Propane:Facility
ElectricityProduced:Facility	Steam:Facility
OtherFuel1:Facility	OtherFuel2:Facility

For the pollutant calculation only the total off-site or purchased electric energy is calculated using Electricity Factors. Off-Site Electricity = Electricity:Facility - ElectricityProduced:Facility, pollutants for the fuel type used by the on-site generator will be calculated, for example Diesel, in these cases.

### 5.1.15.1 Inputs

#### 5.1.15.1.1 Field: Reporting Frequency

Similar to the output variables and meters the environmental impact calculations can be reported at different frequencies. Their resolution is the Zone Timestep interval (Number of Timesteps input). For this frequency, the elemental value of the Environmental Impact Factors Calculation will be reported. For more inclusive frequencies, the summed value along with the maximum and minimum values for the time interval will be reported.

Valid values are Timestep, Hourly, Daily, Monthly, Annual, or **RunPeriod**.

An example of specifying in the IDF:

```
Output:EnvironmentalImpactFactors,
  Monthly;  !- Reporting_Frequency
```

## 5.1.16 EnvironmentalImpactFactors

The EnvironmentalImpactFactors object contains additional information that is not individually specified in the **FuelFactors** object and is the second object needed to complete the calculation. Source to Site conversion factors for District Heating, District Cooling and Steam are entered in this object.

### 5.1.16.1 Inputs

#### 5.1.16.1.1 Field: District Heating Efficiency

The District Heating Efficiency value is used to convert the district (purchased) heating energy to Natural Gas for the environmental impact calculation. The efficiency is a number between 0 and 1 and divided into the district heating energy and the default is 0.3.

#### 5.1.16.1.2 Field: District Cooling COP

The District Cooling COP value is used to convert the district (purchased) cooling energy to electricity for the environmental impact calculation. The Coefficient of Performance (COP) is a number greater than 0 and divided into the purchased cooling energy with a default of 3.0.

#### 5.1.16.1.3 Field: Steam Conversion Efficiency

The Steam Conversion Efficiency is used to convert the Steam usage to Natural Gas for the environmental impact calculation. The efficiency is a number between 0 and 1 and divided into the purchased heating energy and the default is 0.25.

#### 5.1.16.1.4 Field: Total Carbon Equivalent Emission Factor From N<sub>2</sub>O

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. N<sub>2</sub>O (nitrous oxide) can be produced by some Fuel Types and has a default of carbon equivalent emission factor of 80.7272 kg C/kg N<sub>2</sub>O.

#### 5.1.16.1.5 Field: Total Carbon Equivalent Emission Factor From CH<sub>4</sub>

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. CH<sub>4</sub> (methane) can be produced by all Fuel Types and has a default carbon equivalent emission factor of 6.2727 kg C/kg CH<sub>4</sub>.

#### 5.1.16.1.6 Field: Total Carbon Equivalent Emission Factor From CO<sub>2</sub>

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. CO<sub>2</sub> (carbon dioxide) can be produced by all Fuel Types and has a default carbon equivalent emission factor of 0.2727 kg C/kg CO<sub>2</sub>.

An example of specifying in the IDF:

```
EnvironmentalImpactFactors,
0.3,          !- District Heating Efficiency
3.0,          !- District Cooling COP
0.25,         !- Steam Conversion Efficiency
80.7272,      !- Total Carbon Equivalent Emission Factor From N2O
6.2727,       !- Total Carbon Equivalent Emission Factor From CH4
0.2727;       !- Total Carbon Equivalent Emission Factor From CO2
```

### 5.1.17 FuelFactors

#### 5.1.17.1 Inputs

##### 5.1.17.1.1 Field: Existing Fuel Resource Name

This is the name of the Fuel that is being described with this object. Source to Site conversion factors for each tool are entered with these objects. Allowable Fuel Types are: Electricity, NaturalGas, FuelOilNo1, FuelOilNo2, Coal, Gasoline, Propane, Diesel, OtherFuel1, OtherFuel2.

##### 5.1.17.1.2 Field: Units of Measure

Units in mass with kg or by volume in m<sup>3</sup>.

##### 5.1.17.1.3 Field: Energy per Unit Factor

The higher heating value of the fuel type.

#### 5.1.17.1.4 Field: Source Energy Factor

Multiplied by the fuel consumption to compute the source energy contribution for the fuel. If a schedule is also specified in the next field, the value specified here, the schedule value, and the fuel consumption are multiplied together for each timestep to determine the source energy contribution for the fuel. If the multipliers in the schedule specified in the next field fully represent the source energy conversion factor, the value in this field should be set to one. If the TDV files (described in next field) are used the value should be 0.293 for electricity and 0.01 for natural gas to account for the units used in the files. Units of J/J.

#### 5.1.17.1.5 Field: Source Energy Schedule Name

This field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the source energy. Specifically, each value in the schedule are multiplied by the Source Energy Factor field value and by the fuel consumption to determine the source energy consumption for the fuel. If the values in the schedule fully represent the source energy conversion factor, the value in the previous field, Source Energy Factor should be set to one.

The use of this field is required for evaluations using source energy factors that change throughout the year such as Time Dependent Valuation (TDV), the method used to show compliance with to California's Title 24 under the ACM (Alternative Compliance Method). Data files containing TDV factors are in the DataSets\TDV\ directory. An example file for use with TDV file is in the ExampleFiles directory and is named 5zoneTDV.IDF. When using these TDV files with EnergyPlus it is important that a consistent weather file be used. It is also important that the day of the week for January 1 is set to Tuesday since all the TDV and related weather files use 1991 as the year of reference. Also note that the values in the TDV datasets files are in non SI units of measure. The source energy factor field should contain the value of 0.293 for electricity and 0.01 for natural gas to account for the non-standard units used in the files. A summary report that provides a breakdown of the facility energy use in terms of source energy can be obtained by selecting the 'AllSummary' or 'SourceEnergyEndUseComponentsSummary' keywords in the 'Output:Table:SummaryReports' reporting object. To learn more about TDV you can see the original methodology used for the 2005 Standards [here](#) and the 2019 Standards methodology [here](#).

#### WARNING

**THE TDV CALCULATIONS SHOULD ONLY BE PERFORMED ON SIMULATIONS THAT USE THE CALIFORNIA THERMAL ZONE (CTZ REV2) WEATHER FILES.** One must match the correct TDV file to its corresponding CTZ weather file. There are 16 TDV files, one for each of the 16 CTZ weather files. The Time Dependent Valuation of TDV files provides a relative cost estimate of the various fuel sources and their relative costs by time of day, month of year and outside temperature. Outside temperature is important as demand for electricity and thus cost of electricity is influenced by temperature. These TDV files are applicable only to the hourly weather data contained in the California Thermal Zone (CTZ rev2) weather files as the time dependent cost information is partially derived from the timing of temperatures in the weather file. Thus using the TDV files with other weather data would provide meaningless results.

#### 5.1.17.1.6 Field: CO2 Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of carbon dioxide (CO<sub>2</sub>) released into the atmosphere. The units are grams per MegaJoule. Carbon dioxide gas is naturally produced by animals during respiration and through decay of biomass, and used by plants during photosynthesis. Although it only constitutes 0.04 percent of the atmosphere, it is one of the most important greenhouse gases. The combustion of fossil fuels is increasing carbon dioxide concentrations in the atmosphere, which is believed to be contributing to global warming.

#### 5.1.17.1.7 Field: CO<sub>2</sub> Emission Factor Schedule Name

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### 5.1.17.1.8 Field: CO Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of carbon monoxide (CO) released into the atmosphere. The units are grams per MegaJoule. Carbon monoxide is a colorless, odorless and poisonous gas produced by incomplete fossil fuel combustion. Carbon monoxide combines with the haemoglobin of human beings, reducing its oxygen carrying capacity, with effects harmful to human beings.

#### 5.1.17.1.9 Field: CO Emission Factor Schedule Name

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### 5.1.17.1.10 Field: CH<sub>4</sub> Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of methane (CH<sub>4</sub>) released into the atmosphere. The units are grams per MegaJoule. Methane is a colorless, nonpoisonous, flammable gas created by anaerobic decomposition of organic compounds and is one of the more potent greenhouse gases. A major component of natural gas used in the home.

#### 5.1.17.1.11 Field: CH<sub>4</sub> Emission Factor Schedule Name

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### 5.1.17.1.12 Field: NO<sub>x</sub> Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of nitrogen oxides (NO<sub>x</sub>) released into the atmosphere. The units are grams per MegaJoule. Nitrogen oxides refers to nitric oxide gas (NO) and nitrogen dioxide gas (NO<sub>2</sub>) and many other gaseous oxides containing nitrogen. The main source of these gases in urban areas are motor vehicle exhaust and indoor gas stoves and kerosene heaters. The brown haze sometimes seen over cities is mainly nitrogen oxides. These gases are also partly responsible for the generation of ozone, which is produced when nitrogen oxides react with other chemicals in the presence of sunlight. Exposure to high levels of nitrogen dioxide can interfere with the ability of blood to carry oxygen, leading to dizziness and shortness of breath. Prolonged exposure can lead to respiratory failure.

#### 5.1.17.1.13 Field: NO<sub>x</sub> Emission Factor Schedule Name

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine

the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.14 Field: N2O Emission Factor**

The environmental impact coefficient for the Fuel for calculating the mass of nitrous oxide (N<sub>2</sub>O) released into the atmosphere. The units are grams per MegaJoule. Relatively inert oxide of nitrogen produced as a result of microbial action in the soil, use of fertilizers containing nitrogen, burning of timber and coal, chemical industry, and so forth. This nitrogen compound may contribute to greenhouse and ozone-depleting effects.

#### **5.1.17.1.15 Field: N2O Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.16 Field: SO2 Emission Factor**

The environmental impact coefficient for the Fuel for calculating the mass of sulfur dioxide (SO<sub>2</sub>) released into the atmosphere. The units are in grams per MegaJoule. Sulfur dioxide gas is formed when fuel containing sulfur, such as coal and oil, is burned, and when gasoline is extracted from oil, or metals are extracted from ore. Sulfur dioxide reacts with other chemicals in the air to form tiny sulfate particles, associated with increased respiratory symptoms and disease, difficulty in breathing, and premature death. Sulfur dioxide and nitrogen oxides react with other substances in the air to form acids, which fall to earth as rain, fog, snow, or dry particles. Acid rain damages forests and crops, changes the makeup of soil, and makes lakes and streams acidic and unsuitable for fish. Sulfur dioxide accelerates the decay of building materials and paints.

#### **5.1.17.1.17 Field: SO2 Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.18 Field: PM Emission Factor**

The environmental impact coefficient for the Fuel for calculating the mass of particulate matter (PM) released into the atmosphere. The units are grams per MegaJoule. PM is the sum of all particular matter emitted, including PM<sub>10</sub> and PM<sub>2.5</sub>. Particulate matter, or PM, are particles found in the air, including dust, dirt, soot, smoke, and liquid droplets, which can be suspended in the air for long periods of time. Some particles are large or dark enough to be seen as soot or smoke. Others are so small that individually they can only be detected with an electron microscope. Breathing particulate matter is linked to significant respiratory health problems.

#### **5.1.17.1.19 Field: PM Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine

the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.20 Field: PM10 Emission Factor**

The environmental impact coefficient for the Fuel for calculating the mass of particulate matter 10 (PM<sub>10</sub>) released into the atmosphere. The units are grams per MegaJoule. PM<sub>10</sub>, includes particles with an aerodynamic diameter of less than 10 microns. These smaller particles are most likely responsible for the adverse health effects on humans because particles so small can reach the thoracic or lower regions of the respiratory tract.

#### **5.1.17.1.21 Field: PM10 Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.22 Field: PM2.5 Emission Factor**

The environmental impact coefficient for the Fuel for calculating the mass of particulate matter 2.5 (PM<sub>2.5</sub>) released into the atmosphere. The units are grams per MegaJoule. EPA's national air quality standards for fine particles, also known as "PM<sub>2.5</sub> standards," are levels allowed in the outdoor air for particulate matter 2.5 microns in diameter or smaller. EPA issued the PM<sub>2.5</sub> standards in 1997 to protect human health and the environment. Studies have linked increased exposure to PM<sub>2.5</sub> to increases in premature death as well as a range of serious respiratory and cardiovascular effects.

#### **5.1.17.1.23 Field: PM2.5 Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.24 Field: NH3 Emission Factor**

The Environmental impact coefficient for the Fuel for calculating the mass of ammonia (NH<sub>3</sub>) released into the atmosphere. The units are grams per MegaJoule. Ammonia reacts with nitrogen and sulfur compounds in the atmosphere, mainly nitric and sulfuric acids, to form particulate matter.

#### **5.1.17.1.25 Field: NH3 Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.26 Field: NMVOC Emission Factor**

The Environmental impact coefficient for the Fuel for calculating the mass of non-methane volatile organic compounds (NMVOC) released into the atmosphere. The units are grams per MegaJoule. Non-methane volatile organic compounds (NMVOC), which include propane, butane, and ethane, are emitted

primarily from transportation, industrial processes, and non-industrial consumption of organic solvents. Volatile organic compounds react with nitrogen oxides in the atmosphere to form ozone.

#### **5.1.17.1.27 Field: NMVOC Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.28 Field: Hg Emission Factor**

The Environmental impact coefficient for the Fuel for calculating the mass of mercury (Hg) released into the atmosphere. The units are grams per MegaJoule. This heavy metal can accumulate in the environment and is highly toxic if breathed or swallowed. In the U.S., primary sources of mercury air emissions are coal-fired power plants.

#### **5.1.17.1.29 Field: Hg Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.30 Field: Pb Emission Factor**

The Environmental impact coefficient for the Fuel for calculating the mass of lead (Pb) released into the atmosphere. The units are grams per MegaJoule. A heavy metal that is hazardous to health if breathed or swallowed. Its use in gasoline, paints, and plumbing compounds has been sharply restricted or eliminated by federal laws and regulations.

#### **5.1.17.1.31 Field: Pb Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### **5.1.17.1.32 Field: Water Emission Factor**

The environmental impact coefficient for the Fuel for calculating the volume of water (H<sub>2</sub>O) consumed or evaporated in the generation of electricity. The units are liters per MegaJoule or a volume measurement. This is the water consumed in the production of the energy, ie. electricity off-site evaporated in cooling towers or scrubbers, or in the production or processing of the fuel itself, i.e., refinery for gasoline or diesel.

#### **5.1.17.1.33 Field: Water Emission Factor Schedule Name**

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### 5.1.17.1.34 Field: Nuclear High Level Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of high-level nuclear waste, removed as spent nuclear fuel from a nuclear reactor once it no longer is efficient at powering the reactor.. The units are grams per MegaJoule. Once a year, approximately one-third of nuclear fuel is replaced with new fuel. This used fuel is called spent nuclear fuel and is highly radioactive; containing plutonium and other radionuclides. Although there is little information on quantities of high-level nuclear waste, a few utilities are beginning to publish this information.

#### 5.1.17.1.35 Field: Nuclear High Level Emission Factor Schedule Name

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

#### 5.1.17.1.36 Field: Nuclear Low Level Emission factor

The environmental impact coefficient for the Fuel for calculating the volume of low-level nuclear waste, removed from a nuclear reactor after radiation contamination. The units are cubic meters per MegaJoule or a volume measurement. Low-level waste can come from nuclear reactors or other users of radioactive material, like hospitals or research institutes. Low-level waste is less hazardous than high-level waste.

#### 5.1.17.1.37 Field: Nuclear Low Level Emission Factor Schedule Name

Similar to the source energy calculation, this field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the total emission values. Specifically, each value in the schedule are multiplied by the emission factor field value and by the fuel consumption to determine the overall emission factor for the fuel. If the values in the schedule fully represent the emission factor, the value in the previous field, should be set to one.

An example of specifying in the IDF:

### 5.1.17.2 Outputs

Various output variables and meters related to emissions are available when modeling with environmental impact and fuel factor inputs. Output is available as either output variables or output meters. The variables and meters available depending on the number of FuelFactor input objects and the type of fuel used in them. Most of the fuel types have the same set of outputs for emissions that correspond to the types of emission factors in the input objects. The exception is electricity which has two additional outputs to track possible net metering situations that can occur with on-site generation.

The following pollution-emission-related outputs are available for environmental impacts.

- HVAC,Sum,Environmental Impact NaturalGas Source Energy [J]
- HVAC,Sum,Environmental Impact NaturalGas CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact NaturalGas Water Consumption Volume [L]
- HVAC,Sum,Nuclear High Level Waste From NaturalGas [kg]
- HVAC,Sum,Environmental Impact NaturalGas Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact Electricity Source Energy [J]
- HVAC,Sum,Environmental Impact Electricity CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity CO Emissions Mass [kg]

- HVAC,Sum,Environmental Impact Electricity CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Electricity Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact Electricity Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact Electricity Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact Purchased Electricity Source Energy [J]
- HVAC,Sum,Environmental Impact Surplus Sold Electricity Source [J]
- HVAC,Sum,Environmental Impact Coal Source Energy [J]
- HVAC,Sum,Environmental Impact Coal CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Coal Pb Emissions Mass [kg]

- HVAC,Sum,Environmental Impact Coal Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact Coal Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact Coal Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact FuelOilNo2 Source Energy [J]
- HVAC,Sum,Environmental Impact FuelOilNo2 CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact FuelOilNo2 Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo2 Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact FuelOilNo1 Source Energy [J]
- HVAC,Sum,Environmental Impact FuelOilNo1 CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 PM2.5 Emissions Mass [kg]

- HVAC,Sum,Environmental Impact FuelOilNo1 NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact FuelOilNo1 Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact FuelOilNo1 Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact Propane Source Energy [J]
- HVAC,Sum,Environmental Impact Propane CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Propane Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact Propane Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact Propane Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact Gasoline Source Energy [J]
- HVAC,Sum,Environmental Impact Gasoline CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline N2O Emissions Mass [kg]

- HVAC,Sum,Environmental Impact Gasoline SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact Gasoline Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact Gasoline Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact Diesel Source Energy [J]
- HVAC,Sum,Environmental Impact Diesel CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact Diesel Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact Diesel Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact Diesel Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact OtherFuel1 Source Energy [J]
- HVAC,Sum,Environmental Impact OtherFuel1 CO2 Emissions Mass [kg]

- HVAC,Sum,Environmental Impact OtherFuel1 CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 Water Consumption Volume [L]
- HVAC,Sum,Environmental Impact OtherFuel1 Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel1 Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact OtherFuel2 Source Energy [J]
- HVAC,Sum,Environmental Impact OtherFuel2 CO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 CO Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 CH4 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 NOx Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 N2O Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 SO2 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 PM Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 PM10 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 PM2.5 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 NH3 Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 NMVOC Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 Hg Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 Pb Emissions Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 Water Consumption Volume [L]

- HVAC,Sum,Environmental Impact OtherFuel2 Nuclear High Level Waste Mass [kg]
- HVAC,Sum,Environmental Impact OtherFuel2 Nuclear Low Level Waste Volume [m3]
- HVAC,Sum,Environmental Impact Total N2O Emissions Carbon Equivalent Mass [kg]
- HVAC,Sum,Environmental Impact Total CH4 Emissions Carbon Equivalent Mass [kg]
- HVAC,Sum,Environmental Impact Total CO2 Emissions Carbon Equivalent Mass [kg]

#### **5.1.17.2.1 Environmental Impact Electricity Source Energy [J]**

#### **5.1.17.2.2 Environmental Impact Purchased Electricity Source Energy [J]**

#### **5.1.17.2.3 Environmental Impact Surplus Sold Electricity Source [J]**

#### **5.1.17.2.4 Environmental Impact NaturalGas Source Energy [J]**

#### **5.1.17.2.5 Environmental Impact FuelOilNo2 Source Energy [J]**

#### **5.1.17.2.6 Environmental Impact FuelOilNo1 Source Energy [J]**

#### **5.1.17.2.8 Environmental Impact Gasoline Source Energy [J]**

#### **5.1.17.2.9 Environmental Impact Propane Source Energy [J]**

#### **5.1.17.2.10 Environmental Impact Diesel Source Energy [J]**

#### **5.1.17.2.11 Environmental Impact OtherFuel1 Source Energy [J]**

#### **5.1.17.2.12 Environmental Impact OtherFuel2 Source Energy [J]**

These outputs provide results for the source energy embodied in each type of fuel that might be used at the site. The units are Joules. The EnergyPlus models energy use at the site and conversion factors are used to determine the added energy used to create, process or deliver a fuel to the building. There are three types of electricity-related source energy results available. The first “Environmental Impact Electricity Source Energy” is for the electricity consumed at the site that was not produced at the site. The second, “Environmental Impact Purchased Electricity Source Energy,” is similar but includes just the electricity purchased from the utility. The third, “Environmental Impact Surplus Sold Electricity Source,” is the source energy associated with any surplus electricity that is exported to the grid.

#### **5.1.17.2.13 Environmental Impact Electricity CO2 Emissions Mass [kg]**

#### **5.1.17.2.14 Environmental Impact NaturalGas CO2 Emissions Mass [kg]**

#### **5.1.17.2.15 Environmental Impact FuelOilNo2 CO2 Emissions Mass [kg]**

#### **5.1.17.2.16 Environmental Impact FuelOilNo1 CO2 Emissions Mass [kg]**

5.1.17.2.17 Environmental Impact Coal CO2 Emissions Mass [kg]

5.1.17.2.18 Environmental Impact Gasoline CO2 Emissions Mass [kg]

5.1.17.2.19 Environmental Impact Propane CO2 Emissions Mass [kg]

5.1.17.2.20 Environmental Impact Diesel CO2 Emissions Mass [kg]

5.1.17.2.21 Environmental Impact OtherFuel1 CO2 Emissions Mass [kg]

5.1.17.2.22 Environmental Impact OtherFuel2 CO2 Emissions Mass [kg]

These outputs provide results for the carbon dioxide releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

5.1.17.2.23 Environmental Impact Electricity CO Emissions Mass [kg]

5.1.17.2.24 Environmental Impact NaturalGas CO Emissions Mass [kg]

5.1.17.2.25 Environmental Impact FuelOilNo2 CO Emissions Mass [kg]

5.1.17.2.26 Environmental Impact FuelOilNo1 CO Emissions Mass [kg]

5.1.17.2.27 Environmental Impact Coal CO Emissions Mass [kg]

5.1.17.2.28 Environmental Impact Gasoline CO Emissions Mass [kg]

5.1.17.2.29 Environmental Impact Propane CO Emissions Mass [kg]

5.1.17.2.30 Environmental Impact Diesel CO Emissions Mass [kg]

5.1.17.2.31 Environmental Impact OtherFuel1 CO Emissions Mass [kg]

5.1.17.2.32 Environmental Impact OtherFuel2 CO Emissions Mass [kg]

These outputs provide results for the carbon monoxide releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

5.1.17.2.33 Environmental Impact Electricity CH4 Emissions Mass [kg]

5.1.17.2.34 Environmental Impact NaturalGas CH4 Emissions Mass [kg]

5.1.17.2.35 Environmental Impact FuelOilNo2 CH4 Emissions Mass [kg]

5.1.17.2.36 Environmental Impact FuelOilNo1 CH4 Emissions Mass [kg]

5.1.17.2.37 Environmental Impact Coal CH4 Emissions Mass [kg]

5.1.17.2.38 Environmental Impact Gasoline CH4 Emissions Mass [kg]

5.1.17.2.39 Environmental Impact Propane CH4 Emissions Mass [kg]

5.1.17.2.40 Environmental Impact Diesel CH4 Emissions Mass [kg]

5.1.17.2.41 Environmental Impact OtherFuel1 CH4 Emissions Mass [kg]

5.1.17.2.42 Environmental Impact OtherFuel2 CH4 Emissions Mass [kg]

These outputs provide results for the methane releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

5.1.17.2.43 Environmental Impact Electricity NOx Emissions Mass [kg]

5.1.17.2.44 Environmental Impact NaturalGas NOx Emissions Mass [kg]

5.1.17.2.45 Environmental Impact FuelOilNo2 NOx Emissions Mass [kg]

5.1.17.2.46 Environmental Impact FuelOilNo1 NOx Emissions Mass [kg]

5.1.17.2.47 Environmental Impact Coal NOx Emissions Mass [kg]

5.1.17.2.48 Environmental Impact Gasoline NOx Emissions Mass [kg]

5.1.17.2.49 Environmental Impact Propane NOx Emissions Mass [kg]

5.1.17.2.50 Environmental Impact Diesel NOx Emissions Mass [kg]

5.1.17.2.51 Environmental Impact OtherFuel1 NOx Emissions Mass [kg]

5.1.17.2.52 Environmental Impact OtherFuel2 NOx Emissions Mass [kg]

These outputs provide results for the various nitrogen oxide releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

5.1.17.2.53 Environmental Impact Electricity N2O Emissions Mass [kg]

5.1.17.2.54 Environmental Impact NaturalGas N2O Emissions Mass [kg]

5.1.17.2.55 Environmental Impact FuelOilNo2 N2O Emissions Mass [kg]

5.1.17.2.56 Environmental Impact FuelOilNo1 N2O Emissions Mass [kg]

5.1.17.2.57 Environmental Impact Coal N2O Emissions Mass [kg]

5.1.17.2.58 Environmental Impact Gasoline N2O Emissions Mass [kg]

**5.1.17.2.59 Environmental Impact Propane N2O Emissions Mass [kg]**

**5.1.17.2.60 Environmental Impact Diesel N2O Emissions Mass [kg]**

**5.1.17.2.61 Environmental Impact OtherFuel1 N2O Emissions Mass [kg]**

**5.1.17.2.62 Environmental Impact OtherFuel2 N2O Emissions Mass [kg]**

These outputs provide results for the nitrous oxide releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.63 Environmental Impact Electricity SO2 Emissions Mass [kg]**

**5.1.17.2.64 Environmental Impact NaturalGas SO2 Emissions Mass [kg]**

**5.1.17.2.65 Environmental Impact FuelOilNo2 SO2 Emissions Mass [kg]**

**5.1.17.2.66 Environmental Impact FuelOilNo1 SO2 Emissions Mass [kg]**

**5.1.17.2.67 Environmental Impact Coal SO2 Emissions Mass [kg]**

**5.1.17.2.68 Environmental Impact Gasoline SO2 Emissions Mass [kg]**

**5.1.17.2.69 Environmental Impact Propane SO2 Emissions Mass [kg]**

**5.1.17.2.70 Environmental Impact Diesel SO2 Emissions Mass [kg]**

**5.1.17.2.71 Environmental Impact OtherFuel1 SO2 Emissions Mass [kg]**

**5.1.17.2.72 Environmental Impact OtherFuel2 SO2 Emissions Mass [kg]**

These outputs provide results for the sulphur dioxide releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.73 Environmental Impact Electricity PM Emissions Mass [kg]**

**5.1.17.2.74 Environmental Impact NaturalGas PM Emissions Mass [kg]**

**5.1.17.2.75 Environmental Impact FuelOilNo2 PM Emissions Mass [kg]**

**5.1.17.2.76 Environmental Impact FuelOilNo1 PM Emissions Mass [kg]**

**5.1.17.2.77 Environmental Impact Coal PM Emissions Mass [kg]**

**5.1.17.2.78 Environmental Impact Gasoline PM Emissions Mass [kg]**

**5.1.17.2.79 Environmental Impact Propane PM Emissions Mass [kg]**

5.1.17.2.80 Environmental Impact Diesel PM Emissions Mass [kg]

5.1.17.2.81 Environmental Impact OtherFuel1 PM Emissions Mass [kg]

5.1.17.2.82 Environmental Impact OtherFuel2 PM Emissions Mass [kg]

These outputs provide results for particulate matter releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

5.1.17.2.83 Environmental Impact Electricity PM10 Emissions Mass [kg]

5.1.17.2.84 Environmental Impact NaturalGas PM10 Emissions Mass [kg]

5.1.17.2.85 Environmental Impact FuelOilNo2 PM10 Emissions Mass [kg]

5.1.17.2.86 Environmental Impact FuelOilNo1 PM10 Emissions Mass [kg]

5.1.17.2.87 Environmental Impact Coal PM10 Emissions Mass [kg]

5.1.17.2.88 Environmental Impact Gasoline PM10 Emissions Mass [kg]

5.1.17.2.89 Environmental Impact Propane PM10 Emissions Mass [kg]

5.1.17.2.90 Environmental Impact Diesel PM10 Emissions Mass [kg]

5.1.17.2.91 Environmental Impact OtherFuel1 PM10 Emissions Mass [kg]

5.1.17.2.92 Environmental Impact OtherFuel2 PM10 Emissions Mass [kg]

These outputs provide results for particulate matter of 10 microns or less releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

5.1.17.2.93 Environmental Impact Electricity PM2.5 Emissions Mass [kg]

5.1.17.2.94 Environmental Impact NaturalGas PM2.5 Emissions Mass [kg]

5.1.17.2.95 Environmental Impact FuelOilNo2 PM2.5 Emissions Mass [kg]

5.1.17.2.96 Environmental Impact FuelOilNo1 PM2.5 Emissions Mass [kg]

5.1.17.2.97 Environmental Impact Coal PM2.5 Emissions Mass [kg]

5.1.17.2.98 Environmental Impact Gasoline PM2.5 Emissions Mass [kg]

5.1.17.2.99 Environmental Impact Propane PM2.5 Emissions Mass [kg]

5.1.17.2.100 Environmental Impact Diesel PM2.5 Emissions Mass [kg]

**5.1.17.2.101 Environmental Impact OtherFuel1 PM2.5 Emissions Mass [kg]**

**5.1.17.2.102 Environmental Impact OtherFuel2 PM2.5 Emissions Mass [kg]**

These outputs provide results for particulate matter of 2.5 microns or less releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.103 Environmental Impact Electricity NH3 Emissions Mass [kg]**

**5.1.17.2.104 Environmental Impact NaturalGas NH3 Emissions Mass [kg]**

**5.1.17.2.105 Environmental Impact FuelOilNo2 NH3 Emissions Mass [kg]**

**5.1.17.2.106 Environmental Impact FuelOilNo1 NH3 Emissions Mass [kg]**

**5.1.17.2.107 Environmental Impact Coal NH3 Emissions Mass [kg]**

**5.1.17.2.108 Environmental Impact Gasoline NH3 Emissions Mass [kg]**

**5.1.17.2.109 Environmental Impact Propane NH3 Emissions Mass [kg]**

**5.1.17.2.110 Environmental Impact Diesel NH3 Emissions Mass [kg]**

**5.1.17.2.111 Environmental Impact OtherFuel1 NH3 Emissions Mass [kg]**

**5.1.17.2.112 Environmental Impact OtherFuel2 NH3 Emissions Mass [kg]**

These outputs provide results for ammonia releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.113 Environmental Impact Electricity NMVOC Emissions Mass [kg]**

**5.1.17.2.114 Environmental Impact NaturalGas NMVOC Emissions Mass [kg]**

**5.1.17.2.115 Environmental Impact FuelOilNo2 NMVOC Emissions Mass [kg]**

**5.1.17.2.116 Environmental Impact FuelOilNo1 NMVOC Emissions Mass [kg]**

**5.1.17.2.117 Environmental Impact Coal NMVOC Emissions Mass [kg]**

**5.1.17.2.118 Environmental Impact Gasoline NMVOC Emissions Mass [kg]**

**5.1.17.2.119 Environmental Impact Propane NMVOC Emissions Mass [kg]**

**5.1.17.2.120 Environmental Impact Diesel NMVOC Emissions Mass [kg]**

**5.1.17.2.121 Environmental Impact OtherFuel1 NMVOC Emissions Mass [kg]**

**5.1.17.2.122 Environmental Impact OtherFuel2 NMVOC Emissions Mass [kg]**

These outputs provide results for non-methane volatile organic compound releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.123 Environmental Impact Electricity Hg Emissions Mass [kg]****5.1.17.2.124 Environmental Impact NaturalGas Hg Emissions Mass [kg]****5.1.17.2.125 Environmental Impact FuelOilNo2 Hg Emissions Mass [kg]****5.1.17.2.126 Environmental Impact FuelOilNo1 Hg Emissions Mass [kg]****5.1.17.2.127 Environmental Impact Coal Hg Emissions Mass [kg]****5.1.17.2.128 Environmental Impact Gasoline Hg Emissions Mass [kg]****5.1.17.2.129 Environmental Impact Propane Hg Emissions Mass [kg]****5.1.17.2.130 Environmental Impact Diesel Hg Emissions Mass [kg]****5.1.17.2.131 Environmental Impact OtherFuel1 Hg Emissions Mass [kg]****5.1.17.2.132 Environmental Impact OtherFuel2 Hg Emissions Mass [kg]**

These outputs provide results for mercury releases associated with consumption of each type of fuel that might be used at the site. The units are kg.

- 5.1.17.2.161 Environmental Impact OtherFuel1 Nuclear High Level Waste Mass [kg]
- 5.1.17.2.162 Environmental Impact OtherFuel2 Nuclear High Level Waste Mass [kg]

These outputs provide results for high-level nuclear waste associated with consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.163 Environmental Impact Electricity Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.164 Environmental Impact NaturalGas Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.165 Environmental Impact FuelOilNo2 Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.166 Environmental Impact FuelOilNo1 Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.167 Environmental Impact Coal Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.168 Environmental Impact Gasoline Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.169 Environmental Impact Propane Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.170 Environmental Impact Diesel Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.171 Environmental Impact OtherFuel1 Nuclear Low Level Waste Volume [m3]**

**5.1.17.2.172 Environmental Impact OtherFuel2 Nuclear Low Level Waste Volume [m3]**

These outputs provide results for low-level nuclear waste associated with consumption of each type of fuel that might be used at the site. The units are cubic meters.

**5.1.17.2.173 Environmental Impact Total N2O Emissions Carbon Equivalent Mass [kg]**

This output provides the result for equivalent carbon mass associated with the nitrous oxide ( $\text{N}_2\text{O}$ ) releases that stem from the consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.174 Environmental Impact Total CH4 Emissions Carbon Equivalent Mass [kg]**

This output provides the result for equivalent carbon mass associated with the methane releases that stem from the consumption of each type of fuel that might be used at the site. The units are kg.

**5.1.17.2.175 Environmental Impact Total CO2 Emissions Carbon Equivalent Mass [kg]**

This output provides the result for equivalent carbon mass associated with the carbon dioxide releases that stem from the consumption of each type of fuel that might be used at the site. The units are kg.

The following different output meters could appear in the standard meter output (.mdd) file:

- Zone,Meter,Source:Facility [J]

- Zone,Meter,NaturalGasEmissions:Source [J]
- Zone,Meter,CO2:Facility [kg]
- Zone,Meter,NaturalGasEmissions:CO2 [kg]
- Zone,Meter,CO:Facility [kg]
- Zone,Meter,NaturalGasEmissions:CO [kg]
- Zone,Meter,CH4:Facility [kg]
- Zone,Meter,NaturalGasEmissions:CH4 [kg]
- Zone,Meter,NOx:Facility [kg]
- Zone,Meter,NaturalGasEmissions:NOx [kg]
- Zone,Meter,N2O:Facility [kg]
- Zone,Meter,NaturalGasEmissions:N2O [kg]
- Zone,Meter,SO2:Facility [kg]
- Zone,Meter,NaturalGasEmissions:SO2 [kg]
- Zone,Meter,PM:Facility [kg]
- Zone,Meter,NaturalGasEmissions:PM [kg]
- Zone,Meter,PM10:Facility [kg]
- Zone,Meter,NaturalGasEmissions:PM10 [kg]

- Zone,Meter,Carbon Equivalent:Facility [kg]
- Zone,Meter,CarbonEquivalentEmissions:Carbon Equivalent [kg]

What shows up in the output are the Energy Meters that were utilized in this particular input file, the pollutants, and the Total Carbon Equivalent.

### 5.1.18 Output:SQLite

Output from EnergyPlus can be written to SQLite files for manipulation outside some of the standard (such as spreadsheet) tools.

#### 5.1.18.1 Inputs

##### 5.1.18.1.1 Field: Option

Currently, there are limited capabilities for specifying SQLite generation. The Simple option will include all of the predefined database tables as well as time series related data. Using the SimpleAndTabular choice adds database tables related to the tabular reports that are already output by EnergyPlus in other formats. The description for SQLite outputs is described fully in the Output Details document.

##### 5.1.18.1.2 Field: Tabular Unit Conversion

This field determines if any unit conversions will be performed for the values in the tabular reports when the Option field is set to SimpleAndTabular. These conversions are only applied to the tabular reports in the SQL file. No conversions are applied to the time series data and predefined database tables generated by the Simple option (see the list in Table 5.7).

This field is optional and, if not specified, defaults to UseOutputControlTableStyle which uses the same unit conversion that appears in the OutputControl:Table:Style object. Five different input options are available:

- UseOutputControlTableStyle – use the same unit conversion as in OutputControl:Table:Style
- None – no conversions performed
- JtoKWH – Joules converted into kWh (1 / 3,600,000)
- JtoMJ – Joules converted into Megajoules (1 / 1,000,000)
- JtoGJ – Joules converted into Gigajoules (1 / 1,000,000,000)

- InchPound – convert all annual, monthly, economics and timebins tabular values to common Inch-Pound equivalent

The JtoKWH, JtoMJ and JtoGJ unit conversion input option applies only to the Output:Table:Monthly reports and partially to the ABUPS report. For ABUPS, the JtoKWH option changes the report but the JtoMJ and JtoGJ options do not change the report since it is already in MJ/m2 and GJ. In addition, the JtoKWH option also changes results in the LEED Summary report changing GJ to kWh and MJW/m2 to kWh/m2. The InchPound unit conversion input option applies to all annual, monthly, timebins and economic reports that appear in the SQL file.

Since the Output:SQLite tabular unit conversion setting act on the Tabular reports only, the other SQLite reporting will not be affected by this unit conversion setting. The table below lists the affected SQLite tabular tables.

Table 5.7: SQLite Tables Affected by the Tabular Unit Conversions

Table Name	Affected or Not
TabularData	Yes
TabularDataWithString	Yes
ComponentSizes	No
ConstructionLayers	No
Constructions	No
DaylightMapHourlyData	No
DaylightMapHourlyReports	No
DaylightMaps	No
EnvironmentPeriods	No
Errors	No
Materials	No
NominalBaseboardHeaters	No
NominalElectricEquipment	No
NominalGasEquipment	No
NominalHotwaterEquipment	No
NominalInfiltration	No
NominalLighting	No
NominalOtherEquipment	No
NominalPeople	No
NominalSteamEquipment	No
ReportData	No
ReportDataDictionary	No
ReportExtendedData	No
RoomAirModels	No
Schedules	No
Simulations	No
StringTypes	No

InchPound;          !- Unit Conversion
```

---

### 5.1.19 OutputControl:Files

This object controls the output of various files in a central location. This object overrides other output objects in the input file. This object is for advanced users who understand their workflows well since this object can have unintended consequences for external programs.

#### 5.1.19.1 Inputs

##### 5.1.19.1.1 Field: CSV

When this field is “**Yes**”, EnergyPlus will output the Output:Variables and Output:Meters as CSV files using native EnergyPlus. This functionality is equivalent to the external ReadVarsESO program, however, it does not use RVI or MVI files to filter or sort output variables. The native EnergyPlus CSV output has significantly higher performance than ReadVarsESO, especially for large number of output variables. If the “-r” command line flag is used to request ReadVarsESO and “**Yes**” is selected for native CSV, ReadVarsESO will be run instead and a warning message will be given.

##### 5.1.19.1.2 Field: MTR

Conditionally turn on or off MTR file output. This could have unintended consequences for other programs that assume an MTR file is always generated.

##### 5.1.19.1.3 Field: ESO

Conditionally turn on or off ESO file output. This could have unintended consequences for other programs that assume an ESO file is always generated.

##### 5.1.19.1.4 Field: EIO

Conditionally turn on or off EIO file output.

##### 5.1.19.1.5 Field: Tabular

Conditionally turn on or off all tabular output file(s).

##### 5.1.19.1.6 Field: SQLite

Conditionally turn on or off SQLite file output. If tabular output objects are in the input file, “**SimpleAndTabular**” is selected for SQLite output, Tabular output control is “**No**”, and SQLite output control is “**Yes**”, there will still be tabular outputs in the SQLite output file.

##### 5.1.19.1.7 Field: JSON

Conditionally turn on or off JSON output file(s).

##### 5.1.19.1.8 Field: AUDIT

Conditionally turn on or off Audit file output.

##### 5.1.19.1.9 Field: Zone Sizing

Conditionally turn on or off Zone Sizing file output.

**5.1.19.1.10 Field: System Sizing**

Conditionally turn on or off System Sizing file output.

**5.1.19.1.11 Field: DXF**

Conditionally turn on or off DXF file output.

**5.1.19.1.12 Field: BND**

Conditionally turn on or off BND file output.

**5.1.19.1.13 Field: RDD**

Conditionally turn on or off RDD file output.

**5.1.19.1.14 Field: MDD**

Conditionally turn on or off MDD file output.

**5.1.19.1.15 Field: MTD**

Conditionally turn on or off MTD file output.

**5.1.19.1.16 Field: END**

Conditionally turn on or off END file output. This could have unintended consequences for other programs that assume an END file is always generated.

**5.1.19.1.17 Field: SHD**

Conditionally turn on or off SHD file output.

**5.1.19.1.18 Field: DFS**

Conditionally turn on or off DFS file output.

**5.1.19.1.19 Field: GLHE**

Conditionally turn on or off GLHE file output.

**5.1.19.1.20 Field: DelightIn**

Conditionally turn on or off DelightIn file output.

**5.1.19.1.21 Field: DelightELdmp**

Conditionally turn on or off DelightELdmp file output.

**5.1.19.1.22 Field: DelightDFdmp**

Conditionally turn on or off DelightDFdmp file output.

**5.1.19.1.23 Field: EDD**

Conditionally turn on or off EDD file output.

**5.1.19.1.24 Field: DBG**

Conditionally turn on or off Debug file output.

**5.1.19.1.25 Field: PerfLog**

Conditionally turn on or off PerfLog file output.

**5.1.19.1.26 Field: SLN**

Conditionally turn on or off SLN file output.

**5.1.19.1.27 Field: SCI**

Conditionally turn on or off SCI file output.

**5.1.19.1.28 Field: WRL**

Conditionally turn on or off WRL file output.

**5.1.19.1.29 Field: Screen**

Conditionally turn on or off Screen file output.

**5.1.19.1.30 Field: ExtShd**

Conditionally turn on or off ExtShd file output.

**5.1.19.1.31 Field: Tarcog**

Conditionally turn on or off Tarcog file output.

An example of this object follows.

# Chapter 6

## Output

EnergyPlus produces several output files as shown in the section on “Running EnergyPlus”. This section will discuss the data contained in the “standard” output files (**eplusout.eso**, **eplusout.mtr**). They, too, have data dictionaries but unlike the input files, the output data dictionary is contained within the output file. Thus, the basic structure of the standard output file is:

```
Data Dictionary Information
End of Data Dictionary
Data
...
Data
End of Data
```

As with the IDF structure, there are rules associated with the interpretation of the standard output data dictionary. These rules are summarized as follows:

- The first item on each line is an integer which represents the “report code”. This “report code” will be listed in the data section where it will also be the first item on each line, identifying the data. Only 2 lines in the output file will not have an integer as the first item (“End of Data Dictionary” and “End of Data” lines).
- The second item on each line is also an integer. This integer corresponds to the number of items left on the dictionary line. Each string consists of a variable name and units in square brackets. Square brackets are required for all strings. If there are no units associated with a particular variable, then there are no characters between the brackets.

Six standard items appear at the start of every EnergyPlus Standard Output File Data Dictionary:

```
Program Version,EnergyPlus <version number indicated>
1,5,Environment Title[],Latitude[degrees],Longitude[degrees],Time Zone[],Elevation[m]
2,6,Day of Simulation[],Month[],Day of Month[],DST Indicator[1 = yes 0 = no],Hour[],StartMinute[],
    EndMinute[],DayType
3,3,Cumulative Day of Simulation[],Month[],Day of Month[],DST Indicator[1 = yes 0 = no],DayType ! When
    Daily Output variables Requested
4,2,Cumulative Days of Simulation[],Month[] ! When Monthly Output variables Requested
5,1,Cumulative Days of Simulation[] ! When Run Period Output variables Requested
```

- Item 0 is the program version statement.
- Item 1 is produced at the beginning of each new “environment” (design day, run period).
- Item 2 is produced prior to any variable reported at the timestep or hourly intervals. Hourly intervals will be shown with a start minute of 0.0 and an end minute of 60.0. Timestep intervals will show the appropriate start and end minutes.

- Item 3 is produced prior to any variable reported at the daily interval.
- Item 4 is produced prior to any variable reported at the monthly interval.
- Item 5 is produced prior to any variable reported at the end of the “environment”.

Following these five standard lines will be the variables requested for reporting from the input file (ref. **Output:Variable** object). For example:

```
6,1,Environment,Site Outdoor Air Drybulb Temperature [C] !Hourly
40,1,ZONE ONE,Zone Total Internal Latent Gain Energy [J] !Hourly
68,1,ZONE ONE,Zone Mean Radiant Temperature [C] !Hourly
69,1,ZONE ONE,Zone Mean Air Temperature [C] !Hourly
70,1,ZONE ONE,Zone Air Heat Balance Surface Convection Rate [W] !Hourly
71,1,ZONE ONE,Zone Air Heat Balance Air Energy Storage Rate [W] !Hourly
```

This example illustrates the non-consecutive nature of the “report codes”. Internally, EnergyPlus counts each variable that *could* be reported. This is the assigned “report code”. However, the user may not request each possible variable for reporting. Note that, currently, the requested reporting frequency is shown as a comment (!) line in the standard output file.

The data is produced when the actual simulation is performed (after the warmup days unless the **Output:Diagnostics** requesting ReportDuringWarmup is used). Data output is simpler in format than the data dictionary lines. From the dictionary above:

```
1,DENVER STAPLETON INTL ARPT ANN HTG 99% CONDNS DB, 39.74,-105.18, -7.00,1829.00
2,1,12,21, 0, 1, 0.00,60.00,WinterDesignDay
6,-16.
40,0.0
68,-19.8183039170649
69,-19.8220899203323
70,-3.175272922406513E-002
71,-3.181520440307718E-002
```

This output file can be easily turned into a form that is read into commonly used spreadsheet programs where it can be further analyzed, graphed, etc.

More details including graphs are shown in the Output Details and Examples Document under the file **eplusout.eso**.

## 6.1 Using ReadVarsESO

### 6.1.1 Creating Charts and Spreadsheet files from Output Variables

The ReadVarsESO program is distributed with EnergyPlus as a simple approach to converting the standard output files (**eplusout.eso**, **eplusout.mtr**) into files that can be put directly into a spreadsheet program and then used to create graphs or do other statistical operations. ReadVarsESO can read the complex output files and sort the data into time-based form, it is a very quick application but does not have a lot of features. Note that all the **Output:Meter** and **Output:Meter:Cumulative** objects are included on the **eplusout.eso** file as well as the **eplusout.mtr** file. You can choose the **Output:Meter:MeterFileOnly** or **Output:Meter:Cumulative:MeterFileOnly** objects if you do not want a particular meter to show up on the **eplusout.eso** file. If you wish to see only the metered outputs, the **eplusout.mtr** file will typically be a lot smaller than the **eplusout.eso** file.

The ReadVarsESO program has a very simple set of inputs. By default, you will get all the variables listed in the **Output:Variable** (**eplusout.eso**) or **Output:Meter** (**eplusout.mtr**) objects into the appropriate output files, and the outputs will be limited to 255 variables (a legacy Microsoft Excel™ limit). You can tailor how many variables to list by specifying variables for the ReadVarsESO runs.

You can override the 255 variable limit by specifying an argument on the command line (**EP-Launch** has a special option for this). You use “unlimited” or “nolimit” on the command line to get as many variables into your output file as desired. Again, this will be limited either by the number of variables in the **eplusout.eso** or **eplusout.mtr** files or the contents of the “rvi” file. If you want to use this option, you must include two arguments to the command line of the ReadVars program – 1) the “rvi” file and 2) the “unlimited” argument.

By default, ReadVarsESO also included a trailing space on the header line, which can result in parsing difficulties, since the last variable will essentially have a blank character at the end. In EnergyPlus 9.0, a new command line option (fixheader) was added to ReadVarsESO to allow eliminating this extra padding. Just like with the variable limit command line argument, to use this one, you must first include an argument for the rvi file, which is a required first positional argument. If you aren’t using an rvi file, just include blank quotes to indicate no rvi use while satisfying the ReadVarsESO argument requirements.

Table 6.1: ReadVarsESO Command Line Options

Option	Description
< filename >	To use any of these options, you must include a file name (“rvi” file) as the first argument.
Unlimited (or Nolimit)	Variables of any number will be produced on the output file.
FixHeader	The CSV header line will not have a trailing space on the line, to ease with parsing variable information
Timestep	Only variables with reported frequency “timestep” (or detailed) will be produced on the output file.
Hourly	Only variables with reported frequency “hourly” will be produced on the output file.
Daily	Only variables with reported frequency “daily” will be produced on the output file.
Monthly	Only variables with reported frequency “monthly” will be produced on the output file.
Annual (or RunPeriod)	Only variables with reported frequency “runperiod” will be produced on the output file.

In addition, another argument can be used so that the output file is only one time frequency. (By default, all variables – hourly, monthly, annual, etc. are mixed together in the output file). By using “Timestep” as an argument, you would get only the TimeStep reported variables. Using “Monthly”, only the monthly variables. This is not automated in either **EP-Launch** or the **RunEPlus** batch file but can easily be accomplished.

The program is run automatically from the **EP-Launch** program or the **RunEPlus** batch file (both these methods for executing EnergyPlus are described in the GettingStarted document). These programs use <filename>.rvi for input to the ReadVarsESO program executed first after the EnergyPlus execution and <filename>.mvi for the second execution. Ostensibly, the .rvi file would apply to the eplusout.eso file and the .mvi would apply to the eplusout.mtr file, BUT the contents of the files actually specify the “input” reporting file and the “output” reorganized file. Typical contents of an .rvi file are:

Table 6.2: "RVI" file contents

.rvi line description	Actual .rvi File Contents
Input File	eplusout.eso
Output File	eplusout.csv
Variable Name	Site Outdoor Drybulb Temperature
Variable Name	Zone Air Temperature
Variable Name	Zone Air Humidity Ratio
Variable Name	Zone Air System Sensible Cooling Rate
Variable Name	Zone Air System Sensible Heating Rate
Variable Name	Zone Total Internal Latent Gain Rate
Specific Variable Name	COOLING COIL AIR OUTLET NODE, System Node Temperature
Specific Variable Name	AIR LOOP OUTLET NODE, System Node Temperature
Specific Variable Name	AIR LOOP OUTLET NODE, System Node Humidity Ratio
Specific Variable Name	Mixed Air Node, System Node Mass Flow Rate
Specific Variable Name	Outdoor air Inlet Node, System Node Mass Flow Rate
Variable Name	Humidifier Water Consumption Rate
Variable Name	Humidifier Electric Power
Variable Name	Zone Air Relative Humidity
Variable Name	Zone Predicted Moisture Load Moisture Transfer Rate
Termination Line (optional)	0

Note that the first two lines of the file are "input file" (where to read the output variable values from) and "output file" (where to put the reorganized data). If you have only those two lines in an "rvi" file, the program will use all the available variables on indicated input file to produce the output.

ReadVarsESO takes the input stream but recognizes the date/time information and appropriately places the required data onto the "output file". Following these lines are a list of variables to be culled from the "input file" and placed onto the output file. "Variable Name" will take all variables matching that description whereas "Specific Variable Name" will only match the full description of the variable. So, in the above example, "Zone Air Temperature" will report air temperatures for all the zones (but available at the HVAC timestep if you choose the "detailed" reporting frequency in your input file) but "AIR LOOP OUTLET NODE" and "COOLING COIL AIR OUTLET NODE" will be the only values reported for the "System Node Temperature" variable (the node temperature is available for all nodes used in the simulation). The termination line (0) is included to terminate the input to the ReadVarsESO program and begin the scanning.

The output from ReadVarsESO is in the form commonly called "comma de-limited" or "comma separated variable". This format can be read easily in spreadsheet programs, such as Excel<sup>TM</sup>.

Note as described in the "Input for Output" above, only variables as listed on the **eplusout.rdd** file are available for reporting. If you request others, they will become "Warning" messages in the **eplusout.err** file.

```

** Warning ** The following Output variables were requested but not generated
**   ~~~   ** because IDF did not contain these elements or misspelled variable name -- check .rdd file
***** Key = *, VarName = SYSTEM SENSIBLE COOLING RATE

```

The above message was generated from an IDF that requested reporting of the “SYSTEM SENSIBLE COOLING RATE” but that variable was not available from the components in the execution.

Table 6.3: Example ReadVarsESO command lines and results

Command Line	Description/Result
ReadVarsESO	Take eplusout.eso and produce an eplusout.csv file with all variables (up to 255) on it
ReadVarsESO my.rvi	Use the contents of “my.rvi” to produce the appropriate output file (limited to 255 variables)
ReadVarsESO my.rvi unlimited	Use the contents of “my.rvi” to produce the appropriate output file (no longer limited to 255 variables)
ReadVarsESO my.rvi Monthly	Use the contents of “my.rvi” to produce the appropriate output file and only produce those variables reported for “monthly” frequency (up to 255 variables)
ReadVarsESO my.rvi Daily unlimited	Use the contents of “my.rvi” to produce the appropriate output file and only produce those variables reported for “daily” frequency (no longer limited to 255 variables)

# Chapter 7

## Standard Output Reports

The following objects allow standard reports to be defined and utilized in EnergyPlus:

- `Output:Table:TimeBins`
- `Output:Table:Monthly`
- `Output:Table:Annual`
- `Output:Table:SummaryReports`
- `OutputControl:Table:Style`

No **Output:Meter** or **Output:Variable** objects need to be specified to use the standard reports. A good set of example reports are available in the `StandardReports.idf` file in the `DataSets` directory of EnergyPlus.

### 7.1 Output:Table:TimeBins

The `Output:Table:TimeBins` report shows the amount of time in hours that occurs in different bins for the single specific variable or meter specified. Two different types of binning occur: by month and by hour of the day.

The `IntervalStart`, `IntervalSize` and `IntervalCount` determine the size of the bins for many of the types of reports that can be generated. The `IntervalStart` value is the lowest value of the first bin. The first bin is for all values greater or equal to `IntervalStart` and less than `IntervalStart+IntervalSize`. This gets repeated `IntervalCount` times. A bin for below the first interval and above the last interval is automatically created. Each table also has totals for the column and the rows. The report produced by `Report:Table:TimeBins` also indicates the total time simulated (for an annual simulation this would be 8760 hours).

NOTE: For summed variables, such as meters, the values are divided by the length of the timestep in seconds before binning. For example, the bins for a variable in Joules are reported in Joules per second (Watts). The interval values must then be entered accordingly.

#### 7.1.1 Inputs

##### 7.1.1.0.1 Field: Key Value

The `Key Value` field indicates which instance of a variable is reported. An asterisk indicates that a table would be produced for every key.

**7.1.1.0.2 Field: Variable Name**

The variable name to be reported. Reference the eplusout.rdd file for names that are specific to your simulation input file. You do not need to include the units [] field in your names here.

**7.1.1.0.3 Field: Interval Start**

The lower value of the first bin. The first bin is for all values greater or equal to the IntervalStart and less than IntervalStart + IntervalSize. See note above regarding summed variables.

**7.1.1.0.4 Field: Interval Size**

The amount by which each bin range is to increase, i.e. the difference between the upper and lower limits of each bin. See note above regarding summed variables.

**7.1.1.0.5 Field: Interval Count**

The number of bins desired.

**7.1.1.0.6 Field: Schedule Name**

Optional schedule name. If left blank, binning is performed for all hours simulated. If a schedule is specified, binning is performed for non-zero hours in the schedule.

**7.1.1.0.7 Field: Variable Type**

This field is used to indicate the kind of units that may be associated with the variable. It is used by IDF Editor to display the appropriate SI and IP units for the Interval Start and Interval Size values. The available options are shown below.

- Energy
- Temperature
- Flowrate
- Demand

An example of a time bins input object follows.

```
Output:Table:TimeBins,
*,                ! Key Value
Electricity:HVAC, ! Variable Name
4000000,          ! Interval Start
5000000,          ! Interval Size
20;              ! Interval Count
```

## 7.2 Output:Table:Monthly

The Output:Table:Monthly object provides a generic method of setting up tables of monthly results. These tables are good for creating reports that broadly summarize the building performance. At the bottom of the tables, three rows are added for the sum or average depending on the type of variable, the maximum and the minimum of each column. The report produced has multiple columns that are each defined using a repeated group of fields. The fields for the variable name and the aggregation type can be repeated for any number of columns. A single Output:Table:Monthly object often produces multiple tables in the output. A table is produced for every “key” for a particular output variable. A single table of results shows values only for a specific “key”. The exception to this are environment variables, such as outdoor air temperature, that are included in each table, no matter what the key.

## 7.2.1 Inputs

### 7.2.1.0.1 Field: Name

The Name field allows the user to give the output table a label that is shown in the output file.

### 7.2.1.0.2 Field: Digits After Decimal

The Digits After Decimal field is a numeric value that indicates how many digits after the decimal point should be shown on the table of values.

### 7.2.1.0.3 Field Set: Variable or Meter and Aggregation Type

The VariableOrMeterName field and the AggregationType field may be repeated for each column desired in the monthly report. These two fields define each column of the report. The IDD object has been set up to allow up to 25 columns. This object is extensible, so the number of columns may be increased by editing the IDD file and adding the desired number of fields at the end of the object.

### 7.2.1.0.4 Field: Variable or Meter <#> Name

The remainder of this input object consists of pairs of fields that can be repeated. Variable Or Meter Name fields contain the name of a variable (see **Output:Variable** and `eplusout.rdd`), meter (see **Output:Meter** and `eplusout.mdd`), or schedule. This value is shown on a monthly basis using the aggregation method specified. If the selected name is used for both a variable or a meter and a schedule name, the variable or meter will be used.

### 7.2.1.0.5 Field: Aggregation Type for Variable or Meter <#>

The aggregation type determines how the variable is aggregated in the table. The choices for aggregation type are described below:

Simple Aggregation Types

**SumOrAverage** – For “sum” type variables adds up the values for each timestep and reports the sum of the value monthly. For “average” type variables, the value shown will be the average for the month. SumOrAverage is probably the most common choice for aggregation type.

**Maximum** – Reports the maximum value and the time that the maximum value occurred. When the maximum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the maximum for a variable in Joules is reported in Watts.

**Minimum** – Reports the minimum value and the time that the minimum value occurred. When the minimum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the minimum for a variable in Joules is reported in Watts.

**HoursNonZero** – The HoursNonZero option adds up the elapsed time during the month that this variable is non-zero and would be appropriate to determine the number of hour that a fan operates.

**HoursZero** – The HoursZero option adds up the elapsed time during the month that this variable has a zero value and would be appropriate to determine the number of hour that a fan does not operate.

**HoursPositive** – The HoursPositive option adds up the elapsed time during the month that this variable has a positive value. Hours with a zero value are not included.

**HoursNonPositive** – The HoursNonPositive option adds up the elapsed time during the month that this variable has non-positive value. Hours with a negative value and hours with a zero value are all included.

**HoursNegative** – The HoursNegative option adds up the elapsed time during the month that this variable has a negative value. Hours with a zero value are not included.

**HoursNonNegative** – The HoursNonNegative option adds up the elapsed time during the month that this variable has non-negative value. Hours with a positive value and hours with a zero value are all included.

*Advanced Aggregation Types*

The advanced aggregation types are described below. These aggregation types rely on doing an operation on the current variable but only during the time or times defined by a previously defined field. The ValueWhenMaxOrMin displays the value of one variable at the same time as the maximum or minimum is set on a previous field that is defined as either a maximum or minimum. The “Hours—“ aggregation types display then number of hours that a variable meets a condition. The “—DuringHoursShown” aggregation types perform those aggreations but instead of for all the hours in the month, only for the hours that the previous “Hours—“ entry applies. Multiple “—DuringHoursShown” after an “Hours—“ will all be based on that single “Hours—“ entry, in fact the “—DuringHoursShown” is based on the next column to the left that contains an “Hours—“ entry even if other types of aggregations are used in intermediate columns. Order of the variables in the report is important when using the advanced aggregation types since they often depend on a previous entry.

**ValueWhenMaximumOrMinimum** – The ValueWhenMaximumOrMinimum option looks at the previous variable in the report that sets a maximum or minimum and displays the value of the current variable at that same timestep. Order of the variables in the report is important when using ValueWhen-MaxMin. This can be used, for example, when an outdoor temperature should be reported for the time of the maximum cooling load.

**SumOrAverageDuringHoursShown** – Provides the sum or average of the named variable when during the hours that the previous variable displayed with any of the aggregation types starting with “Hours”. For “sum” type variables adds up the values for each timestep and reports the sum of the value monthly during the hours reported on the previous variable. For “average” type variables, the value shown will be the average for the month during the hours reported on the previous variable. Order of the variables in the report is important when using this aggregation type.

**MaximumDuringHoursShown** – Reports the maximum value and the time that the maximum value occurred but only during the hours reported with the previous “hours-“ aggregation type. When the maximum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the maximum for a variable in Joules is reported in Watts. Order of the variables in the report is important when using this aggregation type.

**MinimumDuringHoursShown** - Reports the minimum value and the time that the minimum value occurred but only during the hours reported with the previous “hours-“ aggregation type. When the minimum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the minimum for a variable in Joules is reported in Watts. Order of the variables in the report is important when using this aggregation type.

An example of this object follows.

```
Output:Table:Monthly,
  Building Monthly Cooling Load Report,      ! Name
  3,                                           ! Digits After Decimal
  Zone Air System Sensible Cooling Energy,    ! Variable or Meter 1 Name
  SumOrAverage,                              ! Aggregation Type for Variable or Meter 1
  Zone Air System Sensible Cooling Energy,    ! Variable or Meter 2 Name
  Maximum,                                    ! Aggregation Type for Variable or Meter 2
  Site Outdoor Air Drybulb Temperature,      ! Variable or Meter 3 Name
  ValueWhenMaxMin;                           ! Aggregation Type for Variable or Meter 3
```

## 7.3 Output:Table:Annual

The Output:Table:Annual object provides a generic method of setting up tables of annual results with each row corresponding to an instance of an object. These tables are good for creating reports that broadly summarize the building performance. At the bottom of the tables, three rows are added for the sum or

average depending on the type of variable, the maximum and the minimum of each column. The report produced has multiple columns that are each defined using a repeated group of fields. The fields for the variable name and the aggregation type can be repeated for any number of columns. If the variables from different type of objects are specified in a single `Output:Table:Annual`, all the object names for each type of objects will be shown as rows. Variables that don't apply for certain objects will be left blank for that cell.

### 7.3.1 Inputs

#### 7.3.1.0.1 Field: Name

The Name field allows the user to give the output table a label that is shown in the output file.

#### 7.3.1.0.2 Field: Filter

An optional text string that is compared to the names of the objects referenced by the variables and if they match are included in the table. A footnote will appear that indicates that the objects shown may not be all the objects that of that type that occur in the file.

#### 7.3.1.0.3 Field: Schedule Name

Optional schedule name. If left blank, aggregation is performed for all hours simulated. If a schedule is specified, aggregation is performed for non-zero hours in the schedule.

#### 7.3.1.0.4 Field Set: Variable and Aggregation Type

The Variable Name field and the Aggregation Type field may be repeated for each column desired in the report. These two fields define each column of the report. The IDD object has been set up to allow up to 25 columns. This object is extensible, so the number of columns may be increased by editing the IDD file and adding the desired number of fields at the end of the object.

#### 7.3.1.0.5 Field: Variable or Meter <#> Name

The remainder of this input object consists of pairs of fields that can be repeated. Variable Or Meter Name fields contain the name of a variable (see `Output:Variable` and `eplusout.rdd`), meter (see `Output:Meter` and `eplusout.mdd`), or schedule. This value is shown using the aggregation method specified. If the selected name is used for both a variable or a meter and a schedule name, the variable or meter will be used.

#### 7.3.1.0.6 Field: Aggregation Type for Variable or Meter <#>

The aggregation type determines how the variable is aggregated in the table. The choices for aggregation type are described below:

##### *Simple Aggregation Types*

**SumOrAverage** – For “sum” type variables adds up the values for each timestep and reports the sum of the value. For “average” type variables, the value shown will be the average for the month. SumOrAverage is probably the most common choice for aggregation type.

**Maximum** – Reports the maximum value and the time that the maximum value occurred. When the maximum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the maximum for a variable in Joules is reported in Watts.

**Minimum** – Reports the minimum value and the time that the minimum value occurred. When the minimum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the minimum for a variable in Joules is reported in Watts.

**HoursNonZero** – The HoursNonZero option adds up the elapsed time during the month that this variable is non-zero and would be appropriate to determine the number of hour that a fan operates.

**HoursZero** – The HoursZero option adds up the elapsed time during the month that this variable has a zero value and would be appropriate to determine the number of hour that a fan does not operate.

**HoursPositive** – The HoursPositive option adds up the elapsed time during the month that this variable has a positive value. Hours with a zero value are not included.

**HoursNonPositive** – The HoursNonPositive option adds up the elapsed time during the month that this variable has non-positive value. Hours with a negative value and hours with a zero value are all included.

**HoursNegative** – The HoursNegative option adds up the elapsed time during the month that this variable has a negative value. Hours with a zero value are not included.

**HoursNonNegative** – The HoursNonNegative option adds up the elapsed time during the month that this variable has non-negative value. Hours with a positive value and hours with a zero value are all included.

**HourInTenBinsMinToMax** - Creates 10 columns for the specified variable and shows the number of hours in each of 10 bins based on the minimum and maximum value. The bin sizes will be rounded up to the next most significant digit value (if the min is 0 and the max is 28786.3, the bin size would be 3000 not 2878.63). A table of the bin ranges would be generated below the main table when this option is selected.

**HourInTenBinsZeroToMax** - Creates 11 columns for the specified variable and shows the number of hours in each of 10 bins from zero to the maximum value and a bin for hours below zero. The bin sizes will be rounded up to the next most significant digit value (if the min is 0 and the max is 28786.3, the bin size would be 3000 not 2878.63). A table of the bin ranges would be generated below the main table when this option is selected.

**HourInTenBinsMinToZero** - Creates 11 columns for the specified variable and shows the number of hours in each of 10 bins from zero to the minimum value and a bin for hours above zero. The bin sizes will be rounded up to the next most significant digit value (if the min is 0 and the min is -28786.3, the bin size would be 3000 not 2878.63). A table of the bin ranges would be generated below the main table when this option is selected.

#### *Advanced Aggregation Types*

The advanced aggregation types are described below. These aggregation types rely on doing an operation on the current variable but only during the time or times defined by a previously defined field. The ValueWhenMaxOrMin displays the value of one variable at the same time as the maximum or minimum is set on a previous field that is defined as either a maximum or minimum. The “Hours—“ aggregation types (not including binning) display then number of hours that a variable meets a condition. The “—DuringHoursShown” aggregation types perform those aggregations but instead of for all the hours in the month, only for the hours that the previous “Hours—“ entry applies. Multiple “—DuringHoursShown” after an “Hours—“ will all be based on that single “Hours—“ entry, in fact the “—DuringHoursShown” is based on the next column to the left that contains an “Hours—“ entry even if other types of aggregations are used in intermediate columns. Order of the variables in the report is important when using the advanced aggregation types since they often depend on a previous entry.

**ValueWhenMaximumOrMinimum** – The ValueWhenMaximumOrMinimum option looks at the previous variable in the report that sets a maximum or minimum and displays the value of the current variable at that same timestep. Order of the variables in the report is important when using ValueWhen-MaxMin. This can be used, for example, when an outdoor temperature should be reported for the time of the maximum cooling load.

**SumOrAverageDuringHoursShown** – Provides the sum or average of the named variable when during the hours that the previous variable displayed with any of the aggregation types starting with “Hours”. For “sum” type variables adds up the values for each timestep and reports the sum of the value during the hours reported on the previous variable. For “average” type variables, the value shown will be

the average for the month during the hours reported on the previous variable. Order of the variables in the report is important when using this aggregation type.

**MaximumDuringHoursShown** – Reports the maximum value and the time that the maximum value occurred but only during the hours reported with the previous “hours-“ aggregation type. When the maximum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the maximum for a variable in Joules is reported in Watts. Order of the variables in the report is important when using this aggregation type.

**MinimumDuringHoursShown** - Reports the minimum value and the time that the minimum value occurred but only during the hours reported with the previous “hours-“ aggregation type. When the minimum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the minimum for a variable in Joules is reported in Watts. Order of the variables in the report is important when using this aggregation type.

### 7.3.1.0.7 Field: Digits After Decimal for Variable or Meter <#>

The Digits After Decimal field is a numeric value that indicates how many digits after the decimal point should be shown for that column.

An example of this object follows.

```
Output:Table:Annual,
  Custom Annual Window Report,  !- Name
  , !- Filter
  , !- Schedule Name
  SURFACE WINDOW TRANSMITTED SOLAR RADIATION RATE,  !- Variable, Meter, EMS Int Var, IDF field Name 1
  SumOrAverage,  !- Aggregation Type for 1
  2,  !- Digits After Decimal for 1
  SURFACE WINDOW TRANSMITTED BEAM SOLAR RADIATION RATE,  !- Variable, Meter, EMS Int Var, IDF field Name
  2
  SumOrAverage,  !- Aggregation Type for 2
  2,  !- Digits After Decimal for 2
  SURFACE WINDOW TRANSMITTED DIFFUSE SOLAR RADIATION RATE,  !- Variable, Meter, EMS Int Var, IDF field
  Name 3
  SumOrAverage,  !- Aggregation Type for 3
  2,  !- Digits After Decimal for 3
  SURFACE WINDOW HEAT GAIN RATE,  !- Variable, Meter, EMS Int Var, IDF field Name 4
  SumOrAverage,  !- Aggregation Type for 4
  2,  !- Digits After Decimal for 4
  ACE WINDOW HEAT LOSS RATE,  !- Variable, Meter, EMS Int Var, IDF field Name 5
  SumOrAverage,  !- Aggregation Type for 5
  2;  !- Digits After Decimal for 5
```

## 7.4 Output:Table:SummaryReports

The Output:Table:SummaryReports object controls which predefined tabular reports are produced. The easiest option is to specify “AllSummary” which will produce all of the summary reports described in this section and does not include any of the Component Load Summary reports. In addition, “AllMonthly” will produce all of the monthly reports described. If all predefined reports are needed. “AllSummaryAndMonthly” shows all of the summary and monthly predefined reports and does not include any of the Component Load Summary reports. The “AllSummaryAndSizingPeriod” option and “AllSummaryMonthlyAndSizingPeriod” option are similar and add the Zone Component Load Summary, AirLoop Component Load Summary, and Facility Component Load Summary reports. Including the Component Load Summary reports will increase the simulation run time.

## 7.4.1 Inputs

### 7.4.1.0.1 Field: Report <#> Name

All of the fields in the Output:Table:SummaryReports are the same. A long list of predefined summary reports is available by entering one of the available key choices described below. Each one indicates the name of the predefined reports that should be output. The input AllSummary will cause all the reports described below to be created. The Report <#> Name field can be repeated.

### 7.4.1.1 Predefined Annual Summary Reports

#### 7.4.1.1.1 Annual Building Utility Performance Summary (sometimes called ABUPS)

The Annual Building Utility Performance Summary report often called ABUPS – (key: Annual-BuildingUtilityPerformanceSummary) produces a report that is an overall summary of the utility consumption of the building. It contains a number of subtables that are each described below.

- Site and Source Energy – Indicates the total site and source energy use. For electricity the net electricity from the utility is used for the electric contribution. The site to source conversion factors are based on those entered by the user. These are entered in the **EnvironmentalImpactFactors** object and **FuelFactors** objects.
- Building Area – Shows the total floorspace of the building and the conditioned floorspace.
- End Uses – This shows the total use of electricity, natural gas, other fuels, purchased cooling, purchased heating and water for each major end-use category. The end-use categories are Heating, Cooling, Interior Lighting, Exterior Lighting, Interior Equipment, Exterior Equipment, Fans, Pumps, Heat Rejection, Humidification, Heat Recovery, Hot Water, Refrigeration, and Generators. Not all fuels have corresponding end uses. The values in this sub-table are from output meters. To determine which components are attached to each end-use meter, consult the meter details output file (\*.mtd). The source of the resource does not affect this table – the amount of electricity used for lights does not change if the electricity is from the utility or from an on-site generator. The district heating column also includes steam.
- End Uses By Subcategory – Shows a breakdown of the major end uses by user-defined category. If an end-use subcategory was not input for an object, it is automatically added to the General subcategory for that major end-use category.
- Utility Use Per Floor Area – These two sub-tables show the results from the end-uses table divided by the total floor area defined for the building and for the total conditioned floor area. Only three categories for end-uses are used for these sub-tables, lighting, HVAC and other. HVAC includes fans, pumps, heating, cooling, heat rejection, humidification, and domestic hot water heating. The district heating column also includes steam.
- Electric Loads Satisfied – Shows the different methods that electric loads are satisfied in the building. The values shown for on site power generation are: Fuel-Fired Power Generation, High Temperature Geothermal, Photovoltaic Power, and Wind Power. The flows to and from the electric utility are shown next and finally the total electricity used at the site is compared to the total generated on site plus the net amount from the electric utility. The percentages shown are based on the total electricity used by the end-uses. Note that High Temperature Geothermal and Wind Power are not yet implemented in EnergyPlus.

- On-Site Thermal Sources – Shows the on-site thermal sources of energy such as Water-Side Heat Recovery, Air to Air Heat Recovery for Cooling, Air to Air Heat Recovery for Heating, High-Temperature Geothermal, Solar Water Thermal, Solar Air Thermal. Note that High-Temperature Geothermal Solar Water Thermal, and Solar Air Thermal are not yet implemented in EnergyPlus.
- Water Loads Summary – Shows the different methods the water loads were satisfied. This table shows all zeros because water use is not yet implemented in EnergyPlus.

#### 7.4.1.1.2 Input Verification and Results Summary (or IVRS)

The Input Verification and Results Summary report (key: InputVerificationandResultsSummary) produces a report with several tables including:

- General which includes general information like the Program Version and Build, Weather, Latitude, Longitude, Elevation, Time Zone, North Axis Angle, and Hours Simulated.
- Window-Wall Ratio table for envelope which includes the wall area, the window area and the ratio of the two. These are computed for all walls and for walls that are oriented generally north, south, east and west. All walls are categorized into one of these four cardinal directions. This is computed for walls that have a tilt of 60 to 120 degrees.
- Skylight-Roof Ratio table for envelope which includes the roof area and the skylight area and the ratio of the two. This includes all surfaces with a tilt of less than 60 degrees.
- Zone Summary includes internal load summary for each zone including area, if conditioned, volume, multipliers, above ground gross wall area, underground gross wall area, window area, design lighting, design people, and design plug and process.
- Hybrid Model: Internal Thermal Mass table is only shown when hybrid model: internal thermal mass simulation. This includes Hybrid Modeling (Y/N) for internal mass and Temperature Capacitance Multiplier values for each zone.

#### 7.4.1.1.3 Source Energy End Use Components Summary

The Source Energy End Use Components Summary report produces a report (key: SourceEnergyEndUseComponentsSummary) that includes three tables. These tables display source energy by fuel type that is calculated based on site to source energy factors specified by the user in the **EnvironmentalImpactFactors** and **FuelFactors** objects. The last two tables display the source energy in terms of area normalized metrics. Following is a description of each table:

- Source Energy End Use Components – This shows the total use of source electricity, source natural gas, source values of other fuels, source purchased cooling and purchased heating for each major end-use category. The end-use categories are Heating, Cooling, Interior Lighting, Exterior Lighting, Interior Equipment, Exterior Equipment, Fans, Pumps, Heat Rejection, Humidification, Heat Recovery, Hot Water, Refrigeration, and Generators. Not all fuels have corresponding end uses. The values in this sub-table are from output meters. To determine which components are attached to each end-use meter, consult the meter details output file (\*.mtd). The source of the resource will affect this table – the amount of electricity used for lights will change if the electricity is from the utility or from an on-site generator. The district heating column also includes steam.
- Source Energy End Use Components normalized by Conditioned Floor Area – This table shows the total end uses in source energy normalized by conditioned floor area.
- Source Energy End Use Components normalized by Total Floor Area – This table shows the total end uses in source energy normalized by total floor area.

#### 7.4.1.1.4 Climatic Data Summary

The Climate Summary or Climatic Data Summary report (key: ClimaticDataSummary) produces a report that includes some of the details on each of the design days including: maximum dry-bulb, daily temperature range, humidity value, humidity type, wind speed, and wind direction.

#### 7.4.1.1.5 Envelope Summary

The Envelope Summary report (key: EnvelopeSummary) produces a report that includes the following tables:

- Opaque which includes all opaque surfaces and includes the name of the construction, reflectance, U-Factor, gross area, azimuth, tilt, cardinal direction.
- Fenestration which includes all non-opaque surfaces and includes the name of the construction, areas (glass, frame, divider, single opening, multiplied openings), U-Factor, SHGC (the solar heat gain coefficient based on summer conditions), visible transmittance, conductance (frame, divider), indication of shade control, the name of the parent surface, azimuth, tilt, cardinal direction.

#### 7.4.1.1.6 Surface Shadowing Summary

The Surface Shadowing Summary report (key: SurfaceShadowingSummary) produces a report that includes two tables. Note that surfaces starting with “Mir-“ are automatically generated by EnergyPlus and are the mirror images of user entered surfaces.

- Surfaces (Walls, Roofs, etc) that may be Shadowed by Other Surfaces and includes the name of the surface and a list of surfaces that may possibly cast shadows on that named surface. The list of possible shadow casters does not necessarily mean that they do cast shadows during the simulation, only that their relative position makes it possible that shadows from a surface in the list may fall on the named surface.
- Subsurfaces (Windows and Doors) that may be Shadowed by Surfaces, includes the name of the subsurface such as a window or a door and a corresponding list of surfaces that may be casting shadows on the windows and doors.

#### 7.4.1.1.7 Shading Summary

The Shading Summary report (key: ShadingSummary) produces a report that includes the following tables:

- Sunlit Fraction which shows a list of windows and the fraction of the window that is sunlit for nine specific times of the year. The nine specific times include 9am, noon and 3pm on March 21, June 21, and December 21. These nine times were chosen to represent the range of sun angles. The simulation must include those times for the value to be included in the report.
- Window control includes the names of all windows that have a window shading control (see [Window-ShadingControl](#)) and includes the name of the control, the type of shading, the shaded construction, the kind of control, and if glare control is used.

#### 7.4.1.1.8 Lighting Summary

The Lighting Summary report (key: LightingSummary) produces a report that includes the following tables:

- Interior Lighting which includes the name of the lights object, the zone that it is used in, the lighting power density, zone area, total power, end use subcategory, schedule name, average hours per week, return air fraction, and whether the zone is conditioned.
- Daylighting which includes the names of the daylighting objects, the zone they are used in, the type of daylighting being used, the control type, the fraction of the lighting controlled, the total power of the lighting installed in the zone and the lighting power that is controlled by the daylighting object.
- Exterior Lighting which includes the name of the ExteriorLights object, the total watts described by the object, if the ExteriorLights uses an astronomical clock or just a schedule, the name of the schedule used, and the average hours per week for the named schedule for the year. The effect of the astronomical clock does not get included in the averaged hours per week shown.

#### 7.4.1.1.9 Equipment Summary

The Equipment Summary report (key: EquipmentSummary) produces a report that includes some details on the major HVAC equipment present. The report has seven parts.

- Central Plant includes details on chillers, boilers, and cooling towers including the capacity and efficiency. For **Chiller:Electric:EIR** and **Chiller:Electric:ReformulatedEIR**, IPLV at AHRI standard test conditions is reported.
- Cooling Coils includes the nominal total, sensible and latent capacities, the nominal sensible heat ratio, the nominal efficiency, nominal UA value, and nominal surface area for each cooling coil. These values are calculated by calling the cooling coil simulation routine with the rated inlet conditions: inlet air dry bulb temperature = 26.67C, inlet air wet bulb temperature = 19.44C, inlet chilled water temperature = 6.67C.
- DX Cooling Coils summarizes the Standard Rating (Net) Cooling Capacity, SEER, EER and IEER values at AHRI standard test. Currently, these values are only reported for coil type = **Coil:Cooling:DX:SingleSpeed** and **Coil:Cooling:DX:MultiSpeed** with condenser type = AirCooled. However, the EER value is not reported for the multi-speed DX cooling coil. There are two SEER values reported: *SEER* and *SEER Default*. The *SEER* value is calculated using user specified Part Load Factor (PLF) curve used for energy performance calculation and the *SEER Default* value is calculated using the AHRI Standard 210/240-2008 default PLF curve and cooling coefficient of degradation value of 0.25.
- DX Heating Coils summarizes the High Temperature Heating Standard (Net) Rating Capacity, Low Temperature Heating Standard (Net) Rating Capacity and Heating Seasonal Performance Factor (HSPF) values at AHRI standard test. Currently, these values are only reported for coil type = **Coil:Heating:DX:SingleSpeed**.
- Heating Coils includes the nominal capacity and efficiency for each heating coil. The capacity is calculated by calling the heating coil simulation routine at the rated inlet conditions: inlet air dry bulb temperature = 16.6C, inlet relative humidity = 50%, inlet hot water temperature = 82.2C.
- Fan includes the type of fan, the total efficiency, delta pressure, max flow rate, motor heat in air fraction, and end use.
- Pumps includes the type of pump, control type, head pressure, electric power, and motor efficiency for each pump.
- Service Water Heating includes the type of water heater, the storage volume, input, thermal efficiency, recovery efficiency, and energy factor.

#### 7.4.1.1.10 HVAC Sizing Summary

The HVAC Sizing Summary report (key: HVACSizingSummary) produces a report that includes the following tables:

- Zone Cooling which includes the following columns for each zone: the calculated design load, the user specified design load, the calculated design air flow, the user specified design air flow, the name of the sizing period, the time of the peak load during the sizing period, the temperature at the time of the peak load during the sizing period, and the humidity ratio at the time of the peak load during the sizing period used.
- Zone Heating which includes the following columns for each zone: the calculated design load, the user specified design load, the calculated design air flow, the user specified design air flow, the name of the sizing period, the time of the peak load during the sizing period, the temperature at the time of the peak load during the sizing period, and the humidity ratio at the time of the peak load during the sizing period used.
- System Design Air Flow Rates which includes the following columns for each air loop: the calculated cooling air flow rate, the user specified air flow rate for cooling, the calculated heating air flow rate, the user specified air flow rate for heating.
- Coil Sizing Summary which includes the following types of information for each coil: coil type, HVAC location, capacity and flow rates at the zone peak, system peak, and final values, design day name and time for the zone peak and system peak, zone conditions at the system peak, etc. This table is a subset of the Coil Sizing Details table. See the Output Details and Examples document for a complete description of each column.
- *Note:* values listed as “calculated” are the unaltered result of the zone or system sizing calculations, using the design sizing period weather and schedules specified in the input. Values listed as “user specified” are either the calculated values modified by global or zone sizing factors or values specified with the *flow/zone* or *flow/system* design air flow method.

#### 7.4.1.1.11 Component Sizing Summary

The Component Sizing Summary report (key: ComponentSizingSummary) produces a report that includes different tables depending on the kinds of HVAC components that exist in the input file. A table is shown for each type of HVAC component that is sized. The table lists the objects of that type of component that appear in the input file and one or more parameters related to that component. For example, the **AirTerminal:SingleDuct:VAV:Reheat** component creates a table showing the maximum air flow rate from the sizing calculations and the maximum reheat water flow rate. Another example is the **Fan:VariableVolume** object which shows a table with both the maximum and minimum flow rates for each fan based on the results from the sizing calculations.

#### 7.4.1.1.12 Coil Sizing Details

The Coil Sizing Details report (key: CoilSizingDetails) produces a report that includes the following types of information for each coil: coil type, HVAC location, capacity and flow rates at the zone peak, system peak, and final values, design day name and time for the zone peak and system peak, zone conditions at the system peak, coil entering and leaving conditions, supply fan information, related plant sizing information, etc. See the Output Details and Examples document for a complete description of each column.

#### 7.4.1.1.13 Outdoor Air Summary

The Outdoor Air Summary report (key: OutdoorAirSummary) produces a report that includes the following tables:

- Average Outside Air During Occupied Hours table shows for each zone the average and nominal number of occupants, the zone volume, the average air change rate based on mechanical ventilation, infiltration and simple ventilation during occupied hours.
- Minimum Outside Air During Occupied Hours table shows for each zone the average and nominal number of occupants, the zone volume, the minimum air change rate based on mechanical ventilation, infiltration and simple ventilation during occupied hours.

#### 7.4.1.1.14 Outdoor Air Details

The Outdoor Air Details report (key: OutdoorAirDetails) produces a report that includes the following tables. For descriptions of each column, see the Output Details and Examples document.

- Mechanical Ventilation Parameters by Zone table shows for each zone the average and nominal number of occupants, the zone volume and area, the design outdoor air flow rate  $V_{oz}$  and the minimum dynamic target ventilation flow rate  $V_{oz-dyn-min}$ .
- Total Outdoor Air by Zone table shows for each zone the total mechanical ventilation, natural ventilation, total ventilation (mechanical plus natural), infiltration, total ventilation plus infiltration, dynamic target ventilation  $V_{oz-dyn}$ , the time when total ventilation is below, at, or above  $V_{oz-dyn}$ , and the time ventilation is provided when the zone is unoccupied.
- Average Outdoor Air During Occupancy by Zone - Flow Rates table shows for each zone the average flow rates when the zone is occupied for mechanical ventilation, natural ventilation, total ventilation (mechanical plus natural), infiltration, total ventilation plus infiltration, dynamic target ventilation  $V_{oz-dyn}$  and the time when total ventilation is below, at, or above  $V_{oz-dyn}$ .
- Total Outdoor Air by AirLoop table shows for each airloop the total mechanical ventilation, natural ventilation, total ventilation (mechanical plus natural), sum of the zone dynamic target ventilation  $V_{oz-dyn}$ , the time when total ventilation is below, at, or above  $V_{oz-dyn}$ , and the time ventilation is provided when all zones are unoccupied.
- Average Outdoor Air During Occupancy by AirLoop table shows for each airloop the average flow rates when any zone on the airloop is occupied for mechanical ventilation, natural ventilation, total ventilation (mechanical plus natural), sum of the zone dynamic target ventilation  $V_{oz-dyn}$ , and the time when total ventilation is below, at, or above  $V_{oz-dyn}$ .
- Outdoor Air Controller Limiting Factors by AirLoop table shows for each airloop the time when any zone on the airloop is occupied and various limiting factors control the mechanical ventilation flow rate: no limiting factor, economizer operation, demand controlled ventilation, exhaust flow, high humidity economizer control, night ventilation, limits and scheduled limits, demand limiting, and energy management system override.
- Average Outdoor Air for Limiting Factors During Occupancy table shows for each airloop the average mechanical ventilation flow rates when any zone on the airloop is occupied and various limiting factors control the mechanical ventilation flow rate: no limiting factor, economizer operation, demand controlled ventilation, exhaust flow, high humidity economizer control, night ventilation, limits and scheduled limits, demand limiting, and energy management system override.

#### 7.4.1.1.15 System Summary

The System Summary Report (key: SystemSummary) produces a report that includes the following tables:

- Economizer which includes the following columns for each **Controller:OutdoorAir** object: the high limit shutoff control, the minimum outdoor air flow, the maximum outdoor air flow, if the return air temperature has a control limit, if the return air has an enthalpy limit, the outdoor air temperature limit, and the outdoor air enthalpy limit.
- Demand Controlled Ventilation table is for each **Controller:MechanicalVentilation** object and shows the name, the nominal outdoor air per person and the nominal outdoor air per zone area.
- Time Not Comfortable Based on Simple ASHRAE 55-2004 table shows how many hours that the space is not comfortable for each zone under the criteria of assuming winter clothes, summer clothes or both summer and winter clothes. See the **People** object for more information about this thermal comfort calculation.
- Time Setpoint is Not Met table shows how many hours the space is more than 0.2C from the setpoint during heating and during cooling. The last two columns indicate those hours that the setpoint is not met while the space is occupied.

#### 7.4.1.1.16 Adaptive Comfort Summary

The Adaptive Comfort Summary report (key: AdaptiveComfortSummary) produces a report tabulating the sum of occupied hours not meeting adaptive comfort acceptability limits for each relevant **People** object (**People** objects for which adaptive comfort calculations are requested). These acceptability limits include ASHRAE Std. 55 80%, ASHRAE Std. 55 90%, CEN-15251 Category I, CEN-15251 Category II, and CEN-15251 Category III.

#### 7.4.1.1.17 Sensible Heat Gain Summary

The Sensible Heat Gain Summary (key: SensibleHeatGainSummary) provides results for each zone and the overall building for some of the major heat gain components. The first four columns show the loads satisfied by sensible air heating and cooling as well as radiant heating and cooling surfaces in the zone. The heat gains from people, lighting, equipment, windows, interzone air flow, and infiltration are shown when adding heat to the zone and separately when removing heat from the zone (for applicable components). Finally the balance is shown as “Opaque Surface Conduction and Other Heat Addition” and “Opaque Surface Conduction and Other Heat Removal” which is a term indicating the affect of the walls, floors and ceilings/roof to the zone as well as the impact of the delay between heat gains/losses and loads on the HVAC equipment serving the zone. The following shows each output variable that is used for each column. For each timestep in the simulation, positive values are shown as additions and negative values are shown as removal for most variables.

- HVAC Input Sensible Air Heating

Zone Air Heat Balance System Air Transfer Rate

Zone Air Heat Balance System Convective Heat Gain Rate

- HVAC Input Sensible Air Cooling

Zone Air Heat Balance System Air Transfer Rate

Zone Air Heat Balance System Convective Heat Gain Rate

- HVAC Input Heated Surface Heating

Zone Radiant HVAC Heating Energy

Zone Ventilated Slab Radiant Heating Energy

- HVAC Input Cooled Surface Cooling

Zone Radiant HVAC Cooling Energy

Zone Ventilated Slab Radiant Cooling Energy

- People Sensible Heat Addition

Zone People Sensible Heating Energy

- Lights Sensible Heat Addition

Zone Lights Total Heating Energy

- Equipment Sensible Heat Addition & Equipment Sensible Heat Removal

Zone Electric Equipment Radiant Heating Energy

Zone Gas Equipment Radiant Heating Energy

Zone Steam Equipment Radiant Heating Energy

Zone Hot Water Equipment Radiant Heating Energy

Zone Other Equipment Radiant Heating Energy

Zone Electric Equipment Convective Heating Energy

Zone Gas Equipment Convective Heating Energy

Zone Steam Equipment Convective Heating Energy

Zone Hot Water Equipment Convective Heating Energy

Zone Other Equipment Convective Heating Energy

- Window Heat Addition & Window Heat Removal

Zone Windows Total Heat Gain Energy

- Interzone Air Transfer Heat Addition & Interzone Air Transfer Heat Removal

Zone Air Heat Balance Interzone Air Transfer Rate

- Infiltration Heat Addition & Infiltration Heat Removal

Zone Air Heat Balance Outdoor Air Transfer Rate

The Opaque Surface Conduction and Other Heat Addition and Opaque Surface Conduction and Other Heat Removal columns are also calculated on an timestep basis as the negative value of the other removal and gain columns so that the total for the timestep sums to zero. These columns are derived strictly from the other columns.

#### 7.4.1.1.18 Component Load Summary

Three different component load summary reports can be generated:

- Zone Component Loads Summary
- AirLoop Component Loads Summary
- Facility Component Loads Summary

The AirLoop and Facility level reports are generally aggregations of the results reported in the Zone Component Loads Summary report. The Component Loads Summary reports provide an estimate of the heating and cooling peak loads for each zone, airloop or the entire facility broken down into various components. These reports may help determine which components of the load have the largest impact for the heating and cooling peak design conditions. When specified, the Zone Component Loads Summary report is created for each zone that is conditioned. Similarly, the AirLoop Component Load Summary is generated for each AirLoop and a single Facility Component Loads Summary is generated for the entire facility. The difference between the peak design sensible load and the estimated instant + delayed sensible load (as shown in the *Peak Conditions* subtable) is an indication of how consistent the overall total estimate may be to the computed total peak loads for the zone. When the report is called the zone sizing calculations are repeated twice so this may result in longer simulation times. The keys used to obtain these reports are ZoneComponentLoadSummary, AirLoopComponentLoadSummary, and FacilityComponentLoadSummary. Since including this report may increase the simulation time, new key options have been added that will display all reports but the Zone Component Load Summary those keys used are AllSummaryButZoneComponentLoad and AllSummaryAndMonthlyButZoneComponentLoad.

The report has six parts:

- Estimated Cooling Peak Load Components

Contains the sensible-instant, sensible-delay, sensible-return air, latent, total and %grand total for people, lights, equipment, refrigeration, water use equipment, HVAC equipment loads, power generation equipment, infiltration, zone ventilation, interzone mixing, roof, interzone ceiling, other roof, exterior wall, interzone wall, ground contact wall, other wall, exterior floor, interzone floor, ground contact floor, other floor, fenestration conduction, fenestration solar, opaque door. The values in the sensible-delay column are estimated using a procedure shown in the Engineering Reference. Also shown are the related areas for each type of component. For **People** and **Lights** the floor area is shown but for walls, fenestration. and other surfaces, the area of that surface is used.

- Cooling Peak Conditions

Contains the time of the peak load and the outside dry bulb and wet bulb temperatures as well as the outside humidity ratio for that time. It also shows the zone temperature and relative humidity and humidity ratio for that time. The airflow and outside airflow as well as the supply air temperature are shown. Also the sensible peak load accounting for the sizing factor is shown along with the difference due to the sizing factor.

- Engineering Checks for Cooling

This table shows some ratios that may be handy in evaluating the results. It contains the percentage of outside air, the airflow per floor area, the airflow per capacity, the floor area per capacity and the capacity per floor area. It also shows the number of people.

- Estimated Heating Peak Load Components

Contains the sensible-instant, sensible-delay, sensible-return air, latent, total and %grand total for people, lights, equipment, refrigeration, water use equipment, HVAC equipment loads, power generation equipment, infiltration, zone ventilation, interzone mixing, roof, interzone ceiling, other roof, exterior wall, interzone wall, ground contact wall, other wall, exterior floor, interzone floor, ground contact floor, other floor, fenestration conduction, fenestration solar, opaque door. The values in the sensible-day column are estimated using a procedure shown in the Engineering Reference. Also shown are the related areas for each type of component. For **People** and **Lights** the floor area is shown but for walls, fenestration. and other surfaces, the area of that surface is used.

- Heating Peak Conditions

Contains the time of the peak load and the outside dry bulb and wet bulb temperatures as well as the outside humidity ratio for that time. It also shows the zone temperature and the relative humidity and humidity ratio for that time. The airflow and outside airflow as well as the supply air temperature are shown. Also the sensible peak load accounting for the sizing factor is shown along with the difference due to the sizing factor

- Engineering Checks for Heating

This table shows some ratios that may be handy in evaluating the results. It contains the percentage of outside air, the airflow per floor area, the airflow per capacity, the floor area per capacity and the capacity per floor area. It also shows the number of people.

The Air Loop Component Summary tables also include tables that indicate the zones included in the aggregated results for heating and cooling.

If the time of the peak load for each Zone for cooling exactly matches the time of the peak load for the AirLoop or Facility than the Estimated Cooling Peak Load Components will represent a sum of the values from the corresponding zones. Likewise the Estimated Heating Peak Load Components will add up for the AirLoop or Facility if the times of the heating peaks exactly match. This is not necessarily the case for Peak Conditions or the Engineering Checks tables. Since the sizing of Airloops is based on the system sizing they usually will be different than the sum of the corresponding zones.

#### 7.4.1.1.19 Standard 62.1 Summary

The Standard 62.1 Summary (key: Standard62.1Summary) produces a report that is consistent with many of the outputs needed when doing calculations consistent with ASHRAE Standard 62.1-2010. The report is generated when sizing calculations are specified. The abbreviations used in the report are consistent with the abbreviations used in Appendix A4 of the Standard. The following tables are part of the report:

- System Ventilation Requirements for Cooling containing: Sum of Zone Primary Air Flow -  $V_{pz-sum}$ , System Population -  $P_s$ , Sum of Zone Population -  $P_{z-sum}$ , Occupant Diversity -  $D$ , Uncorrected Outdoor Air Intake Airflow -  $V_{ou}$ , System Primary Airflow -  $V_{ps}$ , Average Outdoor Air Fraction -  $X_s$ , System Ventilation Efficiency -  $E_v$ , Outdoor Air Intake Flow -  $V_{ot}$ , Percent Outdoor Air - %OA.
- System Ventilation Requirements for Heating containing: Sum of Zone Primary Air Flow -  $V_{pz-sum}$ , System Population -  $P_s$ , Sum of Zone Population -  $P_{z-sum}$ , Occupant Diversity -  $D$ , Uncorrected Outdoor Air Intake Airflow -  $V_{ou}$ , System Primary Airflow -  $V_{ps}$ , Average Outdoor Air Fraction -  $X_s$ , System Ventilation Efficiency -  $E_v$ , Outdoor Air Intake Flow -  $V_{ot}$ , Percent Outdoor Air - %OA.

- Zone Ventilation Parameters containing: AirLoop Name, People Outdoor Air Rate – Rp, Zone Population – Pz, Area Outdoor Air Rate – Ra, Zone Floor Area – Az, Breathing Zone Outdoor Airflow – Vbz, Cooling Zone Air Distribution Effectiveness - Ez-clg, Cooling Zone Outdoor Airflow - Voz-clg, Heating Zone Air Distribution Effectiveness - Ez-htg, Heating Zone Outdoor Airflow - Voz-htg.
- System Ventilation Parameters containing: People Outdoor Air Rate – Rp, Sum of Zone Population - Pz-sum, Area Outdoor Air Rate – Ra, Sum of Zone Floor Area - Az-sum, Breathing Zone Outdoor Airflow – Vbz, Cooling Zone Outdoor Airflow - Voz-clg, Heating Zone Outdoor Airflow - Voz-htg.
- Zone Ventilation Calculations for Cooling Design containing: AirLoop Name, Box Type, Zone Primary Airflow – Vpz, Zone Discharge Airflow – Vdz, Minimum Zone Primary Airflow - Vpz-min, Zone Outdoor Airflow Cooling - Voz-clg, Primary Outdoor Air Fraction – Zpz, Primary Air Fraction – Ep, Secondary Recirculation Fraction- Er, Supply Air Fraction- Fa, Mixed Air Fraction – Fb, Outdoor Air Fraction – Fc, Zone Ventilation Efficiency – Evz.
- System Ventilation Calculations for Cooling Design containing: Sum of Zone Primary Airflow - Vpz-sum, System Primary Airflow – Vps, Sum of Zone Discharge Airflow - Vdz-sum, Minimum Zone Primary Airflow - Vpz-min, Zone Outdoor Airflow Cooling - Voz-clg, Zone Ventilation Efficiency - Evz-min.
- Zone Ventilation Calculations for Heating Design containing: AirLoop Name, Box Type, Zone Primary Airflow – Vpz, Zone Discharge Airflow – Vdz, Minimum Zone Primary Airflow - Vpz-min, Zone Outdoor Airflow Cooling - Voz-clg, Primary Outdoor Air Fraction – Zpz, Primary Air Fraction – Ep, Secondary Recirculation Fraction- Er, Supply Air Fraction- Fa, Mixed Air Fraction – Fb, Outdoor Air Fraction – Fc, Zone Ventilation Efficiency – Evz.
- System Ventilation Calculations for Heating Design containing: Sum of Zone Primary Airflow - Vpz-sum, System Primary Airflow – Vps, Sum of Zone Discharge Airflow - Vdz-sum, Minimum Zone Primary Airflow - Vpz-min, Zone Outdoor Airflow Cooling - Voz-clg, Zone Ventilation Efficiency - Evz-min.

#### 7.4.1.1.20 Energy Meters Summary

The Energy Meters Summary (key: EnergyMeters) (which is a slight misnomer as some meters may not be strictly energy) provides the annual period (runperiod) results for each meter (reference the meter data dictionary file (.mdd) and/or the meter details file (.mtd). The results are broken out by fuel type (resource type) in this report.

#### 7.4.1.1.21 Initialization Summary

The Initialization Summary (key: InitializationSummary) provides the information shown in the initialization output file (.eio) but in a tabular format. Due to this, some of the outputs may be difficult to understand without referencing the documentation on the .eio file that is located in the Output Details and Examples document.

#### 7.4.1.1.22 LEED Summary

The LEED Summary report provides many of the simulation results required for certification of Energy and Atmosphere Credit 1 Optimized Energy Performance according to the LEED Green Building Rating System™. The report can be produced by specifying LEEDSummary in Output:Table:SummaryReports which is also part of the AllSummary option. Directly following is an example of this report.

#### 7.4.1.1.23 Tariff Report

The Tariff Report provides the results of the **UtilityCost:Tariff** object. The report consists of a summary table, categories, charges, ratchets, qualifies, native variables, other variables and computation. The key used to obtain this report is **TariffReport**.

#### 7.4.1.1.24 Economic Result Summary

The Economic Result Summary provides a summary of the Tariff Reports. The report consists of annual costs and costs for each tariff considered and why it was or was not selected. The key used to obtain this report is **EconomicResultSummary**.

#### 7.4.1.1.25 Component Cost Economics Summary

The Component Cost Economics Summary provides the construction cost estimate summary for the project. The costs are broken into eight categories and the reference building costs are provided as a comparison. A second table is also produced that provides line item details with one line for every line item object. The key used to obtain this report is **ComponentCostEconomicsSummary**.

#### 7.4.1.1.26 Life Cycle Cost Report

The Life Cycle Cost Report provides a summary of the information from the Life Cycle Cost calculations. This report shows the costs and the timing of costs, often called “cash flows,” along with the present value in several different tables. The tabular results show the present value of all current and future costs. The key used to obtain this report is **LifeCycleCostReport**.

#### 7.4.1.1.27 Heat Emissions Report

The Heat Emissions Report provides a summary of the building heat emission to the ambient air. This report shows the heat emissions from buildings by surface heat transfer, zone exhaust, zone relief, HVAC relief, HVAC heat rejection, as well as the total emissions. The key used to obtain this report is **HeatEmissionsSummary**.

#### 7.4.1.1.28 Thermal Resilience Summary

The Thermal Resilience Summary provides the indoor thermal resilience metrics unmet hours and occupant · hours summary report. This includes the Heat Index Hours and OccupantHours, Humidex Hours and OccupantHours, Heating SET Hours and Cooling SET Hours reports. The Heating SET Hours and Cooling SET Hours are reported only when the Pierce model are chosen for thermal comfort calculations. To activate the Pierce SET calculation in EnergyPlus, users need to define the **People** and chose **Pierce** as the thermal comfort method.

#### 7.4.1.1.29 CO2 Resilience Summary

The CO2 Resilience Summary provides the indoor CO2 level unmet hours and occupant · hours summary report for resilience. This includes the CO2 Level Hours and OccupantHours reports. To activate the CO<sub>2</sub> concentration calculation in EnergyPlus, the **ZoneAirContaminantBalance** object needs to be specified and with the field **Carbon Dioxide Concentration** set to Yes. Users can define a schedule of outdoor air CO<sub>2</sub> concentration in the field **Outdoor Carbon Dioxide Schedule Name**. CO<sub>2</sub> generation rate at the zone level can be specified using the **ZoneContaminantSourceAndSink:CarbonDioxide** object.

#### 7.4.1.1.30 Visual Resilience Summary

The Visual Resilience Summary provides the indoor illuminance level unmet hours and occupant · hours summary report for resilience. This includes the Illuminance Level Hours and OccupantHours reports. To

activate the indoor illuminance calculation in EnergyPlus, users need to define the **Daylighting:Controls** and the **Daylighting:ReferencePoint** objects, even if no daylighting controls are actually implemented in the building simulation model.

#### 7.4.1.2 Predefined Monthly Summary Reports

The predefined monthly report options are shown below. The key name of the predefined monthly report is all that is needed to have that report appear in the tabular output file. After each report name below are the output variables and aggregation types used. These cannot be modified when using the predefined reports but if changes are desired, a **Output:Table:Monthly** can be used instead. The StandardReports.idf file in the DataSets directory includes a **Output:Table:Monthly** that exactly corresponds to the predefined monthly reports shown below. They can be copied into an IDF file and extended if additional variables are desired. A listing of each available key for predefined monthly summary reports follows with a description of the variables included.

##### 7.4.1.2.1 ZoneCoolingSummaryMonthly

- Zone Air System Sensible Cooling Energy (SumOrAverage)
- Zone Air System Sensible Cooling Rate (Maximum)
- Site Outdoor Air Drybulb Temperature (ValueWhenMaxMin)
- Site Outdoor Air Wetbulb Temperature (ValueWhenMaxMin)
- Zone Total Internal Latent Gain Energy (SumOrAverage)
- Zone Total Internal Latent Gain Energy (Maximum)
- Site Outdoor Air Drybulb Temperature (ValueWhenMaxMin)
- Site Outdoor Air Wetbulb Temperature (ValueWhenMaxMin)

##### 7.4.1.2.2 ZoneHeatingSummaryMonthly

- Zone Air System Sensible Heating Energy (SumOrAverage)
- Zone Air System Sensible Heating Rate (Maximum)
- Site Outdoor Air Drybulb Temperature (ValueWhenMaxMin)

##### 7.4.1.2.3 ZoneElectricSummaryMonthly

- Zone Lights Electric Energy (SumOrAverage)
- Zone Lights Electric Energy (Maximum)
- Zone Electric Equipment Electric Energy (SumOrAverage)
- Zone Electric Equipment Electric Energy (Maximum)

#### 7.4.1.2.4 SpaceGainsMonthly

- Zone People Total Heating Energy (SumOrAverage)
- Zone Lights Total Heating Energy (SumOrAverage)
- Zone Electric Equipment Total Heating Energy (SumOrAverage)
- Zone Gas Equipment Total Heating Energy (SumOrAverage)
- Zone Hot Water Equipment Total Heating Energy (SumOrAverage)
- Zone Steam Equipment Total Heating Energy (SumOrAverage)
- Zone Other Equipment Total Heating Energy (SumOrAverage)
- Zone Infiltration Sensible Heat Gain Energy (SumOrAverage)
- Zone Infiltration Sensible Heat Loss Energy (SumOrAverage)

#### 7.4.1.2.5 PeakSpaceGainsMonthly

- Zone People Total Heating Energy (Maximum)
- Zone Lights Total Heating Energy (Maximum)
- Zone Electric Equipment Total Heating Energy (Maximum)
- Zone Gas Equipment Total Heating Energy (Maximum)
- Zone Hot Water Equipment Total Heating Energy (Maximum)
- Zone Steam Equipment Total Heating Energy (Maximum)
- Zone Other Equipment Total Heating Energy (Maximum)
- Zone Infiltration Sensible Heat Gain Energy (Maximum)
- Zone Infiltration Sensible Heat Loss Energy (Maximum)

#### 7.4.1.2.6 SpaceGainComponentsAtCoolingPeakMonthly

- Zone Air System Sensible Cooling Rate (Maximum)
- Zone People Total Heating Energy (ValueWhenMaxMin)
- Zone Lights Total Heating Energy (ValueWhenMaxMin)
- Zone Electric Equipment Total Heating Energy (ValueWhenMaxMin)
- Zone Gas Equipment Total Heating Energy (ValueWhenMaxMin)
- Zone Hot Water Equipment Total Heating Energy (ValueWhenMaxMin)
- Zone Steam Equipment Total Heating Energy (ValueWhenMaxMin)
- Zone Other Equipment Total Heating Energy (ValueWhenMaxMin)
- Zone Infiltration Sensible Heat Gain Energy (ValueWhenMaxMin)
- Zone Infiltration Sensible Heat Loss Energy (ValueWhenMaxMin)

**7.4.1.2.7 EnergyConsumptionElectricityNaturalGasMonthly**

- Electricity:Facility (SumOrAverage)
- Electricity:Facility (Maximum)

## 7.5 OutputControl:Table:Style

The OutputControl:Table:Style object controls how all standardized reports are produced.

### 7.5.1 Inputs

#### 7.5.1.0.1 Field: Column Separator

You have nine different options:

- Comma
- Tab
- Fixed
- HTML
- XML
- CommaAndHTML
- TabAndHTML
- XMLAndHTML
- All

The Comma style produces a text file (eplustbl.csv) with the values of the table separated by commas. This is a good format for importing the results into a spreadsheet. If you do open the file with a spreadsheet, make sure you close the file prior to rerunning EnergyPlus otherwise the file will not be updated.

The Tab style produces a text file (eplustbl.tab) with the values separated by tabs. It is also a good format for using with a spreadsheet program but has the advantage of being more readable in a text editor.

The Fixed style produces a text file (eplustbl.txt) with the values at specific columns. It is the easiest to view using a text editor.

The HTML style produces a file (eplustbl.htm) that can be opened with an internet browser program. The values are shown in a tabular format that is easy to view. One advantage of the HTML style is that the results can be viewed in an internet browser program and EnergyPlus can be rerun and the “refresh” button pressed in the internet browser program to see the new results. . When the HTML style is specified, a Table of Contents for the file is generated and placed near the top of the file after the Annual Building Utility Performance Summary (aka ABUPS) report. The Table of Contents includes the names of each report and links for each table in the file.

The XML style produces a file (eplustbl.xml) that can be opened by any XML editor and many internet browser programs. The XML output is specifically intended for use by other software programs to make it simple to extract specific results.

The last four options combine the previous styles and allow multiple reports with different styles to be produced during a single simulation.

#### 7.5.1.0.2 Field: Unit Conversion

This field is optional and if not specified defaults to no unit conversions. Four different input options are available:

- None – no conversions performed

- JtoKWH – Joules converted into kWh (1 / 3,600,000)
- JtoMJ – Joules converted into Megajoules (1 / 1,000,000)
- JtoGJ – Joules converted into Gigajoules (1 / 1,000,000,000)
- InchPound – convert all annual, monthly, economics and timebins tabular values to common Inch-Pound equivalent

The current options are limited to just how the energy is being reported. The default is to report energy in the form of Joules but since the magnitude of those numbers for many buildings is very large, these other conversion factors are available.

The JtoKWH, JtoMJ and JtoGJ unit conversion input option applies only to the **Output:Table:Monthly** reports and partially to the ABUPS report. For ABUPS, the JtoKWH option changes the report but the JtoMJ and JtoGJ options do not change the report since they it is already in MJ/m<sup>2</sup> and GJ. In addition, the JtoKWH option also changes results in the LEED Summary report changing GJ to kWh and MJW/m<sup>2</sup> to kWh/m<sup>2</sup>. The InchPound unit conversion input option applies to all annual, monthly, timebins and economic reports that appear in the tabular output file. In addition, this option does not effect the standard eplusout.eso file. The eplusout.eso file may be converted by using the ConvertESOMTR utility.

An example IDF input object follows.

```
OutputControl:Table:Style,
  Comma,                ! Column Separator
  InchPound;             ! Unit Conversion
```

Examples of the tabular reports and descriptions are contained in the Output Details and Examples document.

# Chapter 8

## Weather Data

The description of the weather data format (a simple text-based format) is well described in the Auxiliary Programs document and won't be repeated here. Descriptions here will be pertinent to running the EnergyPlus program but you may wish to peruse the other descriptions as the statistics reports from the weather files may be useful during design and simulation.

### 8.1 Missing Weather File Data

The weather description of data contains “missing” descriptors, a new concept not introduced previously in our IDD conventions. In this case, it will be processed as though those values are “missing” in the weather conversions and/or EnergyPlus weather processing. This may not always be desirable though EnergyPlus will fill in “missing” value with something “appropriate”. Eventually, these missing values will be available through the IDD and users will be able to supply their own values or EnergyPlus will calculate those values (such as radiation and illuminance) that are not a simple value replacement. Until then, the following are used:

Table 8.1: Missing weather replacement values

Data item	Supplied Value	Units
Dry-bulb Temperature	6	C
Dewpoint Temperature	3	C
Relative Humidity	50	%
Atmospheric Pressure	Standard** Barometric Pressure (altitude based)	Pa
Wind Speed	2.5	m/s
Wind Direction	180	Deg
Total Sky Cover	5	(tenths)
Opaque Sky Cover	5	(tenths)
Visibility	777.7	Km
Ceiling Height	77777	m
Precipitable Water	0	Mm
Aerosol Optical Depth	0	Broadband turbidity
Snow Depth	0	Cm

Table 8.1: Missing weather replacement values

Data item	Supplied Value	Units
Days Since Last Snow	88	Days
Radiation Values (Direct/Diffuse)	0.0	Wh/m2
Illuminance Values	0.0	lux (or CD/m2)

\*\*Standard Barometric pressure based on location elevation is taken from ASHRAE 2001 Handbook of Fundamentals, Page 6.1 & 2.

## 8.2 Weather Data Hourly Interpolation

Much of the existing weather data is produced in hourly format (refer to the discussion of data formats and weather conversion processing in the Auxiliary Programs Document). In order to match the hourly data in a continuous manner for EnergyPlus (where the timesteps might be less than hourly), simple interpolation between “last hour’s” values and “this hour’s” values is performed; we will refer to this as “Last Hour Interpolation”.

Note that in versions prior to V1.0.3, the interpolation was done between “this hour” and “next hour”. If required, we will refer to this as “Next Hour Interpolation”.

Remember that hour 1 for EnergyPlus is the time interval 00:00:01AM to 1:00:00AM. Hour 2 is 1:00:01AM to 2:00:00AM (hh:mm:ss). With the interpolation scheme (Last Hour Interpolation) and reporting weather data values at timestep resolution, the “hour” values reported should match with the hourly weather data values. (Note that reporting “hourly” resolution will not do this unless your “Number of Timesteps per Hour” is 1).

Note that this interpolation applies to outdoor data only – schedule values are not interpolated in this manner.

The weighting scheme / interpolation is simply:

$$Value_{TimeStep} = LastHourValue \cdot Weight_{LastHour} + ThisHourValue \cdot Weight_{ThisHour} \quad (8.1)$$

where

$$Weight_{ThisHour} = \frac{CurrentTimeStep}{Number\ of\ TimeSteps\ in\ Hour} \quad (8.2)$$

$$Weight_{LastHour} = 1.0 - Weight_{ThisHour} \quad (8.3)$$

To explain further, the weighting for four (4) timesteps in hour is:

Table 8.2: Illustration of Data Interpolation for 15 minute timesteps

TimeStep	Time (mm:ss)	Weight	Weight
1	00:01 to 15:00	.75	.25
2	15:01 to 30:00	.5	.5

Table 8.2: Illustration of Data Interpolation for 15 minute timesteps

TimeStep	Time (mm:ss)	Weight	Weight
3	30:01 to 45:00	.25	.75
4	45:01 to 60:00	0	1.0

And similarly for six (6) timesteps in hour:

Table 8.3: Illustration of Data Interpolation for 10 minute timesteps

TimeStep	Time (mm:ss)	Weight	Weight
1	00:01 to 10:00	0.8333333333333333	0.1666666666666667
2	10:01 to 20:00	0.6666666666666667	0.3333333333333333
3	20:01 to 30:00	.5	.5
4	30:01 to 40:00	0.3333333333333333	0.6666666666666667
5	40:01 to 50:00	0.1666666666666667	0.8333333333333333
6	50:01 to 60:00	0	1.0

This interpolation gives a smooth, continuous look to the outdoor data. For day boundaries (i.e. from hour 24 to hour 1), the values from the previous day's last hour (23:00:01 to 24:00:00). For the a design day, this is the values for hour 24. For the first day of a weather simulation, it is likewise values for hour 24 of that day. For subsequent weather days, it will be the last hour of the previous day.

## 8.3 Weather File Data Reporting (errors) during Simulation

Missing data on the weather file used will be summarized on the **eplusout.err** file. In EnergyPlus, “missing data” is shown only for fields that EnergyPlus will use. For the “WeatherCodes”, an invalid field count (where the number of items in the field does not = 9) will be shown. The number of items count refers to the number of records on the weather file that are in error or missing – for an hourly weather file, this is the number of hours. Likewise out of range values (see specific fields in the previous definition) will be counted for each occurrence and summarized. Note that the out of range values will not be changed by EnergyPlus and could affect your simulation results.

For example:

```

** Warning ** Missing Data Found on Weather Data File
***** Missing Atmospheric Pressure, Number of items =    48
***** Missing Dry Bulb Temperatures, Number of items =    4
** Warning ** Out of Range Data Found on Weather Data File

```

```

***** Out of Range Dry Bulb Temperature [>-70,<70], Number of items =    1

```

# Chapter 9

## Running EnergyPlus

EnergyPlus is written in C++, using many C++11 features. It runs as a console application on Windows, Mac, and Linux (tested on latest Ubuntu LTS). Details on running EnergyPlus are available in a separate document (Running EnergyPlus in Auxiliary Programs). The following files are needed to run EnergyPlus:

- EnergyPlus.exe (the executable file)
- Energy+.ini (described below)
- Energy+.idd (the input data dictionary file)
- in.idf (the input file)
- in.epw – optional (weather data file)

The input data dictionary and input data file have been discussed in the previous sections of this document.

For weather simulations, EnergyPlus accepts EnergyPlus weather files. The actual file name is **in.epw**.

The usual release for Windows platform also includes a dependence on a shared library, EnergyPlusAPI.dll (.so on Linux).

### 9.1 Energy+.ini

The Energy+.ini file is read by the EnergyPlus.exe program and is *very important* to the simulation run. In specific, this file contains a pointer to where the Energy+.idd file will be found. More description of the Energy+.ini contents is contained in the Auxiliary Programs document.

For the advanced user, there is also the “EPMacro” program, described in the Auxiliary programs document. You run it as a separate program before EnergyPlus (the batch file included in the install and shown in the GettingStarted document contains the commands). It is automatically run if you use the EP-Launch program.

EnergyPlus may create several output files. Whether some files are produced depends on the actual simulation (for example, the .rdd file is only produced when you request a Variable Dictionary using the Output:Report object). Similarly, the .dxf file is only produced when a DXF surface report is requested. Common output files are shown in the following table. A complete, up to date list is shown in the “Output Details and Examples Document”.

Table 9.1: EnergyPlus Output Files

FileName	Description
Eplusout.audit	Echo of input
Eplusout.err	Error file
Eplusout.eso	Standard Output File (contains results from both Output:Variable and Output:Meter objects).
Eplusout.eio	One time output file
Eplusout.rdd	Output variable Data Dictionary
Eplusout.dxf	DXF (from Output:Report,Surfaces,DXF;)
Eplusout.mtr	Similar to .eso but only has Meter outputs.
Eplusout.mtd	Meter details report – what variables are on what meters and vice versa.
Eplusout.end	A one line summary of success or failure (useful for Interface programs)
Eplusout.dbg	From Debug Output object – may be useful to support to help track down problems
Eplusout. < ext >	Not directly from EnergyPlus – produced by utility programs that read the .eso file and produce output files for spreadsheet programs
Eplusout.sln	Similar to DXF output but less “formatted”. Results of Report Surface, Lines object.
Epluszsz. < ext >	Results from the Zone Sizing object with extension noted by the Sizing Style object. This file is “spreadsheet” ready.
Eplusssz. < ext >	Results from the System Sizing object with extension noted by the Sizing Style object. This file is “spreadsheet” ready.
Eplusout.bnd	This file contains details about the nodes and branches. Useful in determining if all your nodes are connected correctly.
Eplustbl. < ext >	Results from various “Report Table” and a few other reporting commands. The extension is from the “style” command and this file is “spreadsheet” ready.

## 9.2 Errors

The **eplusout.err** file may contain three levels of errors (Information, Warning, Severe, Fatal) as well as the possibility of just message lines, see Table 9.2. EnergyPlus Errors and Required Actions. These errors may be duplicated in other files (such as the standard output file). These errors are described more completely in the Output Details and Examples document. An example .err file from the 1ZoneUncontrolled example input file:

```

Program Version,EnergyPlus 7.0.0.024, 10/9/2011 4:04 PM,IDD\_Version 7.0.0.024
** Warning ** IP: Note -- Some missing fields have been filled with defaults. See the audit output
file for details.
** Warning ** Weather file location will be used rather than entered Location object.
**   ~~~   ** ..Location object = DENVER STAPLETON INTL ARPT CO USA WMO = 724690
**   ~~~   ** ..Weather File Location = Denver Centennial Golden   Nr CO USA TMY3 WMO\# = 724666
**   ~~~   ** ..due to location differences, Latitude difference = [3.00E-002] degrees, Longitude
difference = [0.31] degrees.

```

```

**   ~~~   ** ..Time Zone difference = [0.0] hour(s), Elevation difference = [13.53] percent, [218.00]
meters.
***** Testing Individual Branch Integrity
***** All Branches passed integrity testing
***** Testing Individual Supply Air Path Integrity
***** All Supply Air Paths passed integrity testing
***** Testing Individual Return Air Path Integrity
***** All Return Air Paths passed integrity testing
***** No node connection errors were found.
***** Beginning Simulation
***** Simulation Error Summary *****
***** EnergyPlus Warmup Error Summary. During Warmup: 0 Warning; 0 Severe Errors.
***** EnergyPlus Sizing Error Summary. During Sizing: 0 Warning; 0 Severe Errors.
***** EnergyPlus Completed Successfully-- 2 Warning; 0 Severe Errors; Elapsed Time = 00hr 00
min 3.91sec

```

Table 9.2: EnergyPlus Errors and Required Actions

Error Level	Action
Information, shown as *****	Informative, usually a follow-on to one of the others. No action required.
~\~ **	This is a continuation of a previous message. String all the word-s/sentences together to form the complete message.
Warning	Take note. Fix as applicable.
Severe	Should Fix
Fatal	Program will abort, Must Fix

EnergyPlus produces several messages as it is executing, as a guide to its progress. These message illustrate the sequence of execution as well as provides checkpoints should the simulation fail.

For example, the run of the 1ZoneUncontrolled example input file produces the log:

```

Running d:\eppgm\intcheck\energyplus.exe
ET Start: Sun 10/09/2011 - 16:04:34.71
Input File : d:\devtests\inputfiles\checkin\1ZoneUncontrolled.idf
Output Files: d:\devtests\inputfiles\outputs\

In the example, the inclusion of the “ReadVars” program is also shown. It is run twice – once for the **epplusout.eso** file and once for the **epplusout.mtr** file.

## 9.3 EnergyPlus Execution Time

Extensive timing studies and fine-tuning of EnergyPlus are an ongoing process. Remember that hourly simulations cannot be directly compared to EnergyPlus with its less than hourly timesteps.

### 9.3.1 Reducing Run Time Tips

Compared with creating energy models either by hand coding the IDF file or by using GUI tools or a combination of both, EnergyPlus run time is normally a small fraction of the total time needed to complete an energy modeling job. Therefore it is very important to build a clean and concise EnergyPlus model up front. Techniques of simplifying large and complex building and systems should be used during the creation of energy models, especially during the early design process when detailed zoning and other information is not available. Producing lots of hourly or sub-hourly reports from EnergyPlus runs can take significant amount of time. Modelers should only request time step reports when necessary. On the other hand, producing summary reports and typical monthly reports take relatively small amount of run time. These reports are valuable references for troubleshooting and model fine tuning.

With powerful personal computers get more and more affordable, EnergyPlus modelers should choose to use current available PCs with 3 or more GHZ and 3 or more GB of RAM. For a large volume of EnergyPlus parametric runs, modelers can launch multiple runs in parallel. For modelers, most time is spent on troubleshooting and fine tuning energy models. During the early modeling process, it is recommended to keep the model as simple as possible and make quick runs to identify problems. Then modify the IDF file to fix problems and re-run the model. This is an iterative process until satisfactory solutions are found. The simulation process can be split into three phases: the diagnostic runs, the preliminary runs, and the

final runs. The three phases would use different simulation settings. The diagnostic runs would use a set of simulation settings to speed up the runs with simulation accuracy being set as the second priority. The diagnostic runs will help catch most model problems by

running simulations on summer and winter design days. The preliminary runs use a tighter set of simulation settings in order to catch problems missed in the diagnostic runs, and provide better results for quality assurance purpose. The final runs use the EnergyPlus recommended set of simulation settings in order to achieve better accuracy for simulation results ready for review and reporting.

You might want to read the report on EnergyPlus run time at <http://repositories.cdlib.org/lbnl/LBNL-1311E/>.

Additional run-time tips may be found in the EnergyPlus “Tips and Tricks” document. Some more tips:

- In the **SimulationControl** object, Run Simulation for Sizing Periods until everything is working well, then switch to Run Simulation for Weather File Run Periods.
- Turn off (comment them out in the text editor using !) daylighting controls while developing the HVAC simulation. Then turn back on for final runs.
- HeatBalanceAlgorithm: ConductionTransferFunction is the fastest option.
- In the **People** object, the thermal comfort reports can be time consuming, especially the KSU model which is more computationally intensive.

# Chapter 10

## Appendix A. Units and Abbreviations

### 10.1 Standard EnergyPlus Conditions

#### 10.1.1 Standard Temperature and Pressure

Several objects specify inputs at “standard temperature and pressure”. Standard Temperature is dry air at 20° C drybulb. The program uses local barometric pressure to account for altitude using the equation for “standard atmospheric” pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$Stdpressure = 101325 \cdot (1.0 - Z \cdot 2.25577^{-5})^{5.2559} \quad (10.1)$$

where

StdPressure = pressure {Pa}

Z = altitude/elevation {m}

### 10.2 Standard EnergyPlus Units

EnergyPlus expects information in a single unit system (SI). This requires interface developers to convert user inputs from those preferred by architects and engineers into the standard metric units of EnergyPlus. EnergyPlus will not perform any units conversions and will not have any unit conversion routines.

ASCII with no spaces is used for abbreviations. Note that exponents appear without any indication of exponentiation: i.e., kg/m3 not kg/m<sup>3</sup> or kg/m\*\*3. Also note the use of dashes. We have W/m2-K not W/m2\*K or W/(m2\*K).

At the end we note the “problem” variables – the inputs that have non-standard units. Inputs using these units will have to be changed and the code checked to see how the quantities are used internally.

Table 10.1: Standard EnergyPlus Units

Quantity	unit	abbreviation
angular degrees	degree	deg
Length	meter	m
Area	square meter	m2
Volume	cubic meter	m3

Table 10.1: Standard EnergyPlus Units
