This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value of compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

#### **1.33.2.1.38 Field: Defrost Energy Input Ratio Modifier Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the weighted average wet-bulb temperature of the air entering the indoor terminal units (variable x) and the outdoor air dry-bulb temperature (variable y). The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. The curve is normalized to a value of 1.0 at the rating point conditions.

#### **1.33.2.1.39 Field: Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active. For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

#### **1.33.2.1.40 Field: Resistive Defrost Heater Capacity**

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

#### **1.33.2.1.41 Field: Maximum Outdoor Dry-bulb Temperature for Defrost Operation**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. If this input field is left blank, the default value is 5°C. Defrost can be completely eliminated by selecting a temperature lower than the minimum expected outdoor temperature found in the weather file.

#### **1.33.2.1.42 Field: Compressor maximum delta Pressure**

This numeric field defines the maximum pressure increase that the compressor can provide. The value should be greater than 0. If this field is blank, the default value of 4,500,000 Pa is used.

#### **1.33.2.1.43 Field: Number of Compressor Loading Index Entries**

This numeric field defines the number of compressor loading index entries. Loading index specifies the VRF operational modes at various load conditions. In a single compressor system, loading index reflects

the compressor speed. The model requires at least two loading indices. The first index represents the minimal capacity operation, while the last index represents full capacity operation.

#### 1.33.2.1.44 Field: Compressor Speed at Loading Index *i*

This numeric field defines the compressor speed at the *i*-th loading index. The value must be greater than 0.

#### 1.33.2.1.45 Field: Loading Index *i* Evaporative Capacity Multiplier Function of Temperature Curve Name

This alpha field defines the name of a BiQuadratic curve for the VRF operational mode corresponding to the *i*-th loading index. It parameterizes the variation of VRF evaporating capacity as a function of operating conditions, i.e., evaporating and condensing temperatures. The output of this curve is a dimensionless multiplier to be applied on the rated evaporative capacity to calculate the actual capacity.

#### 1.33.2.1.46 Field: Loading Index *i* Compressor Power Multiplier Function of Temperature Curve Name

This alpha field defines the name of a BiQuadratic curve for the VRF operational mode corresponding to the *i*-th loading index. It parameterizes the variation of compressor power as a function of operating conditions, i.e., evaporating and condensing temperatures. The output of this curve is a dimensionless multiplier to be applied on the rated compressor power to calculate the actual compressor power.

### 1.33.2.2 Outputs

In addition to the output variables described for the VRF-SysCurve model in Section 1.33.1, the VRF-FluidTCtrl model also provides the following output variables:

- VRF Heat Pump Compressor Rotating Speed [rev/min]
- VRF Heat Pump Compressor Electricity Rate [W]
- VRF Heat Pump Indoor Unit Evaporating Temperature [C]
- VRF Heat Pump Outdoor Unit Condensing Temperature [C]
- VRF Heat Pump Indoor Unit Condensing Temperature [C]
- VRF Heat Pump Outdoor Unit Evaporating Temperature [C]
- VRF Heat Pump Outdoor Unit Fan Power [W]
- VRF Heat Pump Cooling Capacity at Max Compressor Speed [W]
- VRF Heat Pump Heating Capacity at Max Compressor Speed [W]
- VRF Heat Pump Outdoor Unit Evaporator Heat Extract Rate [W]
- VRF Heat Pump Outdoor Unit Condenser Heat Release Rate [W]

Note: refer to the rdd file after a simulation for exact output variable names

#### 1.33.2.2.1 VRF Heat Pump Compressor Rotating Speed [rev/min]

This output only applies for the VRF-FluidTCtrl model. This is the rotating speed of the compressor, which indicates the loading index.

#### 1.33.2.2.2 VRF Heat Pump Compressor Electricity Rate [W]

This output only applies for the VRF-FluidTCtrl model. This is the electric power of the compressor running. This value is related with the compressor speed as well as the operational conditions, i.e., evaporating and condensing temperatures of the system.

**1.33.2.2.3 VRF Heat Pump Indoor Unit Evaporating Temperature [C]**

This output only applies for the VRF-FluidTCtrl model. This is the evaporating temperature of the VRF system operating at cooling mode. This value is manipulated by the VRF system considering the load conditions of all the zones it serves. It affects the indoor unit cooling coil surface temperature and thus the cooling capacity of the indoor unit. It also affects the compressor operating conditions and thus the compressor energy consumption.

**1.33.2.2.4 VRF Heat Pump Outdoor Unit Condensing Temperature [C]**

This output only applies for the VRF-FluidTCtrl model. This is the condensing temperature of the VRF system operating at cooling mode. This value is related with the outdoor air conditions as well as the system operational mode. It affects the condensing capacity of the outdoor unit. It also affects the compressor operating conditions and thus the compressor energy consumption.

**1.33.2.2.5 VRF Heat Pump Indoor Unit Condensing Temperature [C]**

This output only applies for the VRF-FluidTCtrl model. This is the condensing temperature of the VRF system operating at heating mode. This value is manipulated by the VRF system considering the load conditions of all the zones it serves. It affects the indoor unit heating coil surface temperature and thus the heating capacity of the indoor unit. It also affects the compressor operating conditions and thus the compressor energy consumption.

**1.33.2.2.6 VRF Heat Pump Outdoor Unit Evaporating Temperature [C]**

This output only applies for the VRF-FluidTCtrl model. This is the evaporating temperature of the VRF system operating at heating mode. This value is related with the outdoor air conditions as well as the system operational mode. It affects the evaporating capacity of the outdoor unit. It also affects the compressor operating conditions and thus the compressor energy consumption.

**1.33.2.2.7 VRF Heat Pump Outdoor Unit Fan Power [W]**

This output only applies for the VRF-FluidTCtrl model. This is the power consumed by the fan located in the VRF outdoor unit.

**1.33.2.2.8 VRF Heat Pump Cooling Capacity at Max Compressor Speed [W]**

This output field is the maximum cooling capacity of the variable refrigerant flow system at particular operational conditions, corresponding to the maximum compressor speed. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This output only applies for the VRF-FluidTCtrl model.

**1.33.2.2.9 VRF Heat Pump Heating Capacity at Max Compressor Speed [W]**

This output field is the maximum heating capacity of the variable refrigerant flow system at particular operational conditions, corresponding to the maximum compressor speed. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This output only applies for the VRF-FluidTCtrl model.

**1.33.2.2.10 VRF Heat Pump Outdoor Unit Evaporator Heat Extract Rate [W]**

This output field is the heat extract rate of the VRF outdoor unit evaporator in Watts. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This output only applies for the VRF-FluidTCtrl model.

### 1.33.2.2.11 VRF Heat Pump Outdoor Unit Condenser Heat Release Rate [W]

This output field is the heat release rate of the VRF outdoor unit condenser in Watts. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This output only applies for the VRF-FluidTCtrl model. This output only applies for the VRF-FluidTCtrl model.

## 1.33.3 AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl:HR

### 1.33.3.1 Inputs

#### 1.33.3.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a variable refrigerant flow heat recovery system. Any reference to this system will use this name. Since this object is not listed in an AirloopHVAC object, the most likely use of this name would be for reporting purposes.

#### 1.33.3.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the VRF system operates during a given time period. A schedule value equal to 0 denotes that the VRF system must be off for that time period. A value other than 0 denotes that the VRF system is available to operate during that time period. This schedule may be used to completely disable the VRF system (and all of its terminal units) as required. If this field is blank, the unit is enabled the entire simulation.

#### 1.33.3.1.3 Field: Zone Terminal Unit List Name

This alpha field defines the name of the zone terminal unit list. The name specified here should match the name of a valid **ZoneTerminalUnitList** object. In addition, each name specified in this list should match the name of a valid **ZoneHVAC:TerminalUnit:VariableRefrigerantFlow** object. All terminal units connected to this VRF system must be listed in this **ZoneTerminalUnitList** object.

#### 1.33.3.1.4 Field: Refrigerant Type

This alpha field defines the name of the refrigerant used in the VRF system. The name specified here should match the name of a valid **FluidProperties:Name** object.

#### 1.33.3.1.5 Field: Rated Evaporative Capacity

This numeric field defines the total evaporative capacity in watts at rated conditions. This is the capacity corresponding to the max compressor speed at rated conditions. The actual evaporative capacity is obtained by multiplying the rated capacity with the modification factor calculated by Evaporative Capacity Multiplier Function of Temperature Curve. The value must be greater than 0. This field is autosizable.

#### 1.33.3.1.6 Field: Rated Compressor Power Per Unit of Rated Evaporative Capacity

This numeric field defines the rated compressor power per Watt of rated evaporative capacity. Rated compressor power corresponds to the max compressor speed at rated conditions. The actual compressor power is obtained by multiplying the rated power with the modification factor calculated by Compressor Power Multiplier Function of Temperature Curve. The value must be greater than 0. If this field is left blank, a default value of 0.35 W/W is assumed.

**1.33.3.1.7 Field: Minimum Outdoor Air Temperature in Cooling Only Mode**

This numeric field defines the minimum outdoor temperature allowed for cooling only mode. Below this temperature, cooling is disabled. If this field is left blank, the default value is -6°C.

**1.33.3.1.8 Field: Maximum Outdoor Air Temperature in Cooling Only Mode**

This numeric field defines the maximum outdoor temperature allowed for cooling only mode. Above this temperature, cooling is disabled. If this field is left blank, the default value is 43°C.

**1.33.3.1.9 Field: Minimum Outdoor Air Temperature in Heating Only Mode**

This numeric field defines the minimum outdoor temperature allowed for heating only mode. Below this temperature, heating is disabled. If this field is left blank, the default value is -20°C.

**1.33.3.1.10 Field: Maximum Outdoor Air Temperature in Heating Only Mode**

This numeric field defines the maximum outdoor temperature allowed for heating only mode. Above this temperature, heating is disabled. If this field is left blank, the default value is 16°C.

**1.33.3.1.11 Field: Minimum Outdoor Air Temperature in Heat Recovery Mode**

This numeric field defines the maximum outdoor temperature allowed for heat recovery operations. Below this temperature, heat recovery operations is disabled. If this field is left blank, the default value is -20°C.

**1.33.3.1.12 Field: Maximum Outdoor Air Temperature in Heat Recovery Mode**

This numeric field defines the maximum outdoor temperature allowed for heat recovery operations. Above this temperature, heat recovery operations is disabled. If this field is left blank, the default value is 43°C.

**1.33.3.1.13 Field: Refrigerant Temperature Control Algorithm for Indoor Unit**

This alpha field specifies the algorithm for the refrigerant temperature control. Two choices are available: ConstantTemp or VariableTemp. The indoor unit evaporating temperature at cooling mode or condensing temperature at heating are fixed in the ConstantTemp algorithm, while in VariableTemp algorithm they can be varied.

**1.33.3.1.14 Field: Reference Evaporating Temperature for Indoor Unit**

This numeric field defines the reference evaporating temperature for the indoor unit when VRF runs at cooling mode. This field is required if Refrigerant Temperature Control Algorithm is ConstantTemp. If this field is blank, the default value of 6.0°C is used.

**1.33.3.1.15 Field: Reference Condensing Temperature for Indoor Unit**

This numeric field defines the reference condensing temperature for the indoor unit when VRF runs at heating mode. This field is required if Refrigerant Temperature Control Algorithm is ConstantTemp. If this field is blank, the default value of 44.0°C is used.

**1.33.3.1.16 Field: Variable Evaporating Temperature Minimum for Indoor Unit**

This numeric field defines the minimum evaporating temperature for the indoor unit when VRF runs at cooling mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 4.0°C is used.

**1.33.3.1.17 Field: Variable Evaporating Temperature Maximum for Indoor Unit**

This numeric field defines the maximum evaporating temperature for the indoor unit when VRF runs at cooling mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 13.0°C is used.

**1.33.3.1.18 Field: Variable Condensing Temperature Minimum for Indoor Unit**

This numeric field defines the minimum condensing temperature for the indoor unit when VRF runs at heating mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 42.0°C is used.

**1.33.3.1.19 Field: Variable Condensing Temperature Maximum for Indoor Unit**

This numeric field defines the maximum condensing temperature for the indoor unit when VRF runs at heating mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 46.0°C is used.

**1.33.3.1.20 Field: Outdoor Unit Evaporator Reference Superheating**

This numeric field defines the reference superheating degrees of the outdoor unit evaporator. If this field is blank, the default value of 3.0°C is used.

**1.33.3.1.21 Field: Outdoor Unit Condenser Reference Subcooling**

This numeric field defines the reference subcooling degrees of the outdoor unit condenser. If this field is blank, the default value of 5.0°C is used.

**1.33.3.1.22 Field: Outdoor Unit Evaporator Rated Bypass Factor**

This numeric field defines the Rated Bypass Factor of the outdoor unit evaporator. If this field is blank, the default value of 0.4 is used.

**1.33.3.1.23 Field: Outdoor Unit Condenser Rated Bypass Factor**

This numeric field defines the Rated Bypass Factor of the outdoor unit condenser. If this field is blank, the default value of 0.2 is used.

**1.33.3.1.24 Field: Difference between Outdoor Unit Evaporating Temperature and Outdoor Air Temperature in Heat Recovery Mode**

This numeric field defines the difference between Outdoor Unit Evaporating Temperature and Outdoor Air Temperature in the Heat Recovery Mode. This is a key operational parameter that is used in the mode determinations. If this field is blank, the default value of 5.0°C is used.

**1.33.3.1.25 Field: Outdoor Unit Heat Exchanger Capacity Ratio**

This numeric field defines the rated capacity ratio between the main and supplementary outdoor unit heat exchangers. If this field is blank, the default value of 0.3 is used.

**1.33.3.1.26 Field: Outdoor Unit Fan Power Per Unit of Rated Evaporative Capacity**

This numeric field defines the outdoor unit fan power per watt of rated evaporative capacity. If this field is blank, the default value of 4.25E-3 W/W is used.

**1.33.3.1.27 Field: Outdoor Unit Fan Flow Rate Per Unit of Rated Evaporative Capacity**

This numeric field defines the outdoor unit fan volumetric flow rate per watt of rated evaporative capacity. If this field is blank, the default value of  $7.50\text{E-}5 \text{ m}^3/\text{s-W}$  is used.

**1.33.3.1.28 Field: Outdoor Unit Evaporating Temperature Function of Superheating Curve Name**

This alpha field defines the name of a quadratic performance curve that parameterizes the variation of outdoor unit evaporating temperature as a function of superheating degrees. The output of this curve is the temperature difference between the coil surface air temperature and the evaporating temperature.

**1.33.3.1.29 Field: Outdoor Unit Condensing Temperature Function of Subcooling Curve Name**

This alpha field defines the name of a quadratic performance curve that parameterizes the variation of outdoor unit condensing temperature as a function of subcooling degrees. The output of this curve is the temperature difference between the condensing temperature and the coil surface air temperature.

**1.33.3.1.30 Field: Diameter of Main Pipe for Suction Gas**

This numeric field defines the diameter of main pipe for Suction Gas. This value is used to calculate the piping loss of the refrigerant when going through the main pipe, including the heat absorbed and pressure drop. If this field is blank, the default value of 0.0762m is used.

**1.33.3.1.31 Field: Diameter of Main Pipe for Discharge Gas**

This numeric field defines the diameter of main pipe for Suction Gas. This value is used to calculate the piping loss of the refrigerant when going through the main pipe, including the heat loss and pressure drop. If this field is blank, the default value of 0.0762m is used.

**1.33.3.1.32 Field: Length of Main Pipe Connecting Outdoor Unit to the First Branch Joint**

This numeric field defines the length of main pipe connecting outdoor unit to the first branch joint. This value is used to calculate the heat loss of the refrigerant when going through the main pipe. The value should be greater than 0. If this field is blank, the default value of 30m is used.

**1.33.3.1.33 Field: Equivalent Length of Main Pipe Connecting Outdoor Unit to the First Branch Joint**

This numeric field defines the equivalent length of main pipe connecting outdoor unit to the first branch joint. This value is used to calculate the pressure drop of the refrigerant when going through the main pipe. The value should be greater than the real pipe length specified in the above field. If this field is blank, the default value of 36m is used.

**1.33.3.1.34 Field: Height Difference Between Outdoor Unit and Indoor Units**

This numeric field defines the height difference between the outdoor unit node and indoor unit node of the main pipe. This value is used to calculate the piping loss of the refrigerant when going through the main pipe. The value can be positive, zero, or negative. Positive means outdoor unit is higher than indoor unit, while negative means outdoor unit is lower than indoor unit.

**1.33.3.1.35 Field: Main Pipe Insulation Thickness**

This numeric field defines the insulation thickness of the main pipe. This value is used to calculate the heat loss of the refrigerant when going through the main pipe. The value should be greater than 0. If this field is blank, the default value of 0.02m is used.

**1.33.3.1.36 Field: Main Pipe Insulation Thermal Conductivity**

This numeric field defines the thermal conductivity of the main pipe insulation material. This value is used to calculate the heat loss of the refrigerant when going through the main pipe. The value should be greater than 0. If this field is blank, the default value of 0.032 W/m-K is used.

**1.33.3.1.37 Field: Crankcase Heater Power per Compressor**

This numeric field defines the electrical power consumed by the crankcase heater in watts for each compressor. This crankcase heater power is consumed to warm the refrigerant and oil when the compressor is off when the outdoor temperature is below the maximum outdoor dry-bulb temperature for crankcase heater operation. The minimum value for this field is 0. If this field is left blank, the default value is 33 watts. Crankcase heater electrical consumption is applied only when the compressor is off or is applied during the off cycle when the compressor is cycling below the Minimum VRF system Part-Load Ratio. This field is only used to calculate crankcase heater power and has no impact on VRF system performance.

**1.33.3.1.38 Field: Number of Compressors**

This numeric field defines the number of compressors in the VRF system condensing unit and is used exclusively to determine the operating characteristics of the crankcase heater. For example, if the number of compressors is 3, one crankcase heater will operate when the VRF system condensing unit's part-load ratio is less than or equal to 0.67 (when the ratio of compressor size to total compressor capacity input is 0.33) and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. Similarly, two crankcase heaters will operate when the VRF system condensing unit's PLR is less than or equal to 0.33 and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. If the VRF system condensing unit is off, all 3 crankcase heaters will operate if the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. The minimum value for this field is 1. If this field is left blank, the default value is 2. This field is only used to calculate crankcase heater power and has no impact on VRF system performance.

**1.33.3.1.39 Field: Ratio of Compressor Size to Total Compressor Capacity**

This numeric field defines the size of the first stage compressor to the total compressor capacity and is used exclusively for calculating crankcase heater energy. If this field and the previous field are left blank, the default value is 0.5. If this field is left blank and the previous field is not blank, the compressors are assumed to be equally sized. When the number of compressors is greater than 2, the 2<sup>nd</sup> stage compressor and all additional compressors are assumed to be equally sized. This field is only used to calculate crankcase heater power and has no impact on VRF system performance.

**1.33.3.1.40 Field: Maximum Outdoor Dry-bulb Temperature for Crankcase Heater**

This numeric field defines the maximum outdoor temperature, in degrees Celsius, below which the crankcase heater will operate. If this field is left blank, the default value is 5°C. This field is only used to calculate crankcase heater power and has no impact on VRF system performance.

**1.33.3.1.41 Field: Defrost Strategy**

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a

resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle. Defrost can be disabled by entering a resistive defrost strategy using a timed defrost control, a 0 defrost time period fraction and a 0 resistive defrost heater capacity in the following inputs fields. This method is used when the Maximum Outdoor Dry-Bulb Temperature for Defrost Operation field value is greater than the expected minimum outdoor dry-bulb temperature simulated in the weather file.

#### **1.33.3.1.42 Field: Defrost Control**

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value of compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

#### **1.33.3.1.43 Field: Defrost Energy Input Ratio Modifier Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the weighted average wet-bulb temperature of the air entering the indoor terminal units (variable x) and the outdoor air dry-bulb temperature (variable y). The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. The curve is normalized to a value of 1.0 at the rating point conditions.

#### **1.33.3.1.44 Field: Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active. For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

#### **1.33.3.1.45 Field: Resistive Defrost Heater Capacity**

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

#### **1.33.3.1.46 Field: Maximum Outdoor Dry-bulb Temperature for Defrost Operation**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. If this input field is left blank, the default value is 5°C. Defrost can be completely eliminated by selecting a temperature lower than the minimum expected outdoor temperature found in the weather file.

#### **1.33.3.1.47 Field: Initial Heat Recovery Cooling Capacity Fraction**

This numeric field defines the fraction of cooling capacity available when the system transitions from cooling only operation to simultaneous cooling and heating. It is common for the cooling capacity to

decrease before the system recovers. The system will recovery according to the time constant entered in Heat Recovery Cooling Capacity Time Constant input field. If the transition period will not be modeled, this input field must be set to 1.

#### **1.33.3.1.48 Field: Heat Recovery Cooling Capacity Time Constant**

This numeric field defines the cooling capacity time constant, in hours, used to model the time it takes for the system to change from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Cooling Capacity Fraction field must be set to 1.

#### **1.33.3.1.49 Field: Initial Heat Recovery Cooling Energy Fraction**

This numeric field defines the fraction of cooling energy consumed when the system transitions from cooling only operation to simultaneous cooling and heating. It is common for the cooling energy to drop before the system recovers. If the transition period will not be modeled, this input field must be set to 1.

#### **1.33.3.1.50 Field: Heat Recovery Cooling Energy Time Constant**

This numeric field defines the cooling energy time constant, in hours, used to model the time it takes for the system to transition from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Cooling Energy Fraction field must be set to 1.

#### **1.33.3.1.51 Field: Initial Heat Recovery Heating Capacity Fraction**

This numeric field defines the fraction of heating capacity available when the system changes from heating only operation to simultaneous heating and cooling. It is common for the heating capacity to decrease before the system recovers. The system will recovery according to the time constant entered in Heat Recovery Heating Capacity Time Constant input field. If the transition period will not be modeled, this input field must be set to 1.

#### **1.33.3.1.52 Field: Heat Recovery Heating Capacity Time Constant**

This numeric field defines the heating capacity time constant, in hours, used to model the time it takes for the system to transition from heating only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Heating Capacity Fraction field must be set to 1.

#### **1.33.3.1.53 Field: Initial Heat Recovery Heating Energy Fraction**

This numeric field defines the fraction of heating energy consumed when the system changes from heating only operation to simultaneous heating and cooling. It is common for the heating energy to decrease before the system recovers. If the transition period will not be modeled, this input field must be set to 1.

#### **1.33.3.1.54 Field: Heat Recovery Heating Energy Time Constant**

This numeric field defines the heating energy time constant, in hours, used to model the time it takes for the system to change from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Heating Energy Fraction field must be set to 1.

**1.33.3.1.55 Field: Compressor maximum delta Pressure**

This numeric field defines the maximum pressure increase that the compressor can provide. The value should be greater than 0. If this field is blank, the default value of 4,500,000 Pa is used.

**1.33.3.1.56 Field: Compressor Inverter Efficiency**

This numeric field defines the efficiency of compressor inverter. It is the ratio between the output of Compressor Power Multiplier Function of Temperature Curve and the actual compressor power consumption. The value should be greater than 0. If this field is blank, the default value of 0.95 is used.

**1.33.3.1.57 Field: Compressor Evaporative Capacity Correction Factor**

This numeric field defines the evaporative capacity difference because of system configuration difference between test bed and real system. It is the ratio between output of Evaporative Capacity Multiplier Function of Temperature Curve and the actual system evaporative capacity. The value should be greater than 0. If this field is blank, the default value of 1 is used.

**1.33.3.1.58 Field: Number of Compressor Loading Index Entries**

This numeric field defines the number of compressor loading index entries. Loading index specifies the VRF operational modes at various load conditions. In a single compressor system, loading index reflects the compressor speed. The model requires at least two loading indices. The first index represents the minimal capacity operation, while the last index represents full capacity operation.

**1.33.3.1.59 Field: Compressor Speed at Loading Index i**

This numeric field defines the compressor speed at the i-th loading index. The value must be greater than 0.

**1.33.3.1.60 Field: Loading Index i Evaporative Capacity Multiplier Function of Temperature Curve Name**

This alpha field defines the name of a BiQuadratic curve for the VRF operational mode corresponding to the i-th loading index. It parameterizes the variation of VRF evaporating capacity as a function of operating conditions, i.e., evaporating and condensing temperatures. The output of this curve is a dimensionless multiplier to be applied on the rated evaporative capacity to calculate the actual capacity.

**1.33.3.1.61 Field: Loading Index i Compressor Power Multiplier Function of Temperature Curve Name**

This alpha field defines the name of a BiQuadratic curve for the VRF operational mode corresponding to the i-th loading index. It parameterizes the variation of compressor power as a function of operating conditions, i.e., evaporating and condensing temperatures. The output of this curve is a dimensionless multiplier to be applied on the rated compressor power to calculate the actual compressor power.

Following is an example input for a `AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl` system.

### 1.33.4 ZoneTerminalUnitList

The zone terminal unit list defines the names of the terminal units connected to a single variable refrigerant flow air-conditioning system. The zone terminal unit list is used exclusively in the variable refrigerant flow (VRF) air conditioner object (ref: [AirConditioner:VariableRefrigerantFlow](#)). Up to 20 terminal units may

be connected to a single VRF outdoor condensing unit. This list is extensible if additional indoor terminal units are required. The name of this zone terminal unit list object is then input into the corresponding variable refrigerant flow air conditioner object. The following figure demonstrates this concept.

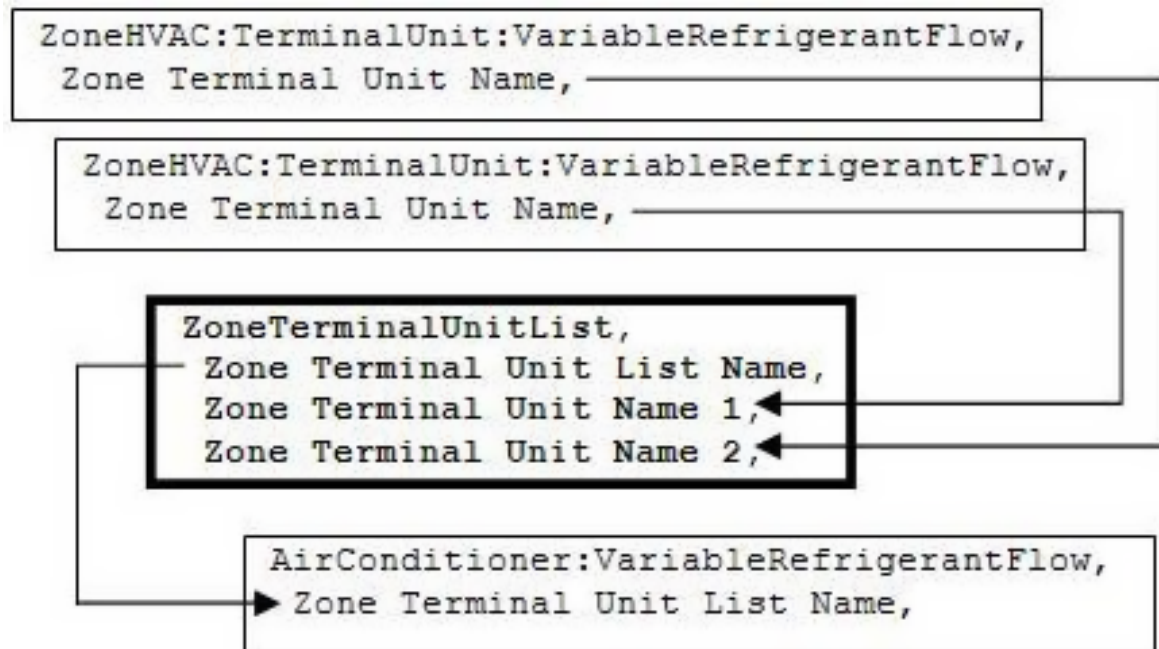

Figure 1.162: Zone Terminal Unit List Diagram

### 1.33.4.1 Inputs

#### 1.33.4.1.1 Field: Zone Terminal List Name

This alpha field specifies the name of the zone terminal unit list. This name must be specified in the `AirConditioner:VariableRefrigerantFlow` object.

#### 1.33.4.1.2 Field: Zone Terminal Unit Name <x>

This alpha field defines the name of the zone terminal unit used in a variable refrigerant air conditioner. The zone terminal unit must be connected to a zone using the `ZoneHVAC:EquipmentConnections` object. The terminal unit air inlet node is the same name as a zone exhaust node. The terminal unit air outlet node is the same name as a zone inlet node. The IDD is supplied with 20 fields for this. The object is extensible and you can change the IDD by adding more fields or, if you are using text editor for your input file, just add to the list of names.

Following is an example input for a `ZoneTerminalUnitList` object.

```

ZoneTerminalUnitList,
  VRF Heat Pump TU List,  !- Zone Terminal Unit List Name
  TU3,                    !- Zone Terminal Unit Name 1
  TU4,                    !- Zone Terminal Unit Name 2
  TU1,                    !- Zone Terminal Unit Name 3
  TU2,                    !- Zone Terminal Unit Name 4
  TU5;                    !- Zone Terminal Unit Name 5
  
```

## 1.34 Group – Radiative / Convective Units

This section describes the radiative/convective zone equipment units. The following units are included in this section:

- ZoneHVAC:Baseboard:Convective:Electric
- ZoneHVAC:Baseboard:RadiantConvective:Water
- ZoneHVAC:Baseboard:RadiantConvective:Steam
- ZoneHVAC:Baseboard:RadiantConvective:Electric
- ZoneHVAC:CoolingPanel:RadiantConvective:Water
- ZoneHVAC:Baseboard:Convective:Water
- ZoneHVAC:HighTemperatureRadiant
- ZoneHVAC:LowTemperatureRadiant:ConstantFlow
- ZoneHVAC:LowTemperatureRadiant:Electric
- ZoneHVAC:LowTemperatureRadiant:VariableFlow

### 1.34.1 ZoneHVAC:Baseboard:RadiantConvective:Water

The objective of this model is to calculate the convective and radiant heat transfer from water baseboard heaters to the people and the surfaces within a zone so that surface heat balances can take into account the radiant heat transfer to the surfaces and thus enhance the accuracy of thermal comfort predictions within the space. The radiant heat gains are distributed to the surfaces by fractions defined by user input.

#### 1.34.1.1 Inputs

##### 1.34.1.1.1 Field: Name

A unique user assigned name for an instance of a hot water baseboard heater unit. Any reference to this unit by another object will use this name.

##### 1.34.1.1.2 Field: Design Object

The name of the object that holds design data for this instance of hot water baseboard heater unit. Multiple input data values are taken from this object.

##### 1.34.1.1.3 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the hot water baseboard heater unit can run during a given time period. A schedule value equal to 0 denotes that the unit must be off for that time period. A value greater than 0 denotes that the unit is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

##### 1.34.1.1.4 Field: Inlet Node Name

This field is the name of the hot water inlet node for the baseboard heater.

##### 1.34.1.1.5 Field: Outlet Node Name

This field is the name of the hot water outlet node for the baseboard heater.

**1.34.1.1.6 Field: Rated Average Water Temperature**

This field is the rated average water temperature for the baseboard heater which is published in the manufacturer's literature in degree Celsius. It typically ranges from 65.56°C to 115.36°C in the I = B = R rating document while the lowest allowable temperature is 32.22°C. The default value is 87.78°C. If the user does not enter this field, the default value is assumed.

**1.34.1.1.7 Field: Rated Water Mass Flow Rate**

This field is the rated standard water flow rate in kg/s which is published as part of the manufacturer's literature. It is used by the manufacturers when determining the rated capacity (see next field). The default value is 0.063kg/s. If it is blank or zero, the default values is assumed.

**1.34.1.1.8 Field: Heating Design Capacity {W}**

This field is the radiant-convective water baseboard rated capacity in watts at a rated water mass flow rate (see input field Rated Mass Flow Rate). Almost all publications from manufacturers indicate it as W/m (Btuh per linear foot). The user thus must multiply it by the active length of the unit. The active length is available in the literature. Manufacturers are required to publish the difference between active and total length of the unit (I = B = R rating for boilers baseboard radiation, 2009). If it is blank or zero, autosizing is assumed. Design day sizing run must be specified for autosizing.

**1.34.1.1.9 Field: Maximum Water Flow Rate**

This field is the maximum water volumetric flow rate in m<sup>3</sup>/sec. It can be autosized by EnergyPlus.

**1.34.1.1.10 Field Set: Surface Name, Fraction of Radiant Energy to Surface**

The following two items are repeated up to a maximum of 20 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

**1.34.1.1.11 Field: Surface <x> Name**

This field is the name of the first surface to which radiant heat transfer from the baseboard heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

**1.34.1.1.12 Field: Fraction of Radiant Energy to Surface <x>**

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the baseboard heater that is incident on a particular surface. Users should take into account the directionality of baseboard heaters and their location when defining the value for this input field.

***Note on Fraction of Radiant Energy Incident on **People** and to Surfaces***

The radiant energy from the baseboard heater is defined by the total energy input to the baseboard heater from the water loop times the fraction radiant field shown above. This radiant energy is distributed to surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions to people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$FractionIndicentOnPeople + \sum FractionToSurfaces = 1 \quad (1.135)$$

An example IDF for the water baseboard is shown below.

```

---

### 1.34.1.2 ZoneHVAC:Baseboard:RadiantConvective:Water:Design

This object contains the design fields for ZoneHVAC:Baseboard:RadiantConvective:Water. The information from one ZoneHVAC:Baseboard:RadiantConvective:Water:Design object can be shared with several ZoneHVAC:Baseboard:RadiantConvective:Water objects.

#### 1.34.1.2.1 Field: Design Object Name

A unique user assigned name for an instance of a hot water baseboard heater unit design object. Any reference to this unit by another object will use this name.

#### 1.34.1.2.2 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity or the method for scalable sizing. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of heating capacity or the program calculates the design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the radiant baseboard unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

#### 1.34.1.2.3 Field: Heating Design Capacity Per Floor Area {W/m2}

Enter the rated heating capacity per unit floor area of radiant-convective water baseboard unit in m3/s-m2. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the radiant baseboard unit and the heating capacity per unit floor area value specified by the user. This field may be left blank.

#### 1.34.1.2.4 Field: Fraction of Autosized Heating Design Capacity

Enter the heating capacity as a fraction of the autosized heating capacity of radiant-convective water baseboard. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized heating capacity

and user specified fraction. Design day sizing run must be specified. This field may be left blank. Default value is 1.0.

#### 1.34.1.2.5 Field: Convergence Tolerance

This field is the control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For hot water baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq ConvergenceTolerance \quad (1.136)$$

The default is 0.001.

#### 1.34.1.2.6 Field: Fraction Radiant

This field specifies what fraction of the power input to the baseboard heater is actually transferred to the space as radiant heat. The fraction should be between 0 and 1. This is the portion of the total power that is modeled as radiation. The portion that is radiant heat transfer from the baseboard heater is distributed to people and specific surfaces using the remaining fields. Note that the sum of the fractions in the remaining fields (people and surfaces) must equal 1.0 so that all the radiant power is distributed properly. For more information on the specification of this parameter, please see the Engineering Reference for EnergyPlus.

#### 1.34.1.2.7 Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of radiant portion of heat transfer to the zone from the baseboard heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that although this energy is “radiant” it is actually modeled in the zone heat balance as convective energy (like an internal gain). The basic assumption here is that most radiant energy falling on people will most likely be rereleased to the zone air by convection. This is a simplification of reality, but it maintains the overall energy balance.

An example IDF for the water baseboard design object is shown below.

```
ZoneHVAC:Baseboard:RadiantConvective:Water:Design,
SPACE2-1 Baseboard Design,      !- Design Object Name
HeatingDesignCapacity,          !- Heating Design Capacity Method
,                                !- Heating Design Capacity Per Floor Area
,                                !- Fraction of Autosized Heating Design Capacity
0.001,                           !- Convergence Tolerance
0.3,                             !- Fraction Radiant
0.3;                             !- Fraction of Radiant Energy Incident on People
```

#### 1.34.1.3 Outputs

- HVAC,Average,Baseboard Total Heating Rate [W]
- HVAC,Average,Baseboard Convective Heating Rate [W]
- HVAC,Average,Baseboard Radiant Heating Rate [W]
- HVAC,Sum,Baseboard Total Heating Energy [J]
- HVAC,Sum,Baseboard Total Heating Energy [J]

- HVAC,Sum,Baseboard Convective Heating Energy [J]
- HVAC,Sum,Baseboard Radiant Heating Energy [J]
- HVAC,Meter,Baseboard:EnergyTransfer [J]

#### **1.34.1.3.1 Baseboard Total Heating Rate [W]**

This is the actual convective heat addition rate of the baseboard to the zone in Watts. This value includes the heat convected to the zone air from the baseboard unit, the heat radiated to people in the zone from the baseboard unit, and the additional convection from surfaces within the zone that have been heated by radiation from the baseboard unit. This value will be different from (and almost always more than) the next field (convective heating rate).

#### **1.34.1.3.2 Baseboard Convective Heating Rate [W]**

This field reports the rate at which convective heat addition is transferred from the baseboard to the zone in Watts. This field in combination with the baseboard radiant heating rate (the next field) equals the total heat addition to the space by the baseboard unit.

#### **1.34.1.3.3 Baseboard Radiant Heating Rate [W]**

This field reports the rate at which radiant heat addition is transferred from the baseboard to the people and the surfaces within the zone in Watts. This field in combination with the baseboard convective heating rate (the previous field) equals the total heat addition to the space by the baseboard unit.

#### **1.34.1.3.4 Baseboard Total Heating Energy [J]**

This is the actual, total convective energy transferred directly and indirectly from the baseboard to the zone it is serving in Joules. Direct convective heat transfer includes the convective portion of the baseboard unit. Indirect convective heat transfer includes heat radiated to people that is then convected to the zone air and heat that is radiated to the surfaces and then convected to the zone air.

#### **1.34.1.3.5 Baseboard Convective Heating Energy [J]**

This field reports the amount of convective energy transferred from the baseboard directly to the zone air in Joules.

#### **1.34.1.3.6 Baseboard Radiant Heating Energy [J]**

This field reports the amount of radiant energy transferred from the baseboard to the zone in Joules.

#### **1.34.1.3.7 Baseboard Hot Water Mass Flow Rate [kg/s]**

This field reports the water mass flow rate at the inlet node of a baseboard unit.

#### **1.34.1.3.8 Baseboard Air Mass Flow Rate [kg/s]**

This field reports the air mass flow rate at the inlet node of a baseboard unit.

#### **1.34.1.3.9 Baseboard Water Inlet Temperature [C]**

This field reports the water temperatures at the inlet node of a baseboard unit.

#### **1.34.1.3.10 Baseboard Water Outlet Temperature [C]**

This field reports the water temperatures at the outlet node of a baseboard unit.

**1.34.1.3.11 Baseboard Air Inlet Temperature [C]**

This field reports the air temperatures at the inlet node of a baseboard unit.

**1.34.1.3.12 Baseboard Air Outlet Temperature [C]**

This field reports the air temperatures at the outlet node of a baseboard unit.

**1.34.2 ZoneHVAC:Baseboard:RadiantConvective:Steam**

The objective of this model is to calculate the convective and radiant heat transfer from steam baseboard heaters to the people and the surfaces within a zone so that surface heat balances can take into account the radiant heat transfer to the surfaces and thus enhance the accuracy of thermal comfort predictions within the space. The radiant heat gains are distributed to the surfaces by fractions defined by the user. Users are requested to provide degree of sub cooling to estimate the outlet conditions of the condensate.

**1.34.2.1 Inputs****1.34.2.1.1 Field: Name**

A unique user assigned name for an instance of a steam baseboard heater unit. Any reference to this unit by another object will use this name.

**1.34.2.1.2 Field: Design Object Name**

The name of the object that holds design data for this instance of steam baseboard heater unit. Multiple input data values is taken from this object.

**1.34.2.1.3 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the steam baseboard heater unit can run during hot water a given time period. A schedule value equal to 0 denotes that the unit must be off for that time period. A value greater than 0 denotes that the unit is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

**1.34.2.1.4 Field: Inlet Node Name**

This field is the name of the steam inlet node for the baseboard heater.

**1.34.2.1.5 Field: Outlet Node Name**

This field is the name of the steam outlet node for the baseboard heater.

**1.34.2.1.6 Field: Heating Design Capacity {W}**

This field is for the a radiant/convective steam baseboard unit heating capacity in watts. This field can be autosized by EnergyPlus. When the Heating Design Capacity Method is *HeatingDesignCapacity* and this input is blank, autosizing is assumed. Design day sizing run must be specified.

**1.34.2.1.7 Field: Degree of SubCooling**

This field is the temperature drop of the condensate in the coil of the baseboard heater. The steam condensates in the coil and changes the phase to the water, giving up the latent heat of steam to the air in the steam to air heat exchanger. The condensate due to the phase change then cools by certain degree in the coil, so that this amount of heat is added to the zone. The minimum value is 1.0° Celsius and default is 5.0° Celsius.

### 1.34.2.1.8 Field: Maximum Steam Flow Rate

This field is the maximum steam volumetric flow rate in  $\text{m}^3/\text{s}$  through the steam baseboard heater. The steam volumetric flow rate is calculated at 100C and 101325 Pa. It can be autosized by EnergyPlus.

### 1.34.2.1.9 Field Set: Surface Name, Fraction of Radiant Energy to Surface

The following two items are repeated up to a maximum of 20 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

### 1.34.2.1.10 Field: Surface <x> Name

This field is the name of the first surface to which radiant heat transfer from the baseboard heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

### 1.34.2.1.11 Field: Fraction of Radiant Energy to Surface <x>

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the baseboard heater that is incident on a particular surface. Users should take into account the directionality of baseboard heaters and their location when defining the value for this input field.

### 1.34.2.1.12 Note on Fraction of Radiant Energy Incident on People and to Surfaces

The radiant energy from the baseboard heater is defined by the total energy input to the baseboard heater from the steam loop times the fraction radiant field shown above. This radiant energy is distributed to surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions to people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$FractionIndicentOnPeople + \sum FractionToSurfaces = 1 \quad (1.137)$$

An example IDF for the steam baseboard is shown below.

### 1.34.2.2 ZoneHVAC:Baseboard:RadiantConvective:Steam:Design

This object contains the design fields for ZoneHVAC:Baseboard:RadiantConvective:Steam. The information from one ZoneHVAC:Baseboard:RadiantConvective:Steam:Design object can be shared with several ZoneHVAC:Baseboard:RadiantConvective:Steam objects.

#### 1.34.2.2.1 Field: Name

A unique user assigned name for an instance of a steam baseboard heater unit design object. Any reference to this unit by another object will use this name.

#### 1.34.2.2.2 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of maximum heating capacity or the program calculates the maximum design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the radiant baseboard unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

#### 1.34.2.2.3 Field: Heating Design Capacity Per Floor Area {W/m2}

Enter the heating capacity per unit floor area in m3/s-m2 of radiant/convective steam baseboard. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the steam baseboard unit and the heating capacity per unit floor area value specified by the user. This field may be left blank.

#### 1.34.2.2.4 Field: Fraction of Autosized Heating Design Capacity

Enter the heating capacity as a fraction of the autosized heating capacity of a radiant/convective steam baseboard unit. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized heat capacity and user specified fraction. Design day sizing run must be specified. This field may be left blank. Default value is 1.0.

#### 1.34.2.2.5 Field: Convergence Tolerance

This field is the control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For steam baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq ConvergenceTolerance \quad (1.138)$$

The default is 0.001.

#### 1.34.2.2.6 Field: Fraction Radiant

This field specifies what fraction of the power input to the baseboard heater is actually transferred to the space as radiant heat. The fraction should be between 0 and 1. This is the portion of the total power that is modeled as radiation. The portion that is radiant heat transfer from the baseboard heater is distributed to people and specific surfaces using the remaining fields. Note that the sum of the fractions

in the remaining fields (people and surfaces) must equal 1.0 so that all the radiant power is distributed properly.

#### 1.34.2.2.7 Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of radiant portion of heat transfer to the zone from the baseboard heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that although this energy is “radiant” it is actually modeled in the zone heat balance as convective energy (like an internal gain). The basic assumption here is that most radiant energy falling on people will most likely be rereleased to the zone air by convection. This is a simplification of reality, but it maintains the overall energy balance.

An example IDF for the steam baseboard design object is shown below.

```
ZoneHVAC:Baseboard:RadiantConvective:Steam:Design,
SPACE1-1 Baseboard Design,      !- Design Object Name
HeatingDesignCapacity,         !- Heating Design Capacity Method
,                               !- Heating Design Capacity Per Floor Area
,                               !- Fraction of Autosized Heating Design Capacity
0.001,                         !- Convergence Tolerance
0.3,                           !- Fraction Radiant
0.3;                           !- Fraction of Radiant Energy Incident on People
```

### 1.34.2.3 Outputs

- HVAC,Average,Baseboard Total Heating Rate [W]
- HVAC,Average,Baseboard Convective Heating Rate [W]
- HVAC,Average,Baseboard Radiant Heating Rate [W]
- HVAC,Sum,Baseboard Total Heating Energy [J]
- HVAC,Sum,Baseboard Convective Heating Energy [J]

- HVAC,Meter,Baseboard:EnergyTransfer [J]
- HVAC,Average,Baseboard Steam Mass Flow Rate [kg/s]
- HVAC,Average,Baseboard Steam Inlet temperature [C]
- HVAC,Average,Baseboard Steam Outlet temperature [C]

#### 1.34.2.3.1 Baseboard Total Heating Rate [W]

This is the actual convective heat addition rate of the baseboard to the zone in Watts. This value includes the heat convected to the zone air from the baseboard unit, the heat radiated to people in the zone from the baseboard unit, and the additional convection from surfaces within the zone that have been heated by radiation from the baseboard unit. This value will be different from (and almost always more than) the next field.

#### 1.34.2.3.2 Baseboard Convective Heating Rate [W]

This field reports the rate at which convective heat addition is transferred from the baseboard to the zone in Watts. This field in combination with the baseboard radiant heating rate (the next field) equals the total heat addition to the space by the baseboard unit.

**1.34.2.3.3 Baseboard Radiant Heating Rate [W]**

This field reports the rate at which radiant heat addition is transferred from the baseboard to the people and the surfaces within the zone in Watts. This field in combination with the baseboard convective heating rate (the previous field) equals the total heat addition to the space by the baseboard unit.

**1.34.2.3.4 Baseboard Total Heating Energy [J]**

This is the actual, total convective energy transferred directly and indirectly from the baseboard to the zone it is serving in Joules. Direct convective heat transfer includes the convective portion of the baseboard unit. Indirect convective heat transfer includes heat radiated to people that is then convected to the zone air and heat that is radiated to the surfaces and then convected to the zone air.

**1.34.2.3.5 Baseboard Convective Heating Energy [J]**

This field reports the amount of convective energy transferred from the baseboard directly to the zone air in Joules.

**1.34.2.3.6 Baseboard Radiant Heating Energy [J]**

This field reports the amount of radiant energy transferred from the baseboard to the zone in Joules.

**1.34.2.3.7 Baseboard Steam Energy [J]****1.34.2.3.8 Baseboard Steam Rate [W]**

These are the total heat addition energy and rate of steam used by the baseboard to heat the zone it is serving in Joules and Watts.

**1.34.2.3.9 Baseboard Steam Mass Flow Rate [kg/s]**

This field reports the steam mass flow rate at the inlet node of a baseboard unit.

**1.34.2.3.10 Baseboard Steam Inlet Temperature [C]**

This field reports the steam temperatures at the inlet node of a baseboard unit.

**1.34.2.3.11 Baseboard Steam Outlet Temperature [C]**

This field reports the steam temperatures at the outlet node of a baseboard unit.

**1.34.3 ZoneHVAC:Baseboard:RadiantConvective:Electric**

The electric baseboard heater is a component in the zone equipment simulation. Heat from this device is radiated to people and surfaces and also convected to the surrounding air. The electric baseboard model includes the impact of the radiant heat addition to people and surfaces so that the thermal comfort and surface heat balances are impacted. The component is controlled to meet any remaining zone load not met by other equipment baseboard operates to meet the remaining zone load and the total electric consumption is calculated by dividing by the efficiency of the baseboard.

**1.34.3.1 Inputs****1.34.3.1.1 Field: Name**

A unique user assigned name for an instance of an electric baseboard heater unit. Any reference to this unit by another object will use this name.

#### 1.34.3.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the electric baseboard heater unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit will be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.34.3.1.3 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of maximum or nominal heating capacity or the program calculates the maximum or nominal design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the radiant baseboard unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

#### 1.34.3.1.4 Field: Heating Design Capacity {W}

This field is for the radiant-convective electric baseboard unit nominal heating capacity in watts. This field can be autosized by EnergyPlus. This input field is autosizable. When the Heating Design Capacity Method is *HeatingDesignCapacity* and this input is blank, autosizing is assumed. Design day sizing run must be specified.

#### 1.34.3.1.5 Field: Heating Design Capacity Per Floor Area {W/m<sup>2</sup>}

Enter the heating capacity per unit floor area in m<sup>3</sup>/s-m<sup>2</sup> of radiant/convective electric baseboard. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the radiant baseboard unit and the heating capacity per unit floor area value specified by the user. This field may be left blank.

#### 1.34.3.1.6 Field: Fraction of Autosized Heating Design Capacity

Enter the heating capacity as a fraction of the autosized heating capacity for radiant/convective electric baseboard. This input field is required when the Heating Design Capacity Method is *FractionOfAutosized-HeatingCapacity*. The program calculates the heating capacity from the design autosized heat capacity and user specified fraction. Design day sizing run must be specified. This field may be left blank. Default value is 1.0.

#### 1.34.3.1.7 Field: Efficiency

This is the overall electrical efficiency of the electric baseboard unit. The zone load met by this unit is divided by the electrical efficiency to obtain the total electric energy used.

#### 1.34.3.1.8 Field: Fraction Radiant

This field specifies what fraction of the power input to the baseboard heater is actually transferred to the space as radiant heat. The fraction should be between 0 and 1. This is the portion of the total power that is modeled as radiation. The portion that is radiant heat transfer from the baseboard heater is distributed to people and specific surfaces using the remaining fields. Note that the sum of the fractions in the remaining fields (people and surfaces) must equal 1.0 so that all the radiant power is distributed properly.

**1.34.3.1.9 Field: Fraction of Radiant Energy Incident on People**

This field specifies the fraction of the radiant portion of heat transfer to the zone from the baseboard heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that although this energy is “radiant” it is actually modeled in the zone heat balance as a convective energy (like an internal gain). The basic assumption here is that radiant energy falling on people will most likely be rereleased to the zone air by convection. This is a simplification of reality, but it maintains the overall energy balance.

**1.34.3.1.10 Field Set: Surface Name, Fraction of Radiant Energy to Surface**

The following two items are repeated up to a maximum of 20 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

**1.34.3.1.11 Field Set: Surface <x> Name**

This field is the name of the first surface to which radiant heat transfer from the baseboard heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

**1.34.3.1.12 Field Set: Fraction of Radiant Energy to Surface <x>**

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the baseboard heater that is incident on a particular surface. Users should take into account the directionality of baseboard heaters and their location when defining the value for this input field.

**1.34.3.1.13 Note on Fraction of Radiant Energy Incident on People and to Surfaces**

The radiant energy from the baseboard heater is defined by the total energy input to the baseboard heater times the fraction radiant field shown above. This radiant energy is distributed to surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions to people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$FractionIncidentOnPeople + \sum FractionToSurfaces = 1 \quad (1.139)$$

Below is an example input for an Electric Baseboard Heater.

- HVAC,Sum,Baseboard Convective Heating Energy [J]
- HVAC,Sum,Baseboard Electricity Energy [J]
- HVAC,Meter,Baseboard:EnergyTransfer [J]
- HVAC,Meter,Heating:Electricity[J]

#### 1.34.3.2.1 Baseboard Total Heating Rate [W]

This is the actual convective heat addition rate of the baseboard to the zone in Watts. This value includes the heat convected to the zone air from the baseboard unit, the heat radiated to people in the zone from the baseboard unit, and the additional convection from surfaces within the zone that have been heated by radiation from the baseboard unit. This value will be different from (and almost always more than) the next field.

#### 1.34.3.2.2 Baseboard Convective Heating Rate [W]

This field reports the rate at which convective heat addition is transferred from the baseboard to the zone in Watts. This field in combination with the baseboard radiant heating rate (the next field) equals the total heat addition to the space by the baseboard unit.

#### 1.34.3.2.3 Baseboard Radiant Heating Rate [W]

This field reports the rate at which radiant heat addition is transferred from the baseboard to the people and the surfaces within the zone in Watts. This field in combination with the baseboard convective heating rate (the previous field) equals the total heat addition to the space by the baseboard unit.

#### 1.34.3.2.4 Baseboard Electricity Energy [J]

This is the electric energy used by the baseboard in Joules.

#### 1.34.3.2.5 Baseboard Electricity Rate [J]

This is the electric power required by the baseboard to heat the zone it is serving in Watts

#### 1.34.3.2.6 Baseboard Total Heating Energy [J]

This is the actual convective energy transferred directly and indirectly from the baseboard heater to the zone it is serving in Joules. Direct convective heat transfer includes the convective portion of the baseboard unit. Indirect convective heat transfer includes heat radiated to people that is then convected to the zone air and heat that is radiated to the surfaces and then convected to the zone air.

**1.34.3.2.7 Baseboard Radiant Heating Energy [J]**

This field reports the amount of radiant energy transferred from the baseboard to the zone in Joules.

**1.34.3.2.8 Baseboard Convective Heating Energy [J]**

This field reports the amount of convective energy transferred from the baseboard directly to the zone air in Joules.

**1.34.4 ZoneHVAC:CoolingPanel:RadiantConvective:Water**

The radiant/convective cooling panel is a type of zone equipment. Chilled water is supplied by the plant and circulated through the panel. Through radiation and convective heat transfer, the panel absorbs energy contained within the zone to provide cooling. Control of the panel is achieved using the methodology used for low temperature radiant systems—a piecewise linear control profile that varies the flow rate to the panel based on a control parameter defined by the user. This is different than being controlled to meet any remaining load like the air-based systems. However, due to the radiant nature of these devices, it is not possible to control precisely on a zone air-based load since this will result in overcooling at the next time step. Despite this, in addition to the piecewise linear controls that have been used with low temperature radiant systems in the past, two new controls are available for this simple model: one that varies the convective output of the system to meet the remaining zone load and one that varies the total convective output of the system to meet the remaining zone load. In these two zone load control types, the user must enter the typical zone thermostat object to replace the setpoint and throttling range input in this object. In this component, control is accomplished by throttling the chilled water flow to the device. Capacity rating information is required as input and is used to calculate a UA value of the unit. The unit is connected to a chilled water loop (demand side) with an inlet and outlet node. The input data dictionary definition of the unit is as follows.

**1.34.4.1 Inputs****1.34.4.1.1 Field: Name**

A unique user assigned name for this instance of a radiant cooling panel. Any reference to this unit by another object will use this name.

**1.34.4.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the radiant cooling panel can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off for the hour.

**1.34.4.1.3 Field: Inlet Node Name**

The name of the water inlet node for the radiant cooling panel.

**1.34.4.1.4 Field: Outlet Node Name**

The name of the water outlet node for the radiant cooling panel.

**1.34.4.1.5 Field: Rated Inlet Water Temperature**

This field is the inlet temperature to the panel under conditions used to rate the capacity of the panel. This value along with the other rating condition parameters is used to calculate the overall heat transfer coefficient (U-Value) that will be used to characterize the heat transfer between the water being circulated through the panel and the air in the zone. The default value is 5°C (41°F).

#### 1.34.4.1.6 Field: Rated Space Temperature

This field is the combined space temperature (air and surface) that the panel is exposed to during the rating process to obtain a rated capacity. This value along with the other rated conditions is used to calculate the overall heat transfer coefficient (U-Value) that will be used to characterize the heat transfer between the water being circulated through the panel and the air in the zone. The default value is 24°C (75.2°F).

#### 1.34.4.1.7 Field: Rated Water Mass Flow Rate

This field is the rated standard water flow rate in kg/s that was used to obtain the design cooling capacity under rated temperature conditions. This value along with the rated space and water inlet temperatures as well as the cooling capacity (whether autosized or entered by the user) is used to calculate the overall heat transfer coefficient (U-Value) that will be used to characterize the heat transfer between the water being circulated through the panel and the air in the space. Users should note that if this value is too low in comparison to the cooling design capacity that the program will produce an error message and the user must adjust one of these two parameters or the rated temperature values. The default value is 0.063kg/s (1 gpm). If it is blank or zero, the default value is assumed.

#### 1.34.4.1.8 Field: Cooling Design Capacity Method

This field defines the method used to determine the cooling design capacity for scalable sizing. The inputs that are allowed for this field include: *CoolingDesignCapacity*, *CapacityPerFloorArea*, or *FractionOfAutosizedCoolingCapacity*. If this input field is left blank, then the *CoolingDesignCapacity* method is assumed to be valid for this unit. *CoolingDesignCapacity* means the user specifies the magnitude of maximum or nominal cooling capacity or the program calculates the maximum or nominal design cooling capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design cooling capacity from the user specified cooling capacity per floor area and the floor area of the zone served by the cooling panel unit. *FractionOfAutosizedCoolingCapacity* means the program calculates the design cooling capacity from a user specified fraction and the auto-sized design cooling capacity.

#### 1.34.4.1.9 Field: Cooling Design Capacity

This field contains the cooling panel unit nominal cooling capacity in Watts at the rated flow rate of water through the unit (see Rated Water Mass Flow Rate field above). This field can be autosized by EnergyPlus. When the Cooling Design Capacity Method is *CoolingDesignCapacity* and this input is blank, autosizing is assumed. A design day sizing run must be specified for this to be autosized.

#### 1.34.4.1.10 Field: Cooling Design Capacity Per Floor Area

This field is used to enter the cooling capacity per unit floor area in W/m<sup>2</sup> for the cooling panel unit. This field is a required field when the Cooling Design Capacity Method is *CapacityPerFloorArea*. The program calculates the cooling capacity from floor area of the zone served by the cooling panel unit and the cooling capacity per unit floor area value specified by the user. This field may be left blank.

#### 1.34.4.1.11 Field: Fraction of Autosized Cooling Design Capacity

This field is used to enter the cooling capacity as a fraction of the autosized cooling capacity for the cooling panel. This input field is required when the Cooling Design Capacity Method is *FractionOfAutosizedCoolingCapacity*. The program calculates the cooling capacity from the design autosized cooling capacity and the user specified fraction. A design day sizing run must be specified. This field may be left blank, and the default value is 1.0.

**1.34.4.1.12 Field: Maximum Chilled Water Flow Rate**

This field specifies the maximum chilled water volumetric flow rate in m3/sec. This field can also be autosized.

**1.34.4.1.13 Field: Control Type**

This field specifies two different types of control categories: temperature or zone load. For one of the temperature based controls, this field along with the throttling range and setpoint schedules determines how the user wishes to control the radiant cooling panel. The temperature denoted in the setpoint schedule can refer to one of five different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, or the outdoor wet-bulb temperature. The current field controls the choice of temperature. For controls that are based more on zone load, the user can make one of two choices based on whether the zone load is met by only the convective output of the unit or the total output of the unit. These zone load controls will not perform as precisely as air-based systems. The convective zone load control will come close to meeting the current setpoint temperature (defined by the typical zone thermostat input by the user) since the convective output of the unit will be set to match the remaining zone load. However, in the long run, this will likely overcool the space since radiant energy is being absorbed by surfaces and this will impact the zone conditions at later time steps. The total zone load control will likely undercool the space in the short term since the total output (radiant and convective) of the unit will be set to meet the remaining zone load. However, this will not fully impact the zone air temperature immediately since some of the energy is being absorbed from surfaces rather than the zone air. The user must select from the following options:

- MeanAirTemperature
- MeanRadiantTemperature
- OperativeTemperature
- OutdoorDryBulbTemperature
- OutdoorWetBulbTemperature
- ZoneConvectiveLoad
- ZoneTotalLoad

Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature. If the user does not select a control type, MeanAirTemperature control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information.

**1.34.4.1.14 Field: Cooling Control Throttling Range**

This field specifies the range of temperature in degrees Celsius over which the radiant cooling panel throttles from zero flow rate up to the maximum defined by the maximum chilled water flow rate field described above. The throttling range parameter is used in conjunction with the control temperature to define the response of the system to various zone conditions. The cooling control temperature schedule specifies the “setpoint” temperature where the flow rate to the system is at half of the maximum flow rate. For example, if the cooling control temperature setpoint is currently 25 C and the cooling throttling range is 2 C, the water flow rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, ODB, or OWB; see control type field above) is at or below 24 C and the maximum flow rate when the controlling temperature is at or above 26 C. This represents a throttling range of 2 C around the setpoint of 25 C. In between 24 C and 26 C, the flow rate to the radiant system is varied linearly. Note that this field is ignored when the control type is either ZoneLoadConvective or ZoneLoadTotal. For the two zone load controls, the user must use a typical zone thermostat and the system output will be dependent on the remaining zone load.

#### 1.34.4.1.15 Field: Cooling Control Temperature Schedule Name

This field specifies the cooling setpoint or control temperature for the radiant cooling panel in degrees Celsius. Used in conjunction with the previous field (cooling control throttling range), it will define whether or not the system is running and the current flow rate. Water flow rate to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum cooling flow rate parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for cooling. The control of the radiant cooling panel is based solely on the cooling control throttling range listed above, the cooling control temperature schedule, and the control temperature type listed above. The radiant cooling panel will not use any zone thermostat that might be used by other systems serving the zone in which this radiant cooling panel resides. Note that this field is ignored when the control type is either `ZoneLoadConvective` or `ZoneLoadTotal`. For the two zone load controls, the user must use a typical zone thermostat and the system output will be dependent on the remaining zone load.

#### 1.34.4.1.16 Field: Condensation Control Type

Since radiant cooling panels provide a cold surface in what could be a humid zone, there is the possibility that condensation will occur on the surface of the panel. This is due to the fact that the surface temperature may drop below the dew-point temperature of the space. When this occurs, condensation on the surface will occur. Since there is no direct calculation of the surface temperature of the radiant cooling panel, the condensation check will be made at the inlet water temperature to the panel. Since the user can utilize the next parameter to adjust the differential between the dewpoint temperature and the inlet water temperature, this will allow some flexibility in controlling when the panel will shutdown to avoid condensation. There are three options for handling potential condensation: `Off`, `SimpleOff`, and `VariableOff`. This parameter is optional and will default to `SimpleOff`.

- `Off` - EnergyPlus will not do anything other than produce a warning message when condensation is predicted to occur. The program will simply continue on; no moisture will be removed from the zone air and there will be no adjustment of the surface temperature as a result of the condensation.
- `SimpleOff` - the program will predict cases where condensation will occur and shut-off the radiant system to avoid this situation. With this option, the user also has the option to adjust when the system will shut down. This is specified with the next parameter (field: `Condensation Differential Parameter`).
- `VariableOff` - the program will attempt to reduce the inlet temperature to the panel by locally recirculating some of the water leaving the panel and mixing it with water from the overall demand side flow. This also means that some of the demand side water will bypass the panel. In reality, this would require a pump to achieve such mixing and recirculation, but due to the simple nature of this model, no pump definition will be required. Like the `SimpleOff` option, the `VariableOff` option uses the condensation dewpoint offset parameter to adjust when the system will try to adjust for the possibility of condensation.

#### 1.34.4.1.17 Field: Condensation Control Dewpoint Offset

This optional parameter is only valid with the `SimpleOff` and `VariableOff` condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed inlet water temperature to the radiant cooling panel before the system shuts down in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down or recirculate water (depending on whether `SimpleOff` or `VariableOff` is used) when the inlet temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down or recirculate water when the inlet

water temperature is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down or recirculate water when the inlet water temperature is the number of degrees Celsius below the dew-point temperature. This strategy allows the user to simulate a situation where small amounts of condensation are tolerable or the resistance of the panel from the water loop to the panel surface is being taken into account as condensation would likely happen at the panel surface. The default value for this parameter is 1°C.

#### 1.34.4.1.18 Field: Fraction Radiant

This field allows the user an opportunity to characterize the heat transfer at the surface of the panel as either purely radiative, purely convective, or some combination of radiant and convective. As a result, through this parameter, EnergyPlus gives the user an opportunity to characterize the zone temperature as a function of the zone mean radiant temperature and the mean air temperature. The performance of the unit is proportional to the difference between the water inlet temperature and the zone temperature where the zone temperature is found using a weighted average of zone mean radiant temperature and mean air temperature. The weighting factor is this parameter, and it is multiplied by the zone mean radiant temperature. The remainder of the zone temperature calculation is made up of the zone mean air temperature. During modeling, it is likewise used to calculate how much of the energy being absorbed by the unit is radiant energy. This parameter can be difficult to quantify as the fraction radiant can vary with zone conditions. However, by definition, a radiant system like this radiant cooling panel exchanges at least half of its energy to the zone via radiation. One study has shown that a fraction radiant between 0.6 and 0.7 is a reasonable estimation. For more information, see the EnergyPlus Engineering Reference in section Radiant System Models, subsection Simple Radiant Cooling Panel.

#### 1.34.4.1.19 Field: Fraction of Radiant Energy Incident on People

This field allows the user to direct some of the radiant energy to be absorbed from people rather than surfaces within the space. This has a direct impact on thermal comfort and depends on the location of the people with respect to the radiant cooling panel. All energy absorbed by the panel would have a cooling effect on people and is subtracted from the total radiant energy absorbed by the panel defined by the previous term.

#### 1.34.4.1.20 Field Set: Surface Name, Fraction of Radiant Energy to Surface

These two fields are repeated for up to 100 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

The radiant energy from the cooling panel is defined by the total energy input to the cooling panel from the chilled water loop times the fraction radiant field shown above. This radiant energy is received from surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions from people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$FractionIncidentOnPeople + \sum FractionToSurfaces = 1 \quad (1.140)$$

#### 1.34.4.1.21 Field Set: Surface <x> Name

The radiant energy absorbed by the radiant cooling panel can be specified to be received from particular surfaces within the space. The next series of pairs of inputs (surface name and fraction of radiant energy) specify where this radiant energy is coming from. In essence, the fraction radiant terms for each surface are similar to a view factor. These pairs can be repeated for up to 100 surfaces giving the user plenty of

flexibility to have the radiant cooling panel interact with many potential surfaces. This first parameter in the pair is the name of the surface defined by user input elsewhere in the input file. Note that the surface must reside in the same zone as all of the other surfaces in the following list (that is, all surfaces listed must be in the same zone).

#### 1.34.4.1.22 Field Set: Fraction of Radiant Energy to Surface <x>

In combination with the previous field, this defines what fraction of the radiant energy being absorbed by the radiant cooling panel comes from the surface named by the previous field. These pairs of surface names and fractions of radiant energy from the surface can be repeated up to 100 times in the input for a particular radiant cooling panel. Note that the sum of all of the surface radiant energy fractions plus the radiant fraction from people must add up to unity just like in the radiant-convective baseboard models. Note that there is a small possibility that a particular surface listed in these pairs is actually lower than the temperature of the panel. This probably will not happen unless there is another cooling surface within the zone. In reality, absorbing net radiant energy from a colder surface would violate the Second Law of Thermodynamics. However, in keeping with the simple nature of this model, EnergyPlus will monitor the inlet water temperature to the panel and produce a warning message if this temperature is lower than any of the surface temperature of the surfaces with which this system is interacting.

An example input for the radiant cooling panel is shown below.

#### 1.34.4.1.23 Cooling Panel Total System Cooling Rate [W]

This field is the total rate of cooling achieved by the radiant cooling panel in Watts. This is the impact of the cooling panel on the space and is the actual impact the system has on the zone. It includes the convective heat transfer rate as well as the decreased convection from zone surfaces as a result of the operation of the unit and the radiation associated with the panel that is absorbed from people.

#### 1.34.4.1.24 Cooling Panel Total Cooling Rate [W]

This variable is the total rate of cooling achieved by the radiant cooling panel on the zone in Watts. This value includes the sum of both the convective and the radiant energy absorbed by the panel.

#### 1.34.4.1.25 Cooling Panel Convective Cooling Rate [W]

This field reports the rate at which convective heat is removed by the radiant cooling panel from the zone in Watts.

#### 1.34.4.1.26 Cooling Panel Radiant Cooling Rate [W]

This field reports the rate at which radiant heat is removed from people and the surfaces of the zone being served by the radiant cooling panel in Watts.

#### 1.34.4.1.27 Cooling Panel Total System Cooling Energy [J]

This field is the total cooling achieved by the radiant cooling panel on the zone in Joules over the timestep being reported. This is the impact of the cooling panel on the space and is the actual impact the system has on the zone. It includes the convective heat transfer rate as well as the decreased convection from zone surfaces as a result of the operation of the unit and the radiation associated with the panel that is absorbed from people.

#### 1.34.4.1.28 Cooling Panel Total Cooling Energy [J]

This field reports the total heat removal from the zone by the radiant cooling panel in Joules over the timestep being reported.

#### 1.34.4.1.29 Cooling Panel Convective Cooling Energy [J]

This field reports the convective heat removal from the zone by the radiant cooling panel in Joules over the timestep being reported.

#### 1.34.4.1.30 Cooling Panel Radiant Cooling Energy [J]

This field reports the amount of radiant heat removal from people and the surfaces of the zone being served by the radiant cooling panel in Joules over the timestep being reported.

#### 1.34.4.1.31 CoolingPanel:EnergyTransfer [J]

This meter report variable is the sum of the total heat removal being accomplished by all radiant cooling panels in the HVAC systems in the simulation.

**1.34.4.1.32 Cooling Panel Water Mass Flow Rate [kg/s]**

This field reports the water mass flow rate at the inlet node of the radiant cooling panel. The water mass flow rate at the inlet and outlet node of the radiant cooling panel is the same value.

**1.34.4.1.33 Cooling Panel Water Inlet Temperature [C]**

This field reports the water temperature at the inlet node of the radiant cooling panel.

**1.34.4.1.34 Cooling Panel Water Outlet Temperature [C]**

This field reports the water temperature at the outlet node of the radiant cooling panel.

**1.34.5 ZoneHVAC:Baseboard:Convective:Water**

The hot water baseboard heater is a component of zone equipment. The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher heating priority. The control is accomplished by throttling the hot water flow. Input resembles that for the simple heating coil: there is an availability schedule, an overall UA, and a maximum hot water mass flow rate. The unit is connected to a hot water loop (demand side) with an inlet and outlet node. Finally, there is the convergence tolerance, which is the tolerance on how closely the baseboard outlet will meet the zone load. Of course, this tolerance is relative to the zone load.

**1.34.5.1 Inputs****1.34.5.1.1 Field: Name**

A unique user assigned name for an instance of a hot water baseboard heater unit. Any reference to this unit by another object will use this name.

**1.34.5.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the hot water baseboard heater unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.34.5.1.3 Field: Inlet Node Name**

The name of the hot water inlet node for the baseboard heater.

**1.34.5.1.4 Field: Outlet Node Name**

The name of the hot water outlet node for the baseboard heater.

**1.34.5.1.5 Field: Heating Design Capacity Method**

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of maximum or nominal heating capacity or the program calculates the maximum or nominal design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the hot water baseboard heater. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

**1.34.5.1.6 Field: Heating Design Capacity {W}**

This field is for the hot water baseboard heater design heating capacity in watts. This field can be autosized by EnergyPlus. This input field is autosizable. When the Heating Design Capacity Method is *HeatingDesignCapacity* and this input is blank, autosizing is assumed. Design day sizing run must be specified if autosize is specified.

**1.34.5.1.7 Field: Heating Design Capacity Per Floor Area {W/m2}**

Enter the heating capacity per unit floor area in m3/s-m2 of hot water baseboard heater. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by hot water baseboard heater and the heating capacity per unit floor area value specified by the user. This field may be left blank.

**1.34.5.1.8 Field: Fraction of Autosized Heating Design Capacity**

Enter the heating capacity as a fraction of the autosized heating capacity for the hot water baseboard heater. This input field is required when the Heating Design Capacity Method is *FractionOfAutosized-HeatingCapacity*. The program calculates the heating capacity from the design autosized heat capacity and user specified fraction. Design day sizing run must be specified. This field may be left blank. Default value is 1.0.

**1.34.5.1.9 Field: U-Factor Times Area Value**

The overall heat transfer coefficient for the baseboard heater in watts per degree Celsius at design conditions. The U-Factor Times Area Value (UA) is used in an NTU - effectiveness calculation. An estimate of the UA can be obtained from:

$$q = UA \times (T_{water,avg} - T_{air,avg}) \quad (1.141)$$

where q is the heat transferred from water to the air in watts;  $T_{water,avg}$  is the average water temperature in degrees C; and  $T_{air,avg}$  is the average air temperature in degrees C. Or the LMTD temperature difference can be used.

**1.34.5.1.10 Field: Maximum Water Flow Rate**

The maximum hot water volumetric flow rate in m<sup>3</sup>/sec.

**1.34.5.1.11 Field Convergence Tolerance**

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For hot water baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq ConvergenceTolerance \quad (1.142)$$

The default is 0.001.

An example IDF for the hot water convective baseboard is shown below.

#### 1.34.5.2.1 Baseboard Total Heating Rate [W]

This is the heat addition rate of the convective baseboard to the zone it is serving in Watts.

#### 1.34.5.2.2 Baseboard Total Heating Energy [J]

This is the heat addition of the convective baseboard to the zone it is serving in Joules over the timestep being reported.

#### 1.34.5.2.3 Baseboard Hot Water Energy [J]

This is the energy in the hot water used by the baseboard to heat the zone, in Joules.

#### 1.34.5.2.4 Baseboard Hot Water Mass Flow Rate [kg/s]

This field reports the water mass flow rate at the inlet node of a baseboard unit.

#### 1.34.5.2.5 Baseboard Air Mass Flow Rate [kg/s]

This field reports the air mass flow rate at the inlet node of a baseboard unit.

#### 1.34.5.2.6 Baseboard Water Inlet Temperature [C]

This field reports the water temperatures at the inlet node of a baseboard unit.

#### 1.34.5.2.7 Baseboard Water Outlet Temperature [C]

This field reports the water temperatures at the outlet node of a baseboard unit.

#### 1.34.5.2.8 Baseboard Air Inlet Temperature [C]

This field reports the air temperatures at the inlet node of a baseboard unit.

**1.34.5.2.9 Baseboard Air Outlet Temperature [C]**

This field reports the air temperatures at the outlet node of a baseboard unit.

**1.34.6 ZoneHVAC:Baseboard:Convective:Electric**

The electric baseboard heater is a component in the zone equipment simulation. The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher heating priority. The control is accomplished by taking the remaining zone load and dividing by the efficiency of the baseboard.

**1.34.6.1 Inputs****1.34.6.1.1 Field: Name**

A unique user assigned name for an instance of a electric baseboard heater unit. Any reference to this unit by another object will use this name.

**1.34.6.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the electric baseboard heater unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.34.6.1.3 Field: Heating Design Capacity Method**

Enter the method used to determine the heating design capacity or enter the method for scalable sizing of heating capacity of electric baseboard unit. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of maximum or nominal heating capacity or the program calculates the maximum or nominal design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the electric convective baseboard unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

**1.34.6.1.4 Field: Heating Design Capacity {W}**

This field is for the convective electric baseboard nominal heating capacity in watts. This field can be autosized by EnergyPlus. This input field is autosizable. Design day sizing run must be specified. This input field may be left blank.

**1.34.6.1.5 Field: Heating Design Capacity Per Floor Area {W/m2}**

Enter the heating capacity per unit floor area in m3/s-m2 of electric convective baseboard unit. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the electric convective baseboard unit and the heating capacity per unit floor area value specified by the user. This field may be left blank.

**1.34.6.1.6 Field: Fraction of Autosized Heating Design Capacity**

Enter the heating capacity as a fraction of the autosized heating capacity for convective electric baseboard unit. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized heating capacity

and user specified fraction. Design day sizing must be specified. This field may be left blank. Default value is 1.0.

#### 1.34.6.1.7 Field: Efficiency

This is the overall electrical efficiency of the electric baseboard. The zone load met by this unit is divided by the electrical efficiency to obtain the total electric energy used.

An example IDF for the electric convective baseboard is shown below.

```
ZoneHVAC:Baseboard:Convective:Electric,

- HVAC,Meter,Baseboard:EnergyTransfer [J]
- HVAC,Sum,Baseboard Electricity Energy [J]
- HVAC,Average,Baseboard Electricity Rate [W]
- HVAC,Meter,Heating:Electricity[J]

#### 1.34.6.2.1 Baseboard Total Heating Rate [W]

This is the heat addition rate of the electric convective baseboard to the zone it is serving in Watts.

#### 1.34.6.2.2 Baseboard Total Heating Energy [J]

This is the heat addition of the convective baseboard to the zone it is serving in Joules over the timestep being reported.

#### 1.34.6.2.3 Baseboard Electricity Energy [J]

This is the total electric consumption of the baseboard for the zone it is serving in Joules over the timestep being reported.

#### 1.34.6.2.4 Baseboard Electricity Rate [W]

This is the electric power required by the baseboard to the zone it is serving in Watts.

### 1.34.7 ZoneHVAC:LowTemperatureRadiant:VariableFlow

This low temperature radiant system (hydronic) is a component of zone equipment that is intended to model any “radiant system” where water is used to supply/remove energy to/from a building surface (wall, ceiling, or floor). The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher priority. The control is accomplished by throttling the hot or chilled water flow to the unit. Note that this system will only control based on the radiant system controls defined by

this input syntax and not via a zone thermostat such as is used for forced air systems. Note also that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

This model covers a wide range of low temperature radiant systems: heating and/or cooling, panel or embedded pipes, etc. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use electric resistance heating should also be defined using separate input syntax (ref: [ZoneHVAC:LowTemperatureRadiant:Electric](#)).

### 1.34.7.1 Inputs

#### 1.34.7.1.1 Field: Name

This field is an unique user assigned name for an instance of a hydronic low temperature radiant system. Any reference to this unit by another object will use this name.

#### 1.34.7.1.2 Field: Design Object

The name of the object that holds design data for this instance of hydronic low temperature radiant system. Multiple input data values is taken from this object.

#### 1.34.7.1.3 Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the hydronic low temperature radiant system can run during a given time period. A schedule value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for that time period. A value greater than 0 (usually 1 is used) denotes that the unit is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.34.7.1.4 Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the hydronic low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

#### 1.34.7.1.5 Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: BuildingSurface) or surface list (Ref: [ZoneHVAC:LowTemperatureRadiant:SurfaceGroup](#)) in which the hydronic tubing is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Note also that surfaces in a list do not need to be in the same zone or in the zone being served by this system (see previous field). Base surfaces (e.g., [BuildingSurface:Detailed](#)), door surfaces and internal mass are valid. Window surfaces are not valid surface types for embedded radiant systems.

#### 1.34.7.1.6 Field: Hydronic Tubing Length

This field is the total length of pipe embedded in the surface named above in the surface name field. The length of the tube should be entered in meters and is used to determine the effectiveness of heat transfer from the fluid being circulated through the tubes and the tube/surface. Longer tubing lengths

result in more heat will be transferred to/from the radiant surface to the circulating fluid. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values. In addition, when the user opts to autosize this calculation, the tube spacing from the construction of each surface associated with this system is used along with each individual surface area to make an approximation of the tubing length.

#### 1.34.7.1.7 Field: Heating Design Capacity {W}

This field is for the low temperature radiant variable flow unit design heating capacity in watts. This field can be autosized by EnergyPlus. This input field is autosizable. When the Heating Design Capacity Method is *HeatingDesignCapacity* and this input is blank, autosizing is assumed. Design day sizing run must be specified if autosized.

#### 1.34.7.1.8 Field: Maximum Hot Water Flow

This field is the maximum flow rate of hot water through the radiant system in m<sup>3</sup>/sec. The controls for the radiant system will vary the flow rate of hot water through the surface using zero flow and the maximum flow rate specified in this field as the lower and upper bounds, respectively. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values.

#### 1.34.7.1.9 Field: Heating Water Inlet Node Name

This field contains the name of the hot water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

#### 1.34.7.1.10 Field: Heating Water Outlet Node Name

This field contains the name of the hot water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

#### 1.34.7.1.11 Field: Cooling Design Capacity {W}

This field is for the low temperature radiant variable flow unit design cooling capacity in watts. This field can be autosized by EnergyPlus. This input field is autosizable. When the Cooling Design Capacity Method is *CoolingDesignCapacity* and this input is blank, autosizing is assumed. Design day sizing run must be specified if autosized.

#### 1.34.7.1.12 Field: Maximum Cold Water Flow

This field is the maximum flow rate of cold water through the radiant system in m<sup>3</sup>/sec. The controls for the radiant system will vary the flow rate of cold water through the surface using zero flow and the maximum flow rate specified in this field as the lower and upper bounds, respectively. Note that this field is optional and not required for a heating only system. Note also that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values.

**1.34.7.1.13 Field: Cooling Water Inlet Node Name**

This field contains the name of the cold water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

**1.34.7.1.14 Field: Cooling Water Outlet Node Name**

This field contains the name of the cold water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

**1.34.7.1.15 Field: Number of Circuits**

This optional input allows the user to choose between modeling each surface in the radiant system as a single hydronic circuit or to allow the program to divide the surface into multiple parallel hydronic circuits based on the next input field *Circuit Length*. To model as a single circuit choose *OnePerSurface*. To model as multiple circuits choose *CalculateFromCircuitLength*. It is recommended that *CalculateFromCircuitLength* be chosen. The default is *OnePerSurface* for backward compatibility with older versions of EnergyPlus.

**1.34.7.1.16 Field: Circuit Length**

The length in meters of each parallel hydronic circuit in a surface. Used when the previous input field is set to *CalculateFromCircuitLength*. The default is 106.7 meters (350 feet), which is the maximum circuit length allowed in Title 24.

An example IDF with a hydronic low temperature radiant system is shown below.

**1.34.7.2 ZoneHVAC:LowTemperatureRadiant:VariableFlow:Design**

This object contains the design fields for ZoneHVAC:LowTemperatureRadiant:VariableFlow. The information from one ZoneHVAC:LowTemperatureRadiant:VariableFlow:Design object can be shared with several ZoneHVAC:LowTemperatureRadiant:VariableFlow objects.

**1.34.7.2.1 Field: Name**

This field is an unique user assigned name for an instance of a hydronic low temperature radiant system design object. Any reference to this unit by another object will use this name.

#### 1.34.7.2.2 Field: Fluid to Radiant Surface Heat Transfer Model

This field is provides the opportunity to control how the heat transfer between the fluid circulating through this radiant system and the radiant system itself. There are two options for this parameter: ConvectionOnly or ISOStandard. The default value is ConvectionOnly. More information on each of these options is provided below.

- ConvectionOnly - This is the default mode and the method that was implemented when the radiant model was first introduced into EnergyPlus. In this modeling option, it is assumed that the impact of the tube material on heat exchange between the fluid and the radiant system and that only the convection between the fluid and the radiant system is the only critical heat transfer mechanism to take into account. The reasoning behind this included the fact that there are other simplifications in the method for calculating heat transfer and that this simplification would not result in any significant difference in the simulated heat transfer performance of the system. Convection between the fluid and the pipe wall of the system is related to physical parameters of the system (pipe/tube inner diameter and length) as well as the flow characteristics.
- ISOStandard - This method is based on the ISO Standard 11855, Part 2 (2012) document entitled “Building environment design — Design, dimensioning, installation and control of embedded radiant heating and cooling systems — Part 2: Determination of the design heating and cooling capacity”, Reference Number ISO 11855-2:2012(E). This standard recommends equations (see Appendix B of this document) to include the effects of convective heat transfer between the fluid and the inside of the piping and conduction through the pipe wall. This model requires both the inner and outer diameter of the pipe/tube, the length of the pipe/tube, and the thermal conductivity of the pipe/tube material. Note that as part of the implementation of this model in EnergyPlus, flow within the piping/tubing is always assumed to be turbulent.

#### 1.34.7.2.3 Field: Hydronic Tubing Inside Diameter

This field is the inside diameter of the tubes through which the fluid is circulated for the system being defined by this statement. The inner diameter should be recorded in meters and is used to determine the convective heat transfer from the water to the inside surface of the hydronic tubing. The default for this parameter is 0.013 which is approximately equivalent to the inner diameter of a typical 1/2” PEX pipe size.

#### 1.34.7.2.4 Field: Hydronic Tubing Outside Diameter

This field is the outside diameter of the tubes through which the fluid is circulated for the system being defined by this statement. The outer diameter should be recorded in meters and is used to determine the conduction through the hydronic tubing and the contact resistance between the tube/pipe and the radiant system itself in the ISOStandard option for the Fluid to Radiant Surface Heat Transfer Model (see above). The default for this parameter is 0.016 which is approximately equivalent to the outer diameter a typical 1/2” PEX pipe size.

#### 1.34.7.2.5 Field: Hydronic Tubing Conductivity

This field is the thermal conductivity of the pipe/tube that is used in this radiant system in Watts per meter-Kelvin (W/m-K). It is used to calculate the resistance to heat transfer through the pipe/tube wall in the ISOStandard option for the Fluid to Radiant Surface Heat Transfer Model (see above). The default for this parameter is 0.35 which is the value given for PEX piping in ISO Standard 11855-2(2012).

#### 1.34.7.2.6 Field: Temperature Control Type

This field specifies along with setpoint (control) and water schedules how the user wishes to control the constant flow radiant system. The temperature denoted in the setpoint schedule can refer to one of seven different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, the outdoor wet-bulb temperature, the radiant surface inside face temperature, or the radiant surface interior temperature. The choice of temperature is controlled by the current field-temperature control type. The user must select from the following options:

- MeanAirTemperature - The mean air temperature of the zone being controlled by this radiant system.
- MeanRadiantTemperature - The mean radiant temperature of the zone being controlled by this radiant system.
- OperativeTemperature - The operative temperature of the zone being controlled by the radiant system. Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature.
- OutdoorDryBulbTemperature - The outdoor dry-bulb temperature of the current outdoor environment.
- OutdoorWetBulbTemperature - The outdoor wet-bulb temperature of the current outdoor environment.
- SurfaceFaceTemperature - This option allows the user to control the radiant system using the inside face surface temperature of the radiant system (the inside surface temperature).
- SurfaceInteriorTemperature - This option will allow the user to control the radiant system using a surface temperature that is calculated inside the radiant system. This point will be defined by the **ConstructionProperty:InternalHeatSource** description for the system. In that input, the user has the option to calculate a temperature at a particular point in the construction. The radiant system will then use this information for controlling the slab not just producing temperatures for outputting at that point. Users should consult the input for Field: Temperature Calculation Requested After Layer Number for more information. Note that for the SurfaceFaceTemperature and SurfaceInteriorTemperature the surface being used for control is the surface listed above in the field for Surface Name. If the user enters a group of surfaces for that input, the *first* surface in the radiant group is the surface for control purposes.

If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information on how the setpoint temperature is established for this particular radiant system.

#### 1.34.7.2.7 Field: Setpoint Control Type

This field has two options (ZeroFlowPower and HalfFlowPower) and is used to determine the response of the low temperature radiant system at the setpoint temperature. The Heating Control Temperature Schedule Name and Cooling Control Temperature Schedule Name (both listed below) define a schedule for a temperature setpoint. The previous field (Temperature Control Type) defines which temperature is being controlled to that setpoint. This field determines the response of the system when the temperature being controlled is at the temperature setpoint. When ZeroFlowPower is chosen for this field, then the system will assume that it should shut off when the temperature controlled arrives at the setpoint. So, if Mean Air Temperature control is used and it becomes equal to the setpoint temperature, then the system will turn off. When HalfFlowPower is chosen for this field, then the system will assume that it should be at half of the maximum water flow when it achieves the setpoint condition.

#### 1.34.7.2.8 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of maximum or nominal heating capacity or the program calculates the design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the low temperature radiant variable flow unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

#### 1.34.7.2.9 Field: Heating Design Capacity Per Floor Area {W/m<sup>2</sup>}

Enter the heating capacity per unit floor area in m<sup>3</sup>/s-m<sup>2</sup> of low temperature radiant variable flow unit. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the low temperature radiant variable flow unit and the heating capacity per unit floor area value specified by the user. This field may be left blank.

#### 1.34.7.2.10 Field: Fraction of Autosized Heating Design Capacity

Enter the heating capacity as a fraction of the autosized heating capacity for low temperature radiant variable flow unit. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized heat capacity and user specified fraction. Design day sizing run must be specified. This field may be left blank. Default value is 1.0.

#### 1.34.7.2.11 Field: Heating Control Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero flow rate up to the maximum defined by the maximum hot water flow rate field described above. The throttling range parameter is used in conjunction with the control temperature and the setpoint type to define the response of the system to various conditions. The Heating Control Temperature Schedule specifies the “setpoint” temperature that is to be met. This is used in conjunction with the Setpoint Type which defines whether the flow rate of the system is at zero flow or half flow when the parameter defined by the Temperature Control Type is equal to the setpoint temperature defined by the Heating Control Temperature Schedule. See these other input parameters of this radiant system for more information on these different parameters. Note that when the throttling range is set to zero that this approximates an on-off system that is either fully on or totally off.

For clarity, here is an example of how the flow rate to the system will be set. In this example, it is assumed that heating control temperature setpoint is currently 15°C, the heating throttling range is 2°C, and that the setpoint type is HalfFlowPower. The water flow rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, etc.; see control type field above) is at or above 16°C and the maximum flow rate when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the flow rate to the radiant system is varied linearly from full flow at a control temperature of 14°C to half flow at 15°C to zero flow at 16°C. If the throttling range is changed to 0°C or on-off control, then the system will be off above 15°C and on below 15°C. However, if the throttling range is kept at 2°C and the setpoint type is changed to ZeroFlowPower, then the system will vary the flow linearly between zero for when the control temperature is at 15°C to full flow at 13°C.

**1.34.7.2.12 Field: Heating Control Temperature Schedule Name**

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating control throttling range), it will define whether or not the system is running and the current flow rate. Water flow rate to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum heating flow rate parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. The control of the radiant system is based solely on the heating control temperature schedule, the cooling control temperature schedule (see below), and the control temperature type listed above. The radiant system will not use any zone thermostat that might be used by other systems serving the zone in which the radiant system resides.

**1.34.7.2.13 Field: Cooling Design Capacity Method**

Enter the method used to determine the cooling design capacity for scalable sizing. Input allowed is either *CoolingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedCoolingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *CoolingDesignCapacity* means user specifies the design cooling capacity or the program calculates the design cooling capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design cooling capacity from user specified heating capacity per floor area and floor area of the zone served by the low temperature radiant variable flow unit. *FractionOfAutosizedCoolingCapacity* means the program calculates the design cooling capacity from user specified fraction and the auto-sized design cooling capacity. The default method is *CoolingDesignCapacity*.

**1.34.7.2.14 Field: Cooling Design Capacity Per Floor Area {W/m<sup>2</sup>}**

Enter the cooling capacity per unit floor area in m<sup>3</sup>/s-m<sup>2</sup> of low temperature radiant variable flow unit. This field is required field when the Cooling Design Capacity Method is *CapacityPerFloorArea*. The program calculates the cooling capacity from floor area of the zone served by the low temperature radiant variable flow unit and the cooling capacity per unit floor area value specified by the user. This field may be left blank.

**1.34.7.2.15 Field: Fraction of Autosized Cooling Design Capacity**

Enter the cooling capacity as a fraction of the autosized cooling capacity for low temperature radiant variable flow unit. This input field is required when the Cooling Design Capacity Method is *FractionOfAutosizedCoolingCapacity*. The program calculates the cooling capacity from the design autosized cooling capacity and user specified fraction. Design day sizing run must be specified. This field may be left blank. Default value is 1.0.

**1.34.7.2.16 Field: Cooling Control Throttling Range**

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero flow rate up to the maximum defined by the maximum cold water flow rate field described above. The throttling range parameter is used in conjunction with the control temperature and the setpoint type to define the response of the system to various conditions. The Cooling Control Temperature Schedule specifies the “setpoint” temperature that is to be met. This is used in conjunction with the Setpoint Type which defines whether the flow rate of the system is at zero flow or half flow when the parameter defined by the Temperature Control Type is equal to the setpoint temperature defined by the Cooling Control Temperature Schedule. See these other input parameters of this radiant system for more information on these different parameters. Note that when the throttling range is set to zero that this approximates an on-off system that is either fully on or totally off.

For clarity, here is an example of how the flow rate to the system will be set. In this example, it is assumed that cooling control temperature setpoint is currently 25°C, the cooling throttling range is 2°C,

and that the setpoint type is HalfFlowPower. The water flow rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, etc.; see control type field above) is at or below 24°C and the maximum flow rate when the controlling temperature is at or above 26°C. This represents a throttling range of 2°C around the setpoint of 25°C. In between 24°C and 26°C, the flow rate to the radiant system is varied linearly from zero flow at a control temperature of 24°C to half flow at 25°C to full flow at 26°C. If the throttling range is changed to 0°C or on-off control, then the system will be on above 25°C and off below 25°C. However, if the throttling range is kept at 2°C and the setpoint type is changed to ZeroFlowPower, then the system will vary the flow linearly between zero for when the control temperature is at 25°C to full flow at 27°C.

#### 1.34.7.2.17 Field: Cooling Control Temperature Schedule Name

This field specifies the cooling setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (cooling control throttling range), it will define whether or not the system is running and the current flow rate. Water flow rate to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum cooling flow rate parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for cooling. The control of the radiant system is based solely on the heating control temperature schedule listed above, the cooling control temperature schedule, and the control temperature type listed above. The radiant system will not use any zone thermostat that might be used by other systems serving the zone in which the radiant system resides.

#### 1.34.7.2.18 Field: Condensation Control Type

When radiant systems do cooling, there is the possibility that condensation will occur on the surface that is being cooled. This is due to the fact that the surface temperature may drop below the dew-point temperature of the space. When this happens, condensation on the surface will occur. There are three options for handling this situation: Off, SimpleOff, and VariableOff. This parameter is optional and will default to SimpleOff.

- Off - EnergyPlus will not do anything other than produce a warning message when condensation is predicted to occur. The program will simply continue on, no moisture will be removed from the zone air, and there will be no adjustment of the surface temperature as a result of the condensation.
- SimpleOff - the program will predict cases where condensation will occur and shut-off the radiant system to avoid this situation. With this option, the users also have the opportunity to adjust when the system will shut down. This is specified with the next parameter (field: Condensation Control Dewpoint Offset).
- VariableOff - the program will determine whether condensation is predicted for the flow rate determined by the unit control scheme. If condensation is predicted, the unit makes one attempt to reduce the flow rate using linear interpolation between the controlled flow rate and a zero flow rate to achieve a surface temperature that would match the dew-point temperature modified by the condensation control dew-point offset (field: Condensation Control Dewpoint Offset). For example, if the controlled flow rate results in a surface temperature of 10°C, a zero flow rate results in a surface temperature of 12°C, and the modified condensation dew-point temperature is 11°C, then the reduced flow rate would be half of the controlled flow rate. If this reduced flow approximation does not result in condensation, then this reduced flow is used for the unit. If the reduced flow approximation still results in condensation, then the unit is turned off to avoid excessive iterations.

**1.34.7.2.19 Field: Condensation Control Dewpoint Offset**

This optional parameter is only valid with the SimpleOff and VariableOff condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed surface temperature to which the surface can drop before the radiant system shuts down (SimpleOff) or reduces its flow rate (VariableOff) to avoid condensation in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down or reduce the flow rate when the surface temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down or reduce the flow rate when the surface is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down or reduce the flow rate when the surface temperature is the number of degrees Celsius below the dew-point temperature. While not recommended, this strategy allows the user to simulate a situation where small amounts of condensation are tolerable. The default value for this parameter is 1°C.

**1.34.7.2.20 Field: Changeover Delay Time Period Schedule**

This field defines a schedule which should be populated with values for the amount of time in hours that is required before this low temperature radiant system can switch between either heating or cooling and the opposite conditioning mode. If this schedule value is set to 1 (hour) at a particular time and the system was previously in heating mode, then it will be locked out from switching into cooling mode until at least one hour of time has passed in the simulation with the system “not operating”. This helps avoid systems bouncing back and forth between the two conditioning modes in successive time steps. This parameter can be set to any positive value, and a zero or negative value will be assumed to have no delay (equivalent to a delay of zero). If the user leaves this field blank, EnergyPlus will assume that no changeover delay is requested (also equivalent to a delay of zero).

An example IDF with a design object for a hydronic low temperature radiant system is shown below.

```
ZoneHVAC:LowTemperatureRadiant:VariableFlow:Design,

**1.34.7.3 Outputs**

- HVAC,Average,Zone Radiant HVAC Heating Rate [W]
- HVAC,Sum,Zone Radiant HVAC Heating Energy [J]
- HVAC,Average,Zone Radiant HVAC Cooling Rate [W]
- HVAC,Sum,Zone Radiant HVAC Cooling Energy [J]

- HVAC,Average,Zone Radiant HVAC Mass Flow Rate [kg/s]
- HVAC,Average,Zone Radiant HVAC Inlet Temperature [C]
- HVAC,Average,Zone Radiant HVAC Outlet Temperature [C]
- HVAC,Sum,Zone Radiant HVAC Moisture Condensation Time[s]
- HVAC,Sum,Zone Radiant HVAC Heating Fluid Energy [J]
- HVAC,Sum,Zone Radiant HVAC Cooling Fluid Energy [J]

#### **1.34.7.3.1 Zone Radiant HVAC Heating Rate [W]**

This field reports the heating input rate to the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

#### **1.34.7.3.2 Zone Radiant HVAC Heating Energy [J]**

This field reports the heating input to the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

#### **1.34.7.3.3 Zone Radiant HVAC Cooling Rate [W]**

This field reports the cooling input rate to the low temperature radiant system in Watts. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

#### **1.34.7.3.4 Zone Radiant HVAC Cooling Energy [J]**

This field reports the cooling input to the low temperature radiant system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

#### **1.34.7.3.5 Zone Radiant HVAC Mass Flow Rate Rate [kg/s]**

This field reports the mass flow rate of water through the low temperature radiant system in kilograms per second.

#### **1.34.7.3.6 Zone Radiant HVAC Inlet Temperature [C]**

This field reports the temperature of water entering the low temperature radiant system in Celsius.

#### **1.34.7.3.7 Zone Radiant HVAC Outlet Temperature [C]**

This field reports the temperature of water leaving the low temperature radiant system in Celsius.

#### **1.34.7.3.8 Zone Radiant HVAC Moisture Condensation Time[s]**

This field reports the amount of time when condensation is occurring. When using the Off condensation control, this simply reports the amount of time when condensation occurs. When using the SimpleOff condensation control, this indicates the amount of time when the system has been shut off because of the potential danger of condensation.

**1.34.7.3.9 Zone Radiant HVAC Heating Fluid Energy [J]**

This is the demand placed on the hot fluid plant loop connection serving the low temperature radiant system, in Joules.

**1.34.7.3.10 Zone Radiant HVAC Cooling Fluid Energy [J]**

This is the demand placed on the cooling fluid plant loop connection serving the low temperature radiant system, in Joules.

**1.34.8 ZoneHVAC:LowTemperatureRadiant:ConstantFlow**

This low temperature radiant system (hydronic) is a component of zone equipment that is intended to model any “radiant system” where water is used to supply/remove energy to/from a building surface (wall, ceiling, or floor). The component is controlled via control schedules as described in the syntax below and does not require a zone thermostat. Note that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

The constant flow system differs from the hydronic system describe above in what it controls. The hydronic system varies the flow rate through the radiant system based on some control temperature. The constant flow system keeps flow rate constant via a local circulation pump and varies the water temperature that is sent to the radiant system. This is accomplished with a mixing valve that is controlled by a sensor. This model covers a wide range of low temperature radiant systems: heating and/or cooling, panel or embedded pipes, etc. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use electric resistance heating should also be defined using separate input syntax (ref: [ZoneHVAC:LowTemperatureRadiant:Electric](#)). Low temperature radiant systems that vary the flow rate through the radiant system should also be defined using separate input syntax (ref: [ZoneHVAC:LowTemperatureRadiant:VariableFlow](#))

One of the other differences between this model and the variable flow hydronic radiant system is that the constant flow radiant system has a built-in local secondary loop. It will recirculate flow coming out of the system and mix this with flow from the loop to arrive at the desired inlet temperature to the radiant system (note that this model has the temperature sensor AFTER the pump to insure proper inlet temperature to the radiant system). The local loop also contains a pump which is assumed to be upstream of the radiant system and after the mixing valve. So, the local loop can have some recirculation. The flow from the main loop may also bypass the radiant system if more than enough flow is available and the main loop is also a constant flow system.

**1.34.8.1 Inputs****1.34.8.1.1 Field: Name**

This field is an unique user assigned name for an instance of a constant flow low temperature radiant system. Any reference to this unit by another object will use this name.

**1.34.8.1.2 Field: Design Object**

The name of the object that holds design data for this instance of constant flow low temperature radiant system. Multiple input data values is taken from this object.

#### 1.34.8.1.3 Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the constant flow low temperature radiant system can run during a given time period. A schedule value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for that time period. A value greater than 0 (usually 1 is used) denotes that the unit is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.34.8.1.4 Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the constant flow low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

#### 1.34.8.1.5 Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: **BuildingSurface:Detailed**) or surface list (Ref: **Zone-HVAC:LowTemperatureRadiant:SurfaceGroup**) in which the hydronic tubing is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Note also that surfaces in a list do not need to be in the same zone or in the zone being served by this system (see previous field). Base surfaces (e.g., **BuildingSurface:Detailed**), door surfaces and internal mass are valid. Window surfaces are not valid surface types for embedded radiant systems.

#### 1.34.8.1.6 Field: Hydronic Tubing Length

This field is the total length of pipe embedded in the surface named above in the surface name field. The length of the tube should be entered in meters and is used to determine the effectiveness of heat transfer from the fluid being circulated through the tubes and the tube/surface. Longer tubing lengths result in more heat will be transferred to/from the radiant surface to the circulating fluid. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values. In addition, when the user opts to autosize this calculation, the tube spacing from the construction of each surface associated with this system is used along with each individual surface area to make an approximation of the tubing length.

#### 1.34.8.1.7 Field: Rated Flow Rate

This field is the maximum flow rate of water through the radiant system in  $\text{m}^3/\text{sec}$ . This flow rate is held constant by the local component pump, but the user has the option of varying this flow rate via a schedule (see next input field). The constant flow system will accept this flow rate and control the inlet temperature based on the control and water temperature schedules defined below. This field is autosizable.

#### 1.34.8.1.8 Field: Pump Flow Rate Schedule Name

This field modifies the maximum flow rate of water through the radiant system in  $\text{m}^3/\text{sec}$ . This input is “optional”. If the user does not enter a schedule, the flow rate through the radiant system is assumed to be constant during all hours that it is operating based on the value entered in the previous input field. Note that the values for this schedule must be between zero and one. The values in this schedule are multipliers on the previous field – Rated Flow Rate.

**1.34.8.1.9 Field: Rated Pump Head**

This numeric field contains the pump's rated head in Pascals.

**1.34.8.1.10 Field: Rated Power Consumption**

This numeric field contains the pump's rated power consumption in Watts.

**1.34.8.1.11 Field: Heating Water Inlet Node Name**

This field contains the name of the hot water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

**1.34.8.1.12 Field: Heating Water Outlet Node Name**

This field contains the name of the hot water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

**1.34.8.1.13 Field: Heating High Water Temperature Schedule Name**

This field specifies the high water temperature in degrees Celsius for the temperature control of a constant flow radiant heating system. Water and control temperatures for heating work together to provide a linear function that determines the water temperature sent to the radiant system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the system will be turned off and the water mass flow rate will be zero. If the control temperature is below the low temperature, then the inlet water temperature is set to the high water temperature. If the control temperature is between the high and low value, then the inlet water temperature is linearly interpolated between the low and high water temperature values. For more information and a graph of how the water and control schedules affect the system operation, please consult the Engineering Reference document.

**1.34.8.1.14 Field: Heating Low Water Temperature Schedule Name**

This field specifies the low water temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

**1.34.8.1.15 Field: Heating High Control Temperature Schedule Name**

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

**1.34.8.1.16 Field: Heating Low Control Temperature Schedule Name**

This field specifies the low control temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

**1.34.8.1.17 Field: Cooling Water Inlet Node Name**

This field contains the name of the cold water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

**1.34.8.1.18 Field: Cooling Water Outlet Node Name**

This field contains the name of the cold water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

**1.34.8.1.19 Field: Cooling High Water Temperature Schedule Name**

This field specifies the high water temperature in degrees Celsius for the temperature control of a constant flow radiant cooling system. Water and control temperatures for heating work together to provide a linear function that determines the water temperature sent to the radiant system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet water temperature is set to the low water temperature. If the control temperature is below the low temperature, then system will be turned off and the water mass flow rate will be zero. If the control temperature is between the high and low value, then the inlet water temperature is linearly interpolated between the low and high water temperature values. For more information and a graph of how the water and control schedules affect the system operation, please consult the Engineering Reference document.

**1.34.8.1.20 Field: Cooling Low Water Temperature Schedule Name**

This field specifies the low water temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

**1.34.8.1.21 Field: Cooling High Control Temperature Schedule Name**

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

**1.34.8.1.22 Field: Cooling Low Control Temperature Schedule Name**

This field specifies the low control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

**1.34.8.1.23 Field: Condensation Control Dewpoint Offset**

This optional parameter is only valid with the SimpleOff and VariableOff condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed surface temperature to which the surface can drop before the radiant system shuts down (SimpleOff) or tries to adjust the inlet water temperature (VariableOff) in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down or adjust the inlet water temperature when the surface temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down or increase the inlet water temperature when the surface is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down or increase the inlet water temperature when the surface temperature is the number of degrees Celsius below the dew-point temperature. While not recommended, this strategy allows the user to simulate a situation where small amounts of condensation are tolerable. The default value for this parameter is 1°C.

#### 1.34.8.1.24 Field: Number of Circuits

This optional input allows the user to choose between modeling each surface in the radiant system as a single hydronic circuit or to allow the program to divide the surface into multiple parallel hydronic circuits based on the next input field *Circuit Length*. To model as a single circuit choose *OnePerSurface*. To model as multiple circuits choose *CalculateFromCircuitLength*. It is recommended that *CalculateFromCircuitLength* be chosen. The default is *OnePerSurface* for backward compatibility with older versions of EnergyPlus.

#### 1.34.8.1.25 Field: Circuit Length

The length in meters of each parallel hydronic circuit in a surface. Used when the previous input field is set to *CalculateFromCircuitLength*. The default is 106.7 meters (350 feet), which is the maximum circuit length allowed in Title 24.

An example IDF with a constant flow low temperature radiant system is shown below.

### 1.34.8.2 ZoneHVAC:LowTemperatureRadiant:ConstantFlow:Design

This object contains the design fields for ZoneHVAC:LowTemperatureRadiant:ConstantFlow. The information from one ZoneHVAC:LowTemperatureRadiant:ConstantFlow:Design object can be shared with several ZoneHVAC:LowTemperatureRadiant:ConstantFlow objects.

#### 1.34.8.2.1 Field: Name

This field is an unique user assigned name for an instance of a constant flow low temperature radiant system design object. Any reference to this unit by another object will use this name.

#### 1.34.8.2.2 Field: Fluid to Radiant Surface Heat Transfer Model

This field is provides the opportunity to control how the heat transfer between the fluid circulating through this radiant system and the radiant system itself. There are two options for this parameter: ConvectionOnly or ISOStandard. The default value is ConvectionOnly. More information on each of these options is provided below.

- **ConvectionOnly** - This is the default mode and the method that was implemented when the radiant model was first introduced into EnergyPlus. In this modeling option, it is assumed that the impact of the tube material on heat exchange between the fluid and the radiant system and that only the convection between the fluid and the radiant system is the only critical heat transfer mechanism to take into account. The reasoning behind this included the fact that there are other simplifications in the method for calculating heat transfer and that this simplification would not result in any significant difference in the simulated heat transfer performance of the system. Convection between the fluid and the pipe wall of the system is related to physical parameters of the system (pipe/tube inner diameter and length) as well as the flow characteristics.
- **ISOStandard** - This method is based on the ISO Standard 11855, Part 2 (2012) document entitled “Building environment design — Design, dimensioning, installation and control of embedded radiant heating and cooling systems — Part 2: Determination of the design heating and cooling capacity”, Reference Number ISO 11855-2:2012(E). This standard recommends equations (see Appendix B of this document) to include the effects of convective heat transfer between the fluid and the inside of the piping and conduction through the pipe wall. This model requires both the inner and outer diameter of the pipe/tube, the length of the pipe/tube, and the thermal conductivity of the pipe/tube material. Note that as part of the implementation of this model in EnergyPlus, flow within the piping/tubing is always assumed to be turbulent.

#### 1.34.8.2.3 Field: Temperature Control Type

This field specifies along with setpoint (control) and water schedules how the user wishes to control the constant flow radiant system. The temperature denoted in the setpoint schedule can refer to one of eight different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, the outdoor wet-bulb temperature, the radiant surface inside face temperature, the radiant surface interior temperature, or the running mean outdoor dry-bulb temperature. The choice of temperature is controlled by the current field-temperature control type. The user must select from the following options:

- **MeanAirTemperature** - The mean air temperature of the zone being controlled by this radiant system.
- **MeanRadiantTemperature** - The mean radiant temperature of the zone being controlled by this radiant system.
- **OperativeTemperature** - The operative temperature of the zone being controlled by the radiant system. Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature.
- **OutdoorDryBulbTemperature** - The outdoor dry-bulb temperature of the current outdoor environment.
- **OutdoorWetBulbTemperature** - The outdoor wet-bulb temperature of the current outdoor environment.
- **SurfaceFaceTemperature** - This option allows the user to control the radiant system using the inside face surface temperature of the radiant system (the inside surface temperature).
- **SurfaceInteriorTemperature** - This option will allow the user to control the radiant system using a surface temperature that is calculated inside the radiant system. This point will be defined by the **Construction:InternalSource** description for the system. In that input, the user has the option to calculate a temperature at a particular point in the construction. The radiant system will then use this information for controlling the slab not just producing temperatures for outputting at that point.

Users should consult the input for Field: Temperature Calculation Requested After Layer Number for more information. Note that for the SurfaceFaceTemperature and SurfaceInteriorTemperature the surface being used for control is the surface listed above in the field for Surface Name. If the user enters a group of surfaces for that input, the *first* surface in the radiant group is the surface for control purposes.

- RunningMeanOutdoorDryBulbTemperature - This option will allow the user to control the inlet water temperature to the system as a function of the running mean outdoor air temperature. The next field (**Running Mean Outdoor Dry-Bulb Temperature Weighting Factor**) will define how this temperature is actually calculated within EnergyPlus.

If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information on how the setpoint temperature is established for this particular radiant system.

#### 1.34.8.2.4 Field: Running Mean Outdoor Dry-Bulb Temperature Weighting Factor

This field specifies the weighting factor that is used to calculate the running mean outdoor dry-bulb temperature. The running mean outdoor dry-bulb temperature is determined using the following equation:

$$\Theta_{rm} = (1 - \alpha)\Theta_{ed-1} + \alpha\Theta_{rm-1} \quad (1.143)$$

where:

$\Theta_{rm}$  is the current running mean outdoor dry-bulb temperature that is used to control the radiant system

$\Theta_{ed-1}$  is the average outdoor dry-bulb temperature from the previous day

$\Theta_{rm-1}$  is the running mean outdoor dry-bulb temperature from the previous day

$\alpha$  is the user defined weighting factor that is defined by this field. It controls the weighting of the running mean outdoor dry-bulb temperature from the previous day and the average outdoor dry-bulb temperature from the previous day for the purposes of calculating the running mean outdoor dry-bulb temperature for the current day. The value for this weighting factor must be between zero and 1.

#### 1.34.8.2.5 Field: Hydronic Tubing Inside Diameter

This field is the inside diameter of the tubes through which the fluid is circulated for the system being defined by this statement. The inner diameter should be recorded in meters and is used to determine the convective heat transfer from the water to the inside surface of the hydronic tubing. The default for this parameter is 0.013 which is approximately equivalent to the inner diameter of a typical 1/2" PEX pipe size.

#### 1.34.8.2.6 Field: Hydronic Tubing Outside Diameter

This field is the outside diameter of the tubes through which the fluid is circulated for the system being defined by this statement. The outer diameter should be recorded in meters and is used to determine the conduction through the hydronic tubing and the contact resistance between the tube/pipe and the radiant system itself in the ISOStandard option for the Fluid to Radiant Surface Heat Transfer Model (see above). The default for this parameter is 0.016 which is approximately equivalent to the outer diameter a typical 1/2" PEX pipe size.

#### 1.34.8.2.7 Field: Hydronic Tubing Conductivity

This field is the thermal conductivity of the pipe/tube that is used in this radiant system in Watts per meter-Kelvin (W/m-K). It is used to calculate the resistance to heat transfer through the pipe/tube wall

in the ISOStandard option for the Fluid to Radiant Surface Heat Transfer Model (see above). The default for this parameter is 0.35 which is the value given for PEX piping in ISO Standard 11855-2(2012).

#### 1.34.8.2.8 Field: Motor Efficiency

This numeric field contains the pump motor's efficiency in decimal form (0 = 0%, 1 = 100%).

#### 1.34.8.2.9 Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump motor's fraction of power loss to the fluid.

#### 1.34.8.2.10 Field: Condensation Control Type

When radiant systems do cooling, there is the possibility that condensation will occur on the surface that is being cooled. This is due to the fact that the surface temperature may drop below the dew-point temperature of the space. When this happens, condensation on the surface will occur. There are three options for handling this situation: Off, SimpleOff, and VariableOff. This parameter is optional and will default to SimpleOff.

- Off - EnergyPlus will not do anything other than produce a warning message when condensation is predicted to occur. The program will simply continue on; no moisture will be removed from the zone air and there will be no adjustment of the surface temperature as a result of the condensation.
- SimpleOff - the program will predict cases where condensation will occur and shut-off the radiant system to avoid this situation. With this option, the users also have the opportunity to adjust when the system will shut down. This is specified with the next parameter (field: Condensation Control Dewpoint Offset).
- VariableOff - the program will determine whether condensation is predicted for the flow rate determined by the unit control scheme. If condensation is predicted, the unit makes one attempt to avoid condensation by increasing the water inlet temperature to the system to match the dew-point temperature modified by the condensation control dew-point offset (field: Condensation Control Dewpoint Offset). For example, if a surface in the space is predicted to be 15°C and the modified condensation dew-point temperature is 17°C, then the inlet water temperature to the unit is reset to 17°C and the system is simulated again with this new inlet water temperature. If this increased inlet water temperature does not result in condensation, then the simulation continues using this operating condition for the system. If the increased inlet water temperature still results in condensation, then the unit is turned off to avoid excessive iterations.

#### 1.34.8.2.11 Field: Condensation Control Dewpoint Offset

This optional parameter is only valid with the SimpleOff and VariableOff condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed surface temperature to which the surface can drop before the radiant system shuts down (SimpleOff) or reduces its flow rate (VariableOff) to avoid condensation in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down or reduce the flow rate when the surface temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down or reduce the flow rate when the surface is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down or reduce the flow rate when the surface temperature is the number of degrees Celsius below the dew-point temperature. While not recommended, this strategy allows the user to simulate a situation where small amounts of condensation are tolerable. The default value for this parameter is 1°C.

### 1.34.8.2.12 Field: Changeover Delay Time Period Schedule

This field defines a schedule which should be populated with values for the amount of time in hours that is required before this low temperature radiant system can switch between either heating or cooling and the opposite conditioning mode. If this schedule value is set to 1 (hour) at a particular time and the system was previously in heating mode, then it will be locked out from switching into cooling mode until at least one hour of time has passed in the simulation with the system “not operating”. This helps avoid systems bouncing back and forth between the two conditioning modes in successive time steps. This parameter can be set to any positive value, and a zero or negative value will be assumed to have no delay (equivalent to a delay of zero). If the user leaves this field blank, EnergyPlus will assume that no changeover delay is requested (also equivalent to a delay of zero).

An example IDF with a design object for constant flow low temperature radiant system is shown below.

#### **1.34.8.3.1 Zone Radiant HVAC Heating Rate [W]**

This field reports the heating input rate to the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

#### **1.34.8.3.2 Zone Radiant HVAC Heating Energy [J]**

This field reports the heating input to the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

#### **1.34.8.3.3 Zone Radiant HVAC Cooling Rate [W]**

This field reports the cooling input rate to the low temperature radiant system in Watts. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

#### **1.34.8.3.4 Zone Radiant HVAC Cooling Energy [J]**

This field reports the cooling input to the low temperature radiant system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

#### **1.34.8.3.5 Zone Radiant HVAC Mass Flow Rate [kg/s]**

This field reports the mass flow rate of water through the low temperature radiant system in kilograms per second. This should be identical to the pump flow rate for the system.

#### **1.34.8.3.6 Zone Radiant HVAC Injection Mass Flow Rate [kg/s]**

This field reports the mass flow rate of water that is injected into the radiant system from the main loop. A valve will control the injection and recirculation mass flow rates (see next field) to match the temperature controls specified by the user and dictated by the current simulation conditions.

#### **1.34.8.3.7 Zone Radiant HVAC Recirculation Mass Flow Rate [kg/s]**

This field reports the mass flow rate of water that is recirculated from the radiant system outlet and mixed with the injection flow from the main loop. A valve will control the injection and recirculation mass flow rates (see next field) to match the temperature controls specified by the user and dictated by the current simulation conditions.

#### **1.34.8.3.8 Zone Radiant HVAC Inlet Temperature [C]**

This field reports the temperature of water entering the low temperature radiant system in Celsius. This may differ from the inlet node temperature for the component since this component has its own local secondary loop.

**1.34.8.3.9 Zone Radiant HVAC Outlet Temperature [C]**

This field reports the temperature of water leaving the low temperature radiant system in Celsius. This may differ from the outlet node temperature for the component since this component has its own local secondary loop.

**1.34.8.3.10 Zone Radiant HVAC Pump Inlet Temperature [C]**

This field reports the temperature of water entering the low temperature radiant system pump in Celsius. This may differ from the inlet node temperature for the component since this component has its own local secondary loop. It is assumed that the pump is upstream of the radiant system.

**1.34.8.3.11 Zone Radiant HVAC Pump Electricity Rate [W]**

This field reports the rate of electric power consumption for the pump which supplies flow to the constant flow radiant system in Watts.

**1.34.8.3.12 Zone Radiant HVAC Pump Electricity Energy [J]**

This field reports the electric power consumption for the pump which supplies flow to the constant flow radiant system in Joules.

**1.34.8.3.13 Zone Radiant HVAC Pump Mass Flow Rate [kg/s]**

This field reports the mass flow rate of water through the low temperature radiant system pump in kilograms per second. This should be identical to the flow rate for the system.

**1.34.8.3.14 Zone Radiant HVAC Pump Fluid Heat Gain Rate [W]**

This field reports the rate at which heat is added to the fluid stream as it passes through the pump in Watts. This heat is reflected in the radiant system inlet temperature which will be different from the pump inlet temperature if this field has a non-zero value.

**1.34.8.3.15 Zone Radiant HVAC Pump Fluid Heat Gain Energy [J]**

This field reports the amount of heat energy added to the fluid stream as it passes through the pump in Joules. This heat is reflected in the radiant system inlet temperature which will be different from the pump inlet temperature if this field has a non-zero value.

**1.34.8.3.16 Zone Radiant HVAC Moisture Condensation Time [s]**

This field reports the amount of time when condensation is occurring. When using the Off condensation control, this simply reports the amount of time when condensation occurs. When using the SimpleOff condensation control, this indicates the amount of time when the system has been shut off because of the potential danger of condensation.

**1.34.8.3.17 Zone Radiant HVAC Cooling Fluid Heat Transfer Energy [J]**

The heat transfer energy for the cooling fluid connection, in Joules.

**1.34.8.3.18 Zone Radiant HVAC Heating Fluid Heat Transfer Energy [J]**

The heat transfer energy for the heating fluid connection, in Joules.

#### 1.34.8.3.19 Zone Radiant HVAC Running Mean Outdoor Dry-Bulb Temperature [C]

This field reports the current running mean outdoor dry-bulb temperature in Celsius. This value is used to control the constant flow low temperature radiant system when the user opts to use the *RunningMeanOutdoorDryBulbTemperature* control type.

#### 1.34.8.3.20 Zone Radiant HVAC Previous Day Running Mean Outdoor Dry-Bulb Temperature [C]

This field reports the running mean outdoor dry-bulb temperature of the previous day in Celsius. This value is used to calculate the running mean outdoor dry-bulb temperature when the user opts to use the *RunningMeanOutdoorDryBulbTemperature* control type.

#### 1.34.8.3.21 Zone Radiant HVAC Previous Day Average Outdoor Dry-Bulb Temperature [C]

This field reports the average of the outdoor dry-bulb temperature for the previous day in Celsius. This value is used to calculate the running mean outdoor dry-bulb temperature when the user opts to use the *RunningMeanOutdoorDryBulbTemperature* control type.

### 1.34.9 ZoneHVAC:LowTemperatureRadiant:Electric

This low temperature radiant system (electric) is a component of zone equipment that is intended to model any “radiant system” where electric resistance heating is used to supply energy (heat) to a building surface (wall, ceiling, or floor). The component is controlled by the radiant system controls that are defined in the syntax below and this control does not require the use of a zone thermostat unless the unit is being autosized. Note also that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

The control is accomplished by varying the electrical power supplied to the unit. This model covers either a radiant panel system or wires embedded in entire walls, floors, or ceilings. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model (ref: [ZoneHVAC:HighTemperatureRadiant](#)) and different input syntax. Low temperature radiant systems that use water flowing through tubes to provide heat to the system should also be defined using separate input syntax (ref: [ZoneHVAC:LowTemperatureRadiant:VariableFlow](#) or [ZoneHVAC:LowTemperatureRadiant:ConstantFlow](#)).

#### 1.34.9.1 Inputs

##### 1.34.9.1.1 Field: Name

This field is an unique user assigned name for an instance of an electric low temperature radiant system. Any reference to this unit by another object will use this name.

##### 1.34.9.1.2 Field: Availability Schedule Name

This field is the name of the schedule (ref: [Schedule](#)) that denotes whether the electric low temperature radiant system can operate during a given time period. A schedule value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for that time period. A value greater than 0 (usually 1 is used) denotes that the unit is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

**1.34.9.1.3 Field: Zone Name**

This field is the name of the zone (Ref: Zone) in which the electric low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

**1.34.9.1.4 Field: Surface Name or Radiant Surface Group Name**

This field is the name of the surface (Ref: BuildingSurface) or surface list (Ref: **Zone-HVAC:LowTemperatureRadiant:SurfaceGroup**) in which the heating element is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how energy flow is split between the various surfaces. Note also that surfaces in a list do not need to be in the same zone or in the zone being served by this system (see previous field). Base surfaces (e.g., **BuildingSurface:Detailed**, **Wall:Detailed**, **RoofCeiling:Detailed**, etc.), door surfaces and internal mass are valid. Window surfaces are not valid surface types for embedded radiant systems.

**1.34.9.1.5 Field: Heating Design Capacity Method**

Enter the method used to determine the maximum electrical power (heating design capacity ) or enter the method for scalable sizing the maximum electrical power of low temperature radiant electric unit. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of maximum or nominal heating capacity or the program calculates the maximum or nominal design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the low temperature radiant electric unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

**1.34.9.1.6 Field: Heating Design Capacity {W}**

This field is for the maximum amount of electric energy rate (electric power) converted into heat in low temperature radiant electric unit in watts. This input field is autosizable. The controls for the radiant system will vary the amount of power supplied to the surface between zero input and the maximum power specified in this field as the lower and upper bounds, respectively. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the low temperature radiant electric unit control values. The default input for this input field is autosize.

**1.34.9.1.7 Field: Heating Design Capacity Per Floor Area {W/m2}**

Enter the heating capacity per unit floor area in m3/s-m2 of low temperature radiant electric system. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the low temperature radiant electric unit and the heating capacity per unit floor area value specified by the user. This field may be left blank.

**1.34.9.1.8 Field: Fraction of Autosized Heating Design Capacity**

Enter the heating capacity as a fraction of the autosized heating capacity of low temperature radiant electric unit. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized heating

capacity and user specified fraction. Design day sizing must be specified. This field may be left blank. The default value is 1.0.

#### 1.34.9.1.9 Field: Temperature Control Type

This field specifies along with setpoint (control) and water schedules how the user wishes to control the constant flow radiant system. The temperature denoted in the setpoint schedule can refer to one of seven different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, the outdoor wet-bulb temperature, the radiant surface inside face temperature, or the radiant surface interior temperature. The choice of temperature is controlled by the current field-temperature control type. The user must select from the following options:

- MeanAirTemperature - The mean air temperature of the zone being controlled by this radiant system.
- MeanRadiantTemperature - The mean radiant temperature of the zone being controlled by this radiant system.
- OperativeTemperature - The operative temperature of the zone being controlled by the radiant system. Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature.
- OutdoorDryBulbTemperature - The outdoor dry-bulb temperature of the current outdoor environment.
- OutdoorWetBulbTemperature - The outdoor wet-bulb temperature of the current outdoor environment.
- SurfaceFaceTemperature - This option allows the user to control the radiant system using the inside face surface temperature of the radiant system (the inside surface temperature).
- SurfaceInteriorTemperature - This option will allow the user to control the radiant system using a surface temperature that is calculated inside the radiant system. This point will be defined by the **ConstructionProperty:InternalHeatSource** description for the system. In that input, the user has the option to calculate a temperature at a particular point in the construction. The radiant system will then use this information for controlling the slab not just producing temperatures for outputting at that point. Users should consult the input for Field: Temperature Calculation Requested After Layer Number for more information. Note that for the SurfaceFaceTemperature and SurfaceInteriorTemperature the surface being used for control is the surface listed above in the field for Surface Name. If the user enters a group of surfaces for that input, the *first* surface in the radiant group is the surface for control purposes.

If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information on how the setpoint temperature is established for this particular radiant system.

#### 1.34.9.1.10 Field: Setpoint Control Type

This field has two options (ZeroFlowPower and HalfFlowPower) and is used to determine the response of the low temperature radiant system at the setpoint temperature. The Heating Setpoint Temperature Schedule Name (see below) defines a schedule for a temperature setpoint. The previous field (Temperature Control Type) defines which temperature is being controlled to that setpoint. This field determines the response of the system when the temperature being controlled is at the temperature setpoint. When ZeroFlowPower is chosen for this field, then the system will assume that it should shut off when the

temperature controlled arrives at the setpoint. So, if Mean Air Temperature control is used and it becomes equal to the setpoint temperature, then the system will turn off. When HalfFlowPower is chosen for this field, then the system will assume that it should be at half of the maximum water flow when it achieves the setpoint condition.

#### 1.34.9.1.11 Field: Heating Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero flow heat input via the electric resistance wires up to the maximum defined by the maximum electrical power field described above. The throttling range parameter is used in conjunction with the control temperature and the setpoint type to define the response of the system to various conditions. The Heating Setpoint Temperature Schedule specifies the “setpoint” temperature that is to be met. This is used in conjunction with the Setpoint Type which defines whether the flow rate of the system is at zero heat input or half heat input when the parameter defined by the Temperature Control Type is equal to the setpoint temperature defined by the Heating Control Temperature Schedule. See these other input parameters of this radiant system for more information on these different parameters. Note that when the throttling range is set to zero that this approximates an on-off system that is either fully on or totally off.

For clarity, here is an example of how the heat input fraction (of the unit capacity) to the system will be set. In this example, it is assumed that heating control temperature setpoint is currently 15°C, the heating throttling range is 2°C, and that the setpoint type is HalfFlowPower. The heat input rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, etc.; see control type field above) is at or above 16°C and the maximum heat input when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the heat input rate to the radiant system is varied linearly from full heat input at a control temperature of 14°C to half heat input at 15°C to zero heat input at 16°C. If the throttling range is changed to 0°C or on-off control, then the system will be off above 15°C and on below 15°C. However, if the throttling range is kept at 2°C and the setpoint type is changed to ZeroFlowPower, then the system will vary the heat input linearly between zero for when the control temperature is at 15°C to full heat input at 13°C.

#### 1.34.9.1.12 Field: Heating Setpoint Temperature Schedule Name

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating throttling range), it will define whether or not the system is running and the current power input to the radiant surface. Power input to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum electrical power parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. In addition, this schedule may be different than the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

An example IDF with an electric low temperature radiant system is shown below.

```
ZoneHVAC:LowTemperatureRadiant:Electric,
Zone 2 Radiant Floor,           !- Name
RadiantPanelAvailSched ,      !- Availability Schedule Name
EAST ZONE ,                    !- Zone name (name of zone system is serving)
Zn002:Flr001 ,                !- Surface Name or Radiant Surface Group Name
HeatingDesignCapacity,        !- Heating Design Capacity Method

### 1.34.9.2 Outputs

- HVAC,Average, Zone Radiant HVAC Electricity Rate [W]
- HVAC,Sum, Zone Radiant HVAC Electricity Energy [J]
- HVAC,Sum,Zone Radiant HVAC Heating Energy [J]
- HVAC,Average, Zone Radiant HVAC Heating Rate [W]

#### 1.34.9.2.1 Zone Radiant HVAC Electricity Rate [W]

This field reports the rate at which electric energy is “burned” in the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

#### 1.34.9.2.2 Zone Radiant HVAC Electricity Energy [J]

This field reports the amount of electric energy “burned” in the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

#### 1.34.9.2.3 Zone Radiant HVAC Heating Energy [J]

#### 1.34.9.2.4 Zone Radiant HVAC Heating Rate [W]

These outputs are the heating provided by the low temperature radiant system to the zone, in Watts or Joules.

## 1.34.10 ZoneHVAC:LowTemperatureRadiant:SurfaceGroup

A low temperature radiant system (hydronic or electric) may consist of multiple active surfaces that serve to condition the space. Surfaces that act serially can be specified as multiple radiant systems using the standard radiant system input described above. However, if the multiple surfaces act in parallel, the Radiant System Surface Group input line is used to specify which surfaces are acting in a coordinated fashion and how energy flow is split between the surfaces. This list of surfaces (the name it is assigned) replaces the name of a single surface in the radiant system input described above. Note that all of the surfaces within a single list do not need to be in the same zone so the zones of these surfaces do not need to match the zone the radiant system is attempting to condition. Keep in mind, however, that if the surfaces within a single surface group do not reside in the zone that these zones must all have the same zone multipliers.

### 1.34.10.1 Inputs

#### 1.34.10.1.1 Field: Name

This field is an unique user assigned name for the list of surfaces that are acting in coordination with one another. Any reference to this list by a radiant system will use this name.

### 1.34.10.1.2 Field Set: Surface Name, Flow Fraction to Surface

The pairs of Surface Name, Flow Fraction to Surface are used in several objects. There can be up to 10 specified. The object is extensible so more can be added.

### 1.34.10.1.3 Field: Surface <x> Name

This field is the name of a surface being conditioned by the radiant system. It should be noted that the surfaces listed in this field do *not* need to be present in the zone being served by the radiant system to which this surface is related. This allows radiant systems to span more than one zone and have surfaces controlled by conditions in another zone. When the user does select surfaces that are in different zones than the zone being served by the radiant system, a warning message is generated to alert the user that the surface is not in the same zone as the zone being served by the radiant system. If this is the intent of the user, this warning message can be ignored. Base surfaces (e.g., **BuildingSurface:Detailed**), door surfaces and internal mass are valid. Window surfaces are not valid surface types for embedded radiant systems.

### 1.34.10.1.4 Field: Flow Fraction for Surface <x>

This field is the fraction of the total radiant system flow rate that is being sent to this particular surface. Note that the Surface Name/Surface Flow Fraction pair can be repeated up to 10 times. Flow rate fractions must sum to unity, otherwise the program will not accept the input as valid.

An example IDF with an electric low temperature radiant system is shown below.

```
ZoneHVAC:LowTemperatureRadiant:SurfaceGroup,
  Zone 1 Radiant Surfaces, !- name of surface list
  Zn001:Flr001,           !- Surface name 1
  0.75,                   !- Flow fraction for surface 1
  Zn002:Flr002,           !- Surface name 2
  0.25;                   !- Flow fraction for surface 2
```

## 1.34.11 ZoneHVAC:HighTemperatureRadiant

The high temperature radiant system (gas-fired or electric) is a component of zone equipment that is intended to model any “high temperature” or “high intensity” radiant system where electric resistance or gas-fired combustion heating is used to supply energy (heat) to a building occupants directly as well as the building surfaces (wall, ceiling, or floor). The component is controlled by the radiant system controls defined in the syntax below and this control does not require the use of a zone thermostat unless the unit is being autosized. Note also that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

The control is accomplished by varying the electrical power supplied to or gas consumed by the unit. It is not intended to simulate low temperature electric or hydronic radiant systems. Those devices will be handled by a separate model and different input syntax (ref: the low temperature systems described elsewhere).

### 1.34.11.1 Inputs

#### 1.34.11.1.1 Field: Name

This field is an unique user assigned name for an instance of the high temperature radiant system. Any reference to this unit by another object will use this name.

#### 1.34.11.1.2 Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the high temperature radiant system can operate during a given time period. A schedule value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for that time period. A value greater than 0 (usually 1 is used) denotes that the unit is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.34.11.1.3 Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the high temperature radiant system is principally located and intended to affect.

#### 1.34.11.1.4 Field: Heating Design Capacity Method

Enter the method used to determine the maximum electrical power (heating design capacity ) or enter the method for scalable sizing the maximum electrical power of high temperature radiant system unit. Input allowed is either *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. If this input field is left blank or zero, then autosizing is assumed. *HeatingDesignCapacity* means user specifies the magnitude of maximum or nominal heating capacity or the program calculates the maximum or nominal design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the high temperature radiant electric unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

#### 1.34.11.1.5 Field: Heating Design Capacity {W}

This field is for the maximum amount of electric energy rate (electric power) converted into heat in high temperature radiant electric unit in watts. This input field is autosizable. The controls for the radiant system will vary the amount of power supplied to the surface between zero input and the maximum power specified in this field as the lower and upper bounds, respectively. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values. The default input for this field is autosize.

#### 1.34.11.1.6 Field: Heating Design Capacity Per Floor Area {W/m2}

Enter the heating capacity per unit floor area in m3/s-m2 of high temperature radiant electric unit. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the high temperature radiant electric unit and the heating capacity per unit floor area value specified by the user. This field may be left blank.

#### 1.34.11.1.7 Field: Fraction of Autosized Heating Design Capacity

Enter the heating capacity as a fraction of the autosized heating capacity for high temperature radiant electric unit. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized heating capacity and user specified fraction. Design day sizing run must be specified. This field may be left blank. The default value is 1.0.

**1.34.11.1.8 Field: Fuel Type**

This field denotes the type of high temperature radiant heater: gas or electric. The user must specify this by inputting either the keyword “**NaturalGas**” or “**Electricity**” for this field.

**1.34.11.1.9 Field: Combustion Efficiency**

This field is the combustion efficiency for a gas high temperature radiant heater. This value should be greater than 0 and less than or equal to 1. It is intended to take into account any potential inefficiencies in the combustion process inside the radiant heater. The heater gas consumption is the ratio of heater output over the combustion efficiency. This parameter has no meaning for an electric high temperature radiant heater and is ignored when the previous field is equal to “Electric”.

**1.34.11.1.10 Field: Fraction of Input Converted to Radiant Energy**

This field specifies what fraction of the power input to the high temperature radiant heater is actually radiant heat transfer. The fraction should be between 0 and 1. In conjunction with the next two parameters, it defines the breakdown of how the power input to the heater is distributed to the rest of the zone. The sum of these fractions must be less than or equal to 1. If the fractions are less than one, the remaining energy is added to the zone as convective heat transfer. The radiant heat transfer from the heat is distributed to people and surfaces using the distribution fractions listed below.

**1.34.11.1.11 Field: Fraction of Input Converted to Latent Energy**

This field specifies the fraction of the power input to the high temperature radiant heater that is converted to a latent heat gain within the space. This may be appropriate when a combustion process produces moisture that is transferred into the space. The latent heat addition from a high temperature radiant heater is handled as any other latent heat gain within the space, affecting the moisture balance on the zone air.

**1.34.11.1.12 Field: Fraction of Input that Is Lost**

This field specifies the fraction of power input to the high temperature radiant heater that is “lost”. This energy is a loss term, and this fraction of the input power has no effect on the zone heat balances.

**1.34.11.1.13 Field: Temperature control type**

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the high temperature radiant system. The temperature denoted in the setpoint schedule can refer to one of three different temperatures: a mean air temperature, a mean radiant temperature, or an operative temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

- MeanAirTemperature
- MeanRadiantTemperature
- OperativeTemperature
- MeanAirTemperatureSetpoint
- MeanRadiantTemperatureSetpoint
- OperativeTemperatureSetpoint

If the user does not select a control type, OperativeTemperature control is assumed by EnergyPlus. For the setpoint control strategies (those ending in Setpoint above), EnergyPlus will attempt to find the correct heater output to meet the heating setpoint temperature (see below) through iteration and interpolation. This will more closely match the operation of an actual thermostat, but it will require significantly longer execution times. For more information on the standard piecewise linear control algorithm used by the Mean Air Temperature, Mean Radiant Temperature, and Operative Temperature control types (the “non-Setpoint” controls), see the throttling range and control temperature schedule fields below for more information.

#### **1.34.11.1.14 Field: Heating Throttling Range**

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero heat input via the electric resistance wires up to the maximum defined by the maximum electrical power field described above. The throttling range parameter is used in conjunction with the control temperature (see below) to define the response of the system to various zone conditions. The heating control temperature schedule specifies the “setpoint” temperature where the power input to the system is at half of the maximum power input. For example, if the heating control temperature setpoint is currently 15°C and the heating throttling range is 2°C, the electrical power supplied to the radiant system will be zero when the controlling temperature (Mean Air Temperature, Mean Radiant Temperature, and Operative Temperature; see control type field above) is at or above 16°C and the maximum power input when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the power input to the radiant system is varied linearly.

#### **1.34.11.1.15 Field: Heating Setpoint Temperature Schedule Name**

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating throttling range), it will define whether or not the system is running and the current power input to the radiant surface. Power input to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum electrical power parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. In addition, this schedule may be different than the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

#### **1.34.11.1.16 Field: Fraction of Radiant Energy Incident on People**

This field specifies the fraction of radiant heat transfer to the zone from the radiant heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that since the thermal comfort models only use the results of the zone heat balances this energy is accounted for within the heat balance as convective energy, directly affecting the zone air heat balance. The basic assumption here is that most radiant energy falling on people will most likely be convected to the surroundings. This is a simplification of reality, but it maintains the overall energy balance.

#### **1.34.11.1.17 Field Set: Surface Name, Fraction of radiant energy to Surface**

The pairs of Surface Name, Fraction of Radiant Energy to Surface are used in several objects. There can be up to 20 specified.

**1.34.11.1.18 Field: Surface <x> Name**

This field is the name of the first surface to which radiant heat transfer from the high temperature radiant heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

**1.34.11.1.19 Field: Fraction of Radiant Energy to Surface <x>**

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the high temperature radiant system that is incident on a particular surface. Users should take into account the directionality of high temperature radiant heaters and their location when defining the value for this input field. Note that the sum of all fractions plus the fraction of radiant energy incident on people must add up to 1 so that all radiant energy is taken into account and none of it is "lost".

An example IDF with a high temperature radiant system is shown below.

```
ZoneHVAC:HighTemperatureRadiant, Zone 2 Radiant Heater,

**1.34.11.2 Outputs**

- HVAC,Average, Zone Radiant HVAC Heating Rate [W]
- HVAC,Sum, Zone Radiant HVAC Heating Energy [J]
- HVAC,Average, Zone Radiant HVAC Gas Rate [W]
- HVAC,Sum, Zone Radiant HVAC Gas Energy [J]
- HVAC,Average, Zone Radiant HVAC Electricity Rate [W]
- HVAC,Sum, Zone Radiant HVAC Electricity Energy [J]

**1.34.11.2.1 Zone Radiant HVAC Heating Rate [W]**

This field reports the rate at which energy is transferred from the high temperature radiant system to the zone in Watts. This rate is determined by the zone conditions and the control scheme defined in

the user input. Note that this amount takes into account any combustion inefficiency and thus could be different than the gas consumption rate in a high temperature gas radiant system.

#### **1.34.11.2.2 Zone Radiant HVAC Heating Energy [J]**

This field reports the amount of energy transferred from the high temperature gas radiant system to the zone in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep. Note that this amount takes into account any combustion inefficiency and thus could be different than the gas consumption in a high temperature gas radiant system.

#### **1.34.11.2.3 Zone Radiant HVAC Gas Rate [W]**

This field reports the rate at which gas is “burned” in a high temperature gas radiant system in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input.

#### **1.34.11.2.4 Zone Radiant HVAC Gas Energy [J]**

This field reports the amount of gas “burned” in a high temperature gas radiant system in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

#### **1.34.11.2.5 Zone Radiant HVAC Electricity Rate [W]**

This field reports the rate at which electric energy is “burned” in a high temperature electric radiant system in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input.

#### **1.34.11.2.6 Zone Radiant HVAC Electricity Energy [J]**

This field reports the amount of electric energy “burned” in a high temperature electric radiant system in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

### **1.34.12 ZoneHVAC:VentilatedSlab**

Ventilated slab systems in general use outdoor air to “precool” slabs with colder nighttime air. This method of precooling the thermal mass of a space can be very effective when nighttime temperatures are low and the mass of the system is high enough to provide a significant amount of cooling potential during the day to counteract internal heat gains within a zone. Nearly all ventilated slabs are simple systems such as that shown in the right side of Figure 1.163. The fan is shown in a blow through position, but the model will allow either a blow or draw through configuration.

#### **1.34.12.1 Inputs**

##### **1.34.12.1.1 Field: Name**

This field is a unique user assigned name for an instance of a ventilated slab system. Any reference to this unit by another object will use this name. Other objects that use this ventilated slab system will reference it by this name.

##### **1.34.12.1.2 Field: Availability Schedule Name**

This field is the name of the schedule (ref: Schedule) that denotes whether the ventilated slab system can run during a given time period. A schedule value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for that time period. A value greater than 0 (usually 1 is used) denotes that the

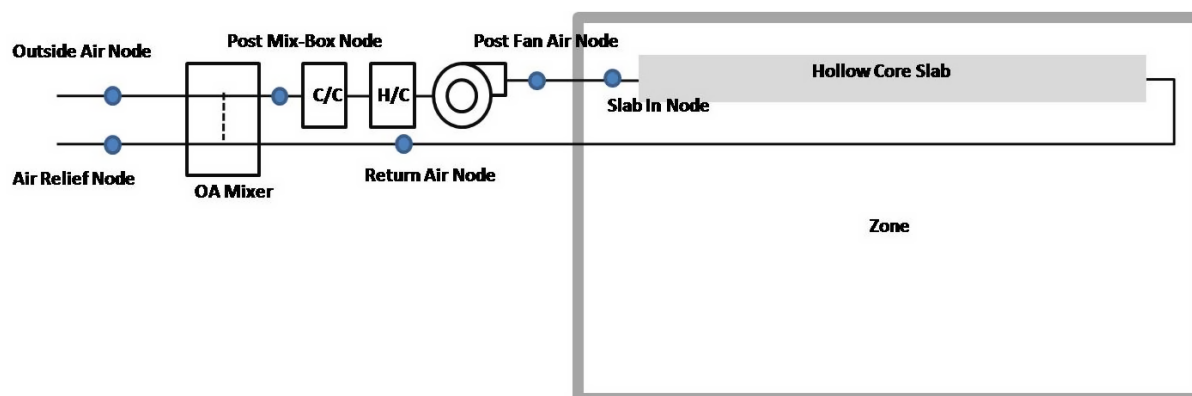

Figure 1.163: Ventilated Slab model - basic system

unit is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

Figure 1.164: Example operating schedule for Ventilated Slab

#### 1.34.12.1.3 Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the ventilated slab system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the system response.

#### 1.34.12.1.4 Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: Surface) or surface list (Ref: **ZoneHVAC:VentilatedSlab:SlabGroup**) in which the hollow cores are embedded/contained. This specification attaches the source or sinks from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (Walls, Roofs, Floors) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

#### 1.34.12.1.5 Field: Maximum Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the ventilated slab system in  $\text{m}^3/\text{sec}$ . This parameter should be some real number greater than zero.

#### 1.34.12.1.6 Field: Outdoor Air Control Type

This field allows the user to control how outdoor air is used in the ventilated slab system. The ventilated slab system described by this syntax has its own outdoor air handler. The three options for outdoor air control are “**VariablePercent**”, “**FixedTemperature**” and “**FixedAmount**”. Those keywords are the only allowed choices for this parameter. In general, the variable percent control will attempt to vary the amount of outdoor air between some minimum and maximum schedules of fractions (see next two fields) to best meet the current heating or cooling load. The fixed temperature control will vary the amount of outdoor air between the minimum schedule (fraction of maximum, see next field) and 100% available outdoor air to come as close as possible to a desired mixed air temperature (see two fields down) that can be scheduled. The fixed amount control will fix the outdoor air flow rate as minimum outdoor air flow rate and schedule specified by the user and automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate. More information on the controls and operation of the ventilated slab are given in the section above (preceding the IDF description).

#### 1.34.12.1.7 Field: Minimum Outdoor Air Flow Rate

This field allows the user to enter the minimum volumetric flow rate of outdoor air (in  $\text{m}^3/\text{sec}$ ) that will be brought in to the ventilated slab. The actual minimum outdoor air flow rate will be this number multiplied by the schedule value from the minimum outdoor air schedule. If “**FixedAmount**” type is selected as the outdoor air control strategy, the outdoor air flow rate will be fixed at the value of this field and the ventilated slab will automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate.

#### 1.34.12.1.8 Field: Minimum Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that should contain values for the minimum outdoor air used by the ventilated slab system for IAQ or other reasons. Note that if the ventilated slab is scheduled off or if there is no load sensed in the zone that the system will not operate even to achieve the minimum air fraction. However, if the system is operating, it will always bring in at least this fraction of the minimum air flow rate (see minimum air flow rate field above). If “**FixedAmount**” type is selected as the outdoor air control strategy, the actual outdoor air flow rate will be this number multiplied by the minimum outdoor air flow rate in the field above. The ventilated slab will automatically set the maximum and minimum outdoor air schedule to be equal by ignoring the maximum outdoor air schedule.

#### 1.34.12.1.9 Field: Maximum Outdoor Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of outdoor air that can be brought into the ventilated slab in  $\text{m}^3/\text{sec}$ . This parameter should be some real number greater than zero. Note that the value for this parameter may be less than the maximum air flow rate of the ventilated slab and this may affect the maximum fraction of outdoor air within the control strategy defined above. This parameter is an absolute maximum and will supercede any scheduled fraction of the ventilated slab maximum airflow rate. If “**FixedAmount**” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air flow rate specified in the field above.

#### 1.34.12.1.10 Field: Maximum Outdoor Air Fraction or Temperature Schedule Name

This field can have one of two meanings depending the type of control selected in the outdoor air control type parameter above. If “VariablePercent” or “FixedAmount” was selected, then this field is a schedule name (ref: Schedule) corresponding to a maximum air fraction schedule. Furthermore, if “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air fraction specified in the field below. Note that this is a fraction of the maximum airflow rate field (see parameter above) for the ventilated slab. If “FixedTemperature” control was selected, then this field is still a schedule name (ref: Schedule), but it corresponds to a schedule of mixed air temperatures that the outdoor air control will try to attain.

#### 1.34.12.1.11 Field: System Configuration Type

This field allows the user to control how the air is circulated using the ventilated slab system. The options for system configuration are

- SlabOnly
- SlabAndZone
- SeriesSlabs

In the **SlabOnly**, the ventilation air is sent to the slab only and does not enter the zone. In the **SlabAndZone**, the air first enters the slab and then is delivered to the zone before returning to the system. With the **SeriesSlabs** option, the user specifies a list of slabs (**ZoneHVAC:VentilatedSlab:SlabGroup**). This list determines the order of slabs through which the air passes. In this option, air is not delivered to any zone.

#### 1.34.12.1.12 Field: Hollow Core Inside Diameter

This field is the inside diameter of the cores through which air is circulated for the system being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the circulated air to the inside surface of the ventilated slab.

#### 1.34.12.1.13 Field: Hollow Core Length

This field is the length of core embedded in the surface named above in the surface name field. In other words, this should be the distance that air travels as it through the slab. The length of the hollow core in the slab should be entered in meters and is used to determine the effectiveness of heat transfer from the air being circulated through the cores and the core inside surface. Longer core lengths result in more heat transferred to/from the radiant surface to the circulating fluid.

#### 1.34.12.1.14 Field: Number of Cores

This field allows the user to specify how many cores there are in the ventilated slab. Air flow will be divided equally among the different cores.

#### 1.34.12.1.15 Field: Temperature Control Type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the ventilated slab system. The temperature denoted in the set temperature schedule can refer to one of seven different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the surface temperature of the ventilated slab, the outdoor dry-bulb temperature, the outdoor wet-bulb temperature, or the dewpoint temperature of zone mean air temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

- MeanAirTemperature
- MeanRadiantTemperature
- OperativeTemperature
- OutdoorDryBulbTemperature
- OutdoorWetBulbTemperature
- SurfaceTemperature
- ZoneAirDewPointTemperature

If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the control temperature schedule fields below for more information.

#### **1.34.12.1.16 Field: Heating High Air Temperature Schedule Name**

This field specifies the high air temperature in degrees Celsius for the temperature control of a ventilated slab system. Air and control temperatures for heating work together to provide a linear function that determines the air temperature sent to the ventilated slab. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet air temperature is set to the low air temperature. If the control temperature is below the low temperature, then the inlet air temperature is set to the high air temperature. If the control temperature is between the high and low value, then the inlet air temperature is linearly interpolated between the low and high air temperature values.

#### **1.34.12.1.17 Field: Heating Low Air Temperature Schedule Name**

This field specifies the low air temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

#### **1.34.12.1.18 Field: Heating High Control Temperature Schedule Name**

This field specifies the high control temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

#### **1.34.12.1.19 Field: Heating Low Control Temperature Schedule Name**

This field specifies the low control temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

#### **1.34.12.1.20 Field: Cooling High Air Temperature Schedule Name**

This field specifies the high air temperature in degrees Celsius for the temperature control of a ventilated slab system. Air and control temperatures for cooling work together to provide a linear function that determines the air temperature sent to the ventilated slab system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet air temperature is set to the low air temperature. If the control temperature is below the low temperature, then the inlet air temperature is set to the high air temperature. If the control temperature is between the high and low value, then the inlet air temperature is linearly interpolated between the low and high air temperature values.

**1.34.12.1.21 Field: Cooling Low Air Temperature Schedule Name**

This field specifies the low air temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

**1.34.12.1.22 Field: Cooling High Control Temperature Schedule Name**

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

**1.34.12.1.23 Field: Cooling Low Control Temperature Schedule Name**

This field specifies the low control temperature in degrees Celsius for the temperature control of a ventilated slab system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

**1.34.12.1.24 Field: Return Air Node Name**

This field is a node name used to identify the node that serves as the zone return air inlet to the ventilated slab system. This node is one of the inlets to the outdoor air mixer which is implicit in the ventilated slab system model. For “SlabAndZone” configuration, the Return Air Node will typically be the same node as a zone exhaust node. For “SlabOnly” or “SeriesSlabs” configuration, this node name is required but will have zero flow.

**1.34.12.1.25 Field: Slab In Node Name**

This field is a node name used to identify the node that serves as the inlet of the ventilated slab or series of slabs, after the outdoor air mixer, fan, and optional coils.

**1.34.12.1.26 Field: Zone Supply Air Node Name**

This field is a node name used to identify the node that serves as the outlet from the ventilated slab system to the zone when using the “SlabAndZone” configuration. It is the node exiting the slab section of the system. This node will typically be the same node as a zone inlet node. In the case of “SlabOnly” or “SeriesSlabs” configuration, this field will be ignored and it should be left BLANK.

**1.34.12.1.27 Field: Outdoor Air Node Name**

This field is a node name used to identify the node associated with fresh outdoor air brought into the ventilated slab system outdoor air mixer. This node should also be specified in an **OutdoorAir:Node** or **OutdoorAir:NodeList** object.

**1.34.12.1.28 Field: Relief Air Node Name**

This field is a node name used to identify the node associated with air exhausted out of the ventilated slab system to the outdoor environment.

**1.34.12.1.29 Field: Outdoor Air Mixer Outlet Node Name**

This field is a node name used to identify the node associated with the “mixed” air of the ventilated slab. These conditions are post-“mixing box” since they are the conditions of the fraction of return air combined with the outdoor air. Since this is a simple system, this can also be viewed as the conditions of the air being sent to the coils.

#### 1.34.12.1.30 Field: Fan Outlet Node Name

This field is a node name used to identify the node that serves as the air outlet from the fan.

#### 1.34.12.1.31 Field: Fan Name

This field is the name of a fan (ref: **Fan:SystemModel** or **Fan:ConstantVolume**) that is part of the ventilated slab system. This name links the ventilated slab to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the ventilated slab system.

#### 1.34.12.1.32 Field: Coil Option Type

This field allows the user to specify the coil operating options as one of the following options:

- None
- Heating
- Cooling
- HeatingAndCooling

If **None** is selected, the ventilated slab does not have any coils, and any other input will be ignored. If either **Heating** or **Cooling** is selected, only a heating or cooling coil, respectively, is present. Thus, only four more inputs will be expected. If **HeatingAndCooling** is selected, both heating and cooling coil input must be entered, and the ventilated slab will have both a heating and a cooling coil.

#### 1.34.12.1.33 Field: Heating Coil Object Type

This field is the type of coil (ref: **Coil:Heating:Water**, **Coil:Heating:Electric**, **Coil:Heating:Fuel**, **Coil:Heating:Steam**) that is used for heating in the ventilated slab system. This field must be one of the following keywords: **Coil:Heating:Water**, **Coil:Heating:Electric**, **Coil:Heating:Fuel**, **Coil:Heating:Steam**. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system.

#### 1.34.12.1.34 Field: Heating Coil Name

This field is the name of the heating coil that is part of the ventilated slab system. It is assumed that there is always some sort of heating coil associated with a ventilated slab system. This name links the ventilated slab to particular heating coil data entered elsewhere in the input data file.

#### 1.34.12.1.35 Field: Hot Water or Steam Inlet Node Name

This field corresponds to the water inlet node to the heating coil for a water coil. The water inlet node controls how a water heating coil operates. This field is ignored/not needed for gas and electric heating coils.

#### 1.34.12.1.36 Field: Cooling Coil Object Type

This field is the name of the cooling coil (ref: **Coil:Cooling:Water**, **Coil:Cooling:Water:DetailedGeometry**, **CoilSystem:Cooling:Water:HeatExchangerAssisted**) that is part of the ventilated slab system. This name links the ventilated slab system to particular cooling coil data entered elsewhere in the input data file. If no cooling coil is present, the previous field may be followed by a semi-colon and the remaining parameters in this statement may be ignored.

**1.34.12.1.37 Field: Cooling Coil Name**

This field is the name of the cooling coil that is part of the ventilated slab system. It is assumed that there is always some sort of cooling coil associated with a ventilated slab system. This name links the ventilated slab to particular cooling coil data entered elsewhere in the input data file.

**1.34.12.1.38 Field: Cold Water Inlet Node Name**

This field corresponds to the water inlet node to the cooling coil. The water inlet node controls how a water cooling coil operates and is required for the ventilated slab system that has a cooling coil associated with it to function properly.

**1.34.12.1.39 Field: Availability Manager List Name**

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this ventilated slab object's fan. If the ventilated slab is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this ventilated slab object should be on or off.

**1.34.12.1.40 Field: Design Specification ZoneHVAC Sizing Object Name**

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Maximum Air Flow Rate in this Ventilated Slab zone HVAC object. The scaled Maximum Air Flow Rate in turn is used to size cooling and heating capacity of the coils.

An example IDF with a ventilated slab is shown below.

#### 1.34.12.2.1 Zone Ventilated Slab Radiant Heating Rate [W]

This field reports the radiant heating input rate of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilated slab system.

**1.34.12.2.2 Zone Ventilated Slab Radiant Heating Energy [J]**

This field is the heating radiant input of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilated slab system, and the timestep.

**1.34.12.2.3 Zone Ventilated Slab Radiant Cooling Rate [W]**

This field reports the radiant cooling input rate to the ventilated slab system in Watts. This is the heat sink to the surface that is defined as the ventilated slab system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

**1.34.12.2.4 Zone Ventilated Slab Radiant Cooling Energy [J]**

This field reports the radiant cooling input to the ventilated slab system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

**1.34.12.2.5 Zone Ventilated Slab Coil Heating Rate [W]**

This field reports the heating input rate of the heating coil of ventilated slab system the zone it is serving in Watts. This is determined by return air and zone air conditions and the mass flow rate through the ventilation slab system.

**1.34.12.2.6 Zone Ventilated Slab Coil Heating Energy [J]**

This field is the heating output of the heating coil of the ventilated slab system the zone it is serving in Joules over the timestep being reported. This is determined by return air and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

**1.34.12.2.7 Zone Ventilated Slab Coil Total Cooling Rate [W]**

This field reports the total cooling (sensible plus latent) output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

**1.34.12.2.8 Zone Ventilated Slab Coil Total Cooling Energy [J]**

This field is the total cooling (sensible plus latent) output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

**1.34.12.2.9 Zone Ventilated Slab Coil Sensible Cooling Rate [W]**

This field reports the sensible cooling output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

**1.34.12.2.10 Zone Ventilated Slab Coil Sensible Cooling Energy [J]**

This field is the sensible cooling output of the cooling coli of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

**1.34.12.2.11 Zone Ventilated Slab Coil Latent Cooling Rate [W]**

This field reports the latent cooling output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

**1.34.12.2.12 Zone Ventilated Slab Coil Latent Cooling Energy [J]**

This field is the latent cooling output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

**1.34.12.2.13 Zone Ventilated Slab Air Mass Flow Rate [kg/s]**

This field reports the mass flow rate of air through the ventilated slab system in kilograms per second.

**1.34.12.2.14 Zone Ventilated Slab Fan Electricity Rate [W]**

This field reports the electric power consumption rate of the fan of the ventilated slab system in Watts.

**1.34.12.2.15 Zone Ventilated Slab Fan Electricity Energy [J]**

This field reports the electric power consumed by the fan of the ventilated slab system over the timestep in Joules.

**1.34.12.2.16 Zone Ventilated Slab Inlet Air Temperature [C]**

This field reports the temperature of air entering the ventilated slab system in Celsius.

**1.34.12.2.17 Zone Ventilated Slab Outlet Air Temperature [C]**

This field reports the temperature of air leaving the ventilated slab system in Celsius.

**1.34.12.2.18 Zone Ventilated Slab Zone Inlet Air Temperature [C]**

This field reports the temperature of air entering the zone in Celsius.

**1.34.12.2.19 Zone Ventilated Slab Return Air Temperature [C]**

This field reports the temperature of air leaving the zone in Celsius. When system does not circulate air to zone (“SlabOnly” Configuration), the slab outlet temperature and return air temperature will be the same.

**1.34.12.2.20 Zone Ventilated Slab Fan Outlet Air Temperature [C]**

This field reports the fan outlet air temperature for the ventilated slab system in Celsius.

**1.34.12.2.21 Zone Ventilated Slab Fan Availability Status []**

This is the availability status of the ventilated slab fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the ventilated slab object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List along with Hybrid Ventilation Manager, rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described

here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

### 1.34.13 ZoneHVAC:VentilatedSlab:SlabGroup

A ventilated slab system may consist of multiple active slabs that are serving to condition the zone. Slabs that act serially can be specified as multiple radiant systems using the standard ventilated slab input described above. This list of surfaces (the name it is assigned) replaces the name of a single surface in the ventilated slab system input described above.

#### 1.34.13.1 Inputs

##### 1.34.13.1.1 Field : Name of Ventilated Slab Surface Group

This field is a unique user assigned name for the list of surfaces that are acting in coordination with one another. Any reference to this list by a ventilated slab system will use this name.

##### 1.34.13.1.2 Field: Zone Name

This field is the name of the zone in which the surface is principally located and intended to affect.

##### 1.34.13.1.3 Field: Surface Name

This field is the name of a surface in the zone being conditioned by the ventilated slab system. Only base surfaces like walls, floors and roofs are valid. Door/Window Surface and Internal Mass are not valid surface types for the ventilated slab system.

##### 1.34.13.1.4 Field: Core Diameter

This field is the inside diameter of the cores through which air is circulated for the surface being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the circulated air to the inside surface of the ventilated slab.

##### 1.34.13.1.5 Field: Core length

This field is the length of core embedded in the surface named above in the surface name field. In other words, this should be the distance that air travels as it through the slab. The length of the hollow core in the surface should be entered in meters and is used to determine the effectiveness of heat transfer from the air being circulated through the cores and the core inside surface. Longer core lengths result in more heat transferred to/from the radiant surface to the circulating fluid.

##### 1.34.13.1.6 Field: Number of Cores

This field allows the user to specify how many cores there are in the ventilated slab. Air flow will be divided equally among the different cores.

##### 1.34.13.1.7 Field: Slab Inlet Node Name

This field is a node name (character string) used to identify the node that serves as the inlet (air side) to the surface. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

### 1.34.13.1.8 Field: Slab Outlet Node Name

This field is a node name (character string) used to identify the node that serves as the outlet (air side) of the surface. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

An Example IDF with a ventilated slab system is shown below

```
ZoneHVAC:VentilatedSlab:SlabGroup,

    Z5VentSlabOut;       !- Slab Outlet Node Name for Surface 3
```

## 1.35 Group – Refrigeration

There are two ways to model a supermarket refrigeration system. The first, and simplest, approach models the combination of compressor(s) and condenser as a single refrigeration compressor rack object. (A list is used to enter multiple case or walk-in names.)

For the first approach, the input objects needed are:

- One **Refrigeration:CompressorRack** object
- At least one refrigeration load, which may be any combination of:
  - **Refrigeration:Case** or
  - **Refrigeration:WalkIn** or
  - **Refrigeration:CaseAndWalkInList** objects .

The second approach requires more input objects but also allows the user to model more complex systems. This detailed approach must be used whenever loads are transferred from one system to another, such as with secondary loops, cascade condensers, or mechanical subcoolers. Again lists are used to enter multiple load or compressor names.

For the detailed approach, the input objects needed are:

- One **Refrigeration:System** object
- At least one refrigeration load object which may include any combination of:

- **Refrigeration:Case**,
- **Refrigeration:WalkIn**,
- **Refrigeration:CaseAndWalkInList** (may include any combination of cases and walk in cooler names, OR, a list of air chiller names)
- **Refrigeration:SecondarySystem**,
- **Refrigeration:Condenser:Cascade** (as a load, cooling a lower-temperature system) objects,
- **Refrigeration:TransferLoadList** (may include cascade condenser loads and/or secondary loop loads)
- **Refrigeration:AirChiller**
- At least one **Refrigeration:Compressor** object (multiple compressors are entered using a **Refrigeration:CompressorList**),
- One condenser object which may be either:
  - **Refrigeration:Condenser:AirCooled**,
  - **Refrigeration:Condenser:EvaporativeCooled**,
  - **Refrigeration:Condenser:WaterCooled**, or
  - **Refrigeration:Condenser:Cascade** (rejecting heat from this system)
- The object **Refrigeration:Subcooler** may optionally be included to describe either a liquid suction or mechanical subcooler.

Output variables are also available to describe the total heat exchange between all refrigeration objects and the zones containing these objects. These variables are described at the end of this section after all the refrigeration objects.

### 1.35.1 Refrigeration:CompressorRack

The refrigeration compressor rack object works in conjunction with the refrigeration case and walkin objects (Ref. **Refrigeration:Case** and **Refrigeration:WalkIn**) to simulate the performance of a refrigerated case system. This object models the electric consumption of the rack compressors and the condenser fans. Heat removed from the refrigerated cases, walkins, and compressor/condenser fan heat can be rejected either outdoors or to a zone. Compressor rack waste heat can also be reclaimed for use by an optional air- or water-heating coil (Ref. **Coil:Heating:Desuperheater** and **Coil:WaterHeating:Desuperheater**).

If heat is rejected outdoors, condenser cooling can either be accomplished by direct air flow, evaporative water cooling, or a by water-cooled condenser with appropriate plant loop piping. With evaporative cooling, water is sprayed through the air stream to effectively lower the air temperature experienced by the condenser coil as a result of water evaporation. The use of a water-cooled condenser requires the definition of a plant loop to supply cooling to the condenser. Waste heat can be reclaimed and stored using a water storage device.

The inputs for the compressor rack object include a name, the heat rejection location, the compressor rack coefficient of performance (COP) at design conditions, the design condenser fan power, and the type of condenser cooling. The model requires two curve objects to describe performance at off-design conditions. If the condenser is water-cooled, the inlet and outlet node names as well as the water outlet temperature schedule name are required. If the condenser has evaporative cooling, additional inputs for evaporative condenser effectiveness, condenser air flow rate, basin heater parameters, water pump power, water source, and an evaporative cooling availability schedule are available. The names of refrigerated cases and walkins connected to the compressor rack are the final inputs to the model.

### 1.35.1.1 Inputs

#### 1.35.1.1.1 Field: Name

A unique user-assigned name for an instance of a refrigeration compressor rack. Any reference to this compressor rack by another object will use this name.

#### 1.35.1.1.2 Field: Heat Rejection Location

The location of the compressor rack's condenser. The compressor rack condenser heat can be directed "Outdoors" to model an outdoor air or water-cooled condenser or "Zone" to model a condenser located in a zone (e.g., a stand-alone packaged refrigerated case with integral condenser located in a conditioned zone). The default for this field is "Outdoors". If the heat rejection location is "Zone" and no walk-in coolers are served by this compressor rack, then all refrigerated cases connected to this compressor rack must be located in the same zone. If however, walk-in coolers are also served by this compressor rack, then the heat rejection zone name must be specified (see Heat Rejection Zone Name field below) and cases and walk-ins can be located in multiple zones.

NOTE: When modeling a heat reclaim coil, the heat rejection location must be "Outdoors". If the heat rejection location is "Zone", the total amount of waste heat available for reclaim (e.g., by a desuperheater heating coil) is set to zero by this compressor rack object and the simulation proceeds.

#### 1.35.1.1.3 Field: Design Compressor Rack COP

The coefficient of performance (COP) for the compressor rack at design conditions (compressors only, excluding condenser fan power). This value must be greater than zero, with a default value of 2.0 if this field is left blank. This value should represent the compressor rack COP corresponding to the lowest evaporating temperature of any case or walkin served by the rack.

#### 1.35.1.1.4 Field: Compressor Rack COP Function of Temperature Curve Name

The name of the curve object defining the change in compressor rack COP as a function of the temperature of air entering the condenser. The curve object will be evaluated using the zone air dry-bulb temperature when rack heat rejection location equals "Zone" and the outdoor air dry-bulb temperature when rack heat rejection location equals "Outdoors" and the condenser type is air-cooled. As explained below, if the condenser is cooled by evaporative or water loop cooling, the curve object is evaluated using an effective temperature. The output from this curve is multiplied by the design compressor rack COP to yield the actual COP at the specific air temperature entering the condenser. This curve must be cubic or quadratic (**Curve:Cubic** or **Curve:Quadratic**), and should be normalized to 1.0 at the condenser entering air temperature at which the design compressor rack COP occurs. This curve should represent the compressor rack COP corresponding to the lowest evaporating temperature of any case served by the rack.

#### 1.35.1.1.5 Field: Design Condenser Fan Power

This field defines the design power for the condenser fan(s) in Watts. This field is applicable for air or evaporative cooling only. If the condenser is water-cooled, the fan power is captured in the cooling object (e.g., cooling tower). If applicable, this value must be greater than 0.0, with a default value of 250 Watts if this field is left blank.

#### 1.35.1.1.6 Field: Condenser Fan Power Function of Temperature Curve Name

This field is the name of the curve object defining the change in condenser fan power as a function of the temperature of air entering the condenser. This curve is used to simulate the modulation of air flow by the condenser fans (e.g., staging, multi-speed, or variable speed) as a function of temperature. The curve object will be evaluated using the zone air dry-bulb temperature when rack heat rejection location equals "Zone" and the outdoor air dry-bulb temperature when rack heat rejection location equals "Outdoors" and

the condenser type is air-cooled. As explained below, if the condenser is cooled by evaporative cooling, the curve object is evaluated using an effective temperature. The output from this curve is multiplied by the design condenser fan power to yield the actual fan power at the specific air temperature entering the condenser. This curve must be cubic or quadratic (**Curve:Cubic** or **Curve:Quadratic**), and should be normalized to 1.0 at the condenser entering air temperature at which the design condenser fan power occurs. The actual condenser fan power is not allowed to exceed the design condenser fan power defined in the previous input field or go below zero (i.e., the output of the curve object is limited to values from 0.0 to 1.0). If this field is left blank, then the model assumes the condenser fan power is at the design power level when any of the refrigerated cases connected to this rack are operating.

#### 1.35.1.1.7 Field: Condenser Type

When the heat rejection location is “Outdoors”, the condenser may be either cooled by dry air by specifying “AirCooled”, by wet evaporative cooling by specifying “EvaporativelyCooled”, or by a water loop by specifying “WaterCooled”. If the condenser type is “WaterCooled”, then a plant cooling loop will need to be defined using other EnergyPlus objects, e.g., plant loop, pump, cooling tower, etc. The default value is “AirCooled”.

#### 1.35.1.1.8 Field: Water-cooled Condenser Inlet Node Name

When the condenser type is “WaterCooled”, a node name for the water-side condenser inlet must be provided.

#### 1.35.1.1.9 Field: Water-cooled Condenser Outlet Node Name

When the condenser type is “WaterCooled”, a node name for the water-side condenser outlet must be provided.

#### 1.35.1.1.10 Field: Water-cooled Loop Flow Type

When the condenser type is “WaterCooled”, the type of flow loop should be specified. The two choices are **VariableFlow**, in which a **Pump:VariableSpeed** needs to be included in the plant loop, or **ConstantFlow**, in which the loop circuit has a constant flow rate, typically associated with a **Pump:ConstantSpeed** object. If the flow type is VariableFlow, the flow needed to remove the condenser heat energy will be calculated and requested of the pump. If the flow type is Constant Flow, the outlet water temperature will be determined based on the fixed loop flow rate and heat energy to be removed. The default type is **VariableFlow**. Refer to additional discussion in the Engineering Reference.

#### 1.35.1.1.11 Field: Water-cooled Condenser Outlet Temperature Schedule Name

When the condenser type is “WaterCooled”, and when the water-cooled loop flow type is “Variable Flow”, the name of a schedule (Ref: Schedule) that defines the desired condenser water outlet temperature must be provided. The schedule may define an outlet temperature that varies through time.

#### 1.35.1.1.12 Field: Water-cooled Condenser Design Flow Rate

When the condenser type is “WaterCooled”, and when the water-cooled loop flow type is “Constant Flow”, this is the design water flow rate in  $\text{m}^3/\text{s}$  that will be requested initially. This requested flow will be passed to the loop simulation, and resulting actual flow will be dependent upon supply system capabilities (e.g., pump capability). The design flow rate must always be less than the maximum flow rate, defined below.

**1.35.1.1.13 Field: Water-cooled Condenser Maximum Flow Rate**

When the condenser type is “Water Cooled”, this is the maximum water flow rate in m<sup>3</sup>/s that will be allowed through the condenser. When the loop flow type is Variable Flow, if the calculated flow rate is higher than the maximum flow rate, an error message will be generated, and the flow rate will be reset to the maximum flow rate.

**1.35.1.1.14 Field: Water-cooled Condenser Maximum Water Outlet Temperature**

When the condenser type is “WaterCooled”, this field specifies the maximum allowed water temperature in degrees C leaving the compressor rack condenser. The default value is 55 degrees C.

**1.35.1.1.15 Field: Water-cooled Condenser Minimum Water Inlet Temperature**

When the condenser type is “WaterCooled”, this field specifies the minimum allowed water temperature in degrees C entering the compressor rack condenser. The default value is 10 degrees C. Refer to additional discussion in the Engineering Reference.

**1.35.1.1.16 Field: Evaporative Condenser Availability Schedule Name**

When the condenser type is “EvaporativelyCooled”, the name of the optional schedule (Ref: Schedule) that specifies the time periods that evaporative cooling is available/unavailable. In some colder climates, evaporative cooling is periodically discontinued and the basin sumps drained to avoid freezing. In these times, the condenser runs as a typical dry air cooled condenser, and related evaporative cooling systems (e.g., water pump, basin heaters) do not operate. Use of this optional schedule permits modeling of planned, seasonal interruptions of evaporative cooling. All schedule values must be greater than or equal to zero. Typically, an ON/OFF schedule type is used with values being either 0 or 1. A schedule value of 1 indicates that evaporative cooling is available during the defined time period, and a value of 0 denotes that evaporative cooling is not available during the defined time period. If the schedule name is omitted (blank) and Condenser Type = “Evap Cooled”, then the model assumes that evaporative cooling of the condenser is available for the entire simulation period.

**1.35.1.1.17 Field: Evaporative Condenser Effectiveness**

When the condenser type is “EvaporativelyCooled”, this field specifies the effectiveness of the evaporative system in modifying the temperature of the air entering the condenser coil. The resulting effective temperature is determined as

$$T_{effective} = T_{owb} + (1 - \varepsilon) * [T_{odb} - T_{owb}] \quad (1.144)$$

where:

$T_{effective}$	= effective dry-bulb temperature of air entering the condenser cooling coil (°C)
$T_{owb}$	= outdoor air wet-bulb temperature (°C)
$T_{odb}$	= outdoor air dry-bulb temperature (°C)
$\varepsilon$	= evaporative condenser effectiveness.

The resulting condenser inlet air temperature is used by the Compressor Rack COP as a Function of Temperature Curve and the Condenser Fan Power as a Function of Temperature Curve. The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0.

If the two function-of-temperature curves (i.e., Compressor Rack COP as a Function of Temperature Curve and Condenser Fan Power as a Function of Temperature Curve) are based on wet-bulb temperature rather than dry-bulb temperature, the evaporative condenser effectiveness should be set to 1.0 for consistency.

**1.35.1.1.18 Field: Evaporative Condenser Air Flow Rate**

When the condenser type is “EvaporativelyCooled”, the air volume flow rate, in m<sup>3</sup>per second, entering the evaporative condenser. This value is used to calculate the amount of water evaporated when evaporatively cooling the condenser inlet air. The value for this field must be greater than zero. This input field is also autocalculatable, equivalent to 0.000144 m<sup>3</sup>/s per watt of total cooling capacity [850 cfm/ton] where the total cooling capacity is the sum of the rated total cooling capacities for the refrigerated cases connected to this compressor rack (Ref. [Refrigeration:Case](#)).

**1.35.1.1.19 Field: Basin Heater Capacity**

When the condenser type is “EvaporativelyCooled”, this field defines the power level of the basin heater, if applicable, used to avoid water freezing in an outdoor evaporative cooler basin. This numeric field contains the capacity of the electric basin heater in Watts per degree Kelvin. This field is used in conjunction with the Basin Heater Set Point Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the dry-bulb temperature of the condenser coil inlet air. The basin heater only operates when the condenser fan is off (i.e., no compressor heat rejection). The basin heater capacity must be greater than or equal to zero, with a default value of 200 W/K if this field is left blank.

**1.35.1.1.20 Field: Basin Heater Setpoint Temperature**

When the condenser type is “EvaporativelyCooled”, this numeric field contains the set point temperature (°C) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this set point temperature, as long as the condenser fan is off. The default value is 2°C if this field is left blank.

**1.35.1.1.21 Field: Design Evaporative Condenser Water Pump Power**

When the condenser type is “EvaporativelyCooled”, the rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The value for this field must be greater than or equal to 0, with a default value of 1000 Watts if this field is left blank. This input field is also autocalculatable, equivalent to 0.004266 W per watt [15 W/ton] of total cooling capacity where the total cooling capacity is the sum of the rated total cooling capacities for the refrigerated cases and walk-ins connected to this compressor rack (Ref. [Refrigeration:Case](#) and [Refrigeration:WalkIn](#))).

**1.35.1.1.22 Field: Evaporative Water Supply Tank Name**

When the condenser type is “EvaporativelyCooled”, this field is used to define where the compressor rack obtains water used for evaporative cooling of its condenser. If this field is left blank, the unit will obtain water directly from the mains (Ref. [Water Mains Temperatures](#)). If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank.

**1.35.1.1.23 Field: Condenser Air Inlet Node Name**

This optional alpha field contains the name of the node from which the outdoor compressor rack condenser draws its outdoor air. This field is applicable only when the heat rejection location is “Outdoors” (if the heat rejection location is “Zone”, this field is disregarded). If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, this node name must also be specified in an [OutdoorAir:Node](#) object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an [OutdoorAir:NodeList](#) object where the outdoor air temperature is taken directly from the weather data.

### 1.35.1.1.24 Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature Rack”). A new meter for reporting is created for each unique subcategory (Ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

### 1.35.1.1.25 Field: Refrigeration Case Name or WalkIn Name or CaseAndWalkInList Name

This alpha field is the name of a single refrigerated case, a single walk in cooler, the name of a CaseAndWalkInList for multiple refrigerated cases and/or walk-ins, the name of a refrigeration chiller, or the name of a CaseAndWalkInList for multiple refrigeration chillers connected to this compressor rack. Note that if a CaseAndWalkInList contains the name(s) of refrigeration chillers, it CANNOT have the name(s) or any refrigerated cases or walkins . This field is required.

### 1.35.1.1.26 Field: Heat Rejection Zone Name

If the Heat Rejection Location is “Zone” and any walk-in coolers are connected to this compressor rack, then this field is required. The compressor rack heat rejection will impact the air heat balance in this zone.

The following is an example input for a Refrigeration Compressor Rack with water cooled condenser.

```
Refrigeration:CompressorRack,
    MediumTempRack,           !- Name
    Outdoors,                 !- Heat Rejection Location

    MediumTempCaseList;       !- Refrigeration Case Name or WalkIn Name or CaseAndWalkInList Name
```

## 1.35.1.2 Outputs

If Condenser Type = Water Cooled:

- System,Average, Refrigeration Compressor Rack Condenser Refrigerant Mass Flow Rate [kg/s]
- System,Average, Refrigeration Compressor Rack Condenser Heat Transfer Rate [W]
- System,Sum, Refrigeration Compressor Rack Condenser Heat Transfer Energy [J]

IF THE RACK SERVES CASES AND/OR WALKINS:

- Zone,Average, Refrigeration Compressor Rack Electricity Rate [W]
- Zone,Sum, Refrigeration Compressor Rack Electricity Energy [J]
- Zone,Average, Refrigeration Compressor Rack Condenser Fan Electricity Rate [W]
- Zone,Sum, Refrigeration Compressor Rack Condenser Fan Electricity Energy [J]
- Zone,Average, Refrigeration Compressor Rack Total Heat Transfer Rate [W]
- Zone,Sum, Refrigeration Compressor Rack Total Heat Transfer Energy [J]
- Zone,Average, Refrigeration Compressor Rack COP [W/W]

If Condenser Type = Evap Cooled:

- Zone,Average, Refrigeration Compressor Rack Evaporative Condenser Pump Electricity Rate [W]
- Zone,Sum, Refrigeration Compressor Rack Evaporative Condenser Pump Electricity Energy [J]
- Zone,Average, Refrigeration Compressor Rack Evaporative Condenser Basin Heater Electricity Rate [W]
- Zone,Sum, Refrigeration Compressor Rack Evaporative Condenser Basin Heater Electricity Energy [J]
- Zone,Average, Refrigeration Compressor Rack Evaporative Condenser Water Volume Flow Rate [m<sup>3</sup>/s]
- Zone,Sum, Refrigeration Compressor Rack Evaporative Condenser Water Volume [m<sup>3</sup>]

If Heat Rejection Location = Zone:

- Zone,Average, Refrigeration Compressor Rack Zone Sensible Heating Rate [W]
- Zone,Sum,Refrigeration Compressor Rack Zone Sensible Heating Energy [J]
- Zone,Average, Refrigeration Compressor Rack Return Air Sensible Heating Rate [W]
- Zone,Sum,Refrigeration Compressor Rack Return Air Sensible Heating Energy [J]

IF THE RACK SERVES REFRIGERATION CHILLERS

- HVAC,Average, Refrigeration Air Chiller Compressor Rack Electricity Rate [W]
- HVAC,Sum, Refrigeration Air Chiller Compressor Rack Electricity Energy [J]
- HVAC,Average,Refrigeration Air Chiller System Compressor Runtime Fraction []
- HVAC,Average, Refrigeration Air Chiller Compressor Rack Condenser Fan Electricity Rate [W]
- HVAC,Sum, Refrigeration Air Chiller Compressor Rack Condenser Fan Electricity Energy [J]
- HVAC,Average, Refrigeration Air Chiller Compressor Rack Total Heat Transfer Rate [W]

- HVAC,Sum, Refrigeration Air Chiller Compressor Rack Total Heat Transfer Energy [J]
- HVAC,Average, Refrigeration Air Chiller Compressor Rack COP [W/W]

If Condenser Type = Evap Cooled:

- HVAC,Average, Refrigeration Air Chiller Compressor Rack Evaporative Condenser Pump Electricity Rate [W]
- HVAC,Sum, Refrigeration Air Chiller Compressor Rack Evaporative Condenser Pump Electricity Energy [J]
- HVAC,Average, Refrigeration Air Chiller Compressor Rack Evaporative Condenser Basin Heater Electricity Rate [W]
- HVAC,Sum, Refrigeration Air Chiller Compressor Rack Electric PowerRefrigeration Air Chiller Compressor Rack Evaporative Condenser Basin Heater Electricity Energy [J]
- HVAC,Average, Refrigeration Air Chiller Compressor Rack Evaporative Condenser Water Volume Flow Rate [m3/s]
- HVAC,Sum, Refrigeration Air Chiller Compressor Rack Evaporative Condenser Water Volume [m3]

If Heat Rejection Location = Zone:

- HVAC,Average, Refrigeration Air Chiller Compressor Rack Zone Sensible Heating Rate [W]
- HVAC,Sum,Refrigeration Air Chiller Compressor Rack Zone Sensible Heating Energy [J]
- HVAC,Average, Refrigeration Air Chiller Compressor Rack Return Air Sensible Heating Rate [W]
- HVAC,Sum,Refrigeration Air Chiller Compressor Rack Return Air Sensible Heating Energy [J]

#### **1.35.1.2.1 Refrigeration Compressor Rack Condenser Mass Flow Rate [kg/s]**

When condenser type is Water Cooled, this is the mass flow rate of water flowing through the water cooled condenser.

#### **1.35.1.2.2 Refrigeration Compressor Rack Condenser Heat Transfer Rate [W]**

When condenser type is Water Cooled, this is the total heat transfer across the condenser (i.e., compressor energy and case cooling).

#### **1.35.1.2.3 Refrigeration Compressor Rack Condenser Heat Transfer Energy [J]**

When condenser type is Water Cooled, this is the total heat energy flowing across the condenser for the timestep being reported.

#### **1.35.1.2.4 IF THE RACK SERVES CASES AND OR WALKINS:**

#### **1.35.1.2.5 Refrigeration Compressor Rack Electricity Rate [W]**

This output is the electric power input to the rack compressor(s) in Watts.

**1.35.1.2.6 Refrigeration Compressor Rack Electricity Energy [J]**

This is the electricity consumption of the rack compressor(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.1.2.7 Refrigeration Compressor Runtime Fraction []**

This is the runtime operating ratio for the compressor.

**1.35.1.2.8 Refrigeration Compressor Rack Condenser Fan Electricity Rate [W]**

This output is the electric input to the rack condenser fan(s) in Watts.

**1.35.1.2.9 Refrigeration Compressor Rack Condenser Fan Electricity Energy [J]**

This is the electricity consumption of the rack condenser fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.1.2.10 Refrigeration Compressor Rack Total Heat Transfer Rate [W]**

This output is the total heat transfer rate of the refrigeration compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected to this rack. This value does not include compressor or condenser fan heat.

**1.35.1.2.11 Refrigeration Compressor Rack Total Heat Transfer Energy [J]**

This is the total heat transfer of the refrigeration compressor rack in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.1.2.12 Refrigeration Compressor Rack COP [W/W]**

This field is the refrigeration compressor rack coefficient of performance. It is the actual compressor rack COP for the timestep being reported, accounting for the COP variation as a function of temperature. It is calculated as the Design Compressor Rack COP times the Compressor Rack COP as a Function of Temperature Curve evaluated at the effective condenser entering air temperature for the timestep being reported.

**1.35.1.2.13 Refrigeration Compressor Rack Evaporative Condenser Pump Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the compressor rack condenser.

**1.35.1.2.14 Refrigeration Compressor Rack Evaporative Condenser Pump Electricity Energy [J]**

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.1.2.15 Refrigeration Compressor Rack Evaporative Condenser Basin Heater Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the compressor rack condenser.

#### **1.35.1.2.16 Refrigeration Compressor Rack Evaporative Condenser Basin Heater Electricity Energy [J]**

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the compressor rack condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.1.2.17 Refrigeration Compressor Rack Evaporative Condenser Water Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate in m<sup>3</sup>/s of water consumed while providing evaporative cooling of the compressor rack condenser.

#### **1.35.1.2.18 Refrigeration Compressor Rack Evaporative Condenser Water Volume [m<sup>3</sup>]**

This is the water consumed by evaporation in m<sup>3</sup> while providing evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.1.2.19 Refrigeration Compressor Rack Zone Sensible Heating Rate [W]**

This field is the rate of sensible heating in Watts provided to the zone by condenser waste heat rejection, which impacts the zone air heat balance.

#### **1.35.1.2.20 Refrigeration Compressor Rack Zone Sensible Heating Energy [J]**

This field is the sensible heating energy in Joules provided to the zone by condenser waste heat rejection for the timestep being reported.

#### **1.35.1.2.21 Refrigeration Compressor Rack Return Air Sensible Heating Rate [W]**

This field is the rate of sensible heating in Watts provided by condenser waste heat rejection to the HVAC return air (zone return air path outlet node), which impacts the HVAC return air temperature. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

#### **1.35.1.2.22 Refrigeration Compressor Rack Return Air Sensible Heating Energy [J]**

This field is the sensible heating energy in Joules provided by condenser waste heat rejection to the HVAC return air (zone return air path outlet node) for the timestep being reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

#### **1.35.1.2.23 IF THE RACK SERVES CHILLERS**

**1.35.1.2.24 Refrigeration Air Chiller Compressor Rack Electricity Rate [W]**

This output is the electric power input to the rack compressor(s) in Watts.

**1.35.1.2.25 Refrigeration Air Chiller Compressor Rack Electricity Energy [J]**

This is the electricity consumption of the rack compressor(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

**1.35.1.2.26 Refrigeration Air Chiller System Compressor Runtime Fraction []**

This is the runtime fraction for the compressor serving air chillers.

**1.35.1.2.27 Refrigeration Air Chiller Compressor Rack Condenser Fan Electricity Rate [W]**

This output is the electric input to the rack condenser fan(s) in Watts.

**1.35.1.2.28 Refrigeration Air Chiller Compressor Rack Condenser Fan Electricity Energy [J]**

This is the electricity consumption of the rack condenser fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

**1.35.1.2.29 Refrigeration Air Chiller Compressor Rack Total Heat Transfer Rate [W]**

This output is the total heat transfer rate of the refrigeration compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected to this rack. This value does not include compressor or condenser fan heat.

**1.35.1.2.30 Refrigeration Air Chiller Compressor Rack Total Heat Transfer Energy [J]**

This is the total heat transfer of the refrigeration compressor rack in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

**1.35.1.2.31 Refrigeration Air Chiller Compressor Rack COP [W/W]**

This field is the refrigeration compressor rack coefficient of performance. It is the actual compressor rack COP for the timestep being reported, accounting for the COP variation as a function of temperature. It is calculated as the Design Compressor Rack COP times the Compressor Rack COP as a Function of Temperature Curve evaluated at the effective condenser entering air temperature for the timestep being reported.

**1.35.1.2.32 Refrigeration Air Chiller Compressor Rack Evaporative Condenser Pump Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the compressor rack condenser.

#### **1.35.1.2.33 Refrigeration Air Chiller Compressor Rack Evaporative Condenser Pump Electricity Energy [J]**

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.1.2.34 Refrigeration Air Chiller Compressor Rack Evaporative Condenser Basin Heater Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the compressor rack condenser.

#### **1.35.1.2.35 Refrigeration Air Chiller Compressor Rack Evaporative Condenser Basin Heater Electricity Energy [J]**

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the compressor rack condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.1.2.36 Refrigeration Air Chiller Compressor Rack Evaporative Condenser Water Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate in m<sup>3</sup>/s of water consumed while providing evaporative cooling of the compressor rack condenser.

#### **1.35.1.2.37 Refrigeration Air Chiller Compressor Rack Evaporative Condenser Water Volume [m<sup>3</sup>]**

This is the water consumed by evaporation in m<sup>3</sup> while providing evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.1.2.38 Refrigeration Air Chiller Compressor Rack Zone Sensible Heating Rate [W]**

This field is the rate of sensible heating in Watts provided to the zone by condenser waste heat rejection, which impacts the zone air heat balance.

#### **1.35.1.2.39 Refrigeration Air Chiller Compressor Rack Zone Sensible Heating Energy [J]**

This field is the sensible heating energy in Joules provided to the zone by condenser waste heat rejection for the timestep being reported.

#### **1.35.1.2.40 Refrigeration Air Chiller Compressor Rack Return Air Sensible Heating Energy [J]**

#### 1.35.1.2.41 Refrigeration Air Chiller Compressor Rack Return Air Sensible Heating Rate [W]

These are the sensible heating energy, in Joules or Watts, provided to the HVAC system return air node by condenser heat rejection at the compressor rack.

### 1.35.2 Refrigeration:Case

The Refrigeration Case object works in conjunction with a compressor rack, a refrigeration system, or a secondary loop object ([Refrigeration:CompressorRack](#), [Refrigeration:System](#), or [Refrigeration:SecondarySystem](#)) to simulate the performance of a refrigerated case system. The refrigerated case model uses performance information at rated conditions along with performance curves for latent case credits and defrost heat load to determine performance at off-rated conditions. Energy use for lights, fans and anti-sweat heaters is modeled based on inputs for nominal power, schedules, and control type. The refrigerated case model accounts for the sensible and latent heat exchange with the surrounding environment (termed “case credits”) which impacts the temperature and humidity in the zone where the case is located.

*A dataset has been provided containing refrigerated case input data for a large number of refrigerated cases from multiple manufacturers. See [RefrigerationCases.idf](#).*

The Refrigeration Case object inputs include a case name, an availability schedule name, the zone name for the location of the case, and the temperature and relative humidity of the ambient (zone) air surrounding the refrigerated case at the rating conditions for case performance. Additional inputs include the total cooling capacity, latent heat ratio, and run time fraction of the refrigerated case at rated conditions. The case length and operating temperature (average temperature of air/products within the case) must also be specified.

The refrigerated case model requires two curves to describe performance at off-rated conditions (i.e., at different zone temperature and humidity levels): the latent case credit curve and the defrost energy correction curve. The user must enter cubic performance curves with the independent variable being user selectable (case temperature, zone relative humidity, or zone dewpoint temperature).

The user can select from eight case defrost types, with additional inputs being required depending on the type selected. The user must enter a defrost schedule (unless Case Defrost Type = None), and an optional defrost drip-down schedule can be specified to allow additional time for melted frost to drain from the cooling coil following the regular defrost period.

Inputs are required for case fans, lights, and anti-sweat heaters. Case lighting can be controlled by the user through entering a schedule. The case fans operate whenever the cooling coil is operating and during defrost periods for certain case defrost types. Anti-sweat heater power can be controlled by several methods which are user selectable. The model assumes that the fans are contained within the thermal envelope of the case and provide a direct heat load on the case cooling coil. For lighting and anti-sweat heaters, the user can specify the fraction of their respective heat loads that directly impact the case cooling coil (with the remainder of their heat load impacting the surrounding zone air).

The user has the option of specifying a case restocking schedule and a schedule for modifying the case credits if needed. Finally, the user can specify the under case HVAC return air fraction which determines the portion of the case credits that directly impact the HVAC return air conditions (with the remainder of the case credits impacting the zone sensible and latent loads).

#### 1.35.2.1 Inputs

##### 1.35.2.1.1 Field: Name

A unique user-assigned name for an instance of a refrigerated case. Any reference to this case by another object will use this name.

#### 1.35.2.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the case will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the refrigerated case will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, cases require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the case is assumed to be available at all time periods.

#### 1.35.2.1.3 Field: Zone Name

The name of the zone where the refrigerated case is located. The refrigerated case will impact the air heat balance in this zone. When modeling multiple refrigerated cases connected to a single compressor rack where the condenser heat is rejected to the zone (ref: **Refrigeration:CompressorRack**), **all** of the refrigerated cases connected to that compressor rack must be located in the same zone.

#### 1.35.2.1.4 Field: Rated Ambient Temperature

Dry-bulb temperature of the ambient (zone) air surrounding the refrigerated case at the rating conditions for refrigerated case performance. The default value for this field is 23.9 °C (75 °F). This temperature must be greater than 0 °C and greater than the case operating temperature.

#### 1.35.2.1.5 Field: Rated Ambient Relative Humidity

Relative humidity of the ambient (zone) air surrounding the refrigerated case at the rating conditions for refrigerated case performance. The default value for this field is 55% RH.

#### 1.35.2.1.6 Field: Rated Total Cooling Capacity per Unit Length

The total, full load cooling capacity (sensible plus latent) in watts per unit length of refrigerated case (W/m) at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, Case Operating Temperature, and with the Standard Case Fan Power per Unit Length and the Standard Case Lighting Power per Unit Length). The value entered for this field must be greater than zero, with a default value of 1900 W/m if the field is blank.

#### 1.35.2.1.7 Field: Rated Latent Heat Ratio

The latent heat ratio (LHR = latent capacity divided by total cooling capacity) of the refrigerated case at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, Case Operating Temperature, and with the Standard Case Fan Power per Unit Length and the Standard Case Lighting Power per Unit Length). The value for this field can range from zero to 1.0, with a default value of 0.3 if the field is blank.

#### 1.35.2.1.8 Field: Rated Runtime Fraction

The runtime fraction of the refrigerated case at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, and Case Operating Temperature). Even at rated conditions, refrigerated cases typically include additional cooling capacity to account for product stocking and recovery from defrost. The rated runtime fraction for refrigerated cases typically ranges from 0.8 to 0.9. The entered value for this field must be greater than 0.0 and less than or equal to 1.0, and the default value is 0.85 if the field is blank.

**1.35.2.1.9 Field: Case Length**

The length of the refrigerated case in meters. The entered value for this field must be greater than 0.0, and the default value is 3 meters if the field is blank.

**1.35.2.1.10 Field: Case Operating Temperature**

The average temperature of the air and products within the refrigerated case in °C. The refrigerated case manufacturer typically provides this information in the product literature. Typical operating temperatures for medium temperature cases are 1.6 °C to 7.2 °C (35 °F to 45 °F). Typical operating temperatures for low temperatures cases are -28.9 °C to -17.8 °C (-20 °F to 0 °F). The entered value for this field must be less than 20 °C and lower than the Rated Ambient Temperature. The default value is 1.1 °C if the field is blank.

**1.35.2.1.11 Field: Latent Case Credit Curve Type**

This alpha field defines the form of the curve used to modify the latent case credits (latent heat removed from the zone where the refrigerated case is located) at off-rated conditions. The valid choices for this field are:

- CaseTemperatureMethod

This method defines the variation in latent case credits as a cubic function of Case Operating Temperature. The result from the cubic curve is multiplied by the difference between the rated ambient relative humidity and the actual zone relative humidity, and one minus this value is multiplied by the Rated LHR to give the operating LHR at the actual zone humidity condition. (Representative coefficient values for single-shelf horizontal and multi-shelf vertical display cases are given in the EnergyPlus Engineering Reference.)

- RelativeHumidityMethod

This method defines the variation in latent case credits as a cubic function of ambient (zone) air relative humidity.

- DewpointMethod

This method defines the variation in latent case credits as a cubic function of ambient (zone) air dewpoint temperature.

The default curve type is the Case Temperature Method. Refer to the Engineering Reference for further information on how latent case credits are modeled.

**1.35.2.1.12 Field: Latent Case Credit Curve Name**

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the latent case credits at off-rated conditions. The curve should be normalized to have a value of 1.0 at the rated ambient air conditions defined above.

**1.35.2.1.13 Field: Standard Case Fan Power per Unit Length**

The total standard fan power in Watts per unit length of refrigerated case (W/m). This value represents the fan power included in the field Rated Total Cooling Capacity per Unit Length, and is used to determine the sensible case credits. The entered value for this field must be greater than or equal to zero, and the default value is 75.0 W/m if the field is blank.

**1.35.2.1.14 Field: Operating Case Fan Power per Unit Length**

The total operating fan power in Watts per unit length of refrigerated case (W/m). Enter the actual power for the installed fans. The entered value for this field must be greater than or equal to zero, and the value is set equal to the standard case fan powers if the field is blank.

**1.35.2.1.15 Field: Standard Case Lighting Power per Unit Length**

The total standard lighting power in Watts per unit length of refrigerated case (W/m). This value should represent the lighting power provided by the case manufacturer and included in the “Rated Total Cooling Capacity per Unit Length” field and is used to determine the sensible case credits. For cases where the manufacturer does not include the lights in the Rated Total Cooling Capacity, this value should be zero (0.0). The entered value for this field must be greater than or equal to zero, and the default value is 90.0 W/m if the field is blank.

**1.35.2.1.16 Field: Installed Case Lighting Power per Unit Length**

The total installed lighting power in Watts per unit length of refrigerated case (W/m). Enter the actual power for the installed lights. This number may be greater or less than the standard lighting power value, depending upon the manufacturer’s practice in specifying the case rated cooling capacity and whether or not energy-efficient lights are being modeled. The next field (i.e. Case Lighting Schedule Name) may be used to specify the name of a schedule that contains the fraction of the Installed Case Lighting Power per Unit Length to be modeled for each timestep of the simulation period. The entered value for this field must be greater than or equal to zero, and the value is set equal to the standard case lighting power if the field is blank.

**1.35.2.1.17 Field: Case Lighting Schedule Name**

The name of the schedule (ref: Schedule) that denotes the fraction of installed refrigerated case lights that operate during a given time period. A schedule value greater than 0 indicates that the lights will operate during that time period (maximum schedule value of 1.0 means lights are fully on at the Installed Case Lighting Power per Unit Length level). A schedule value of zero denotes that the lights are off. The refrigerated case lights will typically operate only when the store is open for business and can be scheduled off as desired via this schedule. If this field is left blank, the default schedule has a value of 1 for all time periods.

**1.35.2.1.18 Field: Fraction of Lighting Energy To Case**

The fraction of the lighting energy that directly contributes to the case heat load. The remainder of the lighting energy ( $1 - \text{fraction}$ ) is a heating load to the zone where the case is located. This field can be used to model lighting ballasts and bulbs located outside the air curtain of the refrigerated case. The value for this field can range from zero to 1.0, with a default value of 1.0 if the field is blank.

**1.35.2.1.19 Field: Case Anti-Sweat Heater Power per Unit Length**

The electric anti-sweat heater power in watts per unit length of refrigerated case (W/m). The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

**1.35.2.1.20 Field: Minimum Anti-Sweat Heater Power per Unit Length**

The minimum electric anti-sweat heater power in watts per unit length of refrigerated case (W/m). Anti-sweat heater power will remain at or above this value for anti-sweat heater control types linear, dewpoint method, or heat balance method. Other anti-sweat heater control types disregard this field. The

entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

#### **1.35.2.1.21 Field: Anti-Sweat Heater Control Type**

The type of anti-sweat heater control used for this refrigerated case. Valid choices are None, Constant, Linear, DewpointMethod, or HeatBalanceMethod. The default is None if the field is blank. Refer to the Engineering Reference for further information on how the different anti-sweat heater controls are modeled.

#### **1.35.2.1.22 Field: Humidity at Zero Anti-Sweat Heater Energy**

The value of this numeric field is only used when the Linear anti-sweat heater control type is selected. Enter the zone relative humidity where anti-sweat heater energy use is zero. Negative values for relative humidity may be entered. Other anti-sweat heater control types disregard this field. The value entered for this field must be less than the Rated Ambient Relative Humidity specified above. The default for this field is -10.0.

#### **1.35.2.1.23 Field: Case Height**

The value of this numeric field is used when Heat Balance Method anti-sweat heater control is selected. Enter the case height in meters. Other anti-sweat heater control types disregard this field. The entered value for this field must be greater than zero when Heat Balance Method anti-sweat heater control is selected, and the default value is 1.5 meters if the field is blank.

#### **1.35.2.1.24 Field: Fraction of Anti-Sweat Heater Energy To Case**

This value denotes the fraction of anti-sweat heater energy that results in a direct heat load to the refrigerated case. The remainder of the anti-sweat heater energy (1-fraction) is a heating load to the zone where the refrigerated case is located. The value for this field can range from zero to 1.0, with a default value of 1.0 if the field is blank.

#### **1.35.2.1.25 Field: Case Defrost Power per Unit Length**

The defrost power in watts per unit length of refrigerated case (W/m). This input is required for hot-gas, hot-fluid, or electric defrost types and is used to evaluate the load on the case as well as power or heat consumption. Refrigerated case manufacturers do not typically provide information on the heat input for hot-gas and hot-fluid defrost. Information provided for electric defrost power can be substituted here for refrigerated cases using hot-gas or hot-fluid defrost if other information is not available. Only electric Case Defrost Types consume electricity during the defrost period. The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

#### **1.35.2.1.26 Field: Case Defrost Type**

The type of defrost used for this refrigerated case. Valid choices are None, OffCycle, HotGas, Hot-GaswithTemperatureTermination, Electric, ElectricwithTemperatureTermination, HotFluid, and HotFluidwithTemperatureTermination. The default defrost type is OffCycle if the field is blank. Refer to the Engineering Reference for further information on how the different case defrost types are modeled. In particular, hot-fluid defrost systems may be effective with much shorter defrost times than other systems, which should be reflected in the defrost and drip-down schedules.

#### **1.35.2.1.27 Field: Case Defrost Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case requires defrosting. A schedule value of 1.0 indicates that defrost will be on during a given time period. A value equal to 0 denotes that the defrost is off. Defrost schedules normally repeat the duration and number of defrost cycles

for each day of the year. The refrigerated case manufacturer typically provides this information with the product literature. The use of Compact Schedules (ref. Schedules) are ideal for this purpose. In a typical supermarket with many cases, it is important to diversify the defrost schedules in order to avoid large swings in the load placed upon the remainder of the refrigeration system.

#### 1.35.2.1.28 Field: Case Defrost Drip-Down Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case requires additional time for draining condensate after the defrost period. A schedule value of 1.0 indicates that the defrost drip-down period is on during a given time period. A value equal to 0 denotes that the defrost drip-down period is over. The refrigerated case manufacturer typically provides this information with the product literature.

Each defrost drip-down period specified in this schedule should start at the same time as the corresponding defrost period specified in the schedule for Case Defrost Schedule, and the drip-down schedule defrost period should always be longer than or equal to the length of the defrost schedule time period. For example, if the case defrost schedule contains a defrost period from 7:00 to 7:15, you would specify a case defrost drip-down period from 7:00 to 7:20 if you wanted to model a 5 minute condensate drip-down period after the regular defrost period. If no drip-down schedule is entered, then the case defrost schedule (specified for the previous input field) will be used. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

#### 1.35.2.1.29 Field: Defrost Energy Correction Curve Type

This alpha field defines the form of the correction curve used to modify the defrost energy use (and the associated load on the case cooling coil) at off-rated conditions. The valid choices for this field are:

- None

This choice specifies that a defrost energy correction curve will not be used.

- CaseTemperatureMethod

This method defines the variation in defrost energy as a cubic function of Case Operating Temperature. The result from the cubic curve is multiplied by the difference between the rated ambient relative humidity and the actual zone relative humidity, and one minus this value is multiplied by the Case Defrost Power to give the (average) operating defrost power at the actual zone humidity condition. (Representative coefficient values for single-shelf horizontal and multi-shelf vertical display cases are given in the EnergyPlus Engineering Reference.)

- RelativeHumidityMethod

This method defines the variation in defrost energy as a cubic function of ambient (zone) air relative humidity.

- DewpointMethod

This method defines the variation in defrost energy as a cubic function of ambient (zone) air dewpoint temperature.

The default curve type is None. The methods described here (e.g. Case Temperature, Relative Humidity, and Dewpoint) are applicable only to Electric with Temperature Termination, Hot-Gas with Temperature Termination, and Hot-Brine with Temperature Termination case defrost types. Refer to the Engineering Reference for further information on how the defrost energy correction types are modeled.

**1.35.2.1.30 Field: Defrost Energy Correction Curve Name**

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the defrost energy (and the associated load on the case cooling coil) at off-rated conditions. The curve should be normalized to have the value of 1.0 at the rated ambient air conditions defined above. The defrost energy correction curve name is used only for the Electric with Temperature Termination, Hot-Gas with Temperature Termination, and Hot-Brine with Temperature Termination case defrost types.

**1.35.2.1.31 Field: Under Case HVAC Return Air Fraction**

This field denotes the fraction of HVAC system (air loop) return air that passes beneath the refrigerated case, if any. At times it is necessary to design HVAC systems with under case returns to avoid overcooling the area around the refrigerated case, thus providing a more comfortable environment for the zone occupants. This return air fraction affects the portion of the case credits (sensible and latent) that are applied to the air returning to the HVAC system, while the remainder of the case credits directly impacts the zone air heat balance. Refer to the Engineering Reference for further information on how this is modeled. The sum of the Under Case HVAC Return Air Fractions for all refrigerated cases located in a single zone must be less than or equal to 1.0. The value for this field can range from zero to 1.0, with a default value of 0 if the field is blank. The return air node name may be specified below.

**1.35.2.1.32 Field: Refrigerated Case Restocking Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case is being restocked with product. The schedule should contain values in units of Watts per unit length of refrigerated case (W/m). This field can be used to denote the additional load imposed on the refrigerated case from stocking the case with product that is warmer than the refrigerated case temperature. This information is difficult to find and may require additional research for proper modeling; however, this schedule is available for this purpose if desired. If restocking of the refrigerated case will not be simulated, enter a schedule with values of zero for all time periods or leave this field blank.

**1.35.2.1.33 Field: Case Credit Fraction Schedule Name**

The name of the schedule (ref: Schedule) that denotes a fraction of both the sensible and latent case credits to be applied to the zone and/or the HVAC system return air. Schedule values must be from 0 to 1. This allows correction of the case credits for various refrigerated case types. For instance, if glass door refrigerated display cases are installed in a store that is operated 12 hours per day, then the doors will remain closed during the unoccupied times and would therefore reduce the sensible and latent case credits during the unoccupied time. Leaving this field blank will result in no case credit fraction being applied during the simulation.

**1.35.2.1.34 Field: Design Evaporator Temperature or Brine Inlet Temperature**

The value of this numeric field is used only with the detailed refrigeration system and is not read for the compressor-rack system. For the refrigeration system, it is used to evaluate compressor performance and is also used when the evaporator pressure and temperature are allowed to float at loads less than the design load. If the case is cooled by a secondary system (ref: **Refrigeration:SecondarySystem**), this value is the brine inlet temperature. The minimum value is -70C and the maximum value is 40C. The default value is 5C less than the case temperature.

**1.35.2.1.35 Field: Average Refrigerant Charge Inventory**

The value of this optional field is the refrigerant inventory present in the refrigerated case during ordinary operation. The value is used to produce an estimate of the total refrigerant present in the refrigeration system. The value is entered in kg/m.

### 1.35.2.1.36 Field: Under Case HVAC Return Air Node Name

Name of the return air node for this case. If left blank, it defaults to the first return air node for this zone.

The following is an example input for a refrigerated case.

```
Refrigeration:Case,
Multi-Deck Dairy/Deli Merchandiser with Synergy-E,  !- Name [Based on Hill Phoenix 6DMLH-NRG]
,  !- Availability Schedule [Used to turn case on/off including all power draws (ie fans, lights,
etc)]
UserProvideZoneName,  !- Zone Name [Location of Fixture]
23.89,  !- Rated Ambient Temperature {C}  [75°F]

#### 1.35.2.2.1 Refrigeration Case Evaporator Total Cooling Rate [W]

This field is the total (sensible plus latent) cooling rate of the refrigerated case evaporator coil in Watts.

#### 1.35.2.2.2 Refrigeration Case Evaporator Total Cooling Energy [J]

This field is the total (sensible plus latent) cooling of the refrigerated case evaporator coil in Joules over the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects).

#### 1.35.2.2.3 Refrigeration Case Evaporator Sensible Cooling Rate [W]

This field is the sensible cooling rate of the refrigerated case evaporator coil in Watts.

**1.35.2.2.4 Refrigeration Case Evaporator Sensible Cooling Energy [J]**

This field is the sensible cooling of the refrigerated case evaporator coil in Joules over the timestep being reported.

**1.35.2.2.5 Refrigeration Case Evaporator Latent Cooling Rate [W]**

This field is the latent cooling (dehumidification) rate of the refrigerated case evaporator coil in Watts.

**1.35.2.2.6 Refrigeration Case Evaporator Latent Cooling Energy [J]**

This field is the latent cooling (dehumidification) of the refrigerated case evaporator coil in Joules over the timestep being reported.

**1.35.2.2.7 Refrigeration Case Zone Sensible Cooling Rate [W]**

This field is the rate of sensible cooling case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

**1.35.2.2.8 Refrigeration Case Zone Sensible Cooling Energy [J]**

This field is the amount of sensible cooling case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

**1.35.2.2.9 Refrigeration Case Zone Sensible Heating Rate [W]**

This field is the rate of sensible heating case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

**1.35.2.2.10 Refrigeration Case Zone Sensible Heating Energy [J]**

This field is the amount of sensible heating case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

**1.35.2.2.11 Refrigeration Case Zone Latent Rate [W]**

This field is the rate of latent cooling (dehumidification) case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the latent case credits are applied to the zone. A negative value (or zero) will be reported when the refrigerated case provides dehumidification (thereby reducing the zone latent load).

**1.35.2.2.12 Refrigeration Case Zone Latent Energy [J]**

This field is the amount of latent cooling (dehumidification) case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the latent case credits are applied to the zone. A negative value (or zero) will be reported when the refrigerated case provides dehumidification (thereby reducing the zone latent load).

**1.35.2.2.13 Refrigeration Case Return Air Sensible Cooling Rate [W]**

This field is the rate of sensible cooling case credits delivered to the return air duct (zone return air node) in Watts. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is cooled by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air

mass flow), then this sensible cooling is actually provided to the zone air instead (even though a non-zero value is reported here).

#### **1.35.2.2.14 Refrigeration Case Return Air Sensible Cooling Energy [J]**

This field is the amount of sensible cooling case credit energy delivered to the return air duct (zone return air node) in Joules. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is cooled by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible cooling is actually provided to the zone air instead (even though a non-zero value is reported here).

#### **1.35.2.2.15 Refrigeration Case Return Air Sensible Heating Rate [W]**

This field is the rate of sensible heating case credits delivered to the return air duct (zone return air node) in Watts. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is heated by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

#### **1.35.2.2.16 Refrigeration Case Return Air Sensible Heating Energy [J]**

This field is the amount of sensible heating case credit energy delivered to the return air duct (thereby reducing the zone latent load). If the HVAC system is off for a simulation timestep (no return air mass flow), then this latent energy is actually provided to the zone air instead (even though a non-zero value is reported here).

#### **1.35.2.2.17 Refrigeration Case Return Air Latent Energy [J]**

#### **1.35.2.2.18 Refrigeration Case Return Air Latent Rate [W]**

These are the amount of latent cooling (dehumidification) case credit energy delivered to the return air duct (zone return air node) in Joules or Watts. If an under case return duct is simulated, only a portion of the latent case credits are applied to the HVAC (zone) return air. A negative value (or zero) will be reported since the refrigerated case provides dehumidification (thereby reducing the zone latent load). If the HVAC system is off for a simulation timestep (no return air mass flow), then this latent energy is actually provided to the zone air instead (even though a non-zero value is reported here).

#### **1.35.2.2.19 Refrigeration Case Evaporator Fan Electricity Rate [W]**

This field is the electric power input to the refrigerated case fan(s) in Watts.

#### **1.35.2.2.20 Refrigeration Case Evaporator Fan Electricity Energy [J]**

This field is the electricity consumption of the refrigerated case fan(s) in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Output: Meter objects).

#### **1.35.2.2.21 Refrigeration Case Lighting Electricity Rate [W]**

This field is the electric power input to the refrigerated case lights in Watts.

**1.35.2.2.22 Refrigeration Case Lighting Electricity Energy [J]**

This field is the electricity consumption of the refrigerated case lights in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects).

**1.35.2.2.23 Refrigeration Case Defrost Energy Correction Curve Value**

This field is the output of the Defrost Energy Correction Curve which denotes the variation in defrost energy at off-rated conditions. The output of the defrost energy correction curve directly impacts the energy used during the defrost time period. It does not, however, impact the duration of the defrost period. This output is available only for Electric with Temperature Termination, Hot-Gas with Temperature Termination, or Hot-Brine with Temperature Termination case defrost types.

**1.35.2.2.24 Refrigeration Case Latent Credit Curve Value []**

This field is the output of the Latent Case Credit Curve which denotes the variation in latent case credits at off-rated conditions. The output of the latent case credit curve directly impacts the amount of frost formation on the refrigerated case evaporator coil and the requirement for defrost.

**1.35.2.2.25 Refrigeration Case Anti Sweat Electricity Rate [W]**

This field is the electric power input to the refrigerated case anti-sweat heater in Watts. This output is available unless anti-sweat heater control type is specified as NONE.

**1.35.2.2.26 Refrigeration Case Anti Sweat Electricity Energy [J]**

This field is the total electricity consumption of the refrigerated case anti-sweat heater in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects). This output is available unless anti-sweat heater control type is specified as NONE.

**1.35.2.2.27 Refrigeration Case Defrost Electricity Rate [W]**

This field is the electric power input to the refrigerated case electric defrost heater(s) in Watts. This output is available if case defrost type is Electric or Electric with Temperature Termination.

**1.35.2.2.28 Refrigeration Case Defrost Electricity Energy [J]**

This field is the total electricity consumption of the refrigerated case electric defrost heater(s) in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects). This output is available if case defrost type is Electric or Electric with Temperature Termination.

**1.35.3 Refrigeration:CaseAndWalkInList**

This object provides a list of all the refrigerated cases and/or walk in coolers cooled by a single refrigeration system (ref: Refrigeration:CompressorRack and **Refrigeration:System**). This list is extensible. Note that the names of all cases, walk-ins, air chillers, and caseandwalkinlists must be unique. That is, you cannot give a list the same name as one of the cases. Similarly, a walkin cannot have the same name as a case. This list may contain a combination of case and walk-in names OR a list of air chiller names. Air chillers may not be included in any list that also includes cases or walk-ins.

### 1.35.3.1 Inputs

#### 1.35.3.1.1 Field: Name

A unique user-assigned name for an instance of a CaseAndWalkInList. Any reference to this list by another object will use this name.

#### 1.35.3.1.2 Field: Case or WalkIn or Air Chiller <x> Name

Identifies a particular refrigerated case or walk-in. The name will be validated against the Refrigeration Case, Refrigeration WalkIn, and Air Chiller names (ref: [Refrigeration:Case](#), [Refrigeration:WalkIn](#), and [Refrigeration:AirChiller](#)) in the input file. Up to 20 are provided in the IDD; this object is extensible.

The following is an example input for a CaseAndWalkInList.

```
Refrigeration:CaseAndWalkInList,
  MediumTempCaselist,      !- Name
  UprightDairyCase,        !- Refrigeration Case or WalkIn Name \#1
  LunchmeatCase,          !- Refrigeration Case or WalkIn Name \#2
  MeatWalkIn,             !- Refrigeration Case or WalkIn Name \#3
  DeliCaseOne;            !- Refrigeration Case or WalkIn Name \#4
```

## 1.35.4 Refrigeration:WalkIn

The Refrigeration WalkIn object works in conjunction with a compressor rack, a refrigeration system, or a refrigeration secondary system object (Ref. [Refrigeration:CompressorRack](#), [Refrigeration:System](#), or [Refrigeration:SecondarySystem](#)) to simulate the performance of a walk-in cooler. The walk-in cooler model uses information at rated conditions along with input descriptions for heat transfer surfaces facing multiple zones to determine performance. Energy use for lights, fans, and floor and anti-sweat heaters is modeled based on inputs for nominal power, schedules, and control type. The walk-in cooler model accounts for the sensible and latent heat exchange with the surrounding environment (termed “case credits”) which impacts the temperature and humidity in each zone adjacent to the walk-in.

The walk-in cooler object inputs include a name, an availability schedule name, the rated cooling capacity, the rated operating temperature, the rated cooling source temperature, the rated total heating power and heating power schedule, the rated fan and lighting power and schedules, defrost type, defrost control type, defrost schedule name, drip-down schedule name, defrost power, the portion of the defrost energy used to melt ice (only for temperature termination control type), restocking schedule, refrigerant inventory, and the floor area and U-value.

For each zone adjacent to the walk-in, the user must input the zone name and the insulated surface area and U-value facing that zone. The user must also specify, for two types of doors, the door area, height, U-value, door opening schedule name, and any door opening protection.

Under case HVAC return air fraction, available for refrigerated cases, is not available for walk-in coolers.

#### 1.35.4.1 Field: Name

A unique user-assigned name for an instance of a refrigerated walk-in. Any reference to this walk-in by another object will use this name.

#### 1.35.4.2 Field: Availability Schedule Name

The name of the schedule (ref: [Schedule](#)) that denotes whether the walk in can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the walkin will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the walkin will

operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, walkins require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the default schedule has a value of 1 for all time periods.

#### **1.35.4.3 Field: Rated Coil Cooling Capacity**

The total, full load cooling capacity (sensible plus latent) in watts (W) at rated conditions The value entered for this field must be greater than zero, with no default value.

#### **1.35.4.4 Field: Operating Temperature**

The rated average temperature of the air and products within the walk-in cooler in ° C. The entered value for this field must be less than 20 ° C. There is no default value.

#### **1.35.4.5 Field: Rated Cooling Source Temperature**

For a DX evaporator coil, enter the saturated evaporating temperature in ° C. For a fluid coil, enter the fluid coil entrance temperature in ° C. There is no default value. This number is used, with temperatures for other refrigeration loads on any one system, to set that system's minimum suction pressure or minimum circulating fluid temperature. (This value is not used if the walkin is cooled by a compressor rack object.)

#### **1.35.4.6 Field: Rated Total Heating Power**

The total heating power in watts including all anti-sweat, door, drip-pan, and floor heaters (W). This value is required and has no default value.

#### **1.35.4.7 Field: Heating Power Schedule Name**

The name of the schedule (ref: Schedule) that denotes the fraction of heater power that operates during a given time period. A schedule value of zero denotes that all heaters are off. A schedule value greater than 0 indicates that some portion of the total heater power will operate during that time period (maximum schedule value of 1.0 means all heaters are fully on). For example, if door and floor heaters represent 50% of the total heater power and are on all the time, the minimum schedule value would be 0.5. If anti-sweat heaters represent 40% of the total heater power and are only on during certain hours, the schedule value during those hours would be increased by 0.4. If this field is left blank, the default schedule has a value of 1 for all time periods.

#### **1.35.4.8 Field: Rated Cooling Coil Fan Power**

The cooling coil fan power in watts (W). This value has a default value of 375W. This fan is assumed to run continuously except during electric, hot brine, or hot gas defrost periods.

#### **1.35.4.9 Field: Rated Circulation Fan Power**

The circulation fan power in watts (W). This value has a default value of 0 W. This fan is assumed to run continuously.

#### **1.35.4.10 Field: Rated Total Lighting Power**

The total lighting power in watts including both display and task lighting (W). This value is required and has no default value.

#### 1.35.4.11 Field: Lighting Schedule Name

The name of the schedule (ref: Schedule) that denotes the fraction of walk-in lights that operate during a given time period. A schedule value greater than 0 indicates that the lights will operate during that time period (maximum schedule value of 1.0 means lights are fully on). A schedule value of zero denotes that the lights are off. If this field is left blank, the default schedule has a value of 1 for all time periods.

#### 1.35.4.12 Field: Defrost Type

The type of defrost used for this walk-in. Valid choices are None, Off-Cycle, HotFluid, and Electric. The default defrost type is Electric if the field is blank. HotFluid includes both hot gas and hot brine defrost systems. Refer to the Engineering Reference for further information on how the different defrost types are modeled.

#### 1.35.4.13 Field: Defrost Control Type

The type of defrost control used for this walkin. Valid choices are TimeSchedule and TemperatureTermination. The default is TimeSchedule if the field is blank. Refer to the Engineering Reference for further information on how the different defrost controls are modeled.

#### 1.35.4.14 Field: Defrost Schedule Name

The name of the schedule (ref: Schedule) that denotes when the walkin requires defrosting. A schedule value of 1.0 indicates that defrost will be on during a given time period if the defrost control type is “TimeSchedule”. For the TemperatureTermination defrost control type, the defrost will start with the schedule value changes from 0 to 1, but will end when the ice is melted. A value equal to 0 denotes that the defrost is off. Defrost schedules normally repeat the duration and number of defrost cycles for each day of the year. The walkin manufacturer typically provides this information with the product literature. If TemperatureTermination control type is used, the defrost schedule is used for the defrost cycle start time and the defrost cycle end time is not allowed to extend beyond the scheduled off time. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

#### 1.35.4.15 Field: Defrost Drip-Down Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the walkin requires additional time for draining condensate after the defrost period. A schedule value of 1.0 indicates that the defrost drip-down period is on during a given time period. A value equal to 0 denotes that the defrost drip-down period is over. The walkin manufacturer typically provides this information with the product literature.

Each defrost drip-down period specified in this schedule should start at the same time as the corresponding defrost period specified in the schedule for Defrost Schedule, and the drip-down schedule defrost period should always be longer than or equal to the length of the defrost schedule time period. For example, if the defrost schedule contains a defrost period from 7:00 to 7:15, you would specify a case defrost drip-down period from 7:00 to 7:20 if you wanted to model a 5 minute condensate drip-down period after the regular defrost period. If no drip-down schedule is entered, then the defrost schedule (specified for the previous input field) will be used. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

#### 1.35.4.16 Field: Defrost Power

The defrost power in watts. This input is required for hot-fluid (hot gas or hot brine), or electric defrost types. Walkin manufacturers do not typically provide information on the heat input for hot gas and hot

brine defrost. Information provided for electric defrost power can be substituted here for walkins using hot-gas or hot-brine defrost if other information is not available. Only electric Defrost Types consume electricity during the defrost period. The entered value for this field must be greater than or equal to zero.

#### 1.35.4.17 Field: Temperature Termination Defrost Fraction to Ice

When cooling coils go through a defrost cycle, only a portion of the defrost energy is actually used to melt the ice. The rest of the defrost energy goes to increasing the temperature of the coils themselves and to the walkin environment. The Temperature Termination defrost control type calculates the end of the defrost cycle that corresponds to melting all the ice. Therefore, the user must input this fractional value. The default value is 0.7 for electric defrost and 0.3 for hot fluid defrost. Refer to the Engineering Reference for further information on how the defrost energy control types are modeled.

#### 1.35.4.18 Field: Restocking Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the walkin is being restocked with product. The schedule should contain values in units of Watts (note this is different from the restocking schedule values for cases that are entered per unit length). This field can be used to denote the additional load imposed on the walkin from stocking the walkin with product that is warmer than the walkin temperature. This information is difficult to find and may required additional research for proper modeling; however, this schedule is available for this purpose if desired. If restocking of the refrigerated walkin will not be simulated, enter a schedule with values of zero for all time periods or leave this field blank.

#### 1.35.4.19 Field: Average Refrigerant Charge Inventory

The value of this optional field is the refrigerant inventory present in the walkin during ordinary operation. The value is used to produce an estimate of the total refrigerant present in the refrigeration system. The value is entered in kg.

#### 1.35.4.20 Field: Insulated Floor Surface Area

The floor area in square meters. This value is required and has no default value.

#### 1.35.4.21 Field: Insulated Floor U-Value

The floor thermal transmittance (in  $\text{W}/\text{m}^2\text{-K}$ ). This value has a default value of 0.3154. (This corresponds to R18 in Archaic American Insulation Units. To convert other R-values to thermal transmittance, divide 5.678 by the R-value. For example, R15 is  $0.3785 \text{ W}/\text{m}^2\text{-K}$  and R5 is  $1.136 \text{ W}/\text{m}^2\text{-K}$ .)

***THE REMAINING 12 FIELDS FOR THE WALK-IN COOLER MUST BE REPEATED FOR EACH ZONE WHICH IS IN CONTACT WITH A WALK-IN WALL, CEILING, OR DOOR. The IDD includes fields for 3 zones, but can be extended by repeating the last 12 values in the object.***

#### 1.35.4.22 Field: Zone <x> Name

The name of a zone adjoining the walkin. The walkin will impact the air heat balance in this zone. This zone must represent a conditioned space, that is, it must appear in a **ZoneHVAC:EquipmentConnections** object.

**1.35.4.23 Field: Total Insulated Surface Area Facing Zone <x>**

The total surface area (walls and ceilings) facing this particular zone in square meters. This value is required and has no default value.

**1.35.4.24 Field: Insulated Surface U-Value Facing Zone <x>**

The surface (walls and ceilings) thermal transmittance (in  $\text{W/m}^2\text{-K}$ ). This value has a default value of 0.3154. (This corresponds to R18 in Archaic American Insulation Units. To convert other R-values to thermal transmittance, divide 5.678 by the R-value. For example, R15 is  $0.3785 \text{ W/m}^2\text{-K}$  and R5 is  $1.136 \text{ W/m}^2\text{-K}$ .)

**1.35.4.25 Field: Area of Glass Reach In Doors Facing Zone <x>**

The total area of glass doors facing this particular zone in square meters. The default is 0.0.

**1.35.4.26 Field: Height of Glass Reach In Doors Facing Zone <x>**

The glass reach in door height in meters. The default is 1.5.

**1.35.4.27 Field: Glass Reach In Door U-Value Facing Zone <x>**

The glass door thermal transmittance (in  $\text{W/m}^2\text{-K}$ ). This field has a default value of 1.136. (This corresponds to R5 in Archaic American Insulation Units.)

**1.35.4.28 Field: Glass Reach In Door Opening Schedule Name Facing Zone <x>**

The name of the schedule (ref: Schedule) that denotes the fraction of time glass doors are open during a given time period. The schedule values should be between 0 and 1.0. If no schedule is specified, the doors are assumed to be open 5% of the time (corresponding to a schedule value of 0.05).

**1.35.4.29 Field: Area of Stocking Doors Facing Zone <x>**

The total area of stock doors facing this particular zone in square meters. The default is 0.0.

**1.35.4.30 Field: Height of Stocking Doors Facing Zone <x>**

The stocking door height in meters. The default is 2.0.

**1.35.4.31 Field: Stocking Door U-Value Facing Zone <x>**

The stocking door thermal transmittance (in  $\text{W/m}^2\text{-K}$ ). This value has a default value of 0.3785. (This corresponds to R15 in Archaic American Insulation Units.)

**1.35.4.32 Field: Stocking Door Opening Schedule Name Facing Zone <x>**

The name of the schedule (ref: Schedule) that denotes the fraction of time stocking doors are open during a given time period. The schedule values should be between 0 and 1.0. If no schedule is specified, the doors are assumed to be open 5% of the time (corresponding to a schedule value of 0.05).

### 1.35.4.33 Field: Stocking Door Opening Protection Type Facing Zone <x>

The type of stocking door opening protection used for this walkin. Valid choices are None, AirCurtain, and StripCurtain. The default is AirCurtain if the field is blank. Use the type, StripCurtain, for both hanging strips and airlock vestibules. Refer to the Engineering Reference for further information on how the door protection types are modeled.

The following is an example input for a refrigeration walkin.

```
Refrigeration:WalkIn,
  WalkInFreezer,          !- Name

#### **1.35.5.1 Refrigeration Walk In Evaporator Total Cooling Rate [W]**

This field is the total (sensible plus latent) cooling rate of the WalkIn evaporator coil in Watts.

#### **1.35.5.2 Refrigeration Walk In Evaporator Total Cooling Energy [J]**

This field is the total (sensible plus latent) cooling of the WalkIn evaporator coil in Joules over the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Building (Ref. **Output:Meter** objects).

#### **1.35.5.3 Refrigeration Walk In Evaporator Sensible Cooling Rate [W]**

This field is the sensible cooling rate of the WalkIn evaporator coil in Watts.

#### **1.35.5.4 Refrigeration Walk In Evaporator Sensible Cooling Energy [J]**

This field is the sensible cooling of the WalkIn evaporator coil in Joules over the timestep being reported.

#### **1.35.5.5 Refrigeration Walk In Evaporator Latent Cooling Rate [W]**

This field is the latent cooling (dehumidification) rate of the WalkIn evaporator coil in Watts.

#### **1.35.5.6 Refrigeration Walk In Evaporator Latent Cooling Energy [J]**

This field is the latent cooling (dehumidification) of the WalkIn evaporator coil in Joules over the timestep being reported.

**1.35.5.7 Refrigeration Walk In Ancillary Electricity Rate [W]**

This field is the total electricity (fan, heaters, lights, and electric defrost) used by the walkin in Watts.

**1.35.5.8 Refrigeration Walk In Ancillary Electricity Energy [J]**

This field is the electricity (fan, heaters, lights, and electric defrost) used by the WalkIn in Joules over the timestep being reported.

**1.35.5.9 Refrigeration Walk In Fan Electricity Rate [W]**

This field is the electric power input to the WalkIn fan(s) in Watts.

**1.35.5.10 Refrigeration Walk In Fan Electricity Energy [J]**

This field is the electricity consumption of the WalkIn fan(s) in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. **Output:Meter** objects).

**1.35.5.11 Refrigeration Walk In Lighting Electricity Rate [W]**

This field is the electric power input to the WalkIn lights in Watts.

**1.35.5.12 Refrigeration Walk In Lighting Electricity Energy [J]**

This field is the electricity consumption of the WalkIn lights in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. **Output:Meter** objects).

**1.35.5.13 Refrigeration Walk In Heater Electricity Rate [W]**

This field is the electric power input to the WalkIn heaters in Watts.

**1.35.5.14 Refrigeration Walk In Heater Electricity Energy [J]**

This field is the total electricity consumption of the WalkIn heaters in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. **Output:Meter** objects).

**1.35.5.15 Refrigeration Walk In Defrost Electricity Rate [W]**

This field is the electric power input to the WalkIn electric defrost heater(s) in Watts. This output is available if case defrost type is Electric.

**1.35.5.16 Refrigeration Walk In Defrost Electricity Energy [J]**

This field is the total electricity consumption of the WalkIn electric defrost heater(s) in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. **Output:Meter** objects). This output is available if case defrost type is Electric.

*The following output variables are available for each zone adjacent to the walkin. An output variable identification is created for each zone exchanging energy with the walkin. For example if the walkin,*

*“DairyWalkIn”, were exchanging energy with the zone, “SalesArea”, the output variable identification would be “DairyWalkInInZoneSalesArea”.*

#### 1.35.5.17 Refrigeration Walk In Zone Sensible Cooling Rate [W]

This field is the rate of sensible cooling case credits delivered to the zone in Watts. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

#### 1.35.5.18 Refrigeration Walk In Zone Sensible Cooling Energy [J]

This field is the amount of sensible cooling case credit energy delivered to the zone in Joules. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

#### 1.35.5.19 Refrigeration Walk In Zone Sensible Heating Rate [W]

This field is the rate of sensible heating case credits delivered to the zone in Watts. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

#### 1.35.5.20 Refrigeration Walk In Zone Sensible Heating Energy [J]

This field is the amount of sensible heating case credit energy delivered to the zone in Joules. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

#### 1.35.5.21 Refrigeration Walk In Zone Latent Rate [W]

This field is the rate of latent cooling (dehumidification) case credits delivered to the zone in Watts. A negative value (or zero) will be reported when the WalkIn provides dehumidification (thereby reducing the zone latent load).

#### 1.35.5.22 Refrigeration Walk In Zone Latent Energy [J]

This field is the amount of latent cooling (dehumidification) case credit energy delivered to the zone in Joules. A negative value (or zero) will be reported when the WalkIn provides dehumidification (thereby reducing the zone latent load).

### 1.35.6 Refrigeration:System

The refrigeration system object simulates the performance of a supermarket refrigeration system when used along with other objects to define the refrigeration load(s), the compressor(s), and the condenser.

At least one refrigeration load object must be defined which may be one of four types of load, a refrigerated case, a walk-in cooler, a chiller providing refrigeration to a secondary loop, or a cascade condenser which absorbs heat rejected by a lower-temperature system (Ref. [Refrigeration:Case](#), [Refrigeration:WalkIn](#), [Refrigeration:SecondarySystem](#), and [Refrigeration:Condenser:Cascade](#)) If multiple loads are served by the same system, the user should use one or both of the list objects available to assign loads to the system. The first list includes all cases and walkins cooled directly by this system (Ref. [Refrigeration:CaseAndWalkInList](#)). The second list includes any ‘transfer’ loads, that is refrigeration loads borne by this system that are transferred from another refrigeration system via either a secondary loop chiller or a cascade condenser (Ref. [Refrigeration:TransferLoadList](#), see the Engineering Reference for more information about these types of systems).

The refrigeration system object is capable of modeling both single-stage and two-stage compression refrigeration systems. The name of at least one compressor must be defined and a list object is available if the system is served by more than one compressor (Ref. [Refrigeration:Compressor](#) and [Refrigeration:CompressorList](#)).

Heat is rejected outdoors in a condenser by direct air flow, evaporative water cooling, by a water-cooled condenser with appropriate plant loop piping, or to a cascade condenser cooled by another refrigeration system (ref: [Refrigeration:Condenser:AirCooled](#), [Refrigeration:Condenser:EvaporativeCooled](#), [Refrigeration:Condenser:WaterCooled](#), [Refrigeration:Condenser:Cascade](#)). With evaporative cooling, water is sprayed through the air stream to effectively lower the air temperature experienced by the condenser coil as a result of water evaporation. The use of a water-cooled condenser requires the definition of a plant loop to supply cooling to the condenser. If a cascade condenser is specified, the refrigeration system absorbing the rejected heat must also be defined.

The refrigeration system may also include a liquid suction and/or mechanical subcooler (Ref. [Refrigeration:Subcooler](#)).

The system object coordinates the energy flows between the other refrigeration objects and is used to set system parameters. Compressor waste heat can also be reclaimed for use by an optional air- or water-heating coil (Ref. [Coil:Heating:Desuperheater](#) and [Coil:WaterHeating:Desuperheater](#)).

The inputs for the refrigeration system object, in addition to the names of the other refrigeration objects described above, include a name for this system, the minimum condensing temperature, the refrigeration system working fluid, and the type of saturated suction temperature control. Optional input fields are also provided for users seeking to keep track of refrigerant inventory and suction pipe heat gains.

### 1.35.6.1 Inputs

#### 1.35.6.1.1 Field: Name

A unique user-assigned name for an instance of a refrigeration system. Any reference to this refrigeration system by another object will use this name.

#### 1.35.6.1.2 Field: Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, a single walkin, single air chiller, or a particular list of refrigerated cases and walkins or air chillers, that is cooled by this refrigeration system. The name will be validated against the case, walkin, air chiller and CaseAndWalkInList names (ref: [Refrigeration:Case](#), [Refrigeration:WalkIn](#), [Refrigeration:AirChiller](#), and [Refrigeration:CaseAndWalkInList](#)) in the input file. Only cases and walkins or air chillers served directly by the system should be included in this list. Any cases, walkins, or air chillers served indirectly via a secondary loop should NOT be included in this list. Note that any system that serves an air chiller cannot also serve a case or walkin.

#### 1.35.6.1.3 Field: Refrigeration Transfer Load or TransferLoad List Name

Identifies a single SecondarySystem, a single Cascade Condenser, OR or a list of Transfer Loads (where the list is comprised of SecondarySystems and/or Cascade Condensers) that are cooled by this refrigeration system. The name will be validated against the secondary system, cascade condenser, and TransferLoad list names (ref: [Refrigeration:SecondarySystem](#), [Refrigeration:Condenser:Cascade](#), and [Refrigeration:TransferLoadList](#)) in the input file. Only secondary systems and cascade condensers served directly by the system should be included in this list. (NOTE – this entry is for a cascade condenser *cooled by* this system, not a condenser *absorbing heat rejected by* this system.)

#### 1.35.6.1.4 Field: Condenser Name

The name of the condenser that is used to *reject heat from* this refrigeration system. The name will be validated against the condenser names (ref: [Refrigeration:Condenser:AirCooled](#),

Refrigeration:Condenser:WaterCooled, Refrigeration:Condenser:EvaporativeCooled, and Refrigeration:Condenser:Cascade) in the input file.

#### 1.35.6.1.5 Field: Compressor or Compressor List Name

Identifies a single compressor, or a particular list of compressors, that provide cooling energy to this refrigeration system. The name will be validated against the compressor list names (ref: List:Refrigeration:Compressors) in the input file. If the refrigeration systems contains two stages of compression, this field identifies the low-stage compressors connected to the two-stage system.

#### 1.35.6.1.6 Field: Minimum Condensing Temperature

This numeric field specifies the minimum condensing temperature (C), which is usually determined by the temperature required to maintain acceptable thermal expansion valve performance.

#### 1.35.6.1.7 Field: Refrigeration System Working Fluid Type

The type of refrigerant used by the system. Valid choices are R11, R123, R134A, R12, R22, R404A, R507A, or R410A. This name will be validated against Fluid Names (ref: Fluid Properties section) in the input file. Note that the corresponding property data, available in FluidPropertiesRefData.idf, must be supplied in the input file.

#### 1.35.6.1.8 Field: Suction Temperature Control Type

The type of saturated suction temperature control used by the system. Valid choices are **FloatSuctionTemperature** and **ConstantSuctionTemperature**. If the field is blank, the default will be **ConstantSuctionTemperature**. See the Engineering Reference section, Variable Evaporator Temperature, for a discussion of this option.

#### 1.35.6.1.9 Field: Mechanical Subcooler Name

This optional field identifies a mechanical subcooler that absorbs heat from this refrigeration system. This field should not be used for a mechanical subcooler that absorbs heat from another system. The name will be validated against the subcooler names (ref: Refrigeration:Subcooler) in the input file.

#### 1.35.6.1.10 Field: Liquid Suction Heat Exchanger Subcooler Name

This optional field Identifies a particular liquid suction heat exchanger (LSHX) subcooler present in this refrigeration system. The name will be validated against the subcooler names (ref: Refrigeration:Subcooler) in the input file.

#### 1.35.6.1.11 Field: Sum UA Suction Piping

This optional field is typically used when trying to determine the impact of pipe heat gains on system performance and zone heat balance, particularly in comparing a DX system to a secondary system. Enter the value for suction piping heat gain (in W/C). That is, sum up the product of the pipe wall insulation conductance times the outer surface area of the pipe insulation. Please see the Engineering Reference for guidance in calculating this value. If the Sum UA Suction Piping is entered, the Suction Piping Zone Name is also required.

#### 1.35.6.1.12 Field: Suction Piping Zone Name

This optional field is typically used when trying to determine the impact of pipe heat gains on system performance, particularly in comparing a DX system to a secondary system. (If the previous field, Sum UA Suction Piping, is blank, this field will not be used.) Enter the name of the zone where the suction piping is located. The suction piping heat gains will be calculated based upon the air temperature within this

zone. The heat balance of this zone will also be affected by the piping heat exchange. Additional output variables are described at the end of this “Group-Refrigeration” section for the total impact of refrigeration on zones, including suction pipe heat exchange.

#### 1.35.6.1.13 Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature Rack”). A new meter for reporting is created for each unique subcategory (Ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

#### 1.35.6.1.14 Field: Number of Compressor Stages

This field determines whether the refrigeration system contains one or two stages of compression. In this field, enter either “1” for single-stage compression systems or “2” for two-stage compression systems. If two stages of compression are selected, then an intercooler will be used between the compressor stages to cool the discharge of the low-stage compressors. The default value is “1”.

#### 1.35.6.1.15 Field: Intercooler Type

This field determines the type of intercooler which is used for two-stage compression systems. Valid choices for this field include “None”, “Flash Intercooler” or “Shell-and-Coil Intercooler”. Single-stage systems require “None” while two-stage systems require either “Flash Intercooler” or “Shell-and-Coil Intercooler”. The default selection is “None”, corresponding to a single-stage compression system.

#### 1.35.6.1.16 Field: Shell-and-Coil Intercooler Effectiveness

When a shell-and-coil intercooler is selected for two-stage compression systems, this field allows the specification of the shell-and-coil intercooler effectiveness. Values in this field will only be valid if “Shell-and-Coil Intercooler” is selected in the “Intercooler Type” field above. The valid range of values for this field is between 0.0 and 1.0. A default value of 0.80 will be used if none is specified.

#### 1.35.6.1.17 Field: High-Stage Compressor or CompressorList Name

Identifies a single compressor, or a particular list of compressors, that comprise the high-stage compression of a two-stage compression refrigeration system. The name will be validated against the compressor list names (ref: List:**Refrigeration:Compressors**) in the input file. Names in this field are only valid if two compressor stages have been specified in the “Number of Compressor Stages” field above.

The following is an example input for a single-stage compression refrigeration system.

```
Refrigeration:System,
  MediumTempSystem,      !- Refrigeration System Name
  MediumTempCaselist,    !- Refrigeration Case or Walkin or CaseAndWalkInList Name

### 1.35.6.2 Outputs

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE CASES AND/OR WALKINS:

- Zone,Average, Refrigeration System Total Compressor Electricity Rate [W]
- Zone,Sum, Refrigeration System Total Compressor Electricity Energy [J]
- Zone,Average, Refrigeration System Average Compressor COP [W/W]
- Zone,Average, Refrigeration System Total Compressor Heat Transfer Rate [W]
- Zone,Sum, Refrigeration System Total Compressor Heat Transfer Energy [J]
- Zone,Average, Refrigeration System Total Cases and Walk Ins Heat Transfer Rate [W]
- Zone,Sum, Refrigeration System Total Cases and Walk Ins Heat Transfer Energy [J]
- Zone,Average, Refrigeration System Total Transferred Load Heat Transfer Rate [W]
- Zone,Sum, Refrigeration System Total Transferred Load Heat Transfer Energy [J]
- Zone,Average, Refrigeration System Total Suction Pipe Heat Gain Rate [W]
- Zone,Sum, Refrigeration System Total Suction Pipe Heat Gain Energy [J]
- Zone,Average, Refrigeration System Net Rejected Heat Transfer Rate [W]
- Zone,Sum, Refrigeration System Net Rejected Heat Transfer Energy [J]
- Zone,Average,Refrigeration System Estimated Refrigerant Inventory Mass [kg]
- Zone,Average, Refrigeration System Liquid Suction Subcooler Heat Transfer Rate [W]
- Zone, Sum, Refrigeration System Liquid Suction Subcooler Heat Transfer Energy [J]
- Zone,Average, Refrigeration System Estimated Refrigerant Inventory [kg]
- Zone,Average, Refrigeration System Estimated Refrigerant Mass Flow Rate [kg/s]

- Zone,Average, Refrigeration System Condensing Temperature [C]'
- Zone,Average, Refrigeration System Evaporating Temperature [C]
- Zone,Average, Refrigeration System Suction Pipe Suction Temperature [C]
- Zone,Average, Refrigeration System Thermostatic Expansion Valve Liquid Temperature [C]
- Zone,Average, Refrigeration System Estimated High Stage Refrigerant Mass Flow Rate [kg/s]
- Zone,Sum,Refrigeration System Total High Stage Compressor Electricity Energy [J]
- Zone,Average,Refrigeration System Total High Stage Compressor Electricity Rate [W]
- Zone,Sum,Refrigeration System Total High Stage Compressor Heat Transfer Energy [J]
- Zone,Average,Refrigeration System Total High Stage Compressor Heat Transfer Rate [W]
- Zone,Sum,Refrigeration System Total Low and High Stage Compressor Electricity Energy [J]
- Zone,Sum,Refrigeration System Total Low Stage Compressor Electricity Energy [J]
- Zone,Average,Refrigeration System Total Low Stage Compressor Electricity Rate [W]
- Zone,Sum,Refrigeration System Total Low Stage Compressor Heat Transfer Energy [J]
- Zone,Average,Refrigeration System Total Low Stage Compressor Heat Transfer Rate [W]
- Zone,Average,Refrigeration System Estimated Low Stage Refrigerant Mass Flow Rate [kg/s]

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE AIR CHILLERS:

- HVAC,Average, Refrigeration Air Chiller System Total Compressor Electricity Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Total Compressor Electricity Energy [J]
- HVAC,Average, Refrigeration Air Chiller System Average Compressor COP [W/W]
- HVAC,Average, Refrigeration Air Chiller System Total Compressor Heat Transfer Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Total Compressor Heat Transfer Energy [J]
- HVAC,Average, Refrigeration Air Chiller System Total Air Chiller Heat Transfer Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Total Case and Walk In Heat Transfer Energy [J]
- HVAC,Average, Refrigeration Air Chiller System Total Transferred Load Heat Transfer Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Total Transferred Load Heat Transfer Energy [J]
- HVAC,Average, Refrigeration Air Chiller System Total Suction Pipe Heat Gain Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Total Suction Pipe Heat Gain Energy [J]
- HVAC,Average, Refrigeration Air Chiller System Net Rejected Heat Transfer Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Net Rejected Heat Transfer Energy [J]
- HVAC,Average, Refrigeration Air Chiller System Liquid Suction Subcooler Heat Transfer Rate [W]

- HVAC, Sum, Refrigeration Air Chiller System Liquid Suction Subcooler Heat Transfer Energy [J]
- HVAC,Average, Refrigeration Air Chiller System Estimated Refrigerant Inventory Mass [kg]
- HVAC,Average, Refrigeration Air Chiller System Estimated Refrigerant Mass Flow Rate [kg/s]

- HVAC,Sum,Refrigeration Air Chiller System Total High Stage Compressor Heat Transfer Energy [J]
- HVAC,Average,Refrigeration Air Chiller System Total High Stage Compressor Heat Transfer Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Total Low and High Stage Compressor Electricity Energy [J]
- HVAC,Sum,Refrigeration Air Chiller System Total Low Stage Compressor Electricity Energy [J]
- HVAC,Average,Refrigeration Air Chiller System Total Low Stage Compressor Electricity Rate [W]
- HVAC,Sum, Refrigeration Air Chiller System Total Low Stage Compressor Heat Transfer Energy [J]
- HVAC,Average,Refrigeration Air Chiller System Total Low Stage Compressor Heat Transfer Rate [W]
- HVAC,Average,Refrigeration Air Chiller System Estimated Low Stage Refrigerant Mass Flow Rate [kg/s]

#### 1.35.6.2.1 THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE CASES AND/OR WALKINS

##### 1.35.6.2.2 Refrigeration System Total Compressor Electricity Rate [W]

This output is the total electric power input to the system compressor(s) in Watts.

##### 1.35.6.2.3 Refrigeration System Total Compressor Electricity Energy [J]

This is the electricity consumption of the system's compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.6.2.4 Refrigeration System Total Low Stage Compressor Electricity Rate [W]**

This output is the total electric power input to the system's low-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

**1.35.6.2.5 Refrigeration System Total Low Stage Compressor Electricity Energy [J]**

This is the electricity consumption of the system's low-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

**1.35.6.2.6 Refrigeration System Total High Stage Compressor Electricity Rate [W]**

This output is the total electric power input to the system's high-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

**1.35.6.2.7 Refrigeration System Total High Stage Compressor Electricity Energy [J]**

This is the electricity consumption of the system's high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

**1.35.6.2.8 Refrigeration System Total Low and High Stage Compressor Electricity Energy [J]**

This is the total electricity consumption of the system's low- and high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

**1.35.6.2.9 Refrigeration System Average Compressor COP [W/W]**

This output is the system average compressor COP, the total refrigeration effect divided by the total power to the compressors.

**1.35.6.2.10 Refrigeration System Total Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the Refrigeration Compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as in input value, the suction pipe heat gains are included in this value.

**1.35.6.2.11 Refrigeration System Total Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the Refrigeration Compressor rack in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.6.2.12 Refrigeration System Total Low Stage Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the low-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser

fan heat. If specified as in input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

#### **1.35.6.2.13 Refrigeration System Total Low Stage Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the low-stage compressors in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

#### **1.35.6.2.14 Refrigeration System Total High Stage Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the high-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as in input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

#### **1.35.6.2.15 Refrigeration System Total High Stage Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the high-stage compressors in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

#### **1.35.6.2.16 Refrigeration System Total Cases and Walk Ins Heat Transfer Rate [W]**

This output is the total heat transfer rate from the refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

#### **1.35.6.2.17 Refrigeration System Total Cases and Walk Ins Heat Transfer Energy [J]**

This output is the total heat transfer energy from the refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

#### **1.35.6.2.18 Refrigeration System Total Transferred Load Heat Transfer Rate [W]**

This output is the sum of the heat transfer rates for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing cooling to this system in Watts. Therefore, if the only transfer load between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

**1.35.6.2.19 Refrigeration System Total Transferred Load Heat Transfer Energy [J]**

This output is the sum of the heat transferred for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing cooling to this system in Joules. Therefore, if the only transfer load between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

**1.35.6.2.20 Refrigeration System Total Suction Pipe Heat Gain Rate [W]**

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

**1.35.6.2.21 Refrigeration System Total Suction Pipe Heat Gain Energy [J]**

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

**1.35.6.2.22 Refrigeration System Net Rejected Heat Transfer Rate [W]**

This output is the total heat rejected by this system to the system condenser in Watts. It does not include system heat rejection that has been recovered for useful purposes. However, if a water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

**1.35.6.2.23 Refrigeration System Net Rejected Heat Transfer Energy [J]**

This output is the total heat rejected by this system to the system condenser in Joules for the timestep being reported. It does not include system heat rejection that has been recovered for useful purposes. However, if a water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

**1.35.6.2.24 Refrigeration System Liquid Suction Subcooler Heat Transfer Rate [W]**

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

**1.35.6.2.25 Refrigeration System Liquid Suction Subcooler Heat Transfer Energy [J]**

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

**1.35.6.2.26 Refrigeration System Estimated Refrigerant Inventory Mass [kg]**

This output is the sum of the input inventory values for the condenser, receiver, cases, and liquid pipes that are a part of this system.

**1.35.6.2.27 Refrigeration System Estimated Refrigerant Mass Flow Rate [kg/s]**

This output is the calculated refrigerant mass flow through the compressors for this system.

**1.35.6.2.28 Refrigeration System Estimated Low Stage Refrigerant Mass Flow Rate [kg/s]**

This output is the calculated refrigerant mass flow through the low-stage compressors for this system. This output is valid only for two-stage compression systems.

**1.35.6.2.29 Refrigeration System Estimated High Stage Refrigerant Mass Flow Rate [kg/s]**

This output is the calculated refrigerant mass flow through the high-stage compressors for this system. This output is valid only for two-stage compression systems.

**1.35.6.2.30 Refrigeration System Intercooler Temperature [C]**

This is the saturation temperature in the intercooler. This output is valid only for two-stage compression systems.

**1.35.6.2.31 Refrigeration System Intercooler Pressure [Pa]**

This is the saturation pressure in the intercooler. This output is valid only for two-stage compression systems.

**1.35.6.2.32 Refrigeration System Condensing Temperature [C]**

This is the saturated condensing temperature.

**1.35.6.2.33 Refrigeration System Evaporating Temperature [C]**

This is the saturated evaporating temperature.

**1.35.6.2.34 Refrigeration System Suction Pipe Suction Temperature [C]**

This is the temperature at the compressor inlet including superheat after the cases and superheat from any liquid suction heat exchangers.

**1.35.6.2.35 Refrigeration System Thermostatic Expansion Valve Liquid Temperature [C]**

This is the temperature entering the thermal expansion valve before the cases, equal to the condensing temperature minus any subcooling included in the condenser or provided by mechanical and/or liquid suction heat exchanger subcoolers.

**1.35.6.2.36 THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE AIR CHILLERS****1.35.6.2.37 Refrigeration Air Chiller System Total Compressor Electricity Rate [W]**

This output is the total electric power input to the system compressor(s) in Watts.

**1.35.6.2.38 Refrigeration Chiller System Total Compressor Electricity Energy [J]**

This is the electricity consumption of the system's compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

#### **1.35.6.2.39 Refrigeration Air Chiller System Total Low Stage Compressor Electricity Rate [W]**

This output is the total electric power input to the system's low-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

#### **1.35.6.2.40 Refrigeration Air Chiller System Total Low Stage Compressor Electricity Energy [J]**

This is the electricity consumption of the system's low-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

#### **1.35.6.2.41 Refrigeration Air Chiller System Total High Stage Compressor Electricity Rate [W]**

This output is the total electric power input to the system's high-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

#### **1.35.6.2.42 Refrigeration Air Chiller System Total High Stage Compressor Electricity Energy [J]**

This is the electricity consumption of the system's high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

#### **1.35.6.2.43 Refrigeration Air Chiller System Total Low and High Stage Compressor Electricity Energy [J]**

This is the total electricity consumption of the system's low- and high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

#### **1.35.6.2.44 Refrigeration Air Chiller System Average Compressor COP [W/W]**

This output is the system average compressor COP, the total refrigeration effect divided by the total power to the compressors

#### **1.35.6.2.45 Refrigeration Air Chiller System Total Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the Refrigeration Compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as in input value, the suction pipe heat gains are included in this value.

#### **1.35.6.2.46 Refrigeration Air Chiller System Total Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the Refrigeration Compressor rack in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Energy/Transfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.6.2.47 Refrigeration Air Chiller System Total Low Stage Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the low-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as in input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

**1.35.6.2.48 Refrigeration Air Chiller System Total Low Stage Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the low-stage compressors in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

**1.35.6.2.49 Refrigeration Air Chiller System Total High Stage Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the high-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as in input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

**1.35.6.2.50 Refrigeration Air Chiller System Total High Stage Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the high-stage compressors in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects). This output is valid only for two-stage compression systems.

**1.35.6.2.51 Refrigeration Air Chiller System Total Air Chiller Heat Transfer Rate [W]**

This output is the total heat transfer rate from the refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

**1.35.6.2.52 Refrigeration Air Chiller System Total Case and Walk In Heat Transfer Energy [J]**

This output is the total heat transfer energy from the refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

**1.35.6.2.53 Refrigeration Air Chiller System Total Transferred Load Heat Transfer Rate [W]**

This output is the sum of the heat transfer rates for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing

cooling to this system in Watts. Therefore, if the only transfer load between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

#### **1.35.6.2.54 Refrigeration Air Chiller System Total Transferred Load Heat Transfer Energy [J]**

This output is the sum of the heat transferred for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing cooling to this system in Joules. Therefore, if the only transfer load between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

#### **1.35.6.2.55 Refrigeration Air Chiller System Total Suction Pipe Heat Gain Rate [W]**

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

#### **1.35.6.2.56 Refrigeration Air Chiller System Total Suction Pipe Heat Gain Energy [J]**

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

#### **1.35.6.2.57 Refrigeration Air Chiller System Net Rejected Heat Transfer Rate [W]**

This output is the total heat rejected by this system to the system condenser in Watts. It does not include system heat rejection that has been recovered for useful purposes. However, if a water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

#### **1.35.6.2.58 Refrigeration Air Chiller System Net Rejected Heat Transfer Energy [J]**

This output is the total heat rejected by this system to the system condenser in Joules for the timestep being reported. It does not include system heat rejection that has been recovered for useful purposes. However, if a water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

#### **1.35.6.2.59 Refrigeration Air Chiller System Liquid Suction Subcooler Heat Transfer Rate [W]**

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

**1.35.6.2.60 Refrigeration Air Chiller System Liquid Suction Subcooler Heat Transfer Energy [J]**

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

**1.35.6.2.61 Refrigeration Air Chiller System Mechanical Subcooler Heat Transfer Energy [J]****1.35.6.2.62 Refrigeration Air Chiller System Estimated Refrigerant Inventory Mass [kg]**

This output is the sum of the input inventory values for the condenser, receiver, cases, and liquid pipes that are a part of this system.

**1.35.6.2.63 Refrigeration Air Chiller System Estimated Refrigerant Mass Flow Rate [kg/s]**

This output is the calculated refrigerant mass flow through the compressors for this system.

**1.35.6.2.64 Refrigeration Air Chiller System Estimated Low Stage Refrigerant Mass Flow Rate [kg/s]**

This output is the calculated refrigerant mass flow through the low-stage compressors for this system. This output is valid only for two-stage compression systems.

**1.35.6.2.65 Refrigeration Air Chiller System Estimated High Stage Refrigerant Mass Flow Rate [kg/s]**

This output is the calculated refrigerant mass flow through the high-stage compressors for this system. This output is valid only for two-stage compression systems.

**1.35.6.2.66 Refrigeration Air Chiller System Intercooler Temperature [C]**

This is the saturation temperature in the intercooler. This output is valid only for two-stage compression systems.

**1.35.6.2.67 Refrigeration Air Chiller System Intercooler Pressure [Pa]**

This is the saturation pressure in the intercooler. This output is valid only for two-stage compression systems.

**1.35.6.2.68 Refrigeration Air Chiller System Condensing Temperature [C]**

This is the saturated condensing temperature.

**1.35.6.2.69 Refrigeration Air Chiller System Evaporating Temperature [C]**

This is the saturated evaporating temperature.

**1.35.6.2.70 Refrigeration Air Chiller System Suction Temperature [C]**

This is the temperature at the compressor inlet including superheat after the cases and superheat from any liquid suction heat exchangers.

### 1.35.6.2.71 Refrigeration Air Chiller System TXV Liquid Temperature [C]

This is the temperature entering the thermal expansion valve before the cases, equal to the condensing temperature minus any subcooling included in the condenser or provided by mechanical and/or liquid suction heat exchanger subcoolers.

## 1.35.7 Refrigeration:TranscriticalSystem

The Refrigeration:TranscriticalSystem object allows users to model detailed transcritical carbon dioxide (CO<sub>2</sub>) booster refrigeration systems used in supermarkets. The object allows for modeling either a single stage system with medium-temperature loads or a two stage system with both medium- and low-temperature loads.

The input objects required to model a detailed transcritical CO<sub>2</sub> refrigeration system include the following:

- One Refrigeration:TranscriticalSystem object,
- At least one refrigeration load object which may include any combination of the following:
  - Refrigeration:Case,
  - Refrigeration:WalkIn,
  - Refrigeration:CaseAndWalkInList (may include both cases and/or walk-in cooler names),
- At least one Refrigeration:Compressor object (multiple compressors are entered using a Refrigeration:CompressorList),
- One Refrigeration:GasCooler:AirCooled object,

Output variables are available to describe the total heat exchange between all the refrigeration objects and the zones containing these objects. These variables are described at the end of this section.

At least one refrigeration load object must be defined which may be one of two types of loads, including a refrigerated display case and a walk-in cooler, (Ref. Refrigeration:Case, and Refrigeration:WalkIn). If multiple loads are served by the same system, the user should use the refrigerated case and walk-in list object available to assign all cases and walk-ins cooled directly by this system (Ref. Refrigeration:CaseAndWalkInList).

The name of at least one compressor must be defined and a list object is available if the system is served by more than one compressor (Ref. Refrigeration:Compressor and Refrigeration:CompressorList).

Heat is rejected to the outdoors via an air-cooled gas cooler (Ref. Refrigeration:GasCooler:AirCooled).

The Refrigeration:TranscriticalSystem object coordinates the energy flows between the other refrigeration objects and is used to set system parameters.

The inputs for the refrigeration system object, in addition to the names of the other refrigeration objects described above, include a name for this system, the receiver pressure, the subcooler effectiveness, and the refrigeration system working fluid. Optional input fields are also provided for users seeking to keep track of suction pipe heat gains.

A detailed description of the transcritical CO<sub>2</sub> booster refrigeration system may be found in the Refrigeration section of the Engineering Reference.

### 1.35.7.1 Inputs

#### 1.35.7.1.1 Field: Name

A unique user-assigned name for an instance of a transcritical CO<sub>2</sub> refrigeration system. Any reference to this refrigeration system by another object will use this name.

#### 1.35.7.1.2 Field: System Type

Identifies the transcritical CO<sub>2</sub> refrigeration system as either a single-stage system with only medium-temperature loads, or a two-stage system with both medium- and low-temperature loads. Valid choices are: SingleStage for single stage systems or TwoStage for two stage systems.

#### 1.35.7.1.3 Field: Medium Temperature Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, a single walk-in, or a particular list of refrigerated cases and walk-ins, that is cooled by the medium-temperature stage of the refrigeration system. The name will be validated against the case, walk-in, and CaseAndWalkInList names (Ref. [Refrigeration:Case](#), [Refrigeration:WalkIn](#), and [Refrigeration:CaseAndWalkInList](#)) in the input file. Only medium temperature cases and walk-ins served directly by the system should be included in this list. Note that this entry is required for both single-stage and two-stage systems.

#### 1.35.7.1.4 Field: Low Temperature Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, a single walk-in, or a particular list of refrigerated cases and walk-ins, that is cooled by the low-temperature stage of the refrigeration system. The name will be validated against the case, walk-in, and CaseAndWalkInList names (Ref. [Refrigeration:Case](#), [Refrigeration:WalkIn](#), and [Refrigeration:CaseAndWalkInList](#)) in the input file. Only low temperature cases and walk-ins served directly by the system should be included in this list. Note that this entry is valid only for two-stage systems.

#### 1.35.7.1.5 Field: Refrigeration Gas Cooler Name

The name of the gas cooler that is used to reject heat from the transcritical refrigeration system. The name will be validated against the gas cooler names (Ref. [Refrigeration:GasCooler:AirCooled](#)) in the input file.

#### 1.35.7.1.6 Field: High Pressure Compressor or Compressor List Name

Identifies a single compressor, or a particular list of compressors, that provides compression for a single-stage system or the high pressure stage of a two-stage system. The name will be validated against the compressor list names (Ref. [List:Refrigeration:Compressors](#)) in the input file. Note that this entry is required for both single-stage and two-stage systems.

#### 1.35.7.1.7 Field: Low Pressure Compressor or Compressor List Name

Identifies a single compressor, or a particular list of compressors, that provides compression for the low pressure stage of a two-stage system. The name will be validated against the compressor list names (Ref. [List:Refrigeration:Compressors](#)) in the input file. Note that this entry is valid only for two-stage systems.

#### 1.35.7.1.8 Field: Receiver Pressure

This numeric field specifies the refrigerant pressure (Pa) in the receiver. The default value for the receiver pressure is  $4.0 \times 10^6$  Pa.

#### 1.35.7.1.9 Field: Subcooler Effectiveness

This numeric field specifies the heat exchanger effectiveness of the subcooler. The default value for the subcooler effectiveness is 0.4.

**1.35.7.1.10 Field: Refrigeration System Working Fluid Type**

The type of refrigerant used by the system. It is assumed that carbon dioxide will be the refrigerant used in the transcritical CO<sub>2</sub> refrigeration system. However, the user must specify the name used in the input file which refers to carbon dioxide. This name will be validated against Fluid Names (Ref. Fluid Properties section) in the input file. Note that the corresponding property data for carbon dioxide (R744), available in FluidPropertiesRefData.idf, must be supplied in the input file.

**1.35.7.1.11 Field: Sum UA Suction Piping for Medium Temperature Loads**

This optional field is typically used to determine the impact of pipe heat gains on system performance and zone heat balance. Enter the value for suction piping heat gain (in W/C) for the medium-temperature suction line, i.e., sum up the product of the pipe wall insulation conductance times the outer surface area of the pipe insulation. Please see the Engineering Reference for guidance in calculating this value. If the Sum UA Suction Piping for Medium Temperature Loads is entered, the Medium Temperature Suction Piping Zone Name is also required.

**1.35.7.1.12 Field: Medium Temperature Suction Piping Zone Name**

This optional field is typically used to determine the impact of pipe heat gains on system performance. If the previous field, Sum UA Suction Piping for Medium Temperature Loads, is blank, this field will not be used. Enter the name of the zone where the medium-temperature suction piping is located. The suction piping heat gains will be calculated based upon the air temperature within this zone. The heat balance of this zone will also be affected by the piping heat exchange. Additional output variables are described at the end of this section for the total impact of refrigeration on zones, including suction pipe heat exchange.

**1.35.7.1.13 Field: Sum UA Suction Piping for Low Temperature Loads**

This optional field is typically used to determine the impact of pipe heat gains on system performance and zone heat balance. Enter the value for suction piping heat gain (in W/C) for the low-temperature suction line, i.e., sum up the product of the pipe wall insulation conductance times the outer surface area of the pipe insulation. Please see the Engineering Reference for guidance in calculating this value. If the Sum UA Suction Piping for Low Temperature Loads is entered, the Low Temperature Suction Piping Zone Name is also required. Note that this entry is valid only for two-stage systems.

**1.35.7.1.14 Field: Low Temperature Suction Piping Zone Name**

This optional field is typically used to determine the impact of pipe heat gains on system performance. If the previous field, Sum UA Suction Piping for Low Temperature Loads, is blank, this field will not be used. Enter the name of the zone where the low-temperature suction piping is located. The suction piping heat gains will be calculated based upon the air temperature within this zone. The heat balance of this zone will also be affected by the piping heat exchange. Additional output variables are described at the end of this section for the total impact of refrigeration on zones, including suction pipe heat exchange. Note that this entry is valid only for two-stage systems.

**1.35.7.1.15 Field: End-Use Subcategory**

This field allows the specification of a user-defined end-use subcategory (e.g., “Medium Temperature System”). A new meter for reporting is created for each unique subcategory (Ref. **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

The following is an example input for a transcritical CO<sub>2</sub> refrigeration system.

#### **1.35.7.2.1 Refrigeration Transcritical System Total High Pressure Compressor Electricity Rate [W]**

This output is the total electric power input to the system's high pressure compressor(s) in Watts.

#### **1.35.7.2.2 Refrigeration Transcritical System Total High Pressure Compressor Electricity Energy [J]**

This is the electricity consumption of the system's high pressure compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

#### **1.35.7.2.3 Refrigeration Transcritical System Low Pressure Compressor Electricity Rate [W]**

This output is the total electric power input to the system's low pressure compressor(s) in Watts.

#### **1.35.7.2.4 Refrigeration Transcritical System Low Pressure Compressor Electricity Energy [J]**

This is the electricity consumption of the system's low pressure compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

#### **1.35.7.2.5 Refrigeration Transcritical System Total Compressor Electricity Energy [J]**

This output is the total electric power input to all of the system's compressor(s) in Watts.

**1.35.7.2.6 Refrigeration Transcritical System Average COP [W/W]**

This output is the system average compressor COP, which is the total refrigeration effect divided by the total power to all of the compressors.

**1.35.7.2.7 Refrigeration Transcritical System Medium Temperature Cases and Walk Ins Heat Transfer Rate [W]**

This output is the total heat transfer rate from the medium temperature refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates for the medium temperature refrigerated cases and walk-ins that are connected directly to this system.

**1.35.7.2.8 Refrigeration Transcritical System Medium Temperature Cases and Walk Ins Heat Transfer Energy [J]**

This output is the total heat transfer energy from the medium temperature refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the medium temperature refrigerated cases and walk-ins that are connected directly to this system.

**1.35.7.2.9 Refrigeration Transcritical System Low Temperature Cases and Walk Ins Heat Transfer Rate [W]**

This output is the total heat transfer rate from the low temperature refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates for the low temperature refrigerated cases and walk-ins that are connected directly to this system.

**1.35.7.2.10 Refrigeration Transcritical System Low Temperature Cases and Walk Ins Heat Transfer Energy [J]**

This output is the total heat transfer energy from the low temperature refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the low temperature refrigerated cases and walk-ins that are connected directly to this system.

**1.35.7.2.11 Refrigeration Transcritical System Total Cases and Walk Ins Heat Transfer Energy [J]**

This output is the total heat transfer energy from all the low- and medium-temperature refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for all the refrigerated cases and walk-ins that are connected directly to this system.

**1.35.7.2.12 Refrigeration Transcritical System Medium Temperature Suction Pipe Heat Transfer Rate [W]**

This output is the total heat transfer rate for the medium-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the medium-temperature suction piping heat gain characteristics in the input.

**1.35.7.2.13 Refrigeration Transcritical System Medium Temperature Suction Pipe Heat Transfer Energy [J]**

This output is the total heat transfer rate for the medium-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the medium-temperature suction piping heat gain characteristics in the input.

#### **1.35.7.2.14 Refrigeration Transcritical System Low Temperature Suction Pipe Heat Transfer Rate [W]**

This output is the total heat transfer rate for the low-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the low-temperature suction piping heat gain characteristics in the input.

#### **1.35.7.2.15 Refrigeration Transcritical System Low Temperature Suction Pipe Heat Transfer Energy [J]**

This output is the total heat transfer rate for the low-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the low-temperature suction piping heat gain characteristics in the input.

#### **1.35.7.2.16 Refrigeration Transcritical System High Pressure Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the high pressure Compressors in Watts. It is the sum of all of the heat transfer rates for the low- and medium-temperature refrigerated cases and walk-ins as well as the low pressure compressors that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as in input value, the suction pipe heat gains are included in this value.

#### **1.35.7.2.17 Refrigeration Transcritical System High Pressure Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the high pressure compressors in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

#### **1.35.7.2.18 Refrigeration Transcritical System Low Pressure Compressor Heat Transfer Rate [W]**

This output is the total heat transfer rate of the low pressure Compressors in Watts. It is the sum of all of the heat transfer rates for the low temperature refrigerated cases and walk-ins that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as in input value, the suction pipe heat gains are included in this value.

#### **1.35.7.2.19 Refrigeration Transcritical System Low Pressure Compressor Heat Transfer Energy [J]**

This is the total heat transfer of the low pressure compressors in Joules for the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

#### **1.35.7.2.20 Refrigeration Transcritical System Net Rejected Heat Transfer Rate [W]**

This output is the total heat rejected by this system to the system gas cooler in Watts. It does not include system heat rejection that has been recovered for useful purposes.

#### **1.35.7.2.21 Refrigeration Transcritical System Net Rejected Heat Transfer Energy [J]**

This output is the total heat rejected by this system to the system gas cooler in Joules for the timestep being reported. It does not include system heat rejection that has been recovered for useful purposes.

**1.35.7.2.22 Refrigeration Transcritical System Estimated Refrigerant Inventory Mass [kg]**

This output is the sum of the input refrigerant inventory values for the gas cooler, receiver, cases, and liquid pipes that are a part of this system.

**1.35.7.2.23 Refrigeration Transcritical System Refrigerant Mass Flow Rate [kg/s]**

This output is the calculated refrigerant mass flow rate through the high pressure compressors for this system.

**1.35.7.2.24 Refrigeration Transcritical System Medium Temperature Evaporating Temperature [C]**

This is the saturated evaporating temperature for the medium temperature loads.

**1.35.7.2.25 Refrigeration Transcritical System Medium Temperature Suction Temperature [C]**

This is the temperature at the high pressure compressor inlet including superheat after the display cases and superheat from the suction line heat exchanger.

**1.35.7.2.26 Refrigeration Transcritical System Low Temperature Evaporating Temperature [C]**

This is the saturated evaporating temperature for the low-temperature loads.

**1.35.7.2.27 Refrigeration Transcritical System Low Temperature Suction Temperature [C]**

This is the temperature at the low pressure compressor inlet including superheat after the display cases.

**1.35.8 Refrigeration:Compressor**

The compressors are described here using manufacturer’s data for curves that provide the efficiency, cooling capacity, and power consumption. The corresponding rated values for cycle superheat and subcooling are also required.

A dataset has been provided containing the compressor rating data, including the performance curve inputs, for a large number of compressors. See `RefrigerationCompressor-Curves.idf`.

**1.35.8.1 Inputs****1.35.8.1.1 Field: Name**

A unique user-assigned name for an instance of a compressor. Any reference to this compressor by another object will use this name.

**1.35.8.1.2 Field: Refrigeration Compressor Power Curve Name**

This required field provides the name of the curve object that describes the compressor power as a function of the evaporating and condensing temperatures, as specified in ARI 540. The curve is of the bicubic form(ref: `Curve:Bicubic`). However, the input order for the Energy Plus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.

N3 is ARI C4 and N4 is ARI C3.

N5 is ARI C6 and N6 is ARI C5,

N7 is ARI C7.

N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.

N11 is the Minimum evaporating temperature and N12 is the Maximum evaporating temperature.

N13 is the the Minimum condensing temperature and N14 is the Maximum condensing temperature

#### 1.35.8.1.3 Field: Refrigeration Compressor Capacity Curve Name

This required field provides the name of the curve object that describes the compressor cooling capacity as a function of the evaporating and condensing temperatures, as specified in ARI 540. The curve is of the bicubic form(ref: [Curve:Bicubic](#)). However, the input order for the Energy Plus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.

N3 is ARI C4 and N4 is ARI C3.

N5 is ARI C6 and N6 is ARI C5,

N7 is ARI C7.

N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.

N11 is the Minimum evaporating temperature and N12 is Maximum evaporating temperature.

N13 is the Minimum condensing temperature and N14 is the Maximum condensing temperature

#### 1.35.8.1.4 Field: Rated Superheat

Some manufacturers specify a constant return gas temperature while others specify a constant superheat (the difference between the saturated evaporating temperature and the actual return gas temperature). Use this field for compressors that provide their rated superheat. (Do NOT use both this field and the Rated Return Gas Temperature field.) The rated superheat is specified in units of delta C.

#### 1.35.8.1.5 Field: Rated Return Gas Temperature

Some manufacturers specify a constant return gas temperature ( which may also be called the Rated Suction Temperature) while others specify a constant superheat. Use this field for compressors that provide their rated return gas temperature. (Do NOT use both this field and the Rated Superheat field.) The rated return gas temperature is specified in units of C.

#### 1.35.8.1.6 Field: Rated Liquid Temperature

Some compressor manufactures rate their equipment according to a constant subcooling (the difference between the saturated condensing temperature and the actual liquid temperature entering the thermal expansion valve before the refrigeration load). Other manufacturers specify a constant liquid temperature. Use this field if the manufacturer specifies the rated liquid temperature. (Do NOT use both this field and the Rated Subcooling field.) The units for this field are degrees C.

#### 1.35.8.1.7 Field: Rated Subcooling

Some compressor manufactures rate their equipment according to a constant subcooling (the difference between the saturated condensing temperature and the actual liquid temperature entering the thermal expansion valve before the refrigeration load). Other manufacturers specify a constant liquid temperature. Use this field if the manufacturer specifies the rated subcooling. (Do NOT use both this field and the Rated Liquid Temperature field.) The units for this field are delta C.

### 1.35.8.1.8 Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature System”). A new meter for reporting is created for each unique subcategory (Ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

### 1.35.8.1.9 Field: Mode-of-Operation

The type of mode of operation. Valid choices are **Subcritical** and **Transcritical**. If this input field is blank, the default will be Subcritical. If Transcritical is selected as mode of operation, the next two input fields are required to model transcritical cycle operation electric power consumption and cooling capacity.

### 1.35.8.1.10 Field: Transcritical-Compressor-Power-Curve-Name

This field is the name of the curve object that describes the transcritical operation compressor power as a function of the saturated suction temperature and the gas cooler pressure. The curve is of the bicubic form(ref: **Curve:Bicubic**). However, the input order of the coefficients for the EnergyPlus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.

N3 is ARI C4 and N4 is ARI C3.

N5 is ARI C6 and N6 is ARI C5,

N7 is ARI C7.

N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.

N11 is the Minimum saturated suction temperature.

N12 is the Maximum saturated suction temperature.

N13 is the the Minimum gas cooler pressure and N14 is the Maximum gas cooler pressure.

If **Transcritical** is selected as *Mode of Operation*, then this input field is required.

### 1.35.8.1.11 Field: Transcritical-Compressor-Capacity-Curve-Name

This field is the name of the curve object that describes the transcritical compressor operation cooling capacity as a function of the saturated suction temperature and the gas cooler outlet enthalpy. The curve is of the bicubic form(ref: **Curve:Bicubic**). However, the input order of the coefficients for the EnergyPlus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.

N3 is ARI C4 and N4 is ARI C3.

N5 is ARI C6 and N6 is ARI C5,

N7 is ARI C7.

N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.

N11 is the Minimum saturated suction temperature.

N12 is the Maximum saturated suction temperature.

N13 is the the Minimum gas cooler outlet enthalpy and N14 is the Maximum gas cooler outlet enthalpy.

If **Transcritical** is selected as *Mode of Operation*, then this input field is required.

The following is an example input for a refrigeration compressor.

```
Refrigeration:Compressor,
  CompressorA,           !- Name
  PowerCurveCompA,       !- Refrigeration Compressor Power Curve Name
  CapCurveCompA,         !- Refrigeration Compressor Capacity Curve Name

### 1.35.8.2 Outputs

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE CASES AND/OR WALKINS:

- Zone,Average,Refrigeration Compressor Electricity Rate [W]
- Zone,Sum,Refrigeration Compressor Electricity Energy [J]
- Zone,Average,Refrigeration Compressor Heat Transfer Rate [W]
- Zone,Sum,Refrigeration Compressor Heat Transfer Energy [J]
- Zone,Sum,Refrigeration Compressor Run Time Fraction []

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE AIR CHILLERS:

- HVAC,Average,Refrigeration Air Chiller System Compressor Electricity Rate [W]
- HVAC,Sum,Refrigeration Air Chiller System Compressor Electricity Energy [J]
- HVAC,Average,Refrigeration Air Chiller System Compressor Heat Transfer Rate [W]
- HVAC,Sum,Refrigeration Air Chiller System Compressor Heat Transfer Energy [J]
- HVAC,Average,Refrigeration Chiller Compressor Run TimeFraction []

#### 1.35.8.2.1 THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE CASES AND/OR WALKINS

##### 1.35.8.2.2 Refrigeration Compressor Electricity Rate [W]

This output is the electric power input to the compressor in Watts.

##### 1.35.8.2.3 Refrigeration Compressor Electricity Energy [J]

This is the electric energy consumed by the compressor in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

##### 1.35.8.2.4 Refrigeration Compressor Heat Transfer Rate [W]

This output is the heat removed from the refrigerated cases by the compressor in Watts.

##### 1.35.8.2.5 Refrigeration Compressor Heat Transfer Energy [J]

This is the heat removed from the refrigerated cases by the compressor in Joules for the timestep being reported.

##### 1.35.8.2.6 Refrigeration Compressor Run Time Fraction []

This is the fraction of the time step when the compressor ran to meet the load. It is a value between 0.0 and 1.0.

### 1.35.8.2.7 THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE AIR CHILLERS

#### 1.35.8.2.8 Refrigeration Air Chiller System Compressor Electricity Rate [W]

This output is the electric power input to the compressor in Watts.

#### 1.35.8.2.9 Refrigeration Air Chiller System Compressor Electricity Energy [J]

This is the electric energy consumed by the compressor in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

#### 1.35.8.2.10 Refrigeration Air Chiller System Compressor Heat Transfer Rate [W]

This output is the heat removed from the refrigerated cases by the compressor in Watts.

#### 1.35.8.2.11 Refrigeration Air Chiller System Compressor Heat Transfer Energy [J]

This is the heat removed from the refrigerated cases by the compressor in Joules for the timestep being reported.

#### 1.35.8.2.12 Refrigeration Chiller Compressor Run Time Fraction []

This is the fraction of the time step when the compressor ran to meet the load. It is a value between 0.0 and 1.0.

### 1.35.9 Refrigeration:CompressorList

This object provides a list of all the compressors included within a single refrigeration system (Ref: **Refrigeration:System**). Each list must contain at least one compressor. The order in which the individual compressors are listed here will be the order in which the compressors are dispatched to meet the system load. That is, at very low loads, only compressor #1 will be operating. As the load increases, the first two compressors will be operating, and so on. This list is extensible.

#### 1.35.9.1 Inputs

##### 1.35.9.1.1 Field: Name

A unique user-assigned name for an instance of a compressor list. Any reference to this compressor list by another object will use this name. The compressor list cannot have the same name as any individual compressor.

##### 1.35.9.1.2 Field: Refrigeration Compressor <x> Name

Identifies a particular compressor that works in conjunction with the other compressors on this list to provides cooling to a single refrigeration system. The name will be validated against the compressor names (ref: **Refrigeration:Compressor**) in the input file. Up to 20 are available in the IDD; this object is extensible.

The following is an example input for a compressor list.

```
Refrigeration:CompressorList,
  MediumTempCompressorList, !- Refrigeration Compressor List Name
  CompressorA,              !- Refrigeration Compressor Name \#1
  CompressorB,              !- Refrigeration Compressor Name \#2
  CompressorC;              !- Refrigeration Compressor Name \#3
```

### 1.35.10 Refrigeration:Subcooler

Two types of subcoolers are modeled by the detailed refrigeration system. As described in the Engineering Reference, the liquid suction heat exchanger uses cool suction gas to subcool the hot condensate after it leaves the condenser and before it reaches the thermal expansion valve. For the liquid suction heat exchanger, both the source and sink of energy are located within the same refrigeration system. In contrast, a mechanical subcooler is used to transfer cooling capacity from one refrigeration system to another. The mechanical subcooler is listed as a part of the system for which the condensate is cooled. However, the input data for the mechanical subcooler includes a field that identifies the system that provides the cooling capacity.

#### 1.35.10.1 Inputs

##### 1.35.10.1.1 Field: Name

A unique user-assigned name for an instance of a subcooler. Any reference to this subcooler by another object will use this name.

##### 1.35.10.1.2 Field: Subcooler Type

The type of subcooler. Valid choices are Mechanical and LiquidSuction. If the field is blank, the default will be LiquidSuction.

##### 1.35.10.1.3 Field: Liquid Suction Design Subcooling Temperature Difference

This numeric field is the design subcooling temperature difference (DeltaC) for a liquid suction heat exchanger and should be blank for a mechanical subcooler.

##### 1.35.10.1.4 Field: Design Liquid Inlet Temperature

This numeric field is the design inlet temperature (C) for the hot liquid entering a liquid suction heat exchanger and should be blank for a mechanical subcooler.

##### 1.35.10.1.5 Field: Design Vapor Inlet Temperature

This numeric field is the design inlet temperature (C) for the cool vapor entering a liquid suction heat exchanger and should be blank for a mechanical subcooler.

##### 1.35.10.1.6 Field: Capacity-Providing System

This field is the name of the refrigeration system object that provides the cooling capacity for the mechanical subcooler (ref: [Refrigeration:System](#) Name). This field should be blank for a liquid suction heat exchanger.

##### 1.35.10.1.7 Field: Outlet Control Temperature

This numeric field is the controlled outlet temperature (C) for subcooled liquid exiting a mechanical subcooler. This field should be blank for a liquid suction heat exchanger.

The following is example input for both liquid suction and mechanical subcoolers.

```
REFRIGERATION:SUBCOOLER,
    SampleLSHx,          !Subcooler Name
    LiquidSuction,       !subcooler type
    6,                   !design liquid suction subcooling {deltaC}
    16,                   !design inlet temperature on liquid side {C}
    0,                   !design inlet temperature on vapor side {C}
    ,                    !Refrigeration System Detailed Name providing cooling capacity
    ;                    !Control Temperature Out for subcooled liquid {C}
```

! Mechanical Subcooler (uses Med Temp System to cool low temp liquid to 10C)

```
REFRIGERATION:SUBCOOLER,
    SampleMSC,          !Subcooler Name
    Mechanical,         !subcooler type
    ,                   !design liquid suction subcooling {C}
    ,                   !design inlet temperature on liquid side {C}
    ,                   !design inlet temperature on vapor side {C}
    MediumTempSystem,   !Refrigeration System Detailed Name providing cooling capacity
    10;                 !Control Temperature Out for subcooled liquid {C}
```

---

### 1.35.10.2 Outputs

FOR SUBCOOLERS ON SYSTEMS SERVING CASES AND/OR WALKINS:

- Zone,Average, Refrigeration System Mechanical Subcooler Heat Transfer Rate [W]
- Zone,Sum, Refrigeration System Mechanical Subcooler Heat Transfer Energy [J]

FOR SUBCOOLERS ON SYSTEMS SERVING AIR CHILLERS:

- Zone,Average, Refrigeration Air Chiller System Mechanical Subcooler Heat Transfer Rate [W]
- Zone,Sum, Refrigeration Air Chiller System Mechanical Subcooler Heat Transfer Energy [J]

#### 1.35.10.2.1 FOR SUBCOOLERS ON SYSTEMS SERVING CASES AND/OR WALKINS:

##### 1.35.10.2.2 Refrigeration System Mechanical Subcooler Heat Transfer Rate [W]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Watts.

##### 1.35.10.2.3 Refrigeration System Mechanical Subcooler Heat Transfer Energy [J]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Joules.

#### 1.35.10.2.4 FOR SUBCOOLERS ON SYSTEMS SERVING AIR CHILLERS

##### 1.35.10.2.5 Refrigeration Air Chiller System Mechanical Subcooler Heat Transfer Rate [W]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Watts.

##### 1.35.10.2.6 Refrigeration Air Chiller System Mechanical Subcooler Heat Transfer Energy [J]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Joules.

### 1.35.11 Refrigeration:Condenser:AirCooled

The refrigeration system requires a single condenser to reject the system heat. The air cooled condenser object is one of four options for this condenser. In an air-cooled condenser, the total heat of rejection is characterized by a linear relationship between the difference between the inlet air (usually the outside drybulb) and condensing temperatures. This curve is commonly found in the condenser manufacturers' literature. This rating curve, which corresponds to ARI 460 standards, also has an associated rated value for subcooling that should be entered. The rated condenser fan power and fan speed control type must be specified. If the condenser is not at ground level, the user may specify an air inlet node name (ref: **OutdoorAir:Node** name). If the condenser is located inside a conditioned zone, the zone name may be specified(ref: bbbZoneNamebbb). Optional input is provided to help the user compare refrigerant inventories for different systems. These inputs represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

#### 1.35.11.1 Inputs

##### 1.35.11.1.1 Field: Name

Identifies a particular condenser that rejects heat for a one or more refrigeration system(s). The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser:\*) in the input file, including names used for evaporative-cooled, water-cooled, and cascade-cooled condensers.

##### 1.35.11.1.2 Field: Rated Effective Total Heat Rejection Rate Curve Name

This field is the name of a curve object defining the condenser heat rejection as a function of the difference between the condensing and entering air temperatures. The curve should be linear (**Curve:Linear**). See the Engineering Reference for more discussion on the curve coefficients.

##### 1.35.11.1.3 Field: Rated Subcooling Temperature Difference

This numeric field specifies the rated subcooling (DeltaC) specified by the manufacturer, consistent with the heat rejection curve rating data.

##### 1.35.11.1.4 Field: Condenser Fan Speed Control Type

The type of fan speed control used by the condenser fan. Valid choices are **Fixed**, **FixedLinear**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

##### 1.35.11.1.5 Field: Rated Fan Power

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions.

##### 1.35.11.1.6 Field: Minimum Fan Air Flow Ratio

Fan controls often include a minimum air flow ratio to avoid overheating the fan motor or for other reasons. This numeric field should be between 0. and 1. and has a default value of 0.2.

##### 1.35.11.1.7 Field: Air Inlet Node Name or Zone Name

This optional alpha field contains the name of the node from which the condenser draws its outdoor air or the name of the conditioned zone where the condenser is located. If this field is left blank, the outdoor air drybulb temperature entering the condenser is taken directly from the weather data. If this field is not blank and an outdoor air node name is entered, this node name must also be specified in an **OutdoorAir:Node**

object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data. If a zone name is entered, the temperature of that zone is used.

#### 1.35.11.1.8 Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature Rack”). A new meter for reporting is created for each unique subcategory (Ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

#### 1.35.11.1.9 Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

#### 1.35.11.1.10 Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

#### 1.35.11.1.11 Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

The following is an example input for an air-cooled condenser.

```
Refrigeration:Condenser:AirCooled,

- HVAC,Average, Refrigeration Air Chiller System Condenser Defrost Recovered Heat Transfer Rate [W]
- HVAC, Sum, Refrigeration Air Chiller System Condenser Defrost Recovered Heat Transfer Energy [J]

#### 1.35.11.2.1 FOR CONDENSERS ON SYSTEMS SERVING CASES AND/OR WALKINS:

##### 1.35.11.2.2 Refrigeration System Condenser Fan Electricity Rate [W]

This output is the electric input to the system's condenser fan(s) in Watts.

##### 1.35.11.2.3 Refrigeration System Condenser Fan Electric Consumption [J]

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

##### 1.35.11.2.4 Refrigeration System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

##### 1.35.11.2.5 Refrigeration System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

**1.35.11.2.6 Refrigeration System Condenser Total Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating.

**1.35.11.2.7 Refrigeration System Condenser Total Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating for the timestep being reported.

**1.35.11.2.8 Refrigeration System Condenser Non Refrigeration Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

**1.35.11.2.9 Refrigeration System Condenser Non Refrigeration Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

**1.35.11.2.10 Refrigeration System Condenser Defrost Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system.

**1.35.11.2.11 Refrigeration System Condenser Defrost Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

**1.35.11.2.12 FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:****1.35.11.2.13 Refrigeration Air Chiller System Condenser Fan Electricity Rate [W]**

This output is the electric input to the system's condenser fan(s) in Watts.

**1.35.11.2.14 Refrigeration Air Chiller System Condenser Fan Electricity Energy [J]**

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

**1.35.11.2.15 Refrigeration Air Chiller System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

**1.35.11.2.16 Refrigeration Air Chiller System Condenser Heat Transfer Energy [J]**

This is the total heat energy flowing across the condenser for the timestep being reported (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

**1.35.11.2.17 Refrigeration Air Chiller System Condenser Total Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating.

**1.35.11.2.18 Refrigeration Air Chiller System Condenser Total Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating for the timestep being reported.

**1.35.11.2.19 Refrigeration Air Chiller System Condenser Non Refrigeration Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

**1.35.11.2.20 Refrigeration Air Chiller System Condenser Non Refrigeration Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

**1.35.11.2.21 Refrigeration Air Chiller System Condenser Defrost Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system.

**1.35.11.2.22 Refrigeration Air Chiller System Condenser Defrost Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

**1.35.12 Refrigeration:Condenser:EvaporativeCooled**

Each refrigeration system requires a single condenser. The evaporative cooled condenser object is one of four options for this condenser. In an evaporative-cooled condenser, the total heat of rejection is characterized by a four-factor relationship between the condensing temperature and the difference between the outside wetbulb and condensing temperatures. This curve must be developed by regression from the condenser manufacturers' literature. This rating curve, which is based upon rated data taken according to ARI 460 standards, also has an associated rated value for subcooling that should be entered. The rated condenser fan power and fan speed control type must be specified. If the condenser is not at ground level, the user may specify an air inlet node name (ref: [OutdoorAir:Node](#) name). Optional input is provided to help the user compare refrigerant inventories for different systems. These input represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Additional inputs are needed for basin heater parameters, water pump power, and water source. An evaporative cooling availability schedule is available.

**1.35.12.1 Inputs****1.35.12.1.1 Field: Name**

Identifies a particular condenser that rejects heat for a one or more refrigeration system(s). The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser:\*) in the input file, including names used for air-cooled, water-cooled and cascade-cooled condensers.

#### 1.35.12.1.2 Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W) at standard rating conditions per ARI 490. Be sure the rating corresponds to the correct refrigerant.

#### 1.35.12.1.3 Field: Rated Subcooling Temperature Difference

This numeric field specifies the rated subcooling (DeltaC) specified by the manufacturer, consistent with the rated value for total heat rejection.

#### 1.35.12.1.4 Field: Fan Speed Control Type

The type of fan speed control used by the condenser fan. Valid choices are **Fixed**, **FixedLinear**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

#### 1.35.12.1.5 Field: Rated Fan Power

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions.

#### 1.35.12.1.6 Field: Minimum Fan Air Flow Ratio

Fan controls often include a minimum air flow ratio to avoid overheating the fan motor or for other reasons. This numeric field has a minimum value of 0. and a default value of 0.2.

#### 1.35.12.1.7 Field: Approach Temperature Constant Term

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where  $T_{wetbulb}$  and  $T_{condense}$  are in C):

$$T_{condense} = A1 + A2(hrcf) + A3/(hrcf) + (1 + A4)(T_{wb})$$

This numeric field is the value for A1 and has a default value of 6.63, a minimum of 0. and a maximum of 20. (C)

#### 1.35.12.1.8 Field: Approach Temperature Coefficient 2

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where  $T_{wetbulb}$  and  $T_{condense}$  are in C):

$$T_{condense} = A1 + A2(hrcf) + A3/(hrcf) + (1 + A4)(T_{wb})$$

This numeric field is the value for A2 and has a default value of 0.468, a minimum of 0, and a maximum of 20 (C).

#### 1.35.12.1.9 Field: Approach Temperature Coefficient 3

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where  $T_{wetbulb}$  and  $T_{condense}$  are in C):

$$T_{condense} = A1 + A2(hrcf) + A3/(hrcf) + (1 + A4)(T_{wb})$$

This numeric field is the value for A3 and has a default value of 17.93, a minimum of 0, and a maximum of 30 (C).

**1.35.12.1.10 Field: Approach Temperature Coefficient 4**

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$T_{\text{condense}} = A1 + A2(\text{hrf}) + A3/(\text{hrf}) + (1 + A4)(T_{\text{wb}})$$

This numeric field is the value for A4 and has a default value of -0.322, a minimum of -20., and a maximum of 20 (dimensionless).

**1.35.12.1.11 Field: Minimum Capacity Factor**

This numeric field is the minimum heat rejection capacity factor in the manufacturer's data used to develop the equation described in the preceding four fields. The default value is 0.5.

**1.35.12.1.12 Field: Maximum Capacity Factor**

This numeric field is the maximum heat rejection capacity factor in the manufacturer's data used to develop the equation described in the preceding four fields. The default value is 5.0.

**1.35.12.1.13 Field: Air Inlet Node Name**

This optional alpha field contains the name of the node from which the condenser draws its outdoor air. If this field is left blank, the outdoor air drybulb temperature entering the condenser is taken directly from the weather data. If this field is not blank, this node name must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

**1.35.12.1.14 Field: Rated Air Flow Rate**

The air volume flow rate, in m<sup>3</sup>per second, entering the evaporative condenser. This value is used to calculate the amount of water evaporated when evaporatively cooling the condenser inlet air. The value for this field must be greater than zero. This input field is also autocalculatable, equivalent to 0.000144 m<sup>3</sup>/s per watt of total cooling capacity [850 cfm/ton] where the total cooling capacity is the total heat of rejection.

**1.35.12.1.15 Field: Basin Heater Capacity**

This field defines the power level of the basin heater, if applicable, used to avoid water freezing in an outdoor evaporative cooler basin. This numeric field contains the capacity of the electric basin heater in Watts per degree C. This field is used in conjunction with the Basin Heater Set Point Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the dry-bulb temperature of the condenser coil inlet air. The basin heater only operates when the condenser fan is off (i.e., no compressor heat rejection). The basin heater capacity must be greater than or equal to zero, with a default value of 200 W/C if this field is left blank.

**1.35.12.1.16 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this set point temperature, as long as the condenser fan is off. The default value is 2°C if this field is left blank.

**1.35.12.1.17 Field: Rated Water Pump Power**

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The value for this field must be greater than or equal to 0, with a default value of 1000 Watts if this field is left blank. This input field is also autocalculatable, equivalent to 0.004266 W per Watt [15 W/ton] of total cooling capacity.

**1.35.12.1.18 Field: Evaporative Water Supply Tank Name**

This field is used to define where the condenser obtains water used for evaporative cooling. If this field is left blank, the unit will obtain water directly from the mains (Ref. Water Mains Temperatures). If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank.

**1.35.12.1.19 Field: Evaporative Condenser Availability Schedule Name**

For evaporative cooled condensers, the name of the optional schedule (Ref: Schedule) that specifies the time periods that evaporative cooling is available/unavailable. In some colder climates, evaporative cooling is periodically discontinued and the basin sumps drained to avoid freezing and to avoid ice formation on the condenser. In these times, the condenser runs as a typical dry air cooled condenser, and related evaporative cooling systems (e.g., water pump, basin heaters) do not operate. Use of this optional schedule permits modeling of planned, seasonal interruptions of evaporative cooling. All schedule values must be greater than or equal to zero. Typically, an ON/OFF schedule type is used with values being either 0 or 1. A schedule value of 1 indicates that evaporative cooling is available during the defined time period, and a value of 0 denotes that evaporative cooling is not available during the defined time period. If the schedule name is omitted (blank), then the model assumes that evaporative cooling of the condenser is available for the entire simulation period. Note: the use of this schedule is the correct way to model an evaporative condenser in a climate subject to freezing weather. However, because some users will take a single model description and run it for a multiple climates, the code also includes an automatic switch from wet to dry operation, as described in the Engineering Reference.

**1.35.12.1.20 Field: End-Use Subcategory**

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature Rack”). A new meter for reporting is created for each unique subcategory (Ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

**1.35.12.1.21 Field: Condenser Refrigerant Operating Charge Inventory**

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

**1.35.12.1.22 Field: Condensate Receiver Refrigerant Inventory**

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

**1.35.12.1.23 Field: Condensate Piping Refrigerant Inventory**

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

The following is an example input for an evaporative condenser

**1.35.12.2.1 FOR CONDENSERS ON SYSTEMS SERVING CASES AND/OR WALKINS:****1.35.12.2.2 Refrigeration System Condenser Fan Electricity Rate [W]**

This output is the electric input to the system's condenser fan(s) in Watts.

**1.35.12.2.3 Refrigeration System Condenser Fan Electricity Energy [J]**

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.12.2.4 Refrigeration System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

**1.35.12.2.5 Refrigeration System Condenser Heat Transfer Energy [J]**

This is the total heat energy flowing across the condenser for the timestep being reported.

**1.35.12.2.6 Refrigeration System Condenser Total Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose.

**1.35.12.2.7 Refrigeration System Condenser Total Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose for the timestep being reported.

**1.35.12.2.8 Refrigeration System Condenser Non Refrigeration Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for purposes such as water or air heating.

**1.35.12.2.9 Refrigeration System Condenser Heat Recovered for Non-Refrigeration Purposes Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for purposes such as water or air heating for the timestep being reported.

**1.35.12.2.10 Refrigeration System Condenser Defrost Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for defrost purposes within the refrigeration system..

**1.35.12.2.11 Refrigeration System Condenser Defrost Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

**1.35.12.2.12 Refrigeration System Condenser Pump Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the condenser.

**1.35.12.2.13 Refrigeration System Condenser Pump Electricity Energy [J]**

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

**1.35.12.2.14 Refrigeration System Condenser Basin Heater Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the condenser.

**1.35.12.2.15 Refrigeration System Condenser Basin Heater Electricity Energy [J]**

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional

subkey category is also available, with default to the General end-use subcategory (Ref. Output: Meter objects).

#### **1.35.12.2.16 Refrigeration System Condenser Evaporated Water Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate in m<sup>3</sup>/s of water consumed while providing evaporative cooling of the condenser.

#### **1.35.12.2.17 Refrigeration System Condenser Evaporated Water Volume [m<sup>3</sup>]**

This is the water consumed by evaporation in m<sup>3</sup> while providing evaporative cooling of the condenser for the timestep being reported. This output is also added to a meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output: Meter objects).

#### **1.35.12.2.18 FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:**

#### **1.35.12.2.19 Refrigeration Air Chiller System Condenser Fan Electricity Rate [W]**

This output is the electric input to the system's condenser fan(s) in Watts.

#### **1.35.12.2.20 Refrigeration Air Chiller System Condenser Fan Electricity Energy [J]**

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

#### **1.35.12.2.21 Refrigeration Air Chiller System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

#### **1.35.12.2.22 Refrigeration Air Chiller System Condenser Heat Transfer Energy [J]**

This is the total heat energy flowing across the condenser for the timestep being reported.

#### **1.35.12.2.23 Refrigeration Air Chiller System Condenser Total Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose.

#### **1.35.12.2.24 Refrigeration Air Chiller System Condenser Total Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose for the timestep being reported.

#### **1.35.12.2.25 Refrigeration Air Chiller System Condenser Non Refrigeration Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for purposes such as water or air heating.

#### **1.35.12.2.26 Refrigeration Air Chiller System Condenser Non Refrigeration Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for purposes such as water or air heating for the timestep being reported.

#### **1.35.12.2.27 Refrigeration Air Chiller System Condenser Defrost Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for defrost purposes within the refrigeration system.

#### **1.35.12.2.28 Refrigeration Air Chiller System Condenser Defrost Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

#### **1.35.12.2.29 Refrigeration Air Chiller System Condenser Pump Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the condenser.

#### **1.35.12.2.30 Refrigeration Air Chiller System Condenser Pump Electricity Energy [J]**

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.12.2.31 Refrigeration Air Chiller System Condenser Basin Heater Electricity Rate [W]**

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the condenser.

#### **1.35.12.2.32 Refrigeration Air Chiller System Condenser Basin Heater Electricity Energy [J]**

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the condenser for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

#### **1.35.12.2.33 Refrigeration Air Chiller System Condenser Evaporated Water Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate in m<sup>3</sup>/s of water consumed while providing evaporative cooling of the condenser.

#### 1.35.12.2.34 Refrigeration Air Chiller System Condenser Evaporated Water Volume [m3]

This is the water consumed by evaporation in m<sup>3</sup> while providing evaporative cooling of the condenser for the timestep being reported. This output is also added to a meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter objects).

### 1.35.13 Refrigeration:Condenser:WaterCooled

The refrigeration system requires a single condenser. The water cooled condenser object is one of four options for this condenser. Manufacturer's data is required for the rated total heat rejection, the rated condensing temperature, and the rated leaving liquid refrigerant temperature, all per ARI 450. These values are used to calculate the subcooling included in the rated capacity. The inlet and outlet node names as well as the water outlet temperature schedule name are required. Optional input is provided to help the user compare refrigerant inventories for different systems. These input represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

#### 1.35.13.1 Inputs

##### 1.35.13.1.1 Field: Name

Identifies a particular condenser that rejects heat for one or more refrigeration system(s). The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser) in the input file, including names used for air-cooled, evaporative-cooled, and cascade-cooled condensers.

##### 1.35.13.1.2 Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W) at standard rating conditions per ARI 450. Be sure the rating corresponds to the correct refrigerant.

##### 1.35.13.1.3 Field: Rated Condensing Temperature

This numeric field provides the rated condensing temperature (C) corresponding to the rated heat rejection capacity.

##### 1.35.13.1.4 Field: Rated Subcooling Temperature Difference

This numeric field provides the rated liquid refrigerant subcooling (DeltaC) corresponding to the rated heat rejection capacity. Note this is equal to the difference between the saturated condensing temperature and the leaving liquid refrigerant temperature.

##### 1.35.13.1.5 Field: Rated Water Inlet Temperature

This numeric field provides the rated water inlet temperature (C) corresponding to the rated heat rejection capacity at the rated condensing temperature.

##### 1.35.13.1.6 Field: Water Inlet Node Name

A node name for the water-side condenser inlet must be provided.

##### 1.35.13.1.7 Field: Water Outlet Node Name

A node name for the water-side condenser outlet must be provided.

#### 1.35.13.1.8 Field: Water-Cooled Loop Flow Type

The type of flow loop should be specified. The two choices are **VariableFlow**, in which a **Pump:VariableSpeed** must be included in the plant loop, or **ConstantFlow**, in which the loop circuit has a constant flow rate, typically associated with a **Pump:ConstantSpeed** object. If the flow type is **VariableFlow**, the flow needed to remove the condenser heat energy will be calculated and requested of the pump. If the flow type is **ConstantFlow**, the outlet water temperature will be determined based on the fixed loop flow rate and heat energy to be removed. The default type is **VariableFlow**. Refer to additional discussion in the Engineering Reference.

#### 1.35.13.1.9 Field: Water Outlet Temperature Schedule Name

When the water-cooled loop flow type is “**VariableFlow**”, the name of a schedule (Ref: Schedule) that defines the desired condenser water outlet temperature must be provided. The schedule may define an outlet temperature that varies through time.

#### 1.35.13.1.10 Field: Water Design Flow Rate

When the water-cooled loop flow type is “**ConstantFlow**”, this is the design water flow rate in  $\text{m}^3/\text{s}$  that will be requested initially. This requested flow will be passed to the loop simulation, and resulting actual flow will be dependent upon supply system capabilities (e.g., pump capability). The design flow rate must always be less than the maximum flow rate, defined below.

#### 1.35.13.1.11 Field: Water Maximum Flow Rate

This numeric field is the maximum water flow rate in  $\text{m}^3/\text{s}$  that will be allowed through the condenser. When the loop flow type is **Variable Flow**, if the calculated flow rate is higher than the maximum flow rate, an error message will be generated, and the flow rate will be reset to the maximum flow rate.

#### 1.35.13.1.12 Field: Maximum Water Outlet Temperature

This numeric field specifies the maximum allowed water temperature in degrees C leaving the condenser. The default value is 55 degrees C.

#### 1.35.13.1.13 Field: Minimum Water Inlet Temperature

This numeric field specifies the minimum allowed water temperature in degrees C entering the compressor rack condenser. The default value is 10 degrees C. Refer to additional discussion in the Engineering Reference.

#### 1.35.13.1.14 Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature System”). A new meter for reporting is created for each unique subcategory (Ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

#### 1.35.13.1.15 Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

#### 1.35.13.1.16 Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

**1.35.13.1.17 Field: Condensate Piping Refrigerant Inventory**

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

The following is an example input for a water cooled condenser.

```
Refrigeration:Condenser:WaterCooled,
    MediumTempCondenser ,      !- Name
    58000. ,                    !- Rated Effective Total Heat Rejection Rate {W}

#### **1.35.13.2.1 FOR CONDENSERS ON SYSTEMS SERVING CASES AND/OR WALKINS:**

##### **1.35.13.2.2 Refrigeration System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

##### **1.35.13.2.3 Refrigeration System Condenser Heat Transfer Energy [J]**

This is the total heat energy flowing across the condenser for the timestep being reported.

##### **1.35.13.2.4 Refrigeration System Condenser Total Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose.

##### **1.35.13.2.5 Refrigeration System Condenser Total Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose for the timestep being reported.

##### **1.35.13.2.6 Refrigeration System Condenser Non Refrigeration Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

##### **1.35.13.2.7 Refrigeration System Condenser Heat Recovered for Non-Refrigeration Purposes Energy [J]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

##### **1.35.13.2.8 Refrigeration System Condenser Defrost Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system..

##### **1.35.13.2.9 Refrigeration System Condenser Heat Energy Recovered for Refrigeration Defrost Energy [J]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

**1.35.13.2.10 Refrigeration System Condenser Water Mass Flow Rate [kg/s]**

This is the mass flow rate of the water used to cool the condenser in kg/s.

**1.35.13.2.11 FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:****1.35.13.2.12 Refrigeration Air Chiller System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

**1.35.13.2.13 Refrigeration Air Chiller System Condenser Heat Transfer Energy [J]**

This is the total heat energy flowing across the condenser for the timestep being reported.

**1.35.13.2.14 Refrigeration Air Chiller System Condenser Total Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose.

**1.35.13.2.15 Refrigeration Air Chiller System Condenser Total Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose for the timestep being reported.

**1.35.13.2.16 Refrigeration Air Chiller System Condenser Non Refrigeration Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

**1.35.13.2.17 Refrigeration Air Chiller System Condenser Non Refrigeration Recovered Heat Transfer Energy [J]**

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

**1.35.13.2.18 Refrigeration Air Chiller System Condenser Defrost Recovered Heat Transfer Rate [W]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system.

**1.35.13.2.19 Refrigeration Chiller System Condenser Heat Energy Recovered for Refrigeration Defrost Energy [J]**

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

**1.35.13.2.20 Refrigeration Air Chiller System Condenser Fluid Mass Flow Rate [kg/s]**

This is the mass flow rate of the water used to cool the condenser in kg/s.

### 1.35.14 Refrigeration:Condenser:Cascade

The refrigeration system requires a single condenser. The cascade condenser object is one of four options for this condenser. The cascade condenser is unlike the other condenser options because it rejects heat to another, higher-temperature, refrigeration system. That is, the cascade condenser acts as a heat rejection object for one system, but acts as a refrigeration load for another system. Therefore, this object will be referenced twice: first for the system rejecting heat (see the field Refrigeration Condenser Name for the object **Refrigeration:System**), and second for the system absorbing the heat (see the input for the field Refrigeration Transfer Load or TransferLoad List Name for the object **Refrigeration:System** or the field Cascade Condenser Name or Secondary System Name for the object **Refrigeration:TransferLoadList**).

Manufacturer's data is required for the rated condensing temperature and the rated approach temperature difference. The user must also specify the condensing temperature control type. There are two choices. The user can specify "Fixed" and the condensing temperature will be held constant at the input value. The user can specify "Float" if they want the condensing temperature to be set by other refrigeration loads served by the higher-temperature system.

The rated heat rejection capacity is not used except as a rough input value check on the overall system sizing. Optional input is provided to help the user compare refrigerant inventories for different systems. These inputs represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

#### 1.35.14.1 Inputs

##### 1.35.14.1.1 Field: Name

Identifies a particular condenser that rejects heat for a single refrigeration system. The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser:\*) in the input file, including names used for air-cooled, evaporative-cooled, and water-cooled condensers.

##### 1.35.14.1.2 Field: Rated Condensing Temperature

This numeric field provides the rated condensing temperature (C).

##### 1.35.14.1.3 Field: Rated Approach Temperature Difference

This numeric field provides the rated difference (Delta C) between the saturated condensing temperature for the system rejecting heat and the saturated evaporating refrigerant temperature for the system absorbing heat. The default value is 3.0 C.

##### 1.35.14.1.4 Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W). Be sure the rating corresponds to the correct refrigerant(s). This value is used for system sizing error checking.

##### 1.35.14.1.5 Field: Condensing Temperature Control Type

The type of control used to set the saturated condensing temperature. Valid choices are **Fixed** and **Float**. If the field is blank, **Fixed** will be used. Fixed will hold the condensing temperature constant at the value specified. **Float** will consider the specified input as a minimum condensing temperature. This value will be compared to the evaporating temperatures required by other loads on the higher-temperature refrigeration system, and will use the lowest temperature required to meet those loads, along with the Approach Temperature Difference, to set the condensing temperature.

**1.35.14.1.6 Field: Condenser Refrigerant Operating Charge Inventory**

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions. This refrigerant is on the side of the condenser rejecting heat, not on the side of the condenser absorbing the heat.

**1.35.14.1.7 Field: Condensate Receiver Refrigerant Inventory**

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

**1.35.14.1.8 Field: Condensate Piping Refrigerant Inventory**

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

The following is an example input for a cascade condenser.

```
Refrigeration:Condenser:Cascade,
  CascadeCondenser1 ,      !- Name
  -4. ,                    !- Rated Condensing Temperature {C}
  3. ,                     !- Rated Approach Temperature Difference {DeltaC}
  20000.0 ,                 !- Rated Effective Total Heat Rejection Rate {W}
  Fixed;                   !- Condensing Temperature Control Type
```

**1.35.14.2 Outputs**

FOR CONDENSERS COOLING SYSTEMS SERVING CASES AND/OR WALKINS:

- Zone,Average, Refrigeration System Condenser Heat Transfer Rate [W]
- Zone, Sum, Refrigeration System Condenser Heat Transfer Energy [J]

FOR CONDENSERS COOLING SYSTEMS SERVING AIR CHILLERS:

- HVAC,Average, Refrigeration Air Chiller System Condenser Heat Transfer Rate [W]
- HVAC, Sum, Refrigeration Air Chiller System Condenser Heat Transfer Energy [J]

**1.35.14.2.1 FOR CONDENSERS ON SYSTEMS SERVING CASES AND/OR WALKINS:****1.35.14.2.2 Refrigeration System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

**1.35.14.2.3 Refrigeration System Condenser Heat Transfer Energy [J]**

This is the total heat energy flowing across the condenser for the timestep being reported.

**1.35.14.2.4 FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:****1.35.14.2.5 Refrigeration Air Chiller System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

**1.35.14.2.6 Refrigeration Air Chiller System Condenser Heat Transfer Energy [J]**

This is the total heat energy flowing across the condenser for the timestep being reported.

**1.35.15 Refrigeration:GasCooler:AirCooled**

The transcritical refrigeration system requires a single gas cooler to reject the system heat. The total heat of rejection is characterized by a linear relationship between the difference between the outside dry-bulb and gas cooler outlet temperatures. The rated gas cooler fan power and fan speed control type must be specified. If the gas cooler is not at ground level, the user may specify an air inlet node name (Ref. **OutdoorAir:Node** name). Optional input is provided to help the user track refrigerant inventories. These inputs represent the design values for the refrigerant inventory within the gas cooler, within a receiver, and in the liquid pipes between the gas cooler and the refrigerated cases.

**1.35.15.1 Inputs****1.35.15.1.1 Field: Name**

Identifies a particular gas cooler that rejects heat for a single refrigeration system. The name must be unique and will be validated against all the gas cooler names (Ref. **Refrigeration:GasCooler:AirCooled**) in the input file.

**1.35.15.1.2 Field: Rated Total Heat Rejection Rate Curve Name**

This field is the name of a curve object defining the gas cooler heat rejection as a function of the difference between the gas cooler outlet and entering air temperatures. The curve should be linear (**Curve:Linear**). See the Engineering Reference for more discussion on the curve coefficients.

**1.35.15.1.3 Field: Gas Cooler Fan Speed Control Type**

The type of fan speed control used by the gas cooler fan. Valid choices are Fixed, FixedLinear, VariableSpeed, and TwoSpeed. If the field is blank, Fixed will be used. Note that fan energy consumption for the air-cooled gas cooler is computed in the same way as that of the air-cooled condenser. For further information on fan energy calculations, see the discussion regarding air-cooled condenser fan energy in the Engineering Reference.

**1.35.15.1.4 Field: Rated Fan Power**

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions. If this field is blank, the default value of 5000 W will be used

**1.35.15.1.5 Field: Minimum Fan Air Flow Ratio**

Fan controls often include a minimum air flow ratio to avoid overheating the fan motor or for other reasons. This numeric field should be between 0. and 1. and has a default value of 0.2.

**1.35.15.1.6 Field: Transition Temperature**

This is the temperature (C) at which the gas cooler and the refrigeration system transitions between subcritical and transcritical operation. If this field is blank, the default value of 27.0°C will be used.

**1.35.15.1.7 Field: Transcritical Approach Temperature**

This is the temperature difference (C) between the refrigerant (CO<sub>2</sub>) exiting the gas cooler and the air entering the gas cooler during transcritical operation. If this field is blank, the default value of 3.0°C will be used.

### 1.35.15.1.8 Field: Subcritical Temperature Difference

This is the temperature difference (C) between the condensing temperature and the ambient air temperature during subcritical operation. If this field is blank, the default value of 10.0°C will be used.

**Field: Minimum Condensing Temperature**

This numeric field specifies the minimum condensing temperature (C) required to maintain stable subcritical operation. If this field is blank, the default value of 10.0°C will be used.

**Field: Air Inlet Node Name**

This optional alpha field contains the name of the node from which the gas cooler draws its outdoor air. If this field is left blank, the outdoor air dry-bulb temperature entering the gas cooler is taken directly from the weather data. If this field is not blank, this node name must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

### 1.35.15.1.9 Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature Rack”). A new meter for reporting is created for each unique subcategory (Ref. **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

### 1.35.15.1.10 Field: Gas Cooler Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the gas cooler (kg) specified by the manufacturer, under standard rating conditions. If this field is blank, the default value of 0.0 kg will be used.

### 1.35.15.1.11 Field: Gas Cooler Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the gas cooler receiver (kg) specified by the manufacturer or system designer, under standard rating conditions. If this field is blank, the default value of 0.0 kg will be used.

### 1.35.15.1.12 Field: Gas Cooler Outlet Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the gas cooling outlet piping (kg) specified by the system designer, under standard rating conditions. If this field is blank, the default value of 0.0 kg will be used.

The following is an example input for an air-cooled gas cooler.

```
Refrigeration:GasCooler:AirCooled,
  RefrigGasCooler,          !- Name
  GasCoolerHRCurve,         !- Rated Total Heat Rejection Rate Curve Name
  Fixed,                    !- Gas Cooler Fan Speed Control Type
  6400,                     !- Rated Fan Power
  0.2,                      !- Minimum Fan Air Flow Ratio
  27.0,                     !- Transition Temperature
  3.0,                      !- Transcritical Approach Temperature
  10.0,                     !- Subcritical Temperature Difference
  10.0,                     !- Minimum Condensing Temperature
  ,                          !- Air Inlet Node Name
  RefrigGasCooler,         !- End-Use Subcategory
  ,                         !- Gas Cooler Refrigerant Operating Charge Inventory
  ,                         !- Gas Cooler Receiver Refrigerant Inventory
  ;                         !- Gas Cooler Outlet Piping Refrigerant Inventory
```

### 1.35.15.2 Outputs

- Zone,Average, Refrigeration Transcritical System Gas Cooler Heat Transfer Rate [W]
- Zone,Sum, Refrigeration Transcritical System Gas Cooler Heat Transfer Energy [J]
- Zone,Average, Refrigeration Transcritical System Gas Cooler Fan Electricity Rate [W]
- Zone,Sum, Refrigeration Transcritical System Gas Cooler Fan Electricity Energy [J]
- Zone,Average, Refrigeration Transcritical System Gas Cooler Outlet Temperature [C]
- Zone,Average, Refrigeration Transcritical System Gas Cooler Outlet Pressure [Pa]
- Zone,Average, Refrigeration Transcritical System Gas Cooler Defrost Recovered Heat Transfer Rate [W]
- Zone,Sum, Refrigeration Transcritical System Gas Cooler Defrost Recovered Heat Transfer Energy [J]

#### 1.35.15.2.1 Refrigeration Transcritical System Gas Cooler Heat Transfer Rate [W]

This output is the total heat transfer rate from the gas cooler in Watts, and includes compressor energy and the refrigeration load.

#### 1.35.15.2.2 Refrigeration Transcritical System Gas Cooler Heat Transfer Energy [J]

This output is the total heat transferred from the gas cooler to the surroundings, in Joules, for the timestep being reported.

#### 1.35.15.2.3 Refrigeration Transcritical System Gas Cooler Fan Electricity Rate [W]

This output is the electric input to the system's gas cooler fan(s) in Watts.

#### 1.35.15.2.4 Refrigeration Transcritical System Gas Cooler Fan Electricity Energy [J]

This is the electricity consumption of the system's gas cooler fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

#### 1.35.15.2.5 Refrigeration Transcritical System Gas Cooler Outlet Temperature [C]

This output is the temperature (in C) of the refrigerant exiting the gas cooler.

#### 1.35.15.2.6 Refrigeration Transcritical System Gas Cooler Outlet Pressure [Pa]

This output is the pressure (in Pa) of the refrigerant exiting the gas cooler.

#### 1.35.15.2.7 Refrigeration Transcritical System Gas Cooler Defrost Recovered Heat Transfer Rate [W]

This is the total heat recovered from the gas cooler inlet flow for defrost purposes within the refrigeration system.

### 1.35.15.2.8 Refrigeration Transcritical System Gas Cooler Defrost Recovered Heat Transfer Energy [J]

This is the total heat recovered from the gas cooler inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

## 1.35.16 Refrigeration:TransferLoadList

A refrigeration system may provide cooling to other, secondary, systems through either a secondary loop or a cascade condenser (Ref. [Refrigeration:SecondarySystem](#) and [Refrigeration:Condenser:Cascade](#)). If multiple transfer loads are served by a single primary system, use this list to group them together for reference by the primary system (see the field “Refrigeration Transfer Load or TransferLoad List Name” in the [Refrigeration:System](#) object).

### 1.35.16.1 Inputs

#### 1.35.16.1.1 Field: Name

A unique user-assigned name for an instance of a refrigeration transfer load list. Any reference to this list by another object will use this name. In particular, the primary refrigeration system absorbing the heat from all the loads listed here will use this name to reference those loads.

#### 1.35.16.1.2 Field: Cascade Condenser Name or Secondary System Name

Identifies a cascade condenser or secondary loop that is cooled, along with the other transfer loads listed here, by a single system. The name will be validated against the [Refrigeration:SecondarySystem](#) and [Refrigeration:Condenser:Cascade](#) names in the input file (the name will also be compared against all the other condenser names, but an error will be issued if it refers to any type of condenser other than a cascade condenser).

The list is extensible; ten fields are provided in the IDD.

The following is an example input for a transfer load list.

```
Refrigeration:TransferLoadList,
    MedTempTransferLoads ,    !- Name
    CascadeCondFrozen,        !- Cascade Condenser Name or Secondary System Name

## 1.35.17 Refrigeration:SecondarySystem

A refrigeration secondary system works in conjunction with refrigerated cases and walkins (Ref. [Refrigeration:SecondarySystem](#), [Refrigeration:CaseAndWalkInList](#), [Refrigeration:Case](#), and [Refrigeration:WalkIn](#)) to simulate the performance of a secondary loop supermarket refrigeration system. Heat from the refrigeration loads served by the secondary loop is absorbed by a primary refrigeration system (ref: [Refrigeration:System](#)). The [SecondarySystem](#) object simulates a heat exchanger that is an evaporator, or refrigeration load, on the primary refrigeration system.

The inputs for the refrigeration secondary system object include a name, which is also referenced to identify the load placed upon the primary refrigeration system. The inputs that describe the loads placed upon the secondary loop include the name of a single refrigerated case, the name of a single walk-in cooler, or a list of cases and walkin coolers. The circulating fluid type specifies whether or not the secondary fluid remains in the liquid state throughout the loop (e.g., a glycol or brine solution) or undergoes a partial phase change while serving the refrigeration loads (e.g., a CO<sub>2</sub> liquid overfeed system). The circulating fluid name must also be specified and must correspond to a name used to provide the fluid properties.

If the secondary fluid remains a liquid, the heat exchanger between the primary and secondary systems functions as an evaporator on the primary side and chills the circulating fluid on the secondary side. Inputs that describe the evaporator performance at rated conditions are used to calculate the heat exchanger effectiveness. These values include the rated evaporator capacity (which can be specified in terms of energy or fluid flow rate), the rated evaporating temperature, the rated approach temperature difference, and the rated range temperature difference.

If the secondary fluid undergoes a partial phase change, the heat exchanger between the primary and secondary systems functions as an evaporator on the primary side and as a condenser on the secondary side. The evaporator capacity, evaporating temperature, and approach temperature difference, all at full-load design conditions, are input.

The balance of the secondary system object describes the pumping system. The pumping options include a single constant speed pump, multiple constant speed pumps, or a variable frequency-drive pump. The user can also keep track of distribution piping and receiver shell heat gains.

### 1.35.17.1 Inputs

#### 1.35.17.1.1 Field: Name

A unique user-assigned name for an instance of a refrigeration secondary system. Any reference to this refrigeration secondary system by another object will use this name. In particular, the primary refrigeration system absorbing the heat from this system will use this name to define that load.

#### 1.35.17.1.2 Field: Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, or walkin, or a particular list of refrigerated cases and walkins, that are cooled by this refrigeration secondary system. The name will be validated against the case, walkin, and CaseAndWalkInList names (ref. [Refrigeration:Case](#), [Refrigeration:WalkIn](#) and [Refrigeration:CaseAndWalkInList](#)) in the input file.

#### 1.35.17.1.3 Field: Circulating Fluid Type

Specifies whether the fluid is always liquid (e.g., glycol solution), or undergoes a partial phase change (e.g., CO<sub>2</sub> liquid overfeed system). The options are “FluidAlwaysLiquid” and “FluidPhaseChange”.

#### 1.35.17.1.4 Field: Circulating Fluid Name

The name of the secondary circulating fluid.

For “FluidAlwaysLiquid”, this name must correspond to either an ethylene or propylene glycol (ref: [FluidProperties:GlycolConcentration](#)) or to a user-defined glycol (ref: [FluidProperties:Name](#) and [FluidProperties:GlycolConcentration](#)) in the input file. Note that the corresponding property data, including [FluidProperties:Concentration](#), [FluidProperties:Temperatures](#), and [FluidProperties:GlycolConcentration](#) must also be included in the input file and are provided in [GlycolPropertiesRefData.idf](#) for typical ethylene and propylene glycols.

For “FluidPhaseChange”, the refrigerant used by the secondary system must be listed in the [FluidProperties:Name](#) object. The corresponding property data must also be supplied in the input file. Property data for many refrigerants, including R11, R123, R134A, R12, R22, R404A, R507A, R410A, and R744, are available in [FluidPropertiesRefData.idf](#).

#### 1.35.17.1.5 Field: Evaporator Capacity

For “FluidAlwaysLiquid”, this numeric field should be the rated heat evaporator capacity (W). Be sure the rating corresponds to the correct refrigerant and secondary circulating fluid. If this variable is specified and the rated evaporator flow rate for secondary fluid is not, then the flow rate will be calculated. At least one of these two input variables is required.

For “FluidPhaseChange”, this numeric field should be the evaporator capacity (W) at full-load design conditions. If this input is left blank, the capacity will be set to the sum of the capacities of the cases and walk-ins served by the secondary loop plus the pump motor load at full-load design conditions.

#### **1.35.17.1.6 Field: Evaporator Flow Rate for Secondary Fluid**

For “FluidAlwaysLiquid” systems, this is the rated evaporator secondary fluid flow rate in  $\text{m}^3/\text{s}$ . If this variable is specified and the rated evaporator capacity in watts is not, then the rated capacity will be calculated. At least one of these two input variables is required.

For “FluidPhaseChange”, this field is not used (see “Phase Change Circulating Rate”).

#### **1.35.17.1.7 Field: Evaporator Evaporating Temperature**

This numeric field provides the evaporating temperature (C) corresponding to the evaporator capacity. This is the evaporating temperature on the primary side of the heat exchanger used to chill or condense the secondary loop circulating fluid. It is NOT the temperature in any cases or walk-ins served by the secondary loop.

#### **1.35.17.1.8 Field: Evaporator Approach Temperature Difference**

For “FluidAlwaysLiquid”, this numeric field is the rated temperature difference (DeltaC) between the circulating secondary fluid leaving the heat exchanger and the heat exchanger’s evaporating temperature.

For “FluidPhaseChange”, this is the temperature difference (DeltaC) between the primary refrigerant evaporating and secondary refrigerant condensing temperatures at full-load design conditions.

#### **1.35.17.1.9 Field: Evaporator Range Temperature Difference**

For “FluidAlwaysLiquid”, this numeric field is the rated temperature difference (DeltaC) between the circulating secondary fluid entering and leaving the heat exchanger. This value is not used for “Fluid-PhaseChange”.

#### **1.35.17.1.10 Field: Number of Pumps in Loop**

This numeric field provides the integer number of pumps used to circulate the secondary heat transfer fluid. The default value is 1. Unless a variable speed pump is specified, pump energy will be calculated in linear steps to achieve the necessary flow rate.

#### **1.35.17.1.11 Field: Total Pump Flow Rate**

This is the secondary fluid circulating flow rate in  $\text{m}^3/\text{s}$  at full-load design conditions. For “FluidAlwaysLiquid”, if no value is input, the Evaporator Flow Rate for Secondary Fluid will be used. For “FluidPhaseChange”, if no value is input, the flow rate will be calculated using the Evaporator Capacity and the PhaseChange Circulating Rate.

#### **1.35.17.1.12 Field: Total Pump Power**

This numeric field should be the pump power (W) at full-load design conditions. Be sure the rating corresponds to the correct secondary circulating fluid at the design fluid temperature. EITHER the Total Pump Power OR the Total Pump Head is required.

#### **1.35.17.1.13 Field: Total Pump Head**

This numeric field should be the design pressure drop, or head, across the secondary loop (Pa) at full load design conditions. Be sure the rating corresponds to the correct secondary circulating fluid at the design fluid temperature. EITHER the Total Pump Power OR the Total Head is required.

**1.35.17.1.14 Field: PhaseChange Circulating Rate**

This field is not used for “FluidAlwaysLiquid”.

For “FluidPhaseChange”, the Circulating Rate is defined as the total mass flow at the pump divided by the mass flow rate of vapor returning to the separator. Values between 2.1 and 3 are common for CO<sub>2</sub> systems and the default is 2.5. If Total Pump Flow Rate is also defined, the PhaseChange Circulating Rate will only be used to check whether the two values are consistent.

**1.35.17.1.15 Field: Pump Drive Type**

Specifies whether the pump(s) is constant speed or variable speed. The options are “Constant” and “Variable”. The default is “Constant”.

**1.35.17.1.16 Field: Variable Speed Pump Cubic Curve Name**

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the variable speed pump power (and the associated load on the secondary refrigeration load) at off-rated conditions. The curve should be normalized to have the value of 1.0 at full-load design conditions. The variable speed pump cubic curve name is used only for the a pump drive type of “Variable”.

**1.35.17.1.17 Field: Pump Motor Heat to Fluid**

This choice field determines how much of the pump motor heat will be added to the circulating secondary fluid. This represents the motor efficiency for a non-hermetic motor. The default is 0.85. For a semi-hermetic motor, enter 1.0. The value entered must be between 0.5 and 1.0.

**1.35.17.1.18 Field: Sum UA Distribution Piping**

This optional field is typically used when trying to compare the impact of pipe heat gains on system performance, particularly in comparing a DX system to a secondary system. Enter the value for secondary loop distribution piping heat gain (in W/C). That is, sum up the product of the pipe insulation conductance times the outer piping insulation surface area. Please see the Engineering Reference for guidance in calculating this value.

**1.35.17.1.19 Field: Distribution Piping Zone Name**

This optional field is used when trying to determine the impact of pipe heat gains on system performance, particularly in comparing a DX system to a secondary system. (If the previous field, Sum UA Distribution Piping, is blank, this field will not be used.) Enter the name of the zone where the Distribution piping is located. The distribution piping heat gains will be calculated based upon the air temperature within this zone and will count as a cooling credit for this zone.

**1.35.17.1.20 Field: Sum UA Receiver/Separator Shell**

This optional field is typically used when trying to compare the impact of refrigeration component heat gains on system performance, particularly in comparing a conventional primary DX system to a secondary system. Enter the value for receiver/separator heat gain (in W/C). That is, sum up the product of the tank insulation conductance times the outer tank insulation surface area. Please see the Engineering Reference for guidance in calculating this value.

**1.35.17.1.21 Field: Receiver/Separator Zone Name**

This optional field is used when trying to determine the impact of refrigeration component heat gains on system performance, particularly in comparing a conventional primary DX system to a secondary system. (If the previous field, Sum UA Receiver/Separator, is blank, this field will not be used.) Enter the name

of the zone where the receiver/separator is located. The heat gains will be calculated based upon the air temperature within this zone and will count as a cooling credit for this zone.

### 1.35.17.1.22 Field: Evaporator Refrigerant Inventory

The secondary loop is chilled by a primary system via a heat exchanger. This field is the refrigerant inventory on the cold (primary) side of that heat exchanger, in kg. The default value is zero.

### 1.35.17.1.23 Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., “Low Temperature Rack”). A new meter for reporting is created for each unique subcategory (Ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is left blank, the equipment will be assigned to the “General” end-use subcategory.

The following is an example input for a brine-type (“FluidAlwaysLiquid”)refrigeration secondary system.

### 1.35.17.2 Outputs

FOR SECONDARY SYSTEMS SERVING CASES AND/OR WALKINS:

- Zone,Average,Refrigeration Secondary Loop Pump Electricity Rate [W]
- Zone,Sum,Refrigeration Secondary Loop Pump Electricity Energy [J]
- Zone,Average,Refrigeration Secondary Loop Load Heat Transfer Rate [W]
- Zone,Sum,Refrigeration Secondary Loop Load Heat Transfer Energy [J]
- Zone,Average,Refrigeration Secondary Loop Total Heat Transfer Rate [W]
- Zone,Sum,Refrigeration Secondary Loop Total Heat Transfer Energy [J]
- Zone,Average,Refrigeration Secondary Loop Estimated Refrigerant Inventory Mass[kg] Zone,Average,Refrigeration Secondary Loop Volume Flow Rate [m3/s]
- Zone,Average,Refrigeration Secondary Loop Pipe Heat Gain Rate [W]
- Zone,Average,Refrigeration Secondary Loop Pipe Heat Gain Energy [J]
- Zone,Average,Refrigeration Secondary Loop Receiver Heat Gain Rate [W]
- Zone,Average,Refrigeration Secondary Loop Receiver Heat Gain Energy [J]

FOR SECONDARY SYSTEMS SERVING AIR CHILLERS:

- HVAC,Average,Refrigeration Air Chiller Secondary Loop Pump Electricity Rate [W]
- HVAC,Sum,Refrigeration Air Chiller Secondary Loop Pump Electricity Energy [J]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Load Heat Transfer Rate [W]
- HVAC,Sum,Refrigeration Air Chiller Secondary Loop Load Heat Transfer Energy [J]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Total Heat Transfer Rate [W]
- HVAC,Sum,Refrigeration Air Chiller Secondary Loop Total Heat Transfer Energy [J]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Estimated Refrigerant Inventory Mass[kg]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Volume Flow Rate [m3/s]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Pipe Heat Gain Rate [W]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Pipe Heat Gain Energy [J]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Receiver Heat Gain Rate [W]
- HVAC,Average,Refrigeration Air Chiller Secondary Loop Receiver Heat Gain Energy [J]

**1.35.17.2.1 FOR SECONDARY SYSTEMS SERVING CASES AND/OR WALKINS:****1.35.17.2.2 Refrigeration Secondary Loop Pump Electricity Rate [W]**

This output is the total electric power input to the pump(s) in Watts.

**1.35.17.2.3 Refrigeration Secondary Loop Pump Electricity Energy [J]**

This is the electricity consumption of the system's pump(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output: Meter objects).

**1.35.17.2.4 Refrigeration Secondary Loop Load Heat Transfer Rate [W]**

This is the amount of refrigeration provided to the cases and walkins served by the secondary loop in W.

**1.35.17.2.5 Refrigeration Secondary Loop Load Heat Transfer Energy [J]**

This is the amount of refrigeration provided to the cases and walkins served by the secondary loop in Joules for the timestep being reported.

**1.35.17.2.6 Refrigeration Secondary Loop Total Heat Transfer Rate [W]**

This is the total amount of refrigeration load placed upon the primary refrigeration system (including loads due to the cases and walkins plus the loads from the secondary loop pumps and any energy absorbed by the loop via pipe heat gains) in W.

**1.35.17.2.7 Refrigeration Secondary Loop Total Heat Transfer Energy [J]**

This is the total amount of energy placed upon the primary refrigeration system by the secondary loop in Joules for the timestep being reported.

**1.35.17.2.8 Refrigeration Secondary Loop Estimated Refrigerant Inventory Mass [kg]**

This output is the sum of the input inventory values for the cases and walkins and the refrigerant circulating through the loop.

**1.35.17.2.9 Refrigeration Secondary Loop Volume Flow Rate [m<sup>3</sup>/s]**

This output is the calculated volume flow through the pumps for this secondary loop.

**1.35.17.2.10 Refrigeration Secondary Loop Pipe Heat Gain Rate [W]**

This output is the total heat transferred to the pipes in Watts.

**1.35.17.2.11 Refrigeration Secondary Loop Pipe Heat Gain Energy [J]**

This is the total heat transferred to the pipes in Joules for the timestep being reported.

**1.35.17.2.12 Refrigeration Secondary Loop Receiver Heat Gain Rate [W]**

This output is the total heat transferred to the receiver in Watts.

**1.35.17.2.13 Refrigeration Secondary Loop Receiver Heat Gain Energy [J]**

This is the total heat transferred to the receiver in Joules for the timestep being reported.

**1.35.17.2.14 FOR SECONDARY SYSTEMS SERVING AIR CHILLERS:****1.35.17.2.15 Refrigeration Air Chiller Secondary Loop Pump Electricity Rate [W]**

This output is the total electric power input to the pump(s) in Watts.

**1.35.17.2.16 Refrigeration Air Chiller Secondary Loop Pump Electricity Energy [J]**

This is the electricity consumption of the system's pump(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Output:Meter objects).

**1.35.17.2.17 Refrigeration Air Chiller Secondary Loop Load Heat Transfer Rate [W]**

This is the amount of refrigeration provided to the air chillers served by the secondary loop in W.

**1.35.17.2.18 Refrigeration Air Chiller Secondary Loop Load Heat Transfer Energy [J]**

This is the amount of refrigeration provided to the air chillers served by the secondary loop in Joules for the timestep being reported.

**1.35.17.2.19 Refrigeration Air Chiller Secondary Loop Total Heat Transfer Rate [W]**

This is the total amount of refrigeration load placed upon the primary refrigeration system (including loads due to the air chillers plus the loads from the secondary loop pumps and any energy absorbed by the loop via pipe heat gains) in W.

**1.35.17.2.20 Refrigeration Air Chiller Secondary Loop Total Heat Transfer Energy [J]**

This is the total amount of energy placed upon the primary refrigeration system by the secondary loop in Joules for the timestep being reported.

**1.35.17.2.21 Refrigeration Air Chiller Secondary Loop Estimated Refrigerant Inventory Mass [kg]**

This output is the sum of the input inventory values for the air chillers and the refrigerant circulating through the loop.

**1.35.17.2.22 Refrigeration Air Chiller Secondary Loop Volume Flow Rate [m<sup>3</sup>/s]**

This output is the calculated volume flow of coolant through the pumps for this secondary loop.

**1.35.17.2.23 Refrigeration Air Chiller Secondary Loop Pipe Heat Gain Rate [W]**

This output is the total heat transferred to the pipes in Watts.

**1.35.17.2.24 Refrigeration Air Chiller Secondary Loop Pipe Heat Gain Energy [J]**

This is the total heat transferred to the pipes in Joules for the timestep being reported.

**1.35.17.2.25 Refrigeration Air Chiller Secondary Loop Receiver Heat Gain Rate [W]**

This output is the total heat transferred to the receiver in Watts.

**1.35.17.2.26 Refrigeration Air Chiller Secondary Loop Receiver Heat Gain Energy [J]**

This is the total heat transferred to the receiver in Joules for the timestep being reported.

**1.35.18 Additional Refrigeration Outputs Available for Each Zone**

Multiple refrigeration cases and walkins may be located within a single zone. Each zone may also exchange heat with refrigeration system suction piping, secondary loop distribution piping, and secondary loop receivers. Output variables have been prepared to sum up the total heat exchange due to all refrigeration objects within a single zone. The output variables that start with “Zone Refrigeration” do not account for refrigeration provided by refrigeration chiller sets or any piping from systems serving air chillers. The output variables that start with “Zone Chillers” account for all the refrigeration system elements serving air chillers.

**1.35.19 Additional Refrigeration Outputs for Each Zone**

FOR THE SUM OF ALL COOLING SYSTEMS SERVING CASES AND/OR WALKINS:

- Zone,Average, Refrigeration Zone Case and Walk In Sensible Cooling Rate [W]
- Zone,Sum, Refrigeration Zone Case and Walk In Sensible Cooling Energy [J]
- Zone,Average, Refrigeration Zone Case and Walk In Heating Rate [W]
- Zone,Sum, Refrigeration Zone Case and Walk In Heating Energy [J]
- Zone,Average, Refrigeration Zone Case and Walk In Total Sensible Cooling Rate [W]
- Zone,Sum, Refrigeration Zone Case and Walk In Total Sensible Cooling Energy [J]
- Zone,Average, Refrigeration Zone Case and Walk In Total Latent Cooling Rate [W]
- Zone,Sum, Refrigeration Zone Case and Walk In Total Latent Cooling Energy [J]
- Zone,Sum, Refrigeration Zone Case and Walk In Total Cooling Energy [J]
- Zone,Average,Refrigeration Zone Case and Walk In Total Cooling Rate [W]
- Zone,Average, Refrigeration Zone Case and Walk In Total Heat Transfer Rate [W]
- Zone,Sum, Refrigeration Zone Case and Walk In Total Heat Transfer Energy [J]

FOR THE SUM OF ALL COOLING SYSTEMS SERVING CHILLERS:

- HVAC,Average, Refrigeration Zone Air Chiller Sensible Heat Transfer Rate [W]
- HVAC,Sum, Refrigeration Zone Air Chiller Sensible Heat Transfer Energy [J]
- HVAC,Average, Refrigeration Zone Air Chiller Latent Cooling Rate [W]
- HVAC,Sum, Refrigeration Zone Air Chiller Latent Cooling Energy [J]
- HVAC,Average, Refrigeration Zone Air Chiller Total Cooling Rate [W]
- HVAC,Sum, Refrigeration Zone Air Chiller Total Cooling Energy [J]

### 1.35.19.1 FOR THE SUM OF ALL COOLING SYSTEMS SERVING CASES AND/OR WALKINS:

#### 1.35.19.2 Refrigeration Zone Case and Walk In Total Sensible Cooling Rate [W]

This output is the total sensible heat transfer between all refrigeration objects located in the zone in Watts. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

##### *Refrigeration Zone Case and Walk In Total Sensible Cooling Energy [J]*

This is the total sensible heat transfer between all refrigeration objects located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

#### 1.35.19.3 Refrigeration Zone Case and Walk In Total Latent Cooling Rate [W]

This output is the total latent heat transfer between all refrigeration objects located in the zone in Watts. A negative value will be reported when the refrigeration equipment provides dehumidification (thereby reducing the zone latent load).

##### *Refrigeration Zone Case and Walk In Total Latent Cooling Energy [J]*

This is the total latent heat transfer between all refrigeration objects located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration equipment provides dehumidification (thereby reducing the zone latent load).

#### 1.35.19.4 Refrigeration Zone Case and Walk In Total Heat Transfer Rate [W]

This output is the total heat transfer (sensible plus latent) between all refrigeration objects located in the zone in Watts. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

##### *Refrigeration Zone Case and Walk In Total Heat Transfer Energy [J]*

This is the total heat transfer (sensible plus latent) between all refrigeration objects located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

#### 1.35.19.5 Refrigeration Zone Case and Walk In Sensible Cooling Rate [W]

This output is the total sensible cooling from all refrigeration objects located in the zone in Watts.

##### *Refrigeration Zone Case and Walk In Sensible Cooling Energy [J]*

This is the total sensible cooling from all refrigeration objects located in the zone in Joules for for the timestep being reported.

#### 1.35.19.6 Refrigeration Zone Case and Walk In Heating Rate [W]

This output is the total heating from all refrigeration objects located in the zone in Watts.

##### *Refrigeration Zone Case and Walk In Heating Energy [J]*

This is the total heating from all refrigeration objects located in the zone in Joules for for the timestep being reported.

#### 1.35.19.7 Refrigeration Zone Case and Walk In Total Cooling Rate [W]

This output is the total cooling (sensible plus latent) from all refrigeration objects located in the zone in Watts.

##### *Refrigeration Zone Case and Walk In Total Cooling Energy [J]*

This is the total cooling (sensible plus latent) from all refrigeration objects located in the zone in Joules for for the timestep being reported.

#### **1.35.19.8 FOR THE SUM OF ALL COOLING SYSTEMS SERVING AIR CHILLERS:**

##### **1.35.19.9 Refrigeration Zone Air Chiller Heating Rate [W]**

This output is the total heating from all air chillers located in the zone in Watts.

###### ***Refrigeration Zone Air Chiller Heating Energy [J]***

This is the total heating from all air chillers located in the zone in Joules for for the timestep being reported.

##### **1.35.19.10 Refrigeration Zone Air Chiller Sensible Cooling Rate [W]**

This output is the total sensible cooling from all air chillers located in the zone in Watts.

###### ***Refrigeration Zone Air Chiller Sensible Cooling Energy [J]***

This is the total sensible cooling from all air chillers located in the zone in Joules for for the timestep being reported.

##### **1.35.19.11 Refrigeration Zone Air Chiller Sensible Heat Transfer Rate [W]**

This output is the total sensible heat transfer from all air chillers located in the zone in Watts. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

##### **1.35.19.12 Refrigeration Zone Air Chiller Sensible Heat Transfer Energy [J]**

This is the total sensible heat transfer from all air chillers located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

##### **1.35.19.13 Refrigeration Zone Air Chiller Latent Cooling Rate [W]**

This output is the total latent cooling from all air chillers located in the zone in Watts.

###### ***Refrigeration Zone Air Chiller Latent Cooling Energy [J]***

This is the total latent cooling from all air chillers located in the zone in Joules for for the timestep being reported.

##### **1.35.19.14 Refrigeration Zone Air Chiller Water Removed Mass Flow Rate [kg/s]**

This is the total amount of water removed by all air chillers located in the zone in kg/s for for the timestep being reported.

##### **1.35.19.15 Refrigeration Zone Air Chiller Total Cooling Rate [W]**

This output is the total cooling (sensible plus latent) from all air chillers located in the zone in Watts.

###### ***Refrigeration Zone Air Chiller Total Cooling Energy [J]***

This is the total cooling (sensible plus latent) from all air chillers located in the zone in Joules for for the timestep being reported.

### 1.35.20 Refrigeration:AirChiller

The Refrigeration:AirChiller object works in conjunction with a refrigeration chiller set, compressor rack, a refrigeration system, or a refrigeration secondary system object (Ref. ZoneHvac:RefrigerationChillerSet, and a [Refrigeration:CompressorRack](#), [Refrigeration:System](#), or [Refrigeration:SecondarySystem](#)) to simulate the performance of an air chiller, similar to one found in a refrigerated warehouse. The air chiller model uses information at rated conditions along with the zone conditions to determine performance. Energy use for fans and heaters is modeled based on inputs for nominal power, schedules, and control type. The refrigeration chiller model accounts for the sensible and latent heat exchange with the surrounding environment.

The refrigeration chiller cooler object inputs include a name, an availability schedule name, the rated cooling capacity, the rated operating temperature, the rated cooling source temperature, the rated total heating power and heating power schedule, the rated fan power and schedules, defrost type, defrost control type, defrost schedule name, drip-down schedule name, defrost power, the portion of the defrost energy used to melt ice (only for temperature termination control type), and refrigerant inventory.

Chiller coils are rated under multiple conventions. Each rating is typically based upon a selected fin material and refrigerant cycle, with correction factors for other materials or refrigerants. Fields are provided here for those correction factors. The performance of all chiller coils depends upon the inlet air temperature, relative humidity, and flow rate. Multiple methods of expressing this relationship are provided here to accommodate the way information is provided by different manufacturers.

#### 1.35.20.1 Inputs

##### 1.35.20.1.1 Field: Name

A unique user-assigned name for an instance of a refrigeration chiller. Any reference to this refrigeration chiller by another object will use this name.

##### 1.35.20.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigeration chiller can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the refrigeration chiller will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the refrigeration chiller will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, refrigeration chillers require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the default schedule has a value of 1 for all time periods.

##### 1.35.20.1.3 Field: Capacity Rating Type

The type of capacity rating used for this refrigeration chiller. Valid choices are UnitLoadFactorSensibleOnly, CapacityTotalSpecificConditions, EuropeanSC1Standard, EuropeanSC1NominalWet, EuropeanSC2Standard, EuropeanSC2NominalWet, EuropeanSC3Standard, EuropeanSC3NominalWet, EuropeanSC4Standard, EuropeanSC4NominalWet, EuropeanSC5Standard, and EuropeanSC5NominalWet. In each case, select the rating option that corresponds to the expected service conditions. For example, U.S. manufacturers quote a separate Unit Load Factor for wet or frosted coils. If the evaporating temperature is less than 0C, input the frosted coil value. Within the European convention, select SC1, 2, 3, 4, or 5 depending upon the expected evaporating temperature. This field is required and there is no default value. Refer to the Engineering Reference for further information on these rating types. NOTE: If the CapacityTotalSpecificConditions rating type is specified, the input file must include the manufacturer's

coil capacity correction curve in tabular form using the [Table:Lookup](#) object. An example of this may be found in the RefrigeratedWarehouse.idf example file.

#### **1.35.20.1.4 NOTE – ONLY ONE OF THE FOLLOWING TWO FIELDS IS USED**

##### **1.35.20.1.5 Field: Rated Unit Load Factor**

The sensible cooling capacity in watts (W/C) at rated conditions. The value entered for this field must be greater than zero, with no default value. This value is only used if the Capacity Rating Type is UnitLoadFactorSensibleOnly. The value given must be based upon the difference between the chiller inlet and outlet air temperatures, not on the difference between the zone mean temperature and the outlet air temperature.

##### **1.35.20.1.6 Field: Rated Capacity**

The cooling capacity in watts (W) at rated conditions. The value entered for this field must be greater than zero, with no default value. This field is only used if the Capacity Rating Type is CapacityTotalSpecificConditions, EuropeanSC1Standard, EuropeanSC1NominalWet, EuropeanSC2Standard, EuropeanSC2NominalWet, EuropeanSC3Standard, EuropeanSC3NominalWet, EuropeanSC4Standard, EuropeanSC4NominalWet, EuropeanSC5Standard, or EuropeanSC5NominalWet. For CapacityTotalSpecificConditions, this capacity includes both sensible and latent at the conditions given in the next two fields. Note that the European Standard ratings are sensible only and the European Nominal ratings include latent capacity as well. The value given here must correspond to the capacity rating type given previously.

##### **1.35.20.1.7 Field: Rated Relative Humidity**

This field is ONLY used if the Capacity Rating Type is CapacityTotalSpecificConditions and represents the relative humidity at rated conditions, expressed as a percent. The default is 85.

##### **1.35.20.1.8 Field: Rated Cooling Source Temperature**

For a DX evaporator coil, enter the saturated evaporating temperature in °C. For a fluid coil, enter the fluid coil entrance temperature in °C. There is no default value. This number is used, with temperatures for other refrigeration loads on any one system, to set that system's minimum suction pressure or minimum circulating fluid temperature.

##### **1.35.20.1.9 Field: Rated Temperature Difference DT1**

The rated difference between the air entering the refrigeration chiller and the cooling source temperature in °C. The entered value for this field must be less than 20 °C. There is no default value.

##### **1.35.20.1.10 Field: Maximum Difference Between Inlet Air and Evaporating Temperature**

The maximum difference between the air entering the refrigeration chiller and the cooling source temperature in °C used to limit capacity during pull-down. The default is 1.3 times the Rated Temperature Difference DT1.

##### **1.35.20.1.11 Field: Coil Material Correction Factor**

This field is used to enter the manufacturer's correction factor for coil material corresponding to the rating previously input. The default is 1.0 (dimensionless).

#### 1.35.20.1.12 Field: Refrigerant Correction Factor

This field is used to enter the manufacturer's correction factor for refrigerant corresponding to the rating previously input. The default is 1.0 (dimensionless). (Note, the refrigerant itself is specified for the detailed system or secondary loop providing the refrigerant to this coil.)

#### 1.35.20.1.13 Field: Capacity Correction Curve Type

The type of capacity correction curve used to account for the impact of the room air conditions on the chiller capacity. Valid choices are LinearSHR60, QuadraticSHR, European, and TabularRHxDt1xTRoom. This field will default to LinearSHR60, unless the CapacityTotalSpecificConditions rating type is specified, in which case, the TabularRHxDt1xTRoom correction curve type must be used. Refer to the Engineering Reference for further information on these curve types. The resulting correction factor for LinearSHR60, QuadraticSHR, and European types will be applied to the sensible capacity and must have output values between 1 and 2. The resulting correction factor for TabularRHxDt1xTRoom will be applied to the CapacityTotalSpecificConditions capacity and can have values between 0.2 and 2. If TabularRHxDt1xTRoom is used, the curve type within the table must be specified as "Quadratic".

#### 1.35.20.1.14 Field: Capacity Correction Curve Name

The name of the curve object defining the total refrigerating capacity. For correction curve types LinearSHR60 and QuadraticSHR, the independent variable is the Sensible Heat Ratio and the output values are between 1.0 and 2.0. For correction curve type European, EnergyPlus contains built-in capacity correction curves and specification of a capacity correction curve name is not required. For correction curve type TabularRHxDt1xTRoom, enter the name of a **Table:Lookup** object that gives the total capacity (in W) as a function of RH, Dt1, and Room Temperature; IN THAT ORDER. An example of a TabularRHxDt1xTRoom correction curve using the Table:Lookup object may be found in the RefrigeratedWarehouse.idf example file.

#### 1.35.20.1.15 Field: SHR60 Correction Factor

This field is only used when the capacity correction curve type is LinearSHR60. It should correspond to the capacity factor, that is, the total capacity divided by the sensible capacity corresponding to a Sensible Heat Ratio of 0.6. The default is 1.48 (dimensionless).

#### 1.35.20.1.16 Field: Rated Total Heating Power

The total heating power in watts including drip-pan and any other heaters (W). This value is required and has no default value.

#### 1.35.20.1.17 Field: Heating Power Schedule Name

The name of the schedule (ref: Schedule) that denotes the fraction of heater power that operates during a given time period. A schedule value of zero denotes that all heaters are off. A schedule value greater than 0 indicates that some portion of the total heater power will operate during that time period (maximum schedule value of 1.0 means all heaters are fully on). If this field is left blank, the default schedule has a value of 1 for all time periods.

#### 1.35.20.1.18 Field: Fan Speed Control Type

The type of fan speed control used by the cooling coil's fan(s). Valid choices are **Fixed**, **FixedLinear**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

**1.35.20.1.19 Field: Rated Fan Power**

The cooling coil fan power in watts (W). This value has a default value of 375W. This fan is assumed to run continuously except during electric, hot brine, or hot gas defrost periods.

**1.35.20.1.20 Field: Rated Air Flow**

The cooling coil fan rated air flow in cubic meters per second ( $\text{m}^3/\text{s}$ ). This value has no default value and must be input.

**1.35.20.1.21 Field: Minimum Fan Air Flow Ratio**

The minimum fraction of the rated air flow for part-load fan operation, must be between 0. and 1.0. The default value is 0.2.

**1.35.20.1.22 Field: Defrost Type**

The type of defrost used for this refrigeration chiller. Valid choices are None, Off-Cycle, HotFluid, and Electric. The default defrost type is Electric if the field is blank. HotFluid includes both hot gas and hot brine defrost systems. Refer to the Engineering Reference for further information on how the different defrost types are modeled.

**1.35.20.1.23 Field: Defrost Control Type**

The type of defrost control used for this refrigeration chiller. Valid choices are TimeSchedule and TemperatureTermination. The default is TimeSchedule if the field is blank. Refer to the Engineering Reference for further information on how the different defrost controls are modeled.

**1.35.20.1.24 Field: Defrost Schedule Name**

The name of the schedule (ref: Schedule) that denotes when the refrigeration chiller requires defrosting. A schedule value of 1.0 indicates that defrost can be on during a given time period. A value equal to 0 denotes that the defrost is off. Defrost schedules normally repeat the duration and number of defrost cycles for each day of the year. The refrigeration chiller manufacturer typically provides this information with the product literature. If TemperatureTermination control type is used, the defrost schedule is used for the defrost cycle start time and the defrost cycle end time is not allowed to extend beyond the scheduled off time. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

**1.35.20.1.25 Field: Defrost Drip-Down Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the refrigeration chiller requires additional time for draining condensate after the defrost period. A schedule value of 1.0 indicates that the defrost drip-down period is on during a given time period. A value equal to 0 denotes that the defrost drip-down period is over. The refrigeration chiller manufacturer typically provides this information with the product literature.

Each defrost drip-down period specified in this schedule should start at the same time as the corresponding defrost period specified in the schedule for Defrost Schedule, and the drip-down schedule defrost period should always be longer than or equal to the length of the defrost schedule time period. For example, if the defrost schedule contains a defrost period from 7:00 to 7:15, you would specify a case defrost drip-down period from 7:00 to 7:20 if you wanted to model a 5 minute condensate drip-down period after the regular defrost period. If no drip-down schedule is entered, then the defrost schedule (specified for the previous input field) will be used. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

### 1.35.20.1.26 Field: Defrost Power

The defrost power in watts. This input is required for hot-fluid (hot gas or hot brine), or electric defrost types. Refrigeration chiller manufacturers do not typically provide information on the heat input for hot gas and hot brine defrost. Information provided for electric defrost power can be substituted here for refrigeration chillers using hot-gas or hot-brine defrost if other information is not available. Only electric Defrost Types consume electricity during the defrost period. The entered value for this field must be greater than or equal to zero.

### 1.35.20.1.27 Field: Temperature Termination Defrost Fraction to Ice

When cooling coils go through a defrost cycle, only a portion of the defrost energy is actually used to melt the ice. The rest of the defrost energy goes to increasing the temperature of the coils themselves and to the refrigeration chiller environment. The Temperature Termination defrost control type calculates the end of the defrost cycle that corresponds to melting all the ice. Therefore, the user must input this fractional value. The default value is 0.7 for electric defrost and 0.3 for hot fluid defrost. Refer to the Engineering Reference for further information on how the defrost energy control types are modeled.

### 1.35.20.1.28 Field: Vertical Location

The vertical location for this refrigeration chiller. Valid choices are Floor, Middle, and Ceiling. The default is Middle if the field is blank. The vertical location is used to transform the mixed zone air temperature to the coil inlet air temperature. Refer to the Engineering Reference for further information on how the different vertical locations are modeled.

### 1.35.20.1.29 Field: Average Refrigerant Charge Inventory

The value of this optional field is the refrigerant inventory present in the refrigeration chiller during ordinary operation. The value is used to produce an estimate of the total refrigerant present in the refrigeration system. The value is entered in kg.

The following is an example input for a refrigeration air chiller.

```

#### **1.35.20.2.1 Refrigeration Zone Air Chiller Total Cooling Rate [W]**

This field is the total (sensible plus latent) cooling rate of the Air Chiller evaporator coil in Watts.

#### **1.35.20.2.2 Refrigeration Zone Air Chiller Total Cooling Energy [J]**

This field is the total (sensible plus latent) cooling of the Air Chiller evaporator coil in Joules over the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects).

#### **1.35.20.2.3 Refrigeration Zone Air Chiller Sensible Cooling Rate [W]**

#### **1.35.20.2.4 Refrigeration Zone Air Chiller Sensible Heat Transfer Rate [W]**

This field is the sensible cooling rate of the Air Chiller evaporator coil in Watts.

#### **1.35.20.2.5 Refrigeration Zone Air Chiller Sensible Cooling Energy [J]**

**1.35.20.2.6 Refrigeration Zone Air Chiller Sensible Heat Transfer Energy [J]**

This field is the sensible cooling of the Air Chiller evaporator coil in Joules over the timestep being reported.

**1.35.20.2.7 Refrigeration Zone Air Chiller Latent Cooling Rate [W]**

This field is the latent cooling (dehumidification) rate of the Air Chiller evaporator coil in Watts.

**1.35.20.2.8 Refrigeration Zone Air Chiller Latent Cooling Energy [J]**

This field is the latent cooling (dehumidification) of the Air Chiller evaporator coil in Joules over the timestep being reported.

**1.35.20.2.9 Refrigeration Zone Air Chiller Water Removed Mass Flow Rate [kg/s]**

This field is the latent cooling (dehumidification) of the Air Chiller evaporator coil in kilograms per second over the timestep being reported.

**1.35.20.2.10 Refrigeration Zone Air Chiller Total Electricity Rate [W]**

This field is the total electricity (fan, heaters, lights, and electric defrost) used by the Air Chiller in Watts.

**1.35.20.2.11 Refrigeration Zone Air Chiller Total Electricity Energy [J]**

This field is the electricity (fan, heaters, lights, and electric defrost) used by the Refrigeration chiller in Joules over the timestep being reported.

**1.35.20.2.12 Refrigeration Zone Air Chiller Fan Electricity Rate [W]**

This field is the electric power input to the Air Chiller fan(s) in Watts.

**1.35.20.2.13 Refrigeration Zone Air Chiller Fan Electricity Energy [J]**

This field is the electricity consumption of the Air Chiller fan(s) in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects).

**1.35.20.2.14 Refrigeration Zone Air Chiller Heater Electric Power [W]**

This field is the electric power input to the Air Chiller heaters in Watts.

**1.35.20.2.15 Refrigeration Zone Air Chiller Heater Electricity Energy [J]**

This field is the total electricity consumption of the Air Chiller heaters in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects).

**1.35.20.2.16 Refrigeration Zone Air Chiller Defrost Electricity Rate [W]**

This field is the electric power input to the Air Chiller electric defrost heater(s) in Watts. This output is available if case defrost type is Electric.

**1.35.20.2.17 Refrigeration Zone Air Chiller Defrost Electricity Energy [J]**

This field is the total electricity consumption of the Air Chiller electric defrost heater(s) in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Output:Meter objects). This output is available if case defrost type is Electric.

**1.35.20.2.18 Refrigeration Zone Air Chiller Sensible Heat Ratio**

This field is the Sensible Cooling Energy Rate divided by the Total Cooling Energy Rate.

**1.35.20.2.19 Refrigeration Zone Air Chiller Frost Accumulation Mass [kg]**

This field is the total amount of frost present on the coil during the timestep being reported.

**1.35.20.2.20 Refrigeration Zone Air Chiller Zone Total Cooling Rate [W]**

This field is the rate of total cooling delivered to the zone in Watts. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

**1.35.20.2.21 Refrigeration Zone Air Chiller Zone Total Cooling Energy [J]**

This field is the amount of total cooling energy delivered to the zone in Joules. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

**1.35.20.2.22 Refrigeration Zone Air Chiller Zone Sensible Cooling Rate [W]**

This field is the rate of sensible cooling delivered to the zone in Watts. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

**1.35.20.2.23 Refrigeration Zone Air Chiller Zone Sensible Cooling Energy [J]**

This field is the amount of sensible cooling energy delivered to the zone in Joules. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

**1.35.20.2.24 Refrigeration Zone Air Chiller Zone Heating Rate [W]**

This field is the rate of sensible heating delivered to the zone in Watts. A positive value is reported when the zone is heated by the air chiller (typically only occurs during defrost), otherwise a zero is reported.

**1.35.20.2.25 Refrigeration Zone Air Chiller Zone Heating Energy [J]**

This field is the amount of sensible heating energy delivered to the zone in Joules. A positive value is reported when the zone is heated by the air chiller (typically only occurs during defrost), otherwise a zero is reported.

*The following output variables are available for each zone served by any Air Chiller. An output variable identification is created for each zone exchanging energy with the Air Chiller. For example if the Air Chiller, “DairyRefrigeration chiller”, were exchanging energy with the zone, “SalesArea”, the output variable identification would be “DairyRefrigeration chillerInZoneSalesArea”.*

**1.35.20.2.26 Refrigeration Zone Air Chiller Sensible Cooling Rate [W]**

This field is the rate of sensible cooling delivered to the zone, net of any auxiliary heat input, in Watts..

**1.35.20.2.27 Refrigeration Zone Air Chiller Sensible Cooling Energy [J]**

This field is the amount of sensible cooling energy, net of any auxiliary heat input, delivered to the zone in Joules.

**1.35.20.2.28 Refrigeration Zone Air Chiller Latent Cooling Rate [W]**

This field is the rate of latent cooling (dehumidification) delivered to the zone in Watts. A negative value will be reported when the Air Chiller provides dehumidification (thereby reducing the zone latent load).

**1.35.20.2.29 Refrigeration Zone Air Chiller Water Removed Mass Flow Rate [kg/s]**

This field is the rate of latent cooling (dehumidification) delivered to the zone in kg/s. A negative value (or zero) will be reported when the Air Chiller provides dehumidification (thereby reducing the zone latent load).

**1.35.20.2.30 Refrigeration Zone Air Chiller Latent Cooling Energy [J]**

This field is the amount of latent cooling (dehumidification) energy delivered to the zone in Joules. A negative value (or zero) will be reported when the Air Chiller provides dehumidification (thereby reducing the zone latent load).

**1.35.20.2.31 Refrigeration Zone Air Chiller Total Cooling Rate [W]**

This field is the total rate of cooling, sensible plus latent, delivered to the zone in Watts.

**1.35.20.2.32 Refrigeration Zone Air Chiller Total Cooling Energy [J]**

This field is the total amount of cooling, sensible plus latent, energy delivered to the zone in Joules.

**1.35.20.2.33 Refrigeration Zone Air Chiller Heating Rate [W]**

This field is the rate of net heating due to any auxiliary or defrost heat input delivered to the zone, in Watts.

**1.35.20.2.34 Refrigeration Zone Air Chiller Heating Energy [J]**

This field is the amount of net heating energy due to any auxiliary heat input, delivered to the zone in Joules.

**1.36 Group - Zone Controls - Thermostats and Humidistats**

Zone Control objects are used to control zone conditions to a specific setpoint. The six types of zone control are described in this section. They are, by name, ZoneControl:<name>.. These types are:

**Thermostat** - The object provides the traditional approach to space control using air temperatures. Each controlled zone contains a thermostat object.

**Humidistat** - The object is used to control a zone to a specified relative humidity.

**Thermostat:ThermalComfort** - The object provides a method to control a zone to a dry-bulb temperature setpoint based on a thermal comfort model (e.g. Fanger) and a user-specified thermal comfort setpoint schedule.

**Thermostat:OperativeTemperature** - The operative temperature control is formulated to reuse all of the traditional thermostat objects. One input object will be used for each thermal zone to indicate if that zone's thermostat control mode should be overridden to effect operative temperature control rather than traditional air temperature control. The user will still have to input all the traditional **ZoneControl:Thermostat** and setpoint objects.

**Thermostat:TemperatureAndHumidity** - This thermostat control works together with the traditional **ZoneControl:Thermostat** object to modify temperature control based on zone air humidity conditions. Currently, this object resets the thermostat's cooling setpoint temperature downward based on elevated zone air humidity levels, typically yielding additional cooling coil operation and associated dehumidification. A **ZoneControl:Thermostat:TemperatureAndHumidity** object should be specified to indicate if a zone's traditional thermostat control mode should be overridden to provide enhanced dehumidification. The user must still input the traditional **ZoneControl:Thermostat** and setpoint objects.

**Thermostat:StagedDualSetpoint** - This thermostat control works alone with “Dual Setpoint” type only. The object provides heating and cooling setpoints, throttling range and offsets, so that zone temperature setpoint used for system load calculation is adjusted by the setpoint and throttling range based on the zone temperature at the previous time step. The stage number is determined by the temperature difference between the setpoint and zone temperature at the previous time step, and offset values. If this object and other zone control thermostat and humidistat are assigned to the same controlled zone, this object takes precedence when the controlled zone is specified in the Controlling Zone or Thermostat Location field of the **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object.

### 1.36.1 ZoneControl:Thermostat

The thermostatic zone control object is used to control a zone to a specified temperature. ZoneControl:Thermostat references a control type schedule and one or more control type objects which in turn reference one or more setpoint schedules. The example at the end of this section illustrates a complete zone thermostat specification including the control type and setpoint schedules.

The control type schedule and the list of control type/name pairs are directly related. The schedule defines the type of control that is to be used throughout the simulation. Valid Control Types are:

- 0 - Uncontrolled (No specification or default)
- 1 - Single Heating Setpoint
- 2 - Single Cooling SetPoint
- 3 - Single Heating/Cooling Setpoint
- 4 - Dual Setpoint (Heating and Cooling) with deadband

Thus, if the schedule referenced in the ZoneControl:Thermostat statement has a control type of 4 for a particular time period, this indicates that during that time period “Dual Setpoint with deadband” control is to be used. The specific “Dual Setpoint (Heating and Cooling) with deadband” control object to be used is specified in the list of control type/name pairs. Then the specific control type objects reference the thermostat setpoint temperature schedule to be used. Because only one control can be specified for each control type in a ZoneControl:Thermostat statement, there are only four pairs possible in a particular ZoneControl:Thermostat type/name list. This is because individual controls can be defined throughout the simulation, thus giving the user a full range of flexibility. Since putting in the name of the control type directly in the schedule would be very cumbersome, the control types are assigned a number which is used in the schedule profile.

#### 1.36.1.1 Inputs

##### 1.36.1.1.1 Field: Name

Unique identifying name for the thermostat.

##### 1.36.1.1.2 Field: Zone or ZoneList Name

Name of the zone or set of zones that is being controlled. When the **ZoneList** option is used then this thermostat definition is applied to each of the zones in the zone list effecting a global definition for thermostatic control in the zone.

##### 1.36.1.1.3 Field: Control Type Schedule Name

Schedule which defines what type of control is active during the simulation. Valid Control Types are:

- 0 - Uncontrolled (No specification or default)
- 1 - Single Heating Setpoint
- 2 - Single Cooling SetPoint
- 3 - Single Heating Cooling Setpoint

#### 4 - Dual Setpoint with Deadband (Heating and Cooling)

Each non-zero control type which is used in this schedule must appear in the following fields which list the specific thermostat control objects to be used for this zone.

##### 1.36.1.1.4 Field Set (Control Object Type, Control Name)

Up to four pairs of Control Object Type and Control Name may be listed to specify which control objects are used for this zone. This list is not order-dependent, and the position in this list has no impact on the control type schedule. In the control type schedule, a value of 1 always means “Single Heating Setpoint”, even if that control type is not first in this list.

##### 1.36.1.1.5 Field: Control Object <x>Type

This field specifies the control type to be used for this zone. Available control types are:

ThermostatSetpoint:SingleHeating

ThermostatSetpoint:SingleCooling

ThermostatSetpoint:SingleHeatingOrCooling

ThermostatSetpoint:DualSetpoint

##### 1.36.1.1.6 Field: Control <x> Name

The corresponding control type name. The name is used in an object with the name of the control type and specifies the schedule.

##### 1.36.1.1.7 Field: Temperature Difference Between Cutout And Setpoint

This optional choice field provides a temperature difference between cutout temperature and setpoint. When the temperature difference is greater than 0.0, the difference is applied to both heating and cooling by possibly revising setpoints based on control types.

If MAT is defined as zone air temperature at previous time step, DeltaT represents the temperature difference between cutout and setpoint and is greater than 0.0, and PredictedLoad represents predicted load calculated in the ZoneTempPredictorCorrector, following action will be taken:

```
0 - Uncontrolled (No specification or default)
    No change

1 - Single Heating Setpoint
    If ( MAT < ThermostatSetpoint:SingleHeating )
        ThermostatSetpoint:SingleHeating = ThermostatSetpoint:SingleHeating + DeltaT
    Else
        No change
    End If

2 - Single Cooling SetPoint
    If ( MAT > ThermostatSetpoint:SingleCooling )
        ThermostatSetpoint:SingleCooling = ThermostatSetpoint:SingleCooling - DeltaT
    Else
        No change
    End If

3 - Single Heating/Cooling Setpoint
    No change

4 - Dual Setpoint (Heating and Cooling) with deadband
    If ( MAT < HeatingSetpoint )
        HeatingSetpoint = HeatingSetpoint + DeltaT
        CoolingSetpoint = No change
    Else If ( MAT > CoolingSetpoint )
        HeatingSetpoint = No change
        CoolingSetpoint = CoolingSetpoint - DeltaT
    Else
        No change
```

---

End If

---

Note that this option should be used in caution. Following recommendations may be used to input the value of Temperature Difference Between Cutout And Setpoint:

1. The heating and cooling setpoints must be separated by at least 2 times the Temperature Difference Between Cutout And Setpoint or there will be a fatal error.
  2. The thermostat setpoint not met hours are incorrect with this option.
  3. This option will cause excess operation of heat pump system supplemental heating coils.
- 

An example of this statement in an IDF is:

```
ZoneControl:Thermostat, Zone 3 Thermostat, NORTH ZONE,
Zone Control Type Sched,
DUAL SETPOINT WITH DEADBAND, VAV Setpoints;
```

---

An example of a global thermostat:

```
ZoneList,AllControlledZones,SPACE1-1,SPACE2-1,SPACE3-1,SPACE4-1,SPACE5-1;

ZoneControl:Thermostat,
AllControlledZones Thermostat,           !- Name
AllControlledZones,                       !- Zone Name
Zone Control Type Sched, !- Control Type Schedule Name
ThermostatSetpoint:SingleCooling,         !- Control 1 Object Type
CoolingSetPoint,                          !- Control 1 Name
ThermostatSetpoint:SingleHeating,         !- Control 2 Object Type
HeatingSetpoint,                         !- Control 2 Name
ThermostatSetpoint:DualSetpoint,         !- Control 3 Object Type
DualSetPoint;                            !- Control 3 Name
```

---

A complete zone thermostat example showing this statement and all of the objects it must reference is:

```

**1.36.1.2.1 Zone Predicted Sensible Load to Setpoint Heat Transfer Rate [W]**

This is the predicted sensible load in W required to meet the current zone thermostat setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active heating and/or cooling setpoints, determines if the zone requires heating or cooling or is in the deadband, and then passes this single load to the equipment. This value is NOT multiplied by zone or group multipliers.

**1.36.1.2.2 Zone Predicted Sensible Load to Heating Setpoint Heat Transfer Rate [W]**

This is the predicted sensible load in W required to meet the current zone thermostat heating setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is NOT multiplied by zone or group multipliers.

**1.36.1.2.3 Zone Predicted Sensible Load to Cooling Setpoint Heat Transfer Rate [W]**

This is the predicted sensible load in W required to meet the current zone thermostat cooling setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is NOT multiplied by zone or group multipliers.

**1.36.1.2.4 Zone System Predicted Sensible Load to Setpoint Heat Transfer Rate [W]**

This is the predicted sensible load in W required to meet the current zone thermostat setpoint at the system level. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active heating and/or cooling setpoints, determines if the zone requires heating or cooling or is in the deadband, and then passes this single load to the equipment. This value is the Zone Predicted Sensible Load to Setpoint Heat Transfer Rate multiplied by zone or group multipliers.

**1.36.1.2.5 Zone System Predicted Sensible Load to Heating Setpoint Heat Transfer Rate [W]**

This is the predicted sensible load in W required to meet the current zone thermostat heating setpoint at the system level. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is the Zone Predicted Sensible Load to Heating Setpoint Heat Transfer Rate multiplied by zone or group multipliers.

**1.36.1.2.6 Zone System Predicted Sensible Load to Cooling Setpoint Heat Transfer Rate [W]**

This is the predicted sensible load in W required to meet the current zone thermostat cooling setpoint at the system level. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is the Zone Predicted Sensible Load to Cooling Setpoint Heat Transfer Rate multiplied by zone or group multipliers.

#### 1.36.1.2.7 Zone Thermostat Control Type []

This is the current zone thermostat control type (0 through 4). This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

#### 1.36.1.2.8 Zone Thermostat Heating Setpoint Temperature [C]

This is the current zone thermostat heating setpoint in degrees C. If there is no heating thermostat active, then the value will be 0. This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

When the Thermostat:StagedDualSetpoint object is applied to the current zone, this output variable reports staged zone heating setpoint. When the staged number is not equal to zero, both staged heating and cooling setpoints are the same. When no cooling or heating is required, the staged heating setpoint is equal to the scheduled heating setpoint  $0.5 * \text{heating throttling range}$ , and the staged cooling setpoint is equal to the scheduled cooling setpoint  $+ 0.5 * \text{cooling throttling range}$ .

#### 1.36.1.2.9 Zone Thermostat Cooling Setpoint Temperature [C]

This is the current zone thermostat cooling setpoint in degrees C. If there is no cooling thermostat active, then the value will be 0. This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

When the Thermostat:StagedDualSetpoint object is applied to the current zone, this output variable reports staged zone cooling setpoint. When the staged number is not equal to zero, both staged heating and cooling setpoints are the same. When no cooling or heating is required, the staged heating setpoint is equal to the scheduled heating setpoint  $0.5 * \text{heating throttling range}$ , and the staged cooling setpoint is equal to the scheduled cooling setpoint  $+ 0.5 * \text{cooling throttling range}$ .

#### 1.36.1.2.10 Zone Thermostat Stage Number []

This is the current zone thermostat stage number when the ZoneControl:Thermostat:StagedDualSetpoint object is specified in this zone. When no heating or cooling is required, the stage number is set to 0. When heating is required, the stage number is positive. When cooling is required, the stage number is negative. The absolute number is sent to the AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed object to specify the speed number accordingly.

#### 1.36.1.2.11 Zone Heating Setpoint Not Met Time [hr]

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint. See the OutputControl:ReportingTolerances object to change the reporting range from 0.2 degrees C.

#### 1.36.1.2.12 Zone Heating Setpoint Not Met While Occupied Time [hr]

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint and when people are present in the zone. To change the reporting range from 0.2 degrees C, see the OutputControl:ReportingTolerances object.

#### 1.36.1.2.13 Zone Cooling Setpoint Not Met Time [hr]

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint. See the OutputControl:ReportingTolerances object to change the reporting range from 0.2 degrees C.

**1.36.1.2.14 Zone Cooling Setpoint Not Met While Occupied Time [hr]**

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint and when people are present in the zone. To change the reporting range from 0.2 degrees C, see the `OutputControl:ReportingTolerances` object.

**1.36.1.2.15 Facility Heating Setpoint Not Met Time [hr]**

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint in any one or more zones. See the `OutputControl:ReportingTolerances` object to change the reporting range from 0.2 degrees C.

**1.36.1.2.16 Facility Heating Setpoint Not Met While Occupied Time [hr]**

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint and when people are present in any one or more zones. To change the reporting range from 0.2 degrees C, see the `OutputControl:ReportingTolerances` object.

**1.36.1.2.17 Facility Cooling Setpoint Not Met Time [hr]**

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint in any one or more zones. See the `OutputControl:ReportingTolerances` object to change the reporting range from 0.2 degrees C.

**1.36.1.2.18 Facility Cooling Setpoint Not Met While Occupied Time [hr]**

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint and when people are present in any one or more zones. To change the reporting range from 0.2 degrees C, see the `OutputControl:ReportingTolerances` object.

**1.36.1.2.19 Zone Oscillating Temperatures Time[hr]**

Hours when the temperature in the zone is oscillating back and forth. Oscillation is defined as times when the three differences between zone temperatures during successive timesteps are greater in magnitude than 0.15 degrees C and the sign of the differences changes from positive to negative to positive or from negative to positive to negative.

This may indicate a simulation with reduced reliability during the oscillation. Some oscillating hours should be expected in all simulations but excessive oscillations call into question the overall validity of the results. If excessive oscillations are occurring, try reducing the minimum system timestep (see `ConvergenceLimits` object) and the zone timestep (see the `TimeStep` object). Reducing these timestep lengths does increase the total computer time needed to complete the simulation. Having the zone timestep and the minimum system timestep the same length of time can also cause more oscillations. What amount of oscillations is considered excessive is difficult to quantify. One approach is comparing the number of oscillations to the case with 15 minute zone timesteps (4 per hour) and 1 minute minimum system timesteps. Often this variable is used as an indicator of the validity of the results when trying to decrease the time needed to perform the simulation.

**1.36.1.2.20 Zone Oscillating Temperatures During Occupancy Time[hr]**

Like Zone Oscillating Temperatures Time but for oscillations that occur only when the zone has occupancy. For zones unoccupied during night or weekend hours, oscillations during those times may not have much impact on the accuracy of the annual energy prediction.

**1.36.1.2.21 Zone Oscillating Temperatures in Deadband Time[hr]**

Like Zone Oscillating Temperatures Time but for oscillations that occur only the zone temperature is within the thermostat deadband or if the zone temperature has increased due to setback. Since less HVAC energy is used when the zone is within the thermostat deadband, if most of the hours that the zone is oscillating are during times when the zone is within the deadband, these hours could be considered less important.

**1.36.1.2.22 Facility Any Zone Oscillating Temperatures Time[hr]**

Hours when any zone in the building has oscillations. See Zone Oscillating Temperatures Time definition above.

**1.36.1.2.23 Facility Any Zone Oscillating Temperatures During Occupancy Time[hr]**

Hours when any zone in the building has oscillations during occupancy time. See Zone Oscillating Temperatures During Occupancy Time definition above.

**1.36.1.2.24 Facility Any Zone Oscillating Temperatures in Deadband Time[hr]**

Hours when any zone in the building has oscillations within the deadband. See Zone Oscillating Temperatures in Deadband Time definition above.

**1.36.2 Zone Thermostat Setpoints**

The syntax for the current set of four zone thermostat setpoint objects is given below. In each case, the keyword is accompanied by an identifying name and either one or two schedule names (depending on whether the control is a single or dual setpoint control). The schedule defines a temperature setpoint for the control type. The schedule would be defined through the standard schedule syntax described earlier in this document. For an uncontrolled zone no thermostat is specified or necessary.

**1.36.3 ThermostatSetpoint:SingleHeating**

This would be for a heating only thermostat. The setpoint can be scheduled and varied throughout the simulation but only heating is allowed with this control type.

**1.36.3.1 Inputs****1.36.3.1.1 Field: Name**

Unique name for this control type.

**1.36.3.1.2 Field: Setpoint Temperature Schedule Name**

The name of the associated schedule. Values in the schedule are temperatures {C}.

**1.36.4 ThermostatSetpoint:SingleCooling**

This would be for a cooling only thermostat. The setpoint can be scheduled and varied throughout the simulation but only cooling is allowed.

**1.36.4.1 Inputs****1.36.4.1.1 Field: Name**

Unique name for this control type.

#### 1.36.4.1.2 Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

### 1.36.5 ThermostatSetpoint:SingleHeatingOrCooling

This would be for heating and cooling thermostat but only heating or cooling can be scheduled at any given time period. The setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

#### 1.36.5.1 Inputs

##### 1.36.5.1.1 Field: Name

Unique name for this control type.

##### 1.36.5.1.2 Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

### 1.36.6 ThermostatSetpoint:DualSetpoint

This would be for heating and cooling thermostat where both a heating and cooling setpoint can be scheduled for any given time period. The setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

#### 1.36.6.1 Inputs

##### 1.36.6.1.1 Field: Name

Unique name for this control type.

##### 1.36.6.1.2 Field: Heating Setpoint Temperature Schedule Name

The heating temperature schedule. Values in the schedule are temperatures {C}.

##### 1.36.6.1.3 Field: Cooling Setpoint Temperature Schedule Name

The cooling temperature schedule. Values in the schedule are temperatures {C}.

Examples of these statements in an IDF are:

```
ThermostatSetpoint:SingleHeating, Heating Setpoint with SB, Heating Setpoints;
ThermostatSetpoint:SingleCooling, Cooling Setpoint with SB, Cooling Setpoints;
ThermostatSetpoint:SingleHeatingOrCooling, Heating Cooling Setpoint Sched, Heating Cooling Setpoints;
ThermostatSetpoint:DualSetpoint, VAV Setpoints, Heating Setpoints, Cooling Setpoints;
```

### 1.36.7 ZoneControl:Thermostat:OperativeTemperature

This object is used to modify the program's behavior for **ZoneControl:Thermostat** objects. One input object is used for each thermal zone to indicate if that zone's thermostat control mode should be overridden to effect operative temperature control rather than traditional air temperature control. Zone Control:Thermostatic and related setpoint objects also need to be included in the input file. When this object is used, the zone can be controlled by a weighted mixture of radiant and air temperatures (rather than just air temperatures).

When using this object, the setpoint temperature values (e.g. input in schedules named in **ThermostatSetpoint:DualSetpoint** objects) become targets for the desired operative temperatures. As of version 8.7

new options are added that allow automatically generating values for the setpoint temperature, as a function of outdoor air temperatures, using various adaptive comfort models based on ASHRAE Standard 55-2010 and CEN 15251-2007. The adaptive comfort model relates the zone operative temperature setpoint to the recent history of the outdoor air temperatures. The adaptive comfort models only apply to cooling mode and generate a single setpoint value for each day. During summer time in hot climates, the zone thermostat setting can be higher than the traditional thermostat setting based on the adaptive thermal comfort model, which results in energy savings of HVAC systems.

This thermostatic operative temperature,  $T_{OP}$ , is defined as:

$$T_{OP} = \gamma T_{MRT} + (1 - \gamma) T_{drybulb} \quad (1.145)$$

where,

$\gamma$  is the radiative fraction,

$T_{MRT}$  is the mean radiant temperature for the thermal zone, and

$T_{drybulb}$  is the mean zone air temperature.

The radiative fraction  $\gamma$  is selected by the user and can be scheduled to vary during the simulation. A typical value is 0.5. The maximum value needs to be less than 0.9 and the minimum is 0.0. A value of 0.0 is the same as controlling on only zone air temperature. If air velocities are higher than 0.2 m/s, then lower values for radiative fraction might apply. Niu and Burnett (1998) cite International Standard ISO 77300 in recommending the values for this fraction listed in the following table.

Table 1.49: Radiative Fraction vs Air Velocity (Operative Temperature Control)

Air Velocity (m/s)	< 0.2	0.2 to 0.6	0.6 to 1.0
$\gamma$	0.5	0.4	0.3

When the adaptive comfort model is selected, the thermostat setpoint temperature schedule for space cooling will be overwritten with the calculated operative temperature based on the selected acceptability limits of the comfort model defined in ASHRAE 55-2010 or CEN 15251-2007. The ASHRAE adaptive comfort model is only applicable when the running average outdoor air temperature for the past 30 days is between 10.0 and 33.5°C; while the CEN 15251-2007 adaptive comfort model is only applicable when the running average outdoor air temperature for the past 7 days is between 10.0 and 30.0°C. The user can choose whether to overwrite the cooling setpoint temperature only when the adaptive setpoint is higher than the user input one for the purpose of energy saving.

- ASHRAE Standard 55-2010. Thermal environment conditions for human occupancy. ASHRAE, Atlanta.

### 1.36.7.1 Inputs

#### 1.36.7.1.1 Field: Thermostat Name

Name of **ZoneControl:Thermostat** object defined elsewhere in the input file whose operation is to be modified to effect control based on operative temperature. If the **ZoneControl:Thermostat** references a **ZoneList** (set of zones) then, this operative temperature thermostat will be applied to each of those zones.

If only a single thermostat/zone is desired, then the name to be put here is <zone name> <Thermostat Name> where the Thermostat name is the thermostat that referenced the set of zones.

### 1.36.7.1.2 Field: Radiative Fraction Input Mode

This field controls whether the input for radiative fraction is a constant value or if it is entered using a schedule. Enter **Constant** here to use a fixed radiative fraction defined in the following field. Enter **Scheduled** to vary the radiative fraction according to the schedule named in the second field below.

### 1.36.7.1.3 Field: Fixed Radiative Fraction

This is the fraction,  $\gamma$ , of the operative temperature that is due to the mean radiant temperature in the zone. This field is used by the program if the previous field is set to **Constant**.

### 1.36.7.1.4 Field: Radiative Fraction Schedule Name

This field contains the name of a schedule, defined elsewhere, that determines the value for radiative fraction  $\gamma$  during the simulation period. This schedule should have fractional values from 0.0 to 0.9. When the value of this schedule is 0.0, the controlling will be equivalent to control based only on zone air temperature. This field is used by the program if the Input Mode field is set to **Scheduled**.

Note that by setting the values in this schedule separately for design days, the user can control how operative temperature control is applied during autosizing. (Operative temperature control tends to increase the equipment capacities calculated during sizing.)

### 1.36.7.1.5 Field: Adaptive Comfort Model Type

This field controls which of the seven adaptive comfort model is chosen, if any, listed as following:

- None. The adaptive comfort model is not applied and the setpoint temperatures are not adjusted from those input in the thermostat setpoints.
- AdaptiveASH55CentralLine. The central line of the acceptability limits of the ASHRAE Standard 55-2010 adaptive comfort model will be used to generate the zone operative temperature setpoint.
- AdaptiveASH5580PercentUpperLine. The upper line of the 80% acceptability limits of the ASHRAE Standard 55-2010 adaptive comfort model will be used to generate the zone operative temperature setpoint.
- AdaptiveASH5590PercentUpperLine. The upper line of the 90% acceptability limits of the ASHRAE Standard 55-2010 adaptive comfort model will be used to generate the zone operative temperature setpoint.
- AdaptiveCEN15251CentralLine. The central line of the acceptability limits of the CEN Standard 15251-2007 adaptive comfort model will be used to generate the zone operative temperature setpoint.
- AdaptiveCEN15251CategoryIUpperLine. The upper line of the Category I of the acceptability limits of the CEN Standard 15251-2007 adaptive comfort model will be used to generate the zone operative temperature setpoint.
- AdaptiveCEN15251CategoryIIUpperLine. The upper line of the Category II of the acceptability limits of the CEN Standard 15251-2007 adaptive comfort model will be generate to adjust the zone operative temperature setpoint; and
- AdaptiveCEN15251CategoryIIIUpperLine. The upper line of the Category III of the acceptability limits of the CEN Standard 15251-2007 adaptive comfort model will be generate as the zone operative temperature setpoint.

### 1.36.7.2 Outputs

- Zone,Average,Zone Thermostat Operative Temperature [C]

#### 1.36.7.2.1 Zone Thermostat Operative Temperature [C]

Operative temperature (OT) is a weighted mixture of Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT), using the current value of Radiative Fraction (RF):  $OT = (1-RF)*MAT + RF*MAT$ . This output variable does not include the direct effect of high temperature radiant systems. See also Zone Operative Temperature.

### 1.36.8 ZoneControl:Thermostat:TemperatureAndHumidity

This object is used to modify the behavior of **ZoneControl:Thermostat** objects (control types **ThermostatSetpoint:SingleCooling** and **ThermostatSetpoint:DualSetpoint** only) based on zone air humidity conditions. Specifically, this TemperatureAndHumidity zone control resets the **ZoneControl:Thermostat**'s cooling set-point temperature downward when the zone air relative humidity exceeds the Dehumidifying Relative

Humidity Setpoint defined in this object. The reduced cooling setpoint temperature typically results in longer cooling coil runtimes and additional dehumidification. The rate at which the cooling setpoint temperature is reduced is dictated by the user-specified Overcool Control Ratio. The maximum reduction in cooling setpoint temperature is defined by the user-entered OverCool Range (user choice of a constant value for the entire simulation or a schedule that can define how the overcool range varies over time). For details regarding the calculations, see the EnergyPlus Engineering Reference.

Note: As described above, this `ZoneControl:Thermostat:TemperatureAndHumidity` control object modifies the cooling setpoint temperature of `ZoneControl:Thermostat` objects. The `ZoneControl:Thermostat:TemperatureAndHumidity` object works independently of the `ZoneControl:Humidistat` object; that is, it does not replace the need for, or coordinate its input fields with, `ZoneControl:Humidistat` objects that are required for other types of high humidity control (e.g., `ZoneControl:Humidistat` objects are required for `ZoneHVAC:Dehumidifier:DX` objects, `AirLoopHVAC:Unitary*` objects with `CoolReheat` or `MultiMode` dehumidification control types, etc.)

### 1.36.8.1 Inputs

#### 1.36.8.1.1 Field: Thermostat Name

Name of `ZoneControl:Thermostat` object defined elsewhere in the input file whose operation is to be modified to effect temperature control based on zone air humidity conditions. If the `ZoneControl:Thermostat` references a `ZoneList` (set of zones), then simply enter the name of the `ZoneControl:Thermostat` object and this `TemperatureAndHumidity` thermostat control will be applied to all zones in the `ZoneList`. If the `ZoneControl:Thermostat` references a `ZoneList` but it is desired that only a single zone within the `ZoneList` be controlled based on `TemperatureAndHumidity` control, then the name to be put here is `<zone name> <Thermostat Name>` where the `Thermostat Name` is the name of the `ZoneControl:Thermostat` object.

#### 1.36.8.1.2 Field: Dehumidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the dehumidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation. This input field is required. This input field has absolutely no relationship or influence on the Dehumidifying Relative Humidity Setpoint Schedule Name optional input field in the `ZoneControl:Humidistat` object.

#### 1.36.8.1.3 Field:Dehumidification Control Type

This input field defines what type of dehumidification control is active during the simulation. Valid control types are `None` and `Overcool`. The default is `Overcool` if this field is left blank. `Overcool` resets the thermostat's cooling setpoint temperature lower based on the zone air relative humidity level. `None` means no overcooling (i.e., traditional zone air temperature control based on the associated `ZoneControl:Thermostat` object [`Thermostat Name` input field above] will be in effect).

#### 1.36.8.1.4 Field: Overcool Range Input Method

This field controls whether the input for the overcool (temperature) range is a constant value or if it is entered using a schedule. Enter **Constant** here to use a constant overcool range defined in the `Overcool Constant Range` input field below. Enter **Scheduled** to vary the overcool range according to the schedule named in the `Overcool Range Schedule Name` input field below. The default is **Constant** if this field is left blank.

#### 1.36.8.1.5 Field: Overcool Constant Range

This field specifies a fixed maximum overcool temperature range for cooling setpoint temperature reduction for zone overcool dehumidification in units of  $\Delta C$ . This field is used if the `Overcool Range Input`

Method is specified as **Constant**. The Overcool dehumidification control type only works with **ZoneControl:Thermostat** control types **ThermostatSetpoint:SingleCooling** and **ThermostatSetpoint:DualSetpoint** . For **ThermostatSetpoint:DualSetpoint** , the model will use the **smaller** of the Overcool Constant Range input value or the difference between the cooling and heating setpoint temperatures specified in the **ThermostatSetpoint:DualSetpoint** object. The Overcool Constant Range must be greater than or equal to zero with a maximum value of 3 °C. A value of 0.0 indicates no zone air overcooling. The default value is 1.7 °C (3 °F) if this input field is left blank.

#### 1.36.8.1.6 Field: Overcool Range Schedule Name

This field contains the name of a schedule, defined elsewhere, that determines the value for the overcool range during the simulation period. This schedule should contain values from 0.0 to  $\leq 3.0$  (deltaC). When the value of this schedule is 0.0, the zone air temperature control will be based only on zone air dry-bulb temperature (i.e., no zone overcooling). This field is used by the program if the Overcool Range Input Method field is set to **Scheduled**. Overcool dehumidification control type only works with **ZoneControl:Thermostat** control types **ThermostatSetpoint:SingleCooling** and **ThermostatSetpoint:DualSetpoint** . For **ThermostatSetpoint:DualSetpoint** , the model will use the **smaller** of the Overcool Range values specified in this schedule or the difference between the cooling and heating setpoint temperatures specified in the **ThermostatSetpoint:DualSetpoint** object.

Note that by setting the values in this schedule separately for design days, the user can control how Overcool Dehumidification Control is applied during autosizing. (Overcool dehumidification control tends to increase the cooling equipment capacities calculated during sizing.)

#### 1.36.8.1.7 Field:Overcool Control Ratio

The value of this input field is used to adjust the cooling setpoint temperature (established by the associated **ZoneControl:Thermostat** object) downward based on the difference between the zone air relative humidity level and the Dehumidifying Relative Humidity Setpoint. This input field is only used with Dehumidification Control Type = Overcool. Input values must be greater than or equal to 0.0 %RH/K. The default value is 3.6 if this field is left blank.

An example of this object follows.

```
ZoneControl:Thermostat:TemperatureAndHumidity,
  Zone Thermostat,                                !- Thermostat Name
  Seasonal Relative Humidity Sch,                 !- Dehumidifying Relative Humidity Setpoint Schedule Name
  Overcool,                                       !- Dehumidification Control Type
  Constant,                                       !- Overcool Range Input Method
  1.7,                                           !- Overcool Constant Range {deltaC}
  ,                                              !- Overcool Range Schedule Name
  3.0;                                           !- Overcool Control Ratio {percent/K}
```

### 1.36.9 ZoneControl:Thermostat:StagedDualSetpoint

The thermostatic zone control staged dual setpoint object is used to control a zone to a specified temperature based on multiple stages. The other types of **ZoneControl:Thermostat** objects reference a control type schedule and one or more control type objects which in turn reference one or more setpoint schedules. This control object does not require a control type schedule and associated one or more control type objects. Instead, the object is defined as a Dual Setpoint type only and has two fields to provide heating and cooling setpoints. The object also provides two fields to specify heating and cooling throttling temperature ranges, so that predicted zone loads may be varied within the throttling ranges for both heating and cooling. The number of stages for both heating and cooling varies from 1 to 4 for the time being to match the number of speeds used in the **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object. The number of stages

may be expanded later to accommodate other objects with the number of speeds higher than 4. The object requires inputs temperature offsets for both heating and cooling based on the number of stages. The stage number is determined by the temperature difference between the setpoint and zone temperature at the previous time step, and offset values. The staged number will be assigned to the speed number for the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` system type.

It should be pointed out that If this object and other zone control thermostat and humidistat are assigned to the same controlled zone, this object takes precedence when the controlled zone is specified in the Controlling Zone or Thermostat Location field of the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object.

### 1.36.9.1 Inputs

#### 1.36.9.1.1 Field: Name

Unique identifying name for the staged dual-setpoint thermostat.

#### 1.36.9.1.2 Field: Zone or ZoneList Name

Name of the zone or set of zones that is being controlled. When the `ZoneList` option is used then this thermostat definition is applied to each of the zones in the zone list effecting a global definition for thermostatic control in the zone.

#### 1.36.9.1.3 Field: Number of Heating Stages

This numerical field defines the number of heating stages, and must be less than or equal to the number of heating speeds defined in the associated heating coil, such as `Coil:Heating:DX:MultiSpeed`. The value for this input field defines the number of heating temperature offsets that must be defined for heating in the fields below. The minimum value for this field is one (1) and the maximum value is four (4).

#### 1.36.9.1.4 Field:Heating Temperature Setpoint Schedule Name

The name of the associated schedule to specify heating temperature setpoint. Values in the schedule are temperatures {C}.

#### 1.36.9.1.5 Field:Heating Throttling Temperature Range

This numeric field defines the heating throttling temperature range in the units of deltaC. When the zone temperature at the previous time step is below the heating temperature setpoint, the zone heating setpoint will be set to the heating temperature setpoint + 0.5 \* heating throttling temperature range. Otherwise, the zone heating setpoint will be set to the heating temperature setpoint - 0.5 \* heating throttling temperature range. The zone heating setpoint is used in the predictor to calculate how much the heating system load is needed to maintain the zone at the heating setpoint.

#### 1.36.9.1.6 Field: Stage 1 Heating Temperature Offset

This numeric field defines the heating temperature offset in the units of deltaC for Stage 1. The value entered here must be equal to or less than 0. The heating temperature offset fields are used to determine the heating stage number for `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object. When the temperature difference between the heating setpoint and the controlled zone temperature at previous time step is less than Stage 1 offset value and greater than Stage 2 offset value, the heating stage number is 1. When the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object is called, Speed 1 is specified.

**1.36.9.1.7 Field: Stage 2 Heating Temperature Offset**

This numeric field defines the heating temperature offset in the units of deltaC for Stage 2. The value entered here must be less than the value at the previous field: Stage 1 Heating Temperature Offset. The heating temperature offset fields are used to determine the heating stage number for **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object. When the temperature difference between the heating setpoint and the controlled zone temperature at previous time step is less than Stage 2 offset value and greater than Stage 3 offset value, the heating stage number is 2. When the **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object is called, Speed 2 is specified.

**1.36.9.1.8 Field: Stage 3 Heating Temperature Offset**

This numeric field defines the heating temperature offset in the units of deltaC for Stage 3. The value entered here must be less than the value at the previous field: Stage 3 Heating Temperature Offset. The heating temperature offset fields are used to determine the heating stage number for **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object. When the temperature difference between the heating setpoint and the controlled zone temperature at previous time step is less than Stage 3 offset value and greater than Stage 4 offset value, the heating stage number is 3. When the **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object is called, Speed 3 is specified.

Note: If the stage number is not equal to the number of heating speed in the **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object, the minimum value is set to the speed number for the heat pump object.

**1.36.9.1.9 Field: Stage 4 Heating Temperature Offset**

This numeric field defines the heating temperature offset in the units of deltaC for Stage 4. The value entered here must be less than the value at the previous field: Stage 4 Heating Temperature Offset. The heating temperature offset fields are used to determine the heating stage number for **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object. When the temperature difference between the heating setpoint and the controlled zone temperature at previous time step is less than Stage 4 offset value, the heating stage number is 4. When the **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object is called, Speed 4 is specified.

Note: If the stage number is not equal to the number of heating speed in the **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** object, the minimum value is set to the speed number for the heat pump object.

**1.36.9.1.10 Field: Number of Cooling Stages**

This field defines the number of cooling stages, and must be less than or equal to the number of cooling speeds defined in the associated cooling coil, such as **Coil:Cooling:DX:MultiSpeed**. The value for this input field defines the number of cooling temperature offsets that must be defined for cooling in the fields below. The minimum value for this field is one (1) and the maximum value is four (4).

**1.36.9.1.11 Field: Cooling Temperature Setpoint Base Schedule Name**

The name of the associated schedule to specify cooling temperature base setpoint. Values in the schedule are temperatures {C}.

**1.36.9.1.12 Field: Cooling Throttling Temperature Range**

This numeric field defines the cooling throttling temperature range in the units of deltaC. When the zone temperature at the previous time step is above the cooling temperature setpoint, the zone cooling setpoint will be set to the cooling temperature setpoint - 0.5 \* cooling throttling temperature range. Otherwise, the zone cooling setpoint will be set to the cooling temperature setpoint + 0.5 \* cooling throttling temperature

range. The zone cooling setpoint is used in the predictor to calculate how much the cooling system load is needed to maintain the zone at the cooling setpoint.

#### 1.36.9.1.13 Field: Stage 1 Cooling Temperature Offset

This numeric field defines the cooling temperature offset in the units of deltaC for Stage 1. The value entered here must be equal to or greater than 0. The cooling temperature offset fields are used to determine the cooling stage number for `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object. When the temperature difference of the cooling setpoint and the controlled zone temperature at previous time step is greater than Stage 1 offset value and less than Stage 2 offset value, the cooling stage number is 1. When the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object is called, Speed 1 is specified.

#### 1.36.9.1.14 Field: Stage 2 Cooling Temperature Offset

This numeric field defines the cooling temperature offset in the units of deltaC for Stage 2. The value entered here must be greater than the value at the previous field: Stage 1 Cooling Temperature Offset. When the number of cooling stage is equal to 1, this field is not used in the program. The cooling temperature offset fields are used to determine the cooling stage number for `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object. When the temperature difference of the cooling setpoint and the controlled zone temperature at previous time step is greater than Stage 2 offset value and less than Stage 3 offset value, the cooling stage number is 2. When the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object is called, Speed 2 is specified.

#### 1.36.9.1.15 Field: Stage 3 Cooling Temperature Offset

This numeric field defines the cooling temperature offset in the units of deltaC for Stage 3. The value entered here must be greater than the value at the previous field: Stage 3 Cooling Temperature Offset. When the number of cooling stage is less than 3, this field is not used in the program. The cooling temperature offset fields are used to determine the cooling stage number for `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object. When the temperature difference of the cooling setpoint and the controlled zone temperature at previous time step is greater than Stage 3 offset value and less than Stage 4 offset value, the cooling stage number is 3. When the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object is called, Speed 3 is specified.

Note: If the stage number is not equal to the number of cooling speed in the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object, the minimum value is set to the speed number for the heat pump object.

#### 1.36.9.1.16 Field: Stage 4 Cooling Temperature Offset

This numeric field defines the cooling temperature offset in the units of deltaC for Stage 4. The value entered here must be greater than the value at the previous field: Stage 4 Cooling Temperature Offset. When the number of cooling stage is less than 4, this field is not used in the program. The cooling temperature offset fields are used to determine the cooling stage number for `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object. When the temperature difference of the cooling setpoint and the controlled zone temperature at previous time step is greater than Stage 4 offset value, the cooling stage number is 4. When the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object is called, Speed 4 is specified.

Note: If the stage number is not equal to the number of cooling speed in the `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` object, the minimum value is set to the speed number for the heat pump object.

An example of this statement in an IDF is:

```

3.0;                     !- Stage 4 Cooling Temperature Offset {deltaC}

```

### 1.36.10 ZoneControl:Humidistat

The humidistat zone control object is used to control a zone to a single relative humidity setpoint schedule, or to dual humidity setpoint schedules (humidifying/ dehumidifying setpoints with deadband). The single setpoint humidistat requires single setpoint input only, and the dual-setpoint humidistat requires inputs of both humidifying and dehumidifying setpoints. The schedules consist of relative humidities, expressed as a percentage (0-100), to be used during the simulation for that zone's moisture prediction calculation. Only one humidistat control statement can be specified for each zone. For a single setpoint humidistat, if the zone relative humidity is below the control relative humidity setpoint and the equipment specified can humidify then that equipment will try and meet the zone's humidification load. The opposite is true if the zone relative humidity is above the control relative humidity setpoint and the equipment can dehumidify. For a dual setpoint humidistat, if the zone relative humidity is below the **humidifying** relative humidity setpoint and the equipment specified can humidify then that equipment will try and meet the zone's humidification load. The opposite is true if the zone relative humidity is above the **dehumidifying** relative humidity setpoint and the equipment can dehumidify.

If the ZoneControl:Humidistat is used by a furnace or unitary system (Ref. Furnace and Unitary Systems) no other objects are required. The signal from the humidistat is used directly by that component. If the Zone Control:Humidistat object is used to control a Humidifier or used in conjunction with a **Controller:WaterCoil** object with control variable **TemperatureAndHumidityRatio** or **HumidityRatio**, the following objects are required to determine a setpoint for those components for a single setpoint humidistat:

- **SetpointManager:SingleZone:Humidity:Minimum**
- **SetpointManager:MultiZone:MinimumHumidity:Average**
- **SetpointManager:MultiZone:MaximumHumidity:Average**
- **SetpointManager:MultiZone:Humidity:Minimum**
- **SetpointManager:MultiZone:Humidity:Maximum**
- **SetpointManager:SingleZone:Humidity:Minimum**

For a dual setpoint humidistat, both a maximum humidity setpoint manager object:

- **SetpointManager:SingleZone:Humidity:Maximum**
- **SetpointManager:MultiZone:MaximumHumidity:Average**

- `SetpointManager:MultiZone:Humidity:Maximum`

and a minimum humidity setpoint manager object:

- `SetpointManager:SingleZone:Humidity:Minimum`
- `SetpointManager:MultiZone:MinimumHumidity:Average`
- `SetpointManager:MultiZone:Humidity:Minimum`

are required to determine the setpoints for the corresponding humidification and dehumidification components.

### 1.36.10.1 Inputs

#### 1.36.10.1.1 Field: Name

Unique identifying name for the humidistat.

#### 1.36.10.1.2 Field: Zone Name

Name of the zone that is being controlled.

#### 1.36.10.1.3 Field: Humidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the humidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation.

**Note:** If only a single setpoint humidistat is desired, then input the single schedule name in the Humidifying Setpoint Schedule Name field (and leave the Dehumidifying Setpoint Schedule Name blank).

#### 1.36.10.1.4 Field: Dehumidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the dehumidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation. This field is optional, only used if a dual setpoint humidistat is to be modeled.

An example of this statement in an IDF is:

```
ZoneControl:Humidistat,
  Zone 2 Humidistat,           !- Humidistat Name
  EAST ZONE,                   !- Zone Name
  Min Rel Hum Set Sch,         !- Humidifying Relative Humidity Setpoint SCHEDULE Name
  Max Rel Hum Set Sch;         !- Dehumidifying Relative Humidity Setpoint SCHEDULE Name
```

An example schedule for the Zone Control:Humidistat

### 1.36.10.2 Outputs

Outputs available from the ZoneControl:Humidistat:

- HVAC,Average,Zone Predicted Moisture Load Moisture Transfer Rate [kgWater/s]
- HVAC,Average,Zone Predicted Moisture Load to Humidifying Setpoint Moisture Transfer Rate [kgWater/s]
- HVAC,Average,Zone Predicted Moisture Load to Dehumidifying Setpoint Moisture Transfer Rate [kgWater/s]
- HVAC,Average,Zone System Predicted Moisture Load Moisture Transfer Rate [kgWater/s]
- HVAC,Average,Zone System Predicted Moisture Load to Humidifying Setpoint Moisture Transfer Rate [kgWater/s]
- HVAC,Average,Zone System Predicted Moisture Load to Dehumidifying Setpoint Moisture Transfer Rate [kgWater/s]

#### 1.36.10.2.1 Zone Predicted Moisture Load Moisture Transfer Rate [kgWater/s]

This is the predicted latent (moisture) load in  $\text{kg}_r/\text{s}$  required to meet the current zone humidistat setpoint. A positive value indicates a humidification load, a negative value indicates a dehumidification load. For a dual setpoint humidistat, the value is zero when the controlled zone's relative humidity is between the defined humidifying and dehumidifying setpoints. This moisture load rate is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat setpoints, determines if the zone requires humidification or dehumidification, and then passes this single load to the equipment for the single setpoint humidistat case. This value is NOT multiplied by zone or group multipliers.

#### 1.36.10.2.2 Zone Predicted Moisture Load to Humidifying Setpoint Moisture Transfer Rate [kgWater/s]

This is the predicted latent (moisture) load in  $\text{kg}_r/\text{s}$  required to meet the current zone humidistat **humidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires humidification or not, and then passes this load to the equipment for the case of a dual setpoint humidistat (see Zone Predicted Moisture Load Moisture Transfer Rate, above, for single setpoint humidistat case). This value is NOT multiplied by zone or group multipliers.

#### 1.36.10.2.3 Zone Predicted Moisture Load to Dehumidifying Setpoint Moisture Transfer Rate [kgWater/s]

This is the predicted latent (moisture) load in  $\text{kg}_r/\text{s}$  required to meet the current zone humidistat **dehumidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires dehumidification or not, and then passes this load to the equipment for a dual setpoint humidistat (see Zone Predicted Moisture Load Moisture Transfer Rate, above, for single setpoint humidistat case). This value is NOT multiplied by zone or group multipliers.

#### 1.36.10.2.4 Zone System Predicted Moisture Load Moisture Transfer Rate [kgWater/s]

This is the predicted latent (moisture) load in  $\text{kg}_r/\text{s}$  required to meet the current zone humidistat setpoint at the system level. A positive value indicates a humidification load, a negative value indicates a dehumidification load. For a dual setpoint humidistat, the value is zero when the controlled zone's relative humidity is between the defined humidifying and dehumidifying setpoints. This moisture load rate is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat setpoints, determines if the zone requires humidification or dehumidification, and then passes this single load to the equipment for the single setpoint humidistat case. This value is the Zone Predicted Moisture Load Moisture Transfer Rate multiplied by zone or group multipliers.

#### 1.36.10.2.5 Zone System Predicted Moisture Load to Humidifying Setpoint Moisture Transfer Rate [kgWater/s]

This is the predicted latent (moisture) load in  $\text{kg}_r/\text{s}$  required to meet the current zone humidistat **humidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires humidification or not, and then passes this load to the equipment for the case of a dual setpoint humidistat (see Zone Predicted Moisture Load Moisture Transfer Rate, above, for single setpoint humidistat case). This value is the Zone Predicted Moisture Load to Humidifying Setpoint Moisture Transfer Rate multiplied by zone or group multipliers.

#### 1.36.10.2.6 Zone System Predicted Moisture Load to Dehumidifying Setpoint Moisture Transfer Rate [kgWater/s]

This is the predicted latent (moisture) load in  $\text{kg}_r/\text{s}$  required to meet the current zone humidistat **dehumidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires dehumidification or not, and then passes this load to the equipment for a dual setpoint humidistat (see Zone Predicted Moisture Load Moisture Transfer Rate, above, for single setpoint humidistat case). This value is the Zone Predicted Moisture Load to Dehumidifying Setpoint Moisture Transfer Rate multiplied by zone or group multipliers.

### 1.36.11 ZoneControl:Thermostat:ThermalComfort

The thermal comfort zone control provides a method to control a zone to a dry-bulb temperature setpoint based on a thermal comfort model (e.g. Fanger) and a user-specified thermal comfort setpoint schedule.

This object references a control type schedule and one or more thermal comfort control type objects which in turn reference one or more setpoint schedules. The example at the end of this section illustrates a complete zone thermal comfort control specification including the control type and setpoint schedules. The control type schedule and the list of control type/name pairs are directly related. The schedule defines the type of control that is to be used during for each hour. Valid Control Types are

- 0 - Uncontrolled (No thermal comfort control)
- 1 - Single Thermal Comfort Heating Setpoint:Fanger
- 2 - Single Thermal Comfort Cooling Setpoint:Fanger
- 3 - Single Thermal Comfort Heating Cooling Setpoint:Fanger
- 4 - Dual Thermal Comfort Setpoint with Deadband:Fanger

Thus, if the schedule referenced in the ZoneControl:Thermostat:ThermalComfort statement has a value of 4 for a particular hour, this indicates that during that hour “Dual Thermal Comfort Setpoint with Deadband:Fanger” is to be used. The specific “Dual Thermal Comfort Setpoint with Deadband:Fanger”

control object to be used is specified in the list of control type/name pairs. Then the specific control type objects reference the thermal comfort control setpoint schedule to be used. Because only one control can be specified for each control type in a `ZoneControl:Thermostat:ThermalComfort` statement, there are only four pairs possible in a particular `ZoneControl:Thermostat:ThermalComfort` type/name list. This is because individual controls can be defined hourly, thus giving the user a full range of flexibility. Since putting in the name of the control type directly in the schedule would be very cumbersome, the control types are assigned a number which is used in the hourly schedule profile.

The `ZoneControl:Thermostat:ThermalComfort` object can be used alone, or with a `ZoneControl:Thermostat` object. When both control objects co-exist for a specific zone and the thermal comfort control type value in the thermal comfort control type schedule is non-zero the thermal comfort object will override the value from the zone thermostat object. If the thermal comfort control is specified as Uncontrolled (thermal comfort control type value of 0) for a particular period, then control will revert to thermostat control if specified. If the thermal comfort control is specified as Uncontrolled for a particular period and thermostat control is not specified in the input, then conditions will float.

This object currently allows only Fanger comfort control (Ref. Thermal Comfort in Engineering Reference). It requires one or more people objects in a specific zone. It also requires inputs of Fields *Activity Level Schedule Name*, *Work Efficiency Schedule Name*, *Clothing Insulation Schedule Name* and *Air Velocity Schedule Name* in the people object(s). When thermal comfort control is used in a zone, the air velocity entered in the Air Velocity Schedule (Ref. `People`) should be greater than or equal to 0.1 and less than or equal to 0.5 m/s. A warning message will be issued if thermal comfort control is active and the air velocity is outside this range.

This object reads input PMV values from a given PMV setpoint schedule to calculate a dry-bulb temperature setpoint based on the selected thermal comfort model. The dry-bulb temperature setpoint calculation uses zone air humidity ratio at the previous system timestep and surface temperatures at the previous zone timestep, along with other conditions at the current timestep (e.g., activity level, clothing level and air velocity from the `PEOPLE` object).

### 1.36.11.1 Inputs

#### 1.36.11.1.1 Field: Name

Unique identifying name for this thermal comfort control object.

#### 1.36.11.1.2 Field: Zone or ZoneList Name

Name of the zone or set of zones that is being controlled. When the `ZoneList` option is used then this thermostat definition is applied to each of the zones in the zone list effecting a global definition for thermostatic control in the zone.

#### 1.36.11.1.3 Field: Averaging Method

This choice field specifies the method for calculating the thermal comfort dry-bulb temperature setpoint for a zone with multiple `People` objects defined. The available choices are: `SpecificObject`, `ObjectAverage`, and `PeopleAverage`. This field is only used when multiple people objects are defined for this zone. If this field is specified as `PeopleAverage` and the total number of people for all people objects is zero for a particular timestep, the `PeopleAverage` method cannot be applied and the program automatically uses the `ObjectAverage` method for this timestep. The default input is `PeopleAverage`.

#### 1.36.11.1.4 Field: Object Name for Specific Object Averaging Method

This choice field specifies the name of the specific `People` object to be used for calculating comfort control when multiple `People` objects are defined. Only used if the Averaging Method is specified as `SpecificObject`.

#### 1.36.11.1.5 Field: Minimum Dry-Bulb Temperature Setpoint

This field specifies the minimum dry-bulb temperature setpoint allowed for this zone. If the dry-bulb temperature calculated by the thermal comfort setpoint model is below this value, then the temperature setpoint will be set to this value. The default value is 0 °C.

#### 1.36.11.1.6 Field: Maximum Dry-Bulb Temperature Setpoint

This field specifies the maximum dry-bulb temperature setpoint allowed for this zone. If the dry-bulb temperature calculated by the thermal comfort setpoint model exceeds this value, then the temperature setpoint will be set to this value. The default value is 50 °C.

Note the minimum and maximum temperature setpoint fields are provided to allow the user to bound the temperature control in a specific zone if necessary. These fields are used to provide boundaries for the dry-bulb temperature setpoint calculated at each system timestep when unrealistic inputs have been specified.

#### 1.36.11.1.7 Field: Thermal Comfort Control Type Schedule Name

Schedule which defines what type of thermal comfort control is active during each simulation timestep.

Valid Control Types are

- 0 - No thermal comfort control
- 1 - Single Thermal Comfort Heating Setpoint:Fanger
- 2 - Single Thermal Comfort Cooling Setpoint:Fanger
- 3 - Single Thermal Comfort Heating Cooling Setpoint:Fanger
- 4 - Dual Thermal Comfort Setpoint with Deadband:Fanger

Each non-zero control type used in this schedule must appear in the following fields which list the specific thermal comfort control objects to be used for this zone.

#### 1.36.11.1.8 Field Set (Thermal Comfort Control Object Type, Thermal Comfort Control Name)

Up to four pairs of Thermal Comfort Control Type and Thermal Comfort Control Type Name fields may be listed to specify which thermal comfort control type objects are used for this zone. This list is not order-dependent, and the position in this list has no impact on the control type schedule. In the control type schedule, a value of 1 always means “Single Thermal Comfort Heating Setpoint:Fanger”, even if that control type is not first in this list.

#### 1.36.11.1.9 Field: Thermal Comfort Control <x> Object Type

This field specifies the first control type name to be used for this zone. Available control types are:

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating  
 ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling  
 ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling  
 ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint

#### 1.36.11.1.10 Field: Thermal Comfort Control <x> Name

The unique name for the corresponding thermal comfort control type.

An example of this statement in an IDF is:

```
ZoneControl:Thermostat:ThermalComfort,
Zone 2 Comfort Control,          !- Thermal Comfort Control Name
EAST_ZONE,                      !- Zone Name

### 1.36.11.2 Outputs

Three outputs are available from the ZoneControl:Thermostat:ThermalComfort object. Two output variables used primarily for the ZoneControl:Thermostat object are also described here to explain their meaning when using thermal comfort control.

#### ZoneControl:ThermalComfort

- Zone,Average,Zone Thermal Comfort Control Type []
- Zone,Average,Zone Thermal Comfort Control Fanger Low Setpoint PMV []
- Zone,Average,Zone Thermal Comfort Control Fanger High Setpoint PMV []

#### ZoneControl:Thermostat

- Zone,Average,Zone Thermostat Heating Setpoint Temperature [C]
- Zone,Average,Zone Thermostat Cooling Setpoint Temperature [C]

#### 1.36.11.2.1 Zone Thermal Comfort Control Type []

This is the current zone thermal comfort control type (0 through 4). This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

#### 1.36.11.2.2 Zone Thermal Comfort Control Fanger Low Setpoint PMV []

This is the current zone thermal comfort low Predicted Mean Vote value. Values range between -3 and +3. If there is no heating thermal comfort active, then the value reported will be -999. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

### 1.36.11.2.3 Zone Thermal Comfort Control Fanger High Setpoint PMV []

This is the current zone thermal comfort high Predicted Mean Vote value. Values range between -3 and +3. If there is no cooling thermal comfort active, then the value reported will be 999. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

### 1.36.11.2.4 Zone Thermostat Heating Setpoint Temperature [C]

The Zone Control:Thermal Comfort object shares the same output variable and overwrites the thermal setpoints defined in object Zone Control:Thermostatic when both objects of Zone Control:Thermostatic and Zone Control:Thermal Comfort co-exist. It outputs the current zone thermal comfort heating setpoint in degrees C when thermal comfort control is active, otherwise this output variable will report the thermostat heating setpoint (Ref. Zone Control:Thermostatic Outputs). If there is no heating thermal comfort active and no thermostat heating setpoint is defined for this zone, this value will be 0. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

### 1.36.11.2.5 Zone Thermostat Cooling Setpoint Temperature [C]

This output variable defined in object Zone Control:Thermostatic. The Thermal Comfort object shares the same output variable and overwrites the thermal setpoints defined in object Zone Control:Thermostatic when both objects of Zone Control:Thermostatic and Zone Control:Thermal Comfort co-exist. It outputs the current zone thermal comfort cooling setpoint in degrees C when thermal comfort control is active, otherwise this output variable will report the thermostat cooling setpoint (Ref. Zone Control:Thermostatic Outputs). If there is no cooling thermal comfort active and no thermostat cooling setpoint is defined for this zone, this value will be 0. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

## 1.36.12 Thermal Comfort Setpoints

The syntax for the current set (4) of zone thermal comfort control types is given below. In each case, the keyword is accompanied by an identifying name and either one or two schedule names (depending on whether the control type is a single or dual setpoint control). The schedule defines a Predicted Mean Vote (PMV) setpoint for the control type. The schedule would be defined through the standard schedule syntax described earlier in this document. For an uncontrolled thermal comfort zone, no Fanger thermal comfort object is specified or necessary. However, the Fanger thermal comfort output variables `Zone Thermal Comfort Fanger Model PMV` and `Zone Thermal Comfort Fanger Model PPD` are reported regardless of whether the zone is uncontrolled (i.e., free floating) or controlled by a thermostat. When the zone is controlled by a thermostat, the air temperature and humidity used to calculate the Fanger PMV and PPD values are based on the values of these parameters at the system time step level. When the zone is uncontrolled, the air conditions used to calculate the Fanger PMV and PPD are the free floating temperature and humidity ratio calculated at the zone time step level. The Fanger PMV and PPD are outputs variables as outlined in the `People` object. For more information on the equations used to calculate the Fanger PMV and PPD, please consult the EnergyPlus Engineering Reference.

### 1.36.13 ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating

This would be used for heating only thermal comfort control. The PMV setpoint can be scheduled and varied throughout the simulation but only heating is allowed with this control type.

### 1.36.13.1 Inputs

#### 1.36.13.1.1 Field: Name

Unique name for this control type.

#### 1.36.13.1.2 Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule containing Zone Thermal Comfort Fanger Model PMV values.

## 1.36.14 ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling

This would be used for cooling only thermal comfort control. The PMV setpoint can be scheduled and varied throughout the simulation but only cooling is allowed with this control type.

### 1.36.14.1 Inputs

#### 1.36.14.1.1 Field: Name

Unique name for this control type.

#### 1.36.14.1.2 Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule, containing Zone Thermal Comfort Fanger Model PMV values.

## 1.36.15 ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling

This would be used for heating and cooling thermal comfort control but only heating or cooling can be scheduled at any given time period. The PMV setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

### 1.36.15.1 Inputs

#### 1.36.15.1.1 Field: Name

Unique name for this control type.

#### 1.36.15.1.2 Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule containing Zone Thermal Comfort Fanger Model PMV values.

## 1.36.16 ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint

This would be used for heating and cooling thermal comfort control where both a heating and cooling PMV setpoint can be scheduled for any given time period. The PMV setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

### 1.36.16.1 Inputs

#### 1.36.16.1.1 Field: Name

Unique name for this control type.

#### 1.36.16.1.2 Field: Fanger Thermal Comfort Heating Schedule Name

The name of the associated schedule containing heating setpoint Zone Thermal Comfort Fanger Model PMV values.

### 1.36.16.1.3 Field: Fanger Thermal Comfort Cooling Schedule Name

The name of the associated schedule containing cooling setpoint Zone Thermal Comfort Fanger Model PMV values.

An example of this statement in an IDF is:

```
ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating,
  Heating Comfort Setpoint,!- Name
  Heating PMV Setpoints;      !- Setpoint Temperature SCHEDULE Name

ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling,
  Cooling Comfort Setpoint,!- Name
  Cooling PMV Setpoints;      !- Setpoint Temperature SCHEDULE Name

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling,
  Heating Cooling Comfort Setpoint,!- Name
  Heating Cooling PMV Setpoints;      !- Setpoint Temperature SCHEDULE Name

ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint,
  Dual Comfort Setpoint,      !- Name
  Heating PMV Setpoints,      !- Fanger Thermal Comfort Heating Setpoint PMV SCHEDULE Name
  Cooling PMV Setpoints;      !- Fanger Thermal Comfort Cooling Setpoint PMV SCHEDULE Name
```

---

## 1.36.17 ZoneControl:ContaminantController

The ZoneControl:ContaminantController object is used for any of the following two purposes based on the system outdoor air method specified in the [Controller:MechanicalVentilation](#).

- 1) To control a zone to a specified indoor level of contaminants. When this zone is served by an [AirLoopHVAC](#), the other zones served by the same [AirLoopHVAC](#) will have the same specified indoor level, if no objects in the other zones served by the same [AirLoop](#) are specified. Currently, the available contaminant controls are carbon dioxide and generic contaminant controls. The specified carbon dioxide setpoint is used to calculate the required outdoor airflow rate through the HVAC system to reach the setpoint. The [AirLoopHVAC](#) system outdoor flow rate is realized by the [Controller:MechanicalVentilation](#) object with System Outdoor Air Method = IndoorAirQualityProcedure. The specified generic contaminant setpoint is used to calculate the required outdoor airflow rate through the HVAC system to reach the setpoint. The [AirLoopHVAC](#) system outdoor flow rate is realized by the [Controller:MechanicalVentilation](#) object with System Outdoor Air Method = IndoorAirQualityProcedure-GenericContaminant.
- 2) To specify minimum or maximum CO2 concentration schedule name for a zone. The [AirLoopHVAC](#) system outdoor flow rate is realized by the [Controller:MechanicalVentilation](#) object with System Outdoor Air Method = ProportionalControlBasedOnOccupancySchedule or ProportionalControlBasedOnDesignOccupancy or ProportionalControlBasedOnDesignOARate. Carbon Dioxide Control Availability Schedule Name determines the availability of ProportionalControl.

For the first purpose above, when multiple zones are served by an [AirLoop](#), those zones that do not have a contaminant controller object specified in the input data file are automatically assigned a carbon dioxide setpoint. Zone objects entered in the input data file are internally assigned an index number from 1 to n (first defined Zone object = 1, next Zone object defined in the input file = 2, etc.). For zones served by an [AirLoop](#) that do not have a contaminant controller specified, the zone's carbon dioxide setpoint will be the same as the zone with the next highest zone index number that has a contaminant controller specified. If a zone with a higher index number and contaminant controller specified does not exist, then

the zone with the next lowest zone index number that has a contaminant controller specified will be used. For example, assume an AirLoop serves zones 1 through 5, but one ZoneControl:ContaminantController object is specified for zone 2, a second ZoneControl:ContaminantController object is specified for zone 4, and no ZoneControl:ContaminantController objects are specified for zones 1, 3 and 5. In this case, zone 1 will be assigned the carbon dioxide setpoint schedule that was specified for zone 2, and zones 3 and 5 will be assigned the carbon dioxide setpoint schedule that was specified for zone 4.

The ZoneControl:ContaminantController object is also used for any of the following two purposes based on the outdoor air method specified in the [DesignSpecification:OutdoorAir](#).

- 1) To control a zone to a specified indoor level of contaminants. When this zone is served by a dedicated outdoor air system [AirLoopHVAC](#) through a terminal unit, some type of terminal units are able to call a [DesignSpecification:OutdoorAir](#) object with Outdoor Air Method = IndoorAirQualityProcedure, so that the required outdoor airflow rate to reach the zone air setpoint can be assigned to the terminal unit. The total outdoor air flow in the [AirLoopHVAC](#) is a sum of all terminal units. In this way, each zone served by the same [AirLoopHVAC](#) can reach the zone air CO2 setpoint precisely.
- 2) To specify minimum CO2 concentration schedule name for a zone. When this zone is served by a dedicated outdoor air system [AirLoopHVAC](#) through a terminal unit, some type of terminal units are able to call a [DesignSpecification:OutdoorAir](#) object with Outdoor Air Method = ProportionalControlBasedOnOccupancySchedule or ProportionalControlBasedOnDesignOccupancy. The outdoor airflow rate is determined by one of proportional control procedures. Then, the calculated outdoor airflow rate is assigned to the terminal unit. The total outdoor air flow in the [AirLoopHVAC](#) is a sum of all terminal units. In this way, each zone served by the same [AirLoopHVAC](#) will receive the outdoor airflow rate based on terminal unit request.

### 1.36.17.1 Inputs

#### 1.36.17.1.1 Field: Name

Unique identifying name for the ZoneControl:ContaminantController.

#### 1.36.17.1.2 Field: Zone Name

Name of the zone that is being controlled.

#### 1.36.17.1.3 Field:Carbon Dioxide Control Availability Schedule Name

This field contains the name of a schedule that determines whether or not the ZoneControl:ContaminantController is available. When the schedule value is zero, the ZoneControl:ContaminantController is bypassed (not available to operate). When the schedule value is greater than zero, the ZoneControl:ContaminantController is available and will be used to calculate the required outdoor airflow rate to reach the carbon dioxide setpoint. If this field is left blank, the schedule has a value of 1 for all time periods. Schedule values must be between 0 and 1.

#### 1.36.17.1.4 Field:Carbon Dioxide Setpoint Schedule Name

This field contains the name of a schedule that contains the zone carbon dioxide concentration setpoint as a function of time. The units for carbon dioxide setpoint are ppm. The setpoint values in the schedule must be between 0 and 2000 ppm. . This field is used when the field System Outdoor Air Method = IndoorAirQualityProcedure in the [Controller:MechanicalVentilation](#) object.

### 1.36.17.1.5 Field:Minimum Carbon Dioxide Concentration Schedule Name

This field contains the name of a schedule that contains the minimum zone carbon dioxide concentration setpoint as a function of time. The units for carbon dioxide setpoint are ppm. This field is used when the field System Outdoor Air Method = ProportionalControlBasedOnOccupancySchedule or ProportionalControlBasedOnDesignOccupancy, or ProportionalControlBasedOnDesignOARate in the **Controller:MechanicalVentilation** object. This field is also used when the field Outdoor Air Method = ProportionalControlBasedOnOccupancySchedule or ProportionalControlBasedOnDesignOccupancy in the **DesignSpecification:OutdoorAir** object.

### 1.36.17.1.6 Field:Maximum Carbon Dioxide Concentration Schedule Name

This field contains the name of a schedule that contains the maximum zone carbon dioxide concentration as a function of time and is used to calculate design CO2 concentration level in the proportional ventilation control. The units for carbon dioxide setpoint are ppm. This field is used when the field System Outdoor Air Method = ProportionalControlBasedOnOccupancySchedule, or ProportionalControlBasedOnDesignOccupancy, or ProportionalControlBasedOnDesignOARate in the **Controller:MechanicalVentilation** object.

### 1.36.17.1.7 Field: Generic Contaminant Control Availability Schedule Name

This field contains the name of a schedule that determines whether or not the ZoneControl:ContaminantController is available. When the schedule value is zero, the generic contaminant control will not be performed. When the schedule value is greater than zero, the ZoneControl:ContaminantController is available and will be used to calculate the required outdoor airflow rate to reach the generic contaminant setpoint. If this field is left blank, the schedule has a value of 1 for all time periods. Schedule values must be between 0 and 1.

### 1.36.17.1.8 Field: Generic Contaminant Setpoint Schedule Name

This field contains the name of a schedule that contains the zone generic contaminant concentration setpoint as a function of time. The units for generic contaminant setpoint are ppm. The setpoint values in the schedule must be  $\geq 0$ .

An IDF example is provided below:

```
ZoneControl:ContaminantController,

## 1.36.17.2 Outputs

The following output variables are available when the ZoneControl:ContaminantController object is specified.

- HVAC,Average,Zone Air CO2 Predicted Load to Setpoint Mass Flow Rate [kg/s]
- HVAC,Average,Zone Air CO2 Setpoint Concentration [ppm]
- HVAC,Average,Zone Generic Air Contaminant Predicted Load to Setpoint Mass Flow Rate [kg/s]
- HVAC,Average,Zone Generic Air Contaminant Setpoint Concentration [ppm]

**1.36.17.2.1 Zone Air CO2 Predicted Load to Setpoint Mass Flow Rate [kg/s]**

This output is the average predicted outdoor airflow rate in kg/s required to meet the current zone carbon dioxide setpoint for the time step being reported. This value is calculated and reported from the Predict step in the Zone Contaminant Predictor-Corrector module. The calculated outdoor airflow rate will be specified in the Controller:MechanicalVentilation object with System Outdoor Air Method = IndoorAirQualityProcedureto provide enough outdoor ventilation air to keep the zone air carbon dioxide concentration level at or below the setpoint.

**1.36.17.2.2 Zone Air CO2 Setpoint Concentration [ppm]**

This output variable is the average carbon dioxide setpoint value, in parts per million, for the time step being reported.

**1.36.17.2.3 Zone Generic Air Contaminant Predicted Load to Setpoint Mass Flow Rate [kg/s]**

This output is the average predicted outdoor airflow rate in kg/s required to meet the current zone generic contaminant setpoint for the time step being reported. This value is calculated and reported from the Predict step in the Zone Contaminant Predictor-Corrector module. The calculated outdoor airflow rate will be specified in the Controller:MechanicalVentilation object with System Outdoor Air Method = IndoorAirQualityProcedure-GenericContaminant\*\*\*\*to provide enough outdoor ventilation air to keep the zone air generic contaminant concentration level at or below the setpoint.

**1.36.17.2.4 Zone Generic Air Contaminant Setpoint Concentration [ppm]**

This output variable is the average generic contaminant setpoint value, in parts per million, for the time step being reported.

**1.37 Group – Air Path****1.37.1 AirLoopHVAC:SupplyPath, AirLoopHVAC:ReturnPath**

The zone supply and return air paths are used to describe the configuration of the flow path that the supply air takes in moving from the main air handler to the zone terminal units and that the return air takes on leaving the zones and returning to the central return air duct. The air paths consist of a group of components **AirLoopHVAC:ZoneSplitters** and **AirLoopHVAC:SupplyPlenums** for the supply path and **AirLoopHVAC:ReturnPlenums** and **AirLoopHVAC:ZoneMixers** for the return path. The connectivity of the paths is established by the components node connections. There are no branches defined in the zone air path constructs.

For a typical single duct air system there will be one **AirLoopHVAC:SupplyPath** and one **AirLoopHVAC:ReturnPath**. A typical dual duct system would have 2 **AirLoopHVAC:SupplyPaths** one for the hot air and one for the cold air and 1 **AirLoopHVAC:ReturnPath**.

The **AirLoopHVAC:SupplyPlenum** component provides the capability to have supply air distributed to the conditioned zones through one or more plenum zones such as would occur in an underfloor air distribution system (UFAD). The **AirLoopHVAC:ReturnPlenum** component allows the program to model return air plenums. Of course plenums are always optional. The simplest **AirLoopHVAC:SupplyPath** would consist of only an **AirLoopHVAC:ZoneSplitter**; similarly the simplest return air path consists of a single **AirLoopHVAC:ZoneMixer**. A UFAD system supply air path might consist of a single **AirLoopHVAC:ZoneSplitter** connecting to multiple **AirLoopHVAC:SupplyPlenums** which in turn could each supply one or more conditioned zones. A system with return plenums would have an **AirLoopHVAC:ReturnPath**

in which the conditioned zones connect to the return plenum inlets and the outlets of the return plenum connect to a single `AirLoopHVAC:ZoneMixer`.

Both the zone supply and return plenums are solved in the heat balance as thermal zones which couple through heat conduction with adjacent zones. Since they are solved as thermal zones the solution scheme involves the zone predictor-corrector technique which will lag the temperature at the system timestep in every zone. See Summary of Predictor-Corrector Procedure in the EnergyPlus Engineering Reference.

Below are the descriptions of the zone supply and return path statements. Note that each statement type has an identifying name, a single inlet/outlet node name, and a list of component type/name pairs. For a single zone being served by an air loop, the inlet to its air distribution unit and the zone return air outlet can be the zone equipment inlet and outlet nodes directly, thus eliminating the need to specify an `AirLoopHVAC:SupplyPath` and an `AirLoopHVAC:ReturnPath`.

## 1.37.2 AirLoopHVAC:SupplyPath

The `AirLoopHVAC:SupplyPath` lists one or more `AirLoopHVAC:ZoneSplitter` and `AirLoopHVAC:SupplyPlenum` components comprising the path. The components are listed in flow order: upstream to downstream and may be in series, parallel, or both. Connectivity is established by means of the individual component inlet and outlet nodes.

### 1.37.2.1 Inputs

#### 1.37.2.1.1 Field: Name

Unique name to identify the supply air path..

#### 1.37.2.1.2 Field: Supply Air Path Inlet Node Name

The name of an inlet node for the zone equipment half of the air loop. This should be one of the nodes named in the `AirLoopHVAC` field: Demand Side Inlet Node Names.

#### 1.37.2.1.3 Field Set Component Type and Name

The remaining fields are sets of two repeated times: a component type and a name. These pairs of fields define the components on the supply air path.

#### 1.37.2.1.4 Field: Component <#> Object Type

Start of the component list for the `AirLoopHVAC:SupplyPath`. This field should contain either `AirLoopHVAC:SupplyPlenum` or `AirLoopHVAC:ZoneSplitter`.

#### 1.37.2.1.5 Field: Component <#> Name

Unique name of the `AirLoopHVAC:SupplyPlenum` or `AirLoopHVAC:ZoneSplitter` component.

## 1.37.3 AirLoopHVAC:ReturnPath

The `AirLoopHVAC:ReturnPath` lists one or more `AirLoopHVAC:ZoneMixer` and `AirLoopHVAC:ReturnPlenum` components comprising the path. The components are listed in flow order: upstream to downstream and may be in series, parallel, or both. Connectivity is established by means of the individual component inlet and outlet nodes. At this time there can only be 1 `AirLoopHVAC:ZoneMixer` in an `AirLoopHVAC:ReturnPath`.

### 1.37.3.1 Inputs

#### 1.37.3.1.1 Field: Name

Unique name to identify the return air path.

#### 1.37.3.1.2 Field: Return Air Path Outlet Node Name

The name of the node that is the outlet to the air loop from the AirLoopHVAC:ReturnPath. This should be the same node named in the **AirLoopHVAC** field: Demand Side Outlet Node Name.

#### 1.37.3.1.3 Field Set Component Type and Name

The remaining fields are sets of two repeated times: a component type and a name. These pairs of fields define the components on the return air path.

#### 1.37.3.1.4 Field: Component <#> Object Type

Start of the component list for the AirLoopHVAC:ReturnPath. This field should contain either *Air-LoopHVAC:ReturnPlenum* or *AirLoopHVAC:ZoneMixer*.

#### 1.37.3.1.5 Field: Component <#> Name

Unique name of the *AirLoopHVAC:ReturnPlenum* or *AirLoopHVAC:ZoneMixer*.

Example inputs are shown below

```
AirLoopHVAC:SupplyPath,
  SupplyAirPath 1,           !- Name
  Zone Equip In Node,       !- Supply Air Path Inlet Node Name
  AirLoopHVAC:SupplyPlenum, !- Component 1 Object Type
  Supply-Plenum-1,          !- Component 1 Name
  AirLoopHVAC:ZoneSplitter, !- Component 2 Object Type
  Zone Supply Air Splitter 1; !- Component 2 Name

AirLoopHVAC:ReturnPath,
  ReturnAirPath1,           !- Name
  PLENUM-1 Out Node,       !- Return Air Path Outlet Node Name
  Zone Return Plenum,      !- Component 1 Object Type
  Return-Plenum-1;         !- Component 1 Name
```

---

## 1.37.4 AirLoopHVAC:ReturnPlenum

The simple building shown in the figure below consists of a controlled zone and a return plenum zone that is used for the return air. This simple configuration contains a ground floor controlled zone with a window and a return plenum zone which handles the roof load. The return air plenum is a special type of component since there is both a heat balance connection and building description and a system airflow connection that transfers the airflow directly from the controlled zone to the return plenum zone in the system air simulation. The input described in this section is mainly just for the system airflow connections in the HVAC algorithms. In addition the return plenum zone must be fully input as a zone object for the heat balance calculation. The zone description needs to contain the wall descriptions - the interzone ceiling and floor, and for this simple case the roof. All the other attributes of a zone that can be specified in the building description can be used with a return plenum zone if necessary: scheduled loads, windows, etc.

After all the building zone attributes are specified, the AirLoopHVAC:ReturnPlenum object is specified and included as one of the named components in an **AirLoopHVAC:ReturnPath**.

Figure 1.165: Illustration of Zone Return Plenum

#### 1.37.4.1 Inputs

##### 1.37.4.1.1 Field: Name

A unique identifying name identifying the AirLoopHVAC:ReturnPlenum system component.

##### 1.37.4.1.2 Field: Zone Name

The zone name specified in the heat balance portion of the input. This piece of input connects the zone return plenum system component to the heat balance data structure.

##### 1.37.4.1.3 Field: Zone Node Name

The name of the zone node. The zone node name connects the heat balance data structure to the system airflow data structure through this node. This node name must be unique otherwise a warning is reported. Do not use the Zone Air Node Name specified in any **ZoneHVAC:EquipmentConnections** object, and since this zone is a plenum a **ZoneHVAC:EquipmentConnections** object is not required for the zone named in the previous field.

##### 1.37.4.1.4 Field: Outlet Node Name

The name of the return plenum outlet node. For the zone return plenum there is only one outlet node that can be specified.

##### 1.37.4.1.5 Field: Induced Air Outlet Node or NodeList Name

The name of an induced air outlet node or the name of a **NodeList** of such nodes. These nodes are to be used as the secondary inlet air nodes of powered induction terminal units (See **AirTerminal:SingleDuct:SeriesPIU:Reheat** and **AirTerminal:SingleDuct:ParallelPIU:Reheat**).

### 1.37.4.1.6 Field: Inlet <#> Node Name

The name of a plenum inlet node. There is no limit to the number of inlet nodes, and there may be no duplicate inlet node names. (Note that some EnergyPlus editing tools may allow only 500 inlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An IDF example of a zone return plenum component specification:

```
AirLoopHVAC:ReturnPlenum,
  Return-Plenum-1,          !- Name
  PLENUM-1,                 !- Zone Name
  PLENUM-1 Node,            !- Zone Node Name
  PLENUM-1 Out Node,        !- Outlet Node Name
  PLENUM-1 Induced Air Nodes, !- Induced Air Outlet Node or NodeList Name
  SPACE1-1 Out Node,        !- Inlet 1 Node Name
  SPACE2-1 Out Node,        !- Inlet 2 Node Name
  SPACE3-1 Out Node,        !- Inlet 3 Node Name
  SPACE4-1 Out Node,        !- Inlet 4 Node Name
  SPACE5-1 Out Node;        !- Inlet 5 Node Name

NodeList,
  PLENUM-1 Induced Air Nodes, !- Name
  SPACE1-1 ATU Sec Node,      !- Node 1 Name
  SPACE2-1 ATU Sec Node,      !- Node 2 Name
  SPACE3-1 ATU Sec Node,      !- Node 3 Name
  SPACE4-1 ATU Sec Node;      !- Node 4 Name
```

Below is an example of the `AirLoopHVAC:ReturnPath` for the simple case shown above.

```
AirLoopHVAC:ReturnPath,
  ReturnAirPath1,           !- Name
  PLENUM-1 Out Node,        !- Return Air Path Outlet Node Name
  AirLoopHVAC:ReturnPlenum, !- Component 1 Object Type
  Return-Plenum-1;          !- Component 1 Name
```

## 1.37.5 AirLoopHVAC:SupplyPlenum

The building shown in the figure below consists of three controlled zones served by an `AirLoopHVAC:SupplyPlenum` beneath the floor.

The `AirLoopHVAC:SupplyPlenum` has a heat balance connection and building description, and a system airflow connection which transfers the airflow from the supply plenum zone to the controlled zones in the system simulation. The input described in this section is mainly just for the system airflow connections in the HVAC algorithms. In addition the supply plenum zone must be fully input in the building zone description. The supply plenum zone description needs to contain the wall descriptions, the interzone ceiling and floor, and the ground connection. All the other attributes of a zone that can be specified in the building description can be utilized with a supply plenum zone if necessary, i.e. scheduled loads, windows, etc.

After all the building zone attributes are specified, the `AirLoopHVAC:SupplyPlenum` object is specified and included as one of the named components in an `AirLoopHVAC:SupplyPath`.

### 1.37.5.1 Inputs

#### 1.37.5.1.1 Field: Name

A unique identifying name identifying the `AirLoopHVAC:SupplyPlenum` system component.

#### 1.37.5.1.2 Field: Zone Name

Figure 1.166: Illustration of AirLoopHVAC:SupplyPlenum

The zone name specified in the heat balance portion of the input. This piece of input connects the AirLoopHVAC:SupplyPlenum system component to the heat balance data structure.

#### 1.37.5.1.3 Field: Zone Node Name

The name of the zone node. The zone node name connects the heat balance data structure to the system airflow data structure through this node. This node name is defined by the user in the field Zone Air Node Name in the **ZoneHVAC:EquipmentConnections** object for the zone named in the previous field.

#### 1.37.5.1.4 Field: Inlet Node Name

The name of the inlet node to the supply plenum. The AirLoopHVAC:SupplyPlenum component can send air to many outlets, but there is only one inlet.

#### 1.37.5.1.5 Field: Outlet <#> Node Name

The name of a plenum outlet node. There is no limit to the number of outlet nodes, and there may be no duplicate outlet node names. (Note that some EnergyPlus editing tools may allow only 500 outlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An IDF example of an AirLoopHVAC:SupplyPlenum component specification:

```
AirLoopHVAC:SupplyPlenum,
  Supply Plenum 1,                ! Name
  SUPPLY PLENUM ZONE,             ! Zone Name
  Supply Plenum 1 Zone Node,      ! Zone Node Name
  Zone Equipment Inlet Node,      ! Inlet Node Name
  Supply Plenum 1 Outlet Node;    ! Outlet 1 Node Name
```

Below is an example of the **AirLoopHVAC:SupplyPath** for the building shown above.

```
AirLoopHVAC:SupplyPath,
  TermReheatSupplyPath,          ! Name
  Zone Equipment Inlet Node,      ! Supply Air Path Inlet Node Name
  AirLoopHVAC:SupplyPlenum,      ! Component 1 Object Type
  Supply Plenum 1,               ! Component 1 Name
  AirLoopHVAC:ZoneSplitter,       ! Component 2 Object Type
  Zone Supply Air Splitter;       ! Component 2 Name
```

### 1.37.6 AirLoopHVAC:ZoneSplitter

The AirLoopHVAC:ZoneSplitter is a component that splits airflow from a single inlet to multiple outlets. This component must be referenced in an **AirLoopHVAC:SupplyPath** object. The input contains only node connection information.

#### 1.37.6.1 Inputs

##### 1.37.6.1.1 Field: Name

Unique name for this zone splitter.

##### 1.37.6.1.2 Field: Inlet Node Name

The name of the single inlet node going into the splitter.

### 1.37.6.1.3 Field: Outlet <#> Node Name

The name of a splitter outlet node. There is no limit to the number of outlet nodes, and there may be no duplicate outlet node names. (Note that some EnergyPlus editing tools may allow only 500 outlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An example is shown below.

```
AirLoopHVAC:ZoneSplitter,
Zone Supply Air Splitter,      ! Name
Zone Equipment Inlet Node,    ! Inlet Node Name
Zone 1 Damper Inlet Node,     ! Outlet 1 Node Name
Zone 2 Damper Inlet Node,     ! Outlet 2 Node Name
Zone 3 Damper Inlet Node;     ! Outlet 3 Node Name
```

---

## 1.37.7 AirLoopHVAC:ZoneMixer

The AirLoopHVAC:ZoneMixer takes the air from multiple inlets and mixes the streams together to be sent out of a single outlet node. This is a simple process of summing flows and averaging the air properties. This component may be part of an air loop return path or part of an induction terminal unit. When used as a return air mixer, this component must be listed in an [AirLoopHVAC:ReturnPath](#) object, and the inlets may be zone return air nodes or [AirLoopHVAC:ReturnPlenum](#) outlet nodes. When used in an induction terminal unit (ref. [AirTerminal:SingleDuct:SeriesPIU:Reheat](#), [AirTerminal:SingleDuct:ParallelPIU:Reheat](#), and [AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction](#)), one inlet node is the supply (primary) air inlet from the central air handler, and the second inlet node is the induced (secondary) air inlet. These node names should match equivalent node names in the terminal unit.

### 1.37.7.1 Inputs

#### 1.37.7.1.1 Field: Name

Unique name for this zone mixer.

#### 1.37.7.1.2 Field: Outlet Node Name

The name of the single outlet node leaving the mixer.

#### 1.37.7.1.3 Field: Inlet <#> Node Name

The name of a mixer inlet node. There is no limit to the number of inlet nodes, and there may be no duplicate inlet node names. (Note that some EnergyPlus editing tools may allow only 500 inlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An input example is shown below.

```
AirLoopHVAC:ZoneMixer,
Zone Return Air Mixer,        ! Name
Return Air Mixer Outlet Node, ! Outlet Node Name
Zone 1 Outlet Node,           ! Inlet 1 Node Name
Zone 2 Outlet Node,           ! Inlet 2 Node Name
Zone 3 Outlet Node;           ! Inlet 3 Node Name
```

---

## 1.37.8 AirLoopHVAC:DedicatedOutdoorAirSystem

The AirLoopHVAC:DedicatedOutdoorAirSystem is a central dedicated outdoor air system (DOAS) and delivers outdoor air to multiple [AirLoopHVAC](#) systems. The amount of delivered outdoor air is based on a sum of outdoor air flow rates from outdoor air stream nodes defined in the [OutdoorAir:Mixer](#). These

OutdoorAir:Mixer objects are a component of served multiple AirLoopHVAC systems. The central DOAS system also pretreats outdoor air before outdoor air distribution into multiple AirLoopHVAC, with given precool and preheat air conditions.

After the object name, the object has four fields to provide the name of AirLoopHVAC:OutdoorAirSystem, system availability, and names of AirLoopHVAC:Mixer and AirLoopHVAC:Splitter. The AirLoopHVAC:OutdoorAirSystem lists a controller to perform controls, and coils and fans to pretreat outdoor air before delivery to served AirLoopHVAC. The Availability Schedule determines times when a system is operationa or shutdownl. The AirLoopHVAC:Mixer and AirLoopHVAC:Splitter provide connection into distribution and relief nodes, respectively.

The next four fields requires inputs for pretreat air conditions, including precooling and preheating.

The last section lists the number of AirLoopHVAC to be served and names of served AirLoopHVAC objects.

### 1.37.8.1 Inputs

#### 1.37.8.1.1 Field: Name

This field is a unique, user assigned name for a single instance of an AirLoopHVAC:DedicatedOutdoorAirSystem object. Any other object referencing this AirLoopHVAC:DedicatedOutdoorAirSystem will use this name.

#### 1.37.8.1.2 Field: AirLoopHVAC:OutdoorAirSystem Name

This field is the name of a AirLoopHVAC:OutdoorAirSystem object. It handles outdoor air based on its own controller.

#### 1.37.8.1.3 Availability Schedule Name

The name of a schedule that specifies when the system is available.

#### 1.37.8.1.4 Field: Preheat Design Temperature

The design air temperature exiting the preheat coil (if any) in degrees Celsius.

#### 1.37.8.1.5 Field: Preheat Design Humidity Ratio

The design humidity ratio exiting the preheat coil (if any) in kilograms of water per kilogram of dry air. (kgWater/kgDryAir)

#### 1.37.8.1.6 Field: Precool Design Temperature

The design air temperature exiting the precooling coil (if any) in degrees Celsius.

#### 1.37.8.1.7 Field: Precool Design Humidity Ratio

The design humidity ratio exiting the precooling coil (if any) in kilograms of water per kilogram of dry air. (kgWater/kgDryAir)

#### 1.37.8.1.8 Field: Number of AirLoopHVAC

The number of AirLoopHVAC, which will be served by this central DOAS.

#### 1.37.8.1.9 Field: AirLoopHVAC <#> Name

The name of an AirLoopHVAC. There is no limit to the number of AirLoopHVACs, and there may be no duplicate AirLoopHVAC names. (Note that some EnergyPlus editing tools may allow only 20 AirLoopHVAC names, but this may be increased by extending the object in the Energy+.idd file.)

An example of this statement in an IDF is:

```

AirLoopHVAC:DedicatedOutdoorAirSystem,
  AirLoopHVAC DOAS,          !- Name
  AirLoopDOAS OA system,     !- AirLoopHVAC:OutdoorAirSystem Name
  ALWAYS_ON,                 !- Availability Schedule Name
  AirLoopDOASMixer,          !- AirLoopHVAC:Mixer Name
  AirLoopDOASSplitter,       !- AirLoopHVAC:Splitter Name
  4.5,                       !- Preheat Design Temperature {C}
  0.004,                     !- Preheat Design Humidity Ratio {kgWater/kgDryAir}
  17.5,                      !- Precool Design Temperature {C}
  0.012,                     !- Precool Design Humidity Ratio {kgWater/kgDryAir}
  5,                         !- Number of AirLoopHVAC
  PSZ-AC:1,                  !- AirLoopHVAC 1 Name
  PSZ-AC:2,                  !- AirLoopHVAC 2 Name
  PSZ-AC:3,                  !- AirLoopHVAC 3 Name
  PSZ-AC:4,                  !- AirLoopHVAC 4 Name
  PSZ-AC:5;                  !- AirLoopHVAC 5 Name

```

---

### 1.37.9 AirLoopHVAC:Mixer

The AirLoopHVAC:Mixer takes the air from multiple inlets and mixes the streams together to be sent out of a single outlet node. This is a simple process of summing flows and averaging the air properties. This component must be referenced in an **AirLoopHVAC:DedicatedOutdoorAirSystem** object. The multiple inlet nodes are relief nodes of **OutdoorAir:Mixer**, which is a component of AirLoopHVAC, served by the AirLoopHVAC:DedicatedOutdoorAirSystem object. The single outlet node is connected into either outdoor or a heat exchanger. The heat exchanger must be listed as a component in AirLoopHVAC:OutdoorAirSystem, referenced in the AirLoopHVAC:DedicatedOutdoorAirSystem object.

#### 1.37.9.1 Inputs

##### 1.37.9.1.1 Field: Name

Unique name for this mixer.

##### 1.37.9.1.2 Field: Outlet Node Name

The name of the single outlet node leaving the mixer.

##### 1.37.9.1.3 Field: Inlet <#> Node Name

The name of a mixer inlet node. There is no limit to the number of inlet nodes, and there may be no duplicate inlet node names. (Note that some EnergyPlus editing tools may allow only 50 inlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An input example is shown below.

```

AirLoopHVAC:Mixer,
  AirLoopDOASMixer,          !- Name
  AirLoopDOASMixerOutlet,    !- Outlet Node Name
  PSZ-AC:1_OARelief Node,    !- Inlet 1 Node Name
  PSZ-AC:2_OARelief Node,    !- Inlet 2 Node Name
  PSZ-AC:3_OARelief Node,    !- Inlet 3 Node Name
  PSZ-AC:4_OARelief Node,    !- Inlet 4 Node Name
  PSZ-AC:5_OARelief Node;    !- Inlet 5 Node Name

```

---

### 1.37.10 AirLoopHVAC:Splitter

The AirLoopHVAC:Splitter is a component that splits airflow from a single inlet to multiple outlets. This component must be referenced in an **AirLoopHVAC:DedicatedOutdoorAirSystem** object. The

input contains only node connection information. The multiple outlet nodes must be outdoor air stream nodes of **OutdoorAir:Mixer**, which is a component of AirLoopHVAC, served by the AirLoopHVAC:DedicatedOutdoorAirSystem object.

### 1.37.10.1 Inputs

#### 1.37.10.1.1 Field: Name

Unique name for this splitter.

#### 1.37.10.1.2 Field: Inlet Node Name

The name of the single inlet node going into the splitter.

#### 1.37.10.1.3 Field: Outlet <#> Node Name

The name of a splitter outlet node. There is no limit to the number of outlet nodes, and there may be no duplicate outlet node names. (Note that some EnergyPlus editing tools may allow only 50 outlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An input example is shown below.

```
AirLoopHVAC:Splitter,
  AirLoopDOASSplitter,      !- Name
  AirLoopDOASSplitterInlet, !- Inlet Node Name
  PSZ-AC:1_OAIInlet Node,   !- Outlet 1 Node Name
  PSZ-AC:2_OAIInlet Node,   !- Outlet 2 Node Name
  PSZ-AC:3_OAIInlet Node,   !- Outlet 3 Node Name
  PSZ-AC:4_OAIInlet Node,   !- Outlet 4 Node Name
  PSZ-AC:5_OAIInlet Node;   !- Outlet 5 Node Name
```

## 1.38 Group – Non-Zone Equipment

The non-zone equipment group consists of plant objects that connect to the demand side of the plant loop but are not associated with a specific Zone (and do not have their own group). There is currently one non-zone equipment object called **LoadProfile:Plant**. This object places a scheduled demand load on the plant.

Non-zone equipment allows the option of performing a plant-only EnergyPlus simulation, i.e. without any zones. This can be useful for comparing the performance of various plant configurations or components without the added complexity of a full building description.

### 1.38.1 LoadProfile:Plant

The LoadProfile:Plant object is used to simulate a scheduled demand profile. This can be useful when the building loads are already known. Demanded load and flow rate are schedules specified in the object definition. The load profile can specify heating and cooling loads. Cooling loads are entered as negative numbers. The actual load met is dependent on the performance of the supply loop components.

The LoadProfile:Plant object must be connected on the demand side of the plant loop. It should be located on a Branch with its control type set to Active. If desired, multiple LoadProfile:Plant objects can be combined in series and/or parallel.

#### 1.38.1.1 Inputs

##### 1.38.1.1.1 Field: Name

The unique name of the LoadProfile:Plant object.

### 1.38.1.1.2 Field: Inlet Node Name

The name of the inlet node connection to the plant loop.  
This node should be on the demand side.

### 1.38.1.1.3 Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

### 1.38.1.1.4 Field: Load Schedule Name

Reference to the schedule object specifying the load profile [W]. The value of load can be positive or negative. Negative values here are for imposing a cooling load on the loop (with a chiller on the supply side, e.g.), while positive values are impose a heating load (with a boiler on the supply side).

### 1.38.1.1.5 Field: Peak Flow Rate

The peak demanded water flow rate [m<sup>3</sup>/s]. This value is multiplied by the flow rate fraction schedule values (below) to determine the actual volumetric flow rate.

### 1.38.1.1.6 Field: Flow Rate Fraction Schedule Name

Reference to the schedule object specifying the flow rate fraction relative to the value in the field Peak Flow Rate (above).

An example of this object follows.

```
LoadProfile:Plant,
  Load Profile 1,                                !- Name
  Demand Load Profile 1 Inlet Node,              !- Inlet Node Name

```

## 1.38.1.2 Outputs

The following output variables and meters are reported for the LoadProfile:Plant object:

- HVAC,Average,Plant Load Profile Mass Flow Rate [kg/s]
- HVAC,Average,Plant Load Profile Heat Transfer Rate [W]
- HVAC,Sum,Plant Load Profile Heat Transfer Energy [J]
- HVAC,Sum,Plant Load Profile Heating Energy [J]
- HVAC,Sum,Plant Load Profile Cooling Energy [J]

### 1.38.1.2.1 Plant Load Profile Mass Flow Rate [kg/s]

This is the mass flow of the fluid passing through the load profile object, in kg/s.

### 1.38.1.2.2 Plant Load Profile Heat Transfer Rate [W]

### 1.38.1.2.3 Plant Load Profile Heat Transfer Energy [J]

These report the overall heat transfer rate and energy for the load profile object, in Watts or Joules.

#### 1.38.1.2.4 Plant Load Profile Cooling Energy [J]Plant Load Profile Heating Energy [J]

These report the overall cooling or heating energy that the load profile object places on the plant loop, in Joules.

The inlet and outlet node temperatures and mass flow rates can be monitored using the system node output variables:

- HVAC,Average,System Node Temperature [C]
- HVAC,Average,System Node Mass Flow Rate [kg/s]

## 1.39 Group Solar Collectors

Solar collectors are thermal devices that convert solar energy into thermal energy by raising the temperature of a circulating heat transfer fluid. The fluid can then be used to heat water for domestic hot water usage or space heating.

In EnergyPlus solar collectors are components that are connected to the plant loop. A solar heating system can be constructed with a combination of solar collectors, pumps, and hot water tanks.

Flat plate solar collectors are defined using two objects: `SolarCollector:FlatPlate:Water` and `SolarCollectorPerformance:FlatPlate`. Similarly, Integral-Collector-Storage (ICS) solar collectors are defined using two objects: `SolarCollector:IntegralCollectorStorage`, and `SolarCollectorPerformance:IntegralCollectorStorage`. The `SolarCollector:FlatPlate:Water` and `SolarCollector:IntegralCollectorStorage` objects describe the plant component connections. These object also reference `SolarCollectorPerformance:FlatPlate` and `SolarCollectorPerformance:IntegralCollectorStorage` performance objects which contains the thermal and optical performance test data for a specific make and model of collector. Parameters are defined separately so that these values can be organized into a reference data set and need only be entered once if for an array of the same type of collectors.

### 1.39.1 SolarCollector:FlatPlate:Water

The flat-plate solar collector model simulates glazed, unglazed, and tubular (i.e. evacuated tube) collectors. The `SolarCollector:FlatPlate:Water` object represents a single collector module connected to the plant loop. The thermal and optical properties of the collector module are taken from the referenced `SolarCollectorPerformance:FlatPlate` object. A surface or shading object defines the collector tilt, azimuth, and gross area. The collector surface participates normally in all shading calculations if the “FullExterior,” “FullInteriorAndExterior,” FullExteriorWithReflections , or FullInteriorAndExteriorWithReflections flags are set in the Solar Distribution field of the Building object. Inlet and outlet nodes are specified for plant connections on the demand side of the plant loop.

#### 1.39.1.1 Inputs

##### 1.39.1.1.1 Field: Name

The unique name of the `SolarCollector:FlatPlate:Water` object.

##### 1.39.1.1.2 Field: Solar Collector Performance Name

Reference name of a `SolarCollectorPerformance:FlatPlate` object that defines the thermal and optical properties of the collector.

### 1.39.1.1.3 Field: Surface Name

Reference to one of the many different types of surfaces such as the `BuildingSurface:Detailed` or the `Shading:Zone:Detailed` objects. The surface named here is used to define the solar collector tilt, azimuth, and gross area.

### 1.39.1.1.4 Field: Inlet Node Name

The name of the inlet node connection to the plant loop.

### 1.39.1.1.5 Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

### 1.39.1.1.6 Field: Maximum Flow Rate

The maximum flow rate [m<sup>3</sup>/s] allowed through the collector. This field is optional. If not specified, the collector will allow as much flow as the rest of the plant can deliver.

An example follows.

```
SolarCollector:FlatPlate:Water,
Collector 1,                                !- Name
ACR Solar International Fireball 2001,      !- Solar Collector Performance Name
Collector Surface,                          !- Surface Name
Collector Inlet Node,                       !- Inlet Node Name
Collector Outlet Node,                     !- Outlet Node Name
0.00005;                                   !- Maximum Flow Rate (m3/s)
```

## 1.39.1.2 Outputs

The following output variables are reported for the `SolarCollector:FlatPlate:Water` object:

- HVAC,Average,Solar Collector Incident Angle Modifier []
- HVAC,Average,Solar Collector Efficiency []
- HVAC,Average,Solar Collector Heat Transfer Rate [W]
- HVAC,Average,Solar Collector Heat Gain Rate [W]
- HVAC,Average,Solar Collector Heat Loss Rate [W]
- HVAC,Sum,Solar Collector Heat Transfer Energy [J]

### 1.39.1.2.1 Solar Collector Incident Angle Modifier []

The incident angle modifier is an important intermediate value used in the SRCC calculation of solar collector performance. The value reported here is the combined result for the current time that includes incident angles of beam solar, diffuse solar from sky, and diffuse solar from ground.

### 1.39.1.2.2 Solar Collector Efficiency []

The overall collector efficiency. This is the ratio of collected energy and the incident solar energy. The efficiency can be greater than 1 at times when the outdoor air temperature is warm enough.

### 1.39.1.2.3 Solar Collector Heat Transfer Rate [W]

**1.39.1.2.4 Solar Collector Heat Transfer Energy [J]**

These are the overall rate (in W) and amount of energy (in J) transferred to the collector's circulating fluid. Positive values indicate heating of the fluid while negative values indicate cooling of the fluid.

**1.39.1.2.5 Solar Collector Heat Gain Rate [W]**

This is the overall rate of heat addition to the collector's circulating fluid in Watts. Values are always positive or zero. If the fluid is actually cooled then the value is zero.

**1.39.1.2.6 Solar Collector Heat Loss Rate [W]**

This is the overall rate of heat loss from the collector's circulating fluid in Watts. Values are always positive or zero. If the fluid is actually heated then the value is zero.

In addition, several surface variables are also relevant for the collector's surface object (BuildingSurface:Detailed or Shading:Zone:Detailed):

- Zone,Average,Surface Outside Face Sunlit Area [m2]
- Zone,Average,Surface Outside Face Sunlit Fraction []
- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area [W/m2]
- Zone,Average,Surface Outside Face Incident Beam Solar Radiation Rate per Area [W/m2]
- Zone,Average,Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area [W/m2]
- Zone,Average,Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area [W/m2]
- Zone,Average,Surface Outside Face Beam Solar Incident Angle Cosine Value []

The temperatures at the inlet and outlet nodes and the collector mass flow rate can be monitored using the system node output variables:

- HVAC,Average,System Node Temperature [C]
- HVAC,Average,System Node Mass Flow Rate [kg/s]

**1.39.2 SolarCollectorPerformance:FlatPlate**

The SolarCollectorPerformance:FlatPlate object contains the thermal and optical performance parameters for a single collector module. These parameters are based on the testing methodologies described in ASHRAE Standards 93 and 96. The Solar Rating and Certification Corporation (SRCC) applies these standards in their rating procedures of solar collectors. The ratings for commercially available collectors in North America are published in the *Directory of SRCC Certified Solar Collector Ratings*. The SRCC database has also been converted into an EnergyPlus data set of SolarCollectorPerformance:FlatPlate objects that is included with the program (see SolarCollectors.idf in the DataSets folder).

The coefficients for the energy conversion efficiency and incident angle modifier allow first order (linear) or second order (quadratic) correlations. To use a first order correlation, the second order coefficient must be left blank or set to zero.

In order for the model to work correctly, the test conditions for which the performance coefficients were measured must be specified in the fields: *Test Fluid*, *Test Volumetric Flow Rate*, and *Test Correlation Type*. Currently, only water is allowed as the *Test Fluid*.

For more detailed information about the performance coefficients, see the *EnergyPlus Engineering Reference Document*.

### 1.39.2.1 Inputs

#### 1.39.2.1.1 Field: Name

The unique name of the SolarCollectorPerformance:FlatPlate object.

#### 1.39.2.1.2 Field: Gross Area

The gross area of the collector module [m<sup>2</sup>]. This value is mainly for reference. The area of the associated collector surface object is used in all calculations.

#### 1.39.2.1.3 Field: Test Fluid

The fluid that was used in the testing procedure that resulted in the thermal and optical performance coefficients below. Currently only Water is allowed. This the fluid during the collector testing, not the fluid used during a particular EnergyPlus run.

#### 1.39.2.1.4 Field: Test Flow Rate

The volumetric flow rate during testing [m<sup>3</sup>/s]. If the value is available as flow rate per unit area, it is recommended to multiply by the *Gross Area* of the collector module, not the net aperture area.

#### 1.39.2.1.5 Field: Test Correlation Type

This field specifies type of temperature used to develop the correlation equations. The testing procedure is based on an experimental correlation using either Inlet, Average, or Outlet temperature. Enter one of these choices. The ASHRAE Standards 93 and 96 always use Inlet temperature.

#### 1.39.2.1.6 Field: Coefficient 1 of Efficiency Equation

First coefficient of efficiency equation for energy conversion [dimensionless]. This is the Y-intercept term.

#### 1.39.2.1.7 Field: Coefficient 2 of Efficiency Equation

Second coefficient of efficiency equation for energy conversion [W/m<sup>2</sup>-K]. This is the first-order term.

#### 1.39.2.1.8 Field: Coefficient 3 of Efficiency Equation

Third coefficient of efficiency equation for energy conversion [W/m<sup>2</sup>-K<sup>2</sup>]. This field is optional. This is the second-order term. If left blank or set to zero, a first-order linear correlation is used.

#### 1.39.2.1.9 Field: Coefficient 2 of Incident Angle Modifier

Second coefficient of the incident angle modifier equation. This the first-order term. (There is no *Coefficient 1 of Incident Angle Modifier* because that number is always 1.0.)

#### 1.39.2.1.10 Field: Coefficient 3 of Incident Angle Modifier

Third coefficient of the incident angle modifier equation. This is the second-order term. This field is optional. If left blank or set to zero, a first order linear correlation is used.

An example of this object follows.

```
SolarCollectorPerformance:FlatPlate,
  Alternate Energy Technologies AE-32,  !- Name
  2.9646,                               !- Gross Area {m2}
  WATER,                                !- Test Fluid
  0.0000388,                             !- Test Flow Rate {m3/s}
  INLET,                                !- Test Correlation Type
  0.691,                                 !- Coefficient 1 of Efficiency Equation {dimensionless}
  -3.396,                               !- Coefficient 2 of Efficiency Equation {W/m2-K}
```

---

-0.00193,	!- Coefficient 3 of Efficiency Equation {W/m2-K2}

-0.0055;	!- Coefficient 3 of Incident Angle Modifier

---

### 1.39.2.2 Outputs

This object does not generate any output; see SolarCollector:FlatPlate:Water Output

## 1.39.3 SolarCollector:IntegralCollectorStorage

The Integral-Collector-Storage (ICS) solar collector model simulates glazed collectors with integral storage unit. The SolarCollector:IntegralCollectorStorage object represents a single collector module connected to the plant loop. The thermal and optical properties of the collector module are calculated from inputs in **SolarCollectorPerformance:IntegralCollectorStorage** object. A surface or shading object defines the collector tilt, and azimuth. The collector surface participates normally in all shading calculations if the “FullExterior,” “FullInteriorAndExterior,” FullExteriorWithReflections , or FullInteriorAndExteriorWithReflections flags are set in the Solar Distribution field of the Building object. Inlet and outlet nodes are specified for plant connections on the demand side of the plant loop. The **SurfaceProperty:ExteriorNaturalVentedCavity**, object is required to describe the surface properties, the characteristics of the cavity and opening for natural ventilation if OtherSideConditionsModel is specified as the collector bottom surface outside boundary condition type.

### 1.39.3.1 Inputs

#### 1.39.3.1.1 Field: Name

The unique name of the SolarCollector:IntegralCollectorStorage object.

#### 1.39.3.1.2 Field: Solar Collector Performance Name

Reference name of a **SolarCollectorPerformance:IntegralCollectorStorage** object that defines the thermal and optical properties of the collector.

#### 1.39.3.1.3 Field: Surface Name

Reference to one of the many different types of surfaces such as the **BuildingSurface:Detailed** or the **Shading:Zone:Detailed** objects. The surface named here is used to define the solar collector tilt, and azimuth. The collector shades the surface it is mounted on and hence impacts the surface heat balance.

#### 1.39.3.1.4 Field: Bottom surface Boundary Conditions Type

This field contains the type of boundary conditions applicable to the ICS collector bottom surface. Allowed boundary condition types are: AmbientAir and OtherSideConditionsModel. If the other side conditions model is selected, specify the name of the **SurfaceProperty:OtherSideConditionsModel** object in the next input field, otherwise, leave the next input field blank. The AmbientAir boundary condition uses outdoor air temperature as boundary condition, hence the subsurface is assumed to be exposed to the sun and wind.

#### 1.39.3.1.5 Field: Other Side Conditions Model Name

This field contains the name of a **SurfaceProperty:OtherSideConditionsModel** object declared elsewhere in the input file. This will connect the collector to the exterior boundary conditions for the underlying heat transfer surface specified above..

#### 1.39.3.1.6 Field: Inlet Node Name

The name of the inlet node connection to the plant loop.

#### 1.39.3.1.7 Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

#### 1.39.3.1.8 Field: Maximum Flow Rate

The maximum flow rate [m<sup>3</sup>/s] allowed through the collector. This field is optional. If not specified, the collector will allow as much flow as the rest of the plant can deliver.

An example follows.

```
SolarCollector:IntegralCollectorStorage,
Collector 1,                                !- Name
ICS Solar Collector,                        !- Solar Collector Performance Name
ICS Collector Surface,                      !- Surface Name
OtherSideConditionsModel,                  !- Bottom Surface Boundary Conditions Type
ICS OSCM,                                  !- Boundary Condition Model Name
Collector Inlet Node,                      !- Inlet Node Name
Collector Outlet Node,                     !- Outlet Node Name
0.00005;                                   !- Maximum Flow Rate (m3/s)
```

### 1.39.4 SolarCollectorPerformance:IntegralCollectorStorage

The SolarCollectorPerformance:IntegralCollectorStorage object contains the thermal and optical performance parameters for a single collector module. The transmittance-absorptance product of the absorber and cover system is determined from optical properties specified. For more detailed information about the calculation procedure, see the *EnergyPlus Engineering Reference* Document.

#### 1.39.4.1 Inputs

##### 1.39.4.1.1 Field: Name

The unique name of the SolarCollectorPerformance:IntegralCollectorStorage object.

##### 1.39.4.1.2 Field: ICS Collector Type

This input field is the ICS collector type. Currently only RectangularTank type is allowed.

##### 1.39.4.1.3 Field: Gross Area

This input field is the gross area of the collector module in m<sup>2</sup>. This gross area is used in the energy balance equations.

##### 1.39.4.1.4 Field: Collector Water Volume

This input field is the volume of water in the solar collector in m<sup>3</sup>.

##### 1.39.4.1.5 Field: Bottom Heat Loss Conductance

This input field is the collector bottom heat loss conductance in W/m<sup>2</sup>K. This value is calculated from thermal conductivity and thickness of the bottom insulation.

##### 1.39.4.1.6 Field: Side Heat Loss Conductance

This input field is the collector side heat loss conductance in W/m<sup>2</sup>K. This value is calculated from thermal conductivity and thickness of the side insulation.

**1.39.4.1.7 Field: Collector Aspect Ratio**

This input field is the ratio of the short side (width) of the collector to the long side (length) of the collector. This value is used only for calculating the collector side area along with the collector side height specified in the next input field. This ratio is less or equal to 1.0.

**1.39.4.1.8 Field: Collector Side Height**

This input field is height of collector side in m. This height is used to estimate the collector side area for heat loss calculations along with heat loss coefficient specified in the input field above.

**1.39.4.1.9 Field: Thermal Mass of Absorber Plate**

This input field is thermal-mass of the absorber plate per unit area of the collector in  $[J/m^2 \times K]$ . This input value multiplied by the absorber gross area determines the thermal mass of the absorber plate. It is estimated from the specific heat, density and average thickness of the absorber plate. If zero is specified then the absorber plate energy balance reduces to steady state form.

**1.39.4.1.10 Field: Number of Covers**

Number of transparent collector covers. Common practice is to use two covers: glass as the outer cover and Teflon as the inner cover. If single cover is specified leave the inner cover optical and thermal properties input fields blank.

**1.39.4.1.11 Field: Cover Spacing**

This input field provides the spacing between the two transparent covers, and the spacing between the inner cover and the absorber plate in m. Default value is 0.05m.

**1.39.4.1.12 Field: Refractive Index of Outer Cover**

This is the average Refractive index for solar spectrum range of the outer transparent cover material. Glass is used as the outer cover. Average refractive index value for non-absorbing glass used in solar collectors over solar spectrum range is 1.526.

**1.39.4.1.13 Field: Extinction Coefficient Times Thickness of Outer Cover**

This input field is the product of the extinction coefficient and the thickness of the out cover material. The extinction coefficient for glass types approximately varies from  $4m^{-1}$  to  $32 m^{-1}$ . The extinction coefficient for low-iron glass, which is the default outer cover material, is  $15 m^{-1}$ . The default value for extinction coefficient times thickness (KL) is 0.045 ( =  $15.0 \times 0.003$  ), which is the product of the default extinction coefficient of  $15m^{-1}$  and 3.0mm thick glass.

**1.39.4.1.14 Field: Emissivity of Outer Cover**

This input field value is thermal emissivity of the outer collector cover. The default value assumes low-iron glass with thermal emissivity of 0.88.

**1.39.4.1.15 Field: Refractive Index of Inner Cover**

This input field is the average Refractive index of the inner transparent cover of the collector. Commonly Teflon (PolytetraFluoroethylene) is used as the inner cover. The average refractive index value over the solar spectrum range for Teflon is 1.37.

#### 1.39.4.1.16 Field: Extinction Coefficient Times Thickness of Inner Cover

This input field is the product of the extinction coefficient ( $K$ ) and the thickness ( $L$ ) of the inner cover material. The inner cover material is more transparent than the out cover, very thin and hence their thickness can be assumed to be negligible. The default value for extinction coefficient times thickness ( $KL$ ) is 0.008 ( $= 40.0 \times 0.0002$ ), which is the product of extinction coefficient of  $40\text{m}^{-1}$  and a thickness of 0.2mm.

#### 1.39.4.1.17 Field: Emissivity of Inner Cover

This input field value is thermal emissivity of the inner transparent collector cover. The default value assumes plastic sheet with thermal emissivity of 0.30. This value is used in the thermal analysis only.

#### 1.39.4.1.18 Field: Absorptance of Absorber Plate

This input field is shortwave or solar absorptance of the absorber plate. The default value is 0.96.

#### 1.39.4.1.19 Field: Emissivity of Absorber Plate

This input field value is thermal emissivity of the absorber plate. Default value is 0.30. This input value is used in the thermal analysis only.

An example follows.

```
SolarCollectorPerformance: IntegralCollectorStorage,
  ICS Experimental,           !- Name

### 1.39.4.2 Outputs

The following output variables are reported for the SolarCollector: IntegralCollectorStorage object:

- HVAC,Average,Solar Collector Storage Water Temperature [C]
- HVAC,Average,Solar Collector Absorber Plate Temperature [C]
- HVAC,Average,Solar Collector Overall Top Heat Loss Coefficient [W/m2-C]
- HVAC,Average,Solar Collector Thermal Efficiency []
- HVAC,Average,Solar Collector Storage Heat Transfer Rate [W]
- HVAC,Sum,Solar Collector Storage Heat Transfer Energy [J]
- HVAC,Average,Solar Collector Heat Transfer Rate [W]

- HVAC,Sum,Solar Collector Heat Transfer Energy [J]
- HVAC,Average,Solar Collector Skin Heat Transfer Rate [W]
- HVAC,Sum, Solar Collector Skin Heat Transfer Energy [J]
- HVAC,Average,Solar Collector Transmittance Absorptance Product []

#### 1.39.4.2.1 Solar Collector Storage Water Temperature [C]

This output variable is the ICS collector stored water average temperature at a given time steps in degree Celsius. This temperature is the same as the collector ICS collector leaving water temperature.

#### 1.39.4.2.2 Solar Collector Absorber Plate Temperature [C]

This output variable is the ICS collector absorber plate average temperature at a given time steps in degree Celsius.

#### 1.39.4.2.3 Solar Collector Thermal Efficiency []

This output variable is the instantaneous thermal efficiency of the ICS solar collector in per cent. This value is determined from net useful energy collected and the total incident solar radiation for each time step. The net useful energy collected is the sum of the energy stored in the collector and net useful energy delivered.

#### 1.39.4.2.4 Solar Collector Storage Heat Transfer Rate [W]

#### 1.39.4.2.5 Solar Collector Storage Heat Transfer Energy [J]

These output variables are the instantaneous rate of change of the energy and the change in energy of the water in the ICS solar collector in Watts, and Joules, respectively.

#### 1.39.4.2.6 Solar Collector Skin Heat Transfer Rate [W]

#### 1.39.4.2.7 Solar Collector Skin Heat Transfer Energy [J]

These output variables are the instantaneous skin heat loss rate and the heat loss energy of the ICS solar collector for each time steps in Watts, and Joules respectively. The skin heat loss rate is the sum of the heat losses through the top, bottom and sides of the collector surfaces. This value is mostly negative, but can have a positive value (heat gain) when the outdoor air temperature is warmer than the collector.

#### 1.39.4.2.8 Solar Collector Heat Transfer Rate [W]

#### 1.39.4.2.9 Solar Collector Heat Transfer Energy [J]

This output variable is the heat rate and Energy transferred from the ICS collector to the collector loop fluid (water) in Watts and Joule, respectively. This value is determined from the collector water mass flow rate, specific heat of water and the temperature difference between the collector water outlet and inlet nodes at each time step. The value is positive when the fluid is heated or negative when cooled.

#### 1.39.4.2.10 Solar Collector Transmittance Absorptance Product []

This output variable is the transmittance-absorptance product of the covers and absorber system of the ICS solar collector. This value ranges from 0.0 to less than 1.0.

#### 1.39.4.2.11 Solar Collector Overall Top Heat Loss Coefficient [W/m<sup>2</sup>-C]

This output variable is the overall heat loss coefficient from the absorber plate to the ambient air calculated for each time step.

### 1.39.5 SolarCollector:FlatPlate:PhotovoltaicThermal

This object is used to model hybrid photovoltaic-thermal (PVT) solar collectors that convert incident solar energy into both electricity and useful thermal energy. This object describes the PVT solar collector by referencing other objects that provide more detail or connections to other parts of the EnergyPlus model.

The PVT solar collectors need to be connected to either an HVAC air system or a plant loop for collected thermal energy to be utilized. The input field for the type of thermal working fluid informs the program how the PVT collector is expected to be connected. If the the working fluid is air, then the PVT collectors are modeled as a ventilation air pretreatment component and connected to an outdoor air system. If the working fluid is water, then the PVT collectors are modeled as a hot water solar collector and are connected to a plant loop with a water thermal storage tank.

#### 1.39.5.1 Inputs

##### 1.39.5.1.1 Field: Name

This field should contain a unique name chosen by the user to identify a specific PVT collector in the building model.

##### 1.39.5.1.2 Field: Surface Name

This field is the user-defined name of a surface object (defined elsewhere) to which the PVT module is attached. These can be any type of building surface that is exposed to the exterior environment. The model uses the named surface's geometry for the PVT solar collector.

##### 1.39.5.1.3 Field: Photovoltaic-Thermal Model Performance Name

This field is the user-defined name of an object (defined elsewhere) that provides the performance details of the PVT module. This should be the name of a **SolarCollectorPerformance:PhotovoltaicThermal:Simple** object. Multiple different SolarCollector:FlatPlate:PhotovoltaicThermal objects can reference the same object that provides performance details.

##### 1.39.5.1.4 Field: Photovoltaic Generator Name

This field is the user-defined name of a **Generator:Photovoltaic** object (defined elsewhere) that will be used to model the solar electric portion of the PVT solar collector. The PVT models make any adjustments needed to model PV performance in the context of the PVT collector.

##### 1.39.5.1.5 Field: Thermal Working Fluid Type

This field is the user's choice for the type of fluid used to collect thermal energy. PVT solar collectors can capture thermal energy in either air or water streams. The choices available for this field are Water or Air. If the choice is Air then the PVT collector needs to be connected to an HVAC air system loop. The PVT collector should be situated as the first component on an outdoor air inlet stream. If the choice is Water then the PVT collector needs to be connected to a Plant water system loop. The connections are made via node names which are defined in the following fields, depending on the working fluid type.

##### 1.39.5.1.6 Field: Water Inlet Node Name

This field is the name of Plant loop node that serves as the inlet to the PVT collector. This field is only used if the Thermal Working Fluid Type is set to Plant/Water.

**1.39.5.1.7 Field: Water Outlet Node Name**

This field is the name of a plant loop node that serves as the outlet from the PVT collector. This field is only used if the Thermal Working Fluid Type is set to Plant/Water.

**1.39.5.1.8 Field: Air Inlet Node Name**

This field is the name of HVAC air loop node that serves as the inlet to the PVT collector. This field is only used if the Thermal Working Fluid Type is set to HVAC/Air.

**1.39.5.1.9 Field: Air Outlet Node Name**

This field is the name of HVAC air loop node that serves as the outlet from the PVT collector. This field is only used if the Thermal Working Fluid Type is set to HVAC/Air.

**1.39.5.1.10 Field: Design Flow Rate**

This field is used to describe the nominal volume flow rate of the thermal working fluid. The units are m<sup>3</sup>/s. The volume flow rate is autosizable.

An example of this object follows.

```
SolarCollector:FlatPlate:PhotovoltaicThermal,
  PVT: 1_Ceiling ,                               !- Name
  1_Ceiling ,                                     !- Surface Name
  30percentPVThalfArea ,                         !- Photovoltaic-Thermal Model Performance Name
  PV:ZN_1_FLR_1_SEC_1_Ceiling ,                  !- Photovoltaic Name
  Air ,                                           !- Thermal Working Fluid Type
  ,                                               !- Water Inlet Node Name
  ,                                               !- Water Outlet Node Name
  ZN_1_FLR_1_SEC_1:Sys_OAInlet Node ,            !- Air Inlet Node Name
  PVT:ZN_1_FLR_1_SEC_1_Ceiling Outlet ,          !- Air Outlet Node Name
  Autosize ;                                     !- Design Flow Rate
```

**1.39.5.2 Outputs**

The output variables that are available for flat plate PVT include the following.

- HVAC,Average,Generator Produced Thermal Rate [W]
- HVAC,Sum,Generator Produced Thermal Energy [J]
- HVAC,Average,Generator PVT Fluid Bypass Status []
- HVAC,Average,Generator PVT Fluid Inlet Temperature [C]
- HVAC,Average,Generator PVT Fluid Outlet Temperature [C]
- HVAC,Average,Generator PVT Fluid Mass Flow Rate [kg/s]

**1.39.5.2.1 Generator Produced Thermal Rate [W]****1.39.5.2.2 Generator Produced Thermal Energy [J]**

These outputs are the thermal energy and power produced by the PVT collector. PVT collectors are a type of cogenerator, producing both electrical and thermal power and these variables report the thermal portion in the same manner as other fuel-based cogenerators. The thermal energy is placed on HeatProduced meter and is attributed to SolarWater or SolarAir depending on the type of working fluid. The generator thermal production is also reported at the load center level.

### 1.39.5.2.3 Generator PVT Fluid Bypass Status []

This output variable indicates the status a bypass damper. It is only available for air-based PVT. There are no dimensions and the range is between 0.0 and 1.0. If the value is 0.0, then there is no bypassing and all the working fluid goes through the collector. If the value is 1.0, then there is complete bypassing and all the working fluid goes around the collector. If the value is between 0.0 and 1.0, then the model is effectively mixing bypass and collector streams to target a temperature setpoint placed on the outlet node.

### 1.39.5.2.4 Generator PVT Fluid Inlet Temperature [C]

This report is the inlet temperature of the working fluid that enters the PVT collector

### 1.39.5.2.5 Generator PVT Fluid Outlet Temperature [C]

This report is the outlet temperature of the working fluid that leaves the PVT collector

### 1.39.5.2.6 Generator PVT Fluid Mass Flow Rate [kg/s]

This report is the mass flow rate of the working fluid through the PVT collector. This is the overall mass flow rate, portions of the flow may be internally bypassed around the collector itself for control modulation.

## 1.39.6 SolarCollectorPerformance:PhotovoltaicThermal:Simple

This object is used to provide performance details for the simple PVT model. This is a simple user-defined efficiency model. Thermal conversion efficiency is a constant or scheduled value. There are no output variable for this object, reporting is done by the parent PVT object.

### 1.39.6.1 Inputs

#### 1.39.6.1.1 Field: Name

This field is the unique name for this object.

#### 1.39.6.1.2 Field: Fraction of Surface Area with Active Thermal Collector

This field is the fraction of the surface area that is active. It should be a decimal fraction between 0.0 and 1.0. The area of the PVT s surface will be multiplied by this fraction to determine the active area of the PVT collector(s).

#### 1.39.6.1.3 Field: Thermal Conversion Efficiency Input Mode Type

This field is used to determine how the thermal efficiency is input. There are two choices, Fixed or Scheduled. If this field is set to Fixed, then a constant value for thermal efficiency will be used (set in next field). If this field is set to Scheduled, then the thermal efficiency values are defined in a schedule.

#### 1.39.6.1.4 Field: Value for Thermal Conversion Efficiency if Fixed

This field is used to provide a value for the efficiency with which solar energy is collected in the working fluid. This field is only used if the input mode is set to Fixed in the previous field. Efficiency is defined as the thermal energy collected divided by the incident solar radiation. The value should be between 0.0 and 1.0. The user should be careful that the thermal efficiency and the electrical efficiency be consistent with each other because the overall efficiency of the PVT collector is the combination of both thermal and electrical.

### 1.39.6.1.5 Field: Name of Schedule for Thermal Conversion Efficiency

This field is used for the name of a schedule that provides values for the efficiency with which solar energy is collected in the working fluid. This field is only used if the input mode is set to Scheduled in the field above. Efficiency is defined as the thermal energy collected divided by the incident solar radiation. The values in the named schedule should be between 0.0 and 1.0. The user should be careful that the thermal efficiency and the electrical efficiency be consistent with each other because the overall efficiency of the PVT collector is the combination of both thermal and electrical.

### 1.39.6.1.6 Field: Front Surface Emittance

This field is used to describe an average value for the total hemispherical emittance of the collector's front face exposed to the sky. This is used to model cooling applications where the PVT collectors are operated at night to cool the working fluid.

An example input object follows.

```
SolarCollectorPerformance:PhotovoltaicThermal:Simple,
  20percentEffPVhalfArea ,           !- Name
  0.5 ,                               !- Fraction of Surface Area with Active
    Thermal Collector                 !- Thermal Conversion Efficiency Input Mode
Fixed ,                               !- Value for Thermal Conversion Efficiency
  Type                                !- Name of Schedule for Thermal
  0.2 ,                               !- Front Surface Emittance
    if Fixed
  ,
  Conversion Efficiency
  0.84 ;
```

## 1.39.7 Solar Collector Heating System Plant Connections

This section provides an overview of how to model solar heating systems. A solar heating system can be constructed using a combination of solar collectors, pumps, water tanks and water heaters. The solar collector must be connected on the demand side of the plant loop. Multiple collector modules can be combined in series and parallel using the normal plant connection rules. The supply side of the plant loop should contain a water heater with the solar collector loop connecting to the *Source Side Inlet* and *Source Side Outlet* nodes. As usual, the pump must be the first component on the supply side.

If the solar heating system is for domestic hot water (or service water heating) usage only, the field *Use Flow Rate Fraction Schedule Name* of the **WaterHeater:Mixed** object can be used to avoid additional plant connections. If the system has more complicated hot water requirements or if the system is for space heating, the *Use Side Inlet* and *Use Side Outlet* nodes must be connected to another plant loop to serve zone and non-zone equipment. (See the **WaterHeater:Mixed** object documentation for more information.)

NOTE: The EnergyPlus plant simulation requires the pump to be the first component on the supply side. This may be different from the way the solar heating system is actually configured. This should not affect the validity of the simulation results.

In order to realize energy savings with a solar heating system, it is best to use a two-tank system with a storage tank and auxiliary water heater. The storage tank gathers heat directly from the solar collectors and stores it for later use. The storage tank is modeled using a **WaterHeater:Mixed** object with the *Heater Maximum Capacity* set to zero. The auxiliary water heater is positioned downstream of the storage tank on the supply side of the main plant loop. The auxiliary water heater, or booster water heater, provides additional heat if the storage tank water is not hot enough. The auxiliary water heater can be modeled as an instantaneous/tankless water heater or as a standard tanked water heater with heating source (see **WaterHeater:Mixed**).

Another strategy to consider for solar heating systems is to allow the storage tank to reach a much higher temperature than necessary for the end use. This allows the tank to store more energy from the

Figure 1.167: Solar Collector Plant Loop Connection Diagram

solar collectors, when it is available. However, for applications such as domestic hot water, it is undesirable and unsafe to supply excessive hot water temperatures at the point of demand. To take advantage of higher storage temperatures, yet still avoid scalding temperatures at the faucet, the hot water leaving the storage tank can be tempered with cold water using a three-way valve to achieve the target temperature. See the [TemperingValve](#) object documentation for more details.

A complete two-tank solar heating system with tempering valve is shown below.

### 1.39.8 Solar Heating System Control

There are several options for controlling a solar heating system in EnergyPlus. Since the solar collectors request a constant flow demand based on their *Maximum Flow Rate*, the limiting factor is actually the flow rate determined by the loop pump. Therefore the entire system can be controlled using the *Pump Flow Rate Schedule* of the pump. If the schedule is omitted, the pump and system will run all the time (without any other controls specified). This is usually not the best way to operate a solar heating system.

To better control the collector loop, a differential thermostat can be used to compare the temperature in the water heater to the temperature in the collector so that the pump is only turned on when there is a useful heat gain. The differential thermostat is simulated using the [AvailabilityManager:DifferentialThermostat](#) object. For a typical system, the *Hot Node Name* field refers to an outlet node of one of the collector modules. The *Cold Node Name* field refers to the *Source Side Outlet* node, i.e. the cold storage water leaving the water heater. The fields *Temperature Difference On Limit* and *Temperature Difference Off Limit* are usually 8 12 C and 1 3 C respectively. If the two temperature differences are too close, it is possible for the system to turn on and off rapidly without much useful heat gain. This can also occur if the flow rate through the collector is too high. Without flow the fluid in the collector heats up more quickly; when high flow is turned on, all of the hot fluid is removed and the temperature drops, forcing the system off again.

Another control method is to use a photovoltaic panel to power the pump. The system begins pumping when there is enough solar radiation to operate the pump. This is not yet implemented in EnergyPlus.

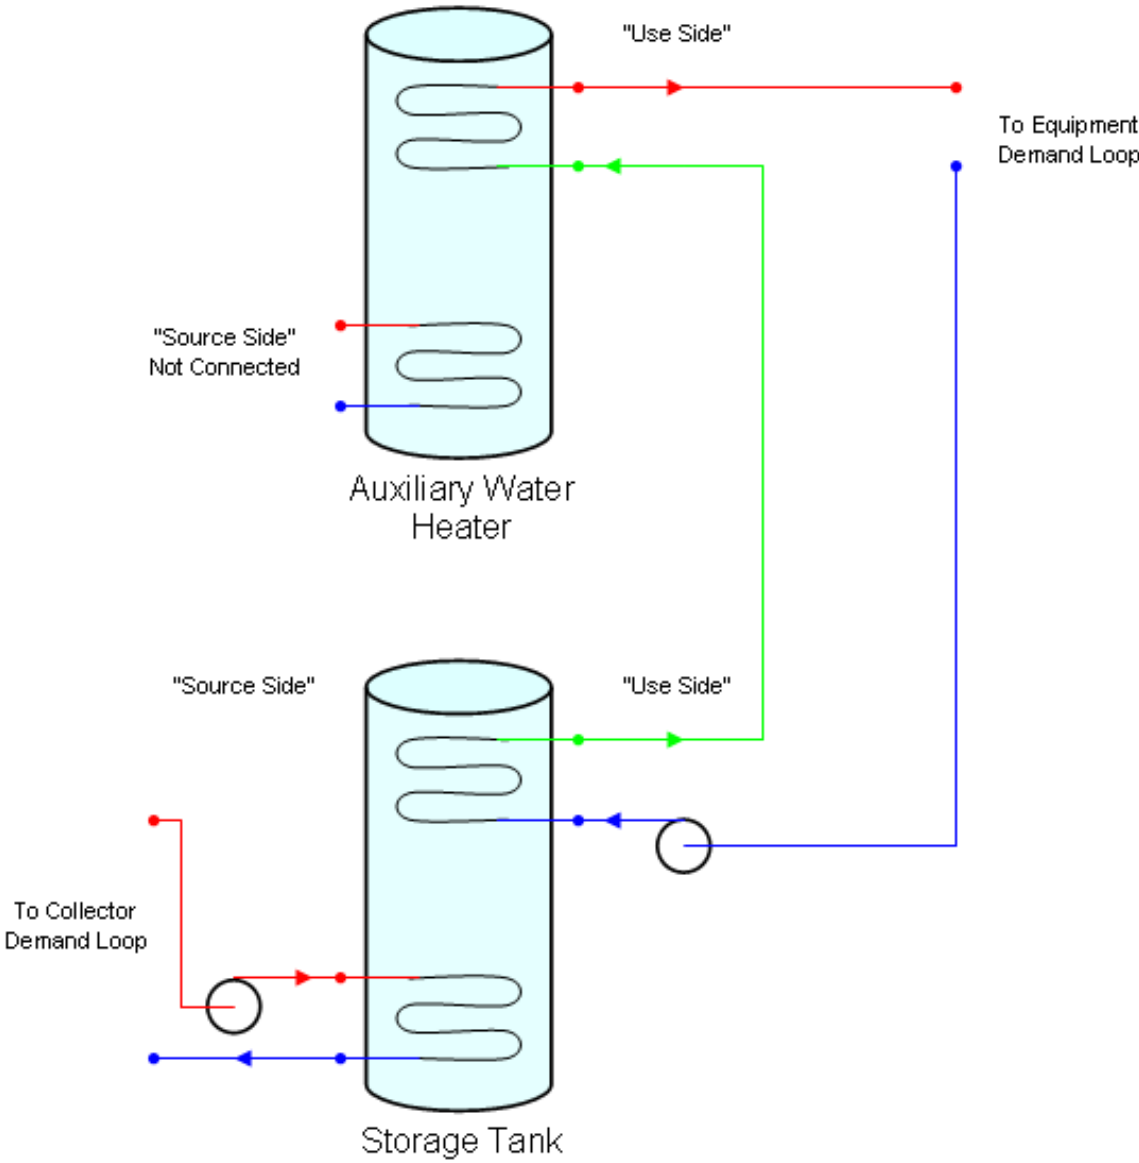

Figure 1.168: Two-Tank Solar Heating System Connection Diagram

Figure 1.169: Two-Tank Solar Heating System with Tempering Valve

### 1.39.8.1 Freeze Prevention

In climates with a cold season, the solar heating system must be designed to avoid the risk of fluid freezing in the solar collector or exposed pipes and causing damage. This is not a problem if air is the heat transfer fluid. With water, however, there are several strategies that can minimize the risk.

*Seasonal schedule.* The simplest strategy is to not use the system during the cold season. This is a hassle because it requires the collector to be manually drained of all fluid. The benefits of the solar heating system are also lost during this time. This can be simulated in EnergyPlus with the appropriate pump schedule for the collector system.

*Antifreeze.* The freezing point of the liquid is decreased by adding antifreeze to the water or using a different heat transfer liquid with a lower freezing point. This cannot yet be simulated in EnergyPlus because only pure water is currently allowed in plant loops.

*Drain-back system.* This strategy automatically empties the collector when the pump is not running. This scenario is modeled by default in EnergyPlus, although the extra pump energy required to start the system is not taken into account.

*Recirculation system.* This strategy automatically recirculates warm liquid from the storage tank back through the collector to maintain the system above the freezing point. There are system losses using this method. This can be simulated in EnergyPlus by using **AvailabilityManager:LowTemperatureTurnOn** to force the system to turn on when the outdoor air temperature or collector outlet temperature falls below a specified minimum.

### 1.39.8.2 Additional Controls

In addition to freeze prevention, it is also necessary to prevent the system from becoming too hot. This is usually a safety issue for the water heater. For this case it is important to have a high temperature cutoff to stop the pump before damaging the water heater. This is accomplished with a **AvailabilityManager:HighTemperatureTurnOff**.

### 1.39.8.3 System Availability Manager List Example

To use the availability managers for the control cases described above, a **AvailabilityManagerAssignmentList** must be defined and referenced in the **PlantLoop** object of the collector loop. An example of a differential thermostat, recirculation for freeze prevention, and high temperature cutoff is shown below:

[illegible]

```

AvailabilityManager:DifferentialThermostat,      ! For useful heat gain from collector to tank
Differential Thermostat Availability Manager,    !- Name
Collector Outlet Node,                          !- Hot Node Name
Water Heater Source Outlet Node,                !- Cold Node Name
10.0,                                           !-
    Temperature Difference On Limit (delta C)
2.0;                                           !-
    Temperature Difference Off Limit (delta C)

```

The `AvailabilityManager:DifferentialThermostat` object must always be the last manager in the availability manager list. See the `AvailabilityManagerAssignmentList` object documentation for more information.

### 1.39.9 SolarCollector:UnglazedTranspired

This object is used to model unglazed transpired solar collectors (UTSC) used to condition outdoor air. These collectors are generally used to heat air drawn through perforated absorbers that are heated by the sun and also recover heat conducted out through the underlying wall. The `SolarCollector:UnglazedTranspired` object represents a single collector attached to one or more `BuildingSurface:Detailed` objects and to one or more outdoor air systems. Therefore the transpired collector is part of both the thermal envelope and the HVAC system. An example file is provided called `TranspiredCollectors.idf`.

The area and orientation of the collector is obtained from `BuildingSurface:Detailed` objects, which are referenced by name. Although the collector surface itself is slightly detached from the underlying building wall (or roof), no additional surface object is needed to represent the collector itself. When modeling transpired collectors, it is important to consider the size of the collector when developing the building model's `BuildingSurface:Detailed` objects because the underlying surfaces must match the collector. For example, if the collector covers only part of the wall, then that wall should be split into separate surfaces where one matches the size of the collector. A single collector can be associated with as many `BuildingSurface:Detailed` objects as desired (although if you need to use more than 10 surfaces, then the IDD will need to be extended). The collector can be arranged at any tilt angle by describing the surfaces appropriately. The surfaces need not be contiguous nor have the same orientation, but the program will issue warnings if surfaces have widely ranging tilts and azimuths.

The collector conditions outdoor air and is connected to the outdoor air system using the usual method of specifying node names. Using the UTSC model requires specifying a relatively complete HVAC air system that includes an outdoor air path. This will typically require using a set of objects that, at a minimum, will include: `AirLoopHVAC:ControllerList`, `AirLoopHVAC:OutdoorAirSystem:EquipmentList`, `AirLoopHVAC:OutdoorAirSystem`, `OutdoorAir:NodeList`, `OutdoorAir:Mixer`, `SetpointManager:MixedAir`, and `Controller:OutdoorAir`. A single UTSC can serve more than one outdoor air system but requires also using a separate object, called `SolarCollector:UnglazedTranspired:Multisystem` to specify node connections.

Controls for the UTSC involve setting the rate of air flow and the status of a bypass damper. If the bypass damper is open, then all the ventilation air goes straight into the outdoor air mixer; if it closed, then all the air first passes through the UTSC. The bypass damper is modeled as completely open or completely closed. The UTSC bypass damper control is determined by an availability manager, the airflow set by the outdoor air mixer controls, and thermostatic type controls that decide if heating is useful. An availability schedule is used to bypass the collector for certain times of the year, eg. summer cooling season. The air flow rates are set by controls associated with the outdoor air mixer (see `SetpointManager:MixedAir`, and `Controller:OutdoorAir`). Thermostatic type control decides if the collector will provide useful heating based on either of two types of setpoints. The first type of temperature setpoint is managed by `SetpointManager:MixedAir`, where the UTSC model looks at a control node, usually the mixed air node. The

second type is an extra setpoint especially for free heating that is managed within this object where the UTSC model looks at the zone air node.

### 1.39.9.1 Inputs

#### 1.39.9.1.1 Field: Name

This field contains a unique name for the unglazed transpired solar collector.

#### 1.39.9.1.2 Field: Boundary Conditions Model Name

This field contains the name of a `SurfaceProperty:OtherSideConditionsModel` object declared elsewhere in the input file. This will connect the collector to the exterior boundary conditions for the underlying heat transfer surface.

#### 1.39.9.1.3 Field: Availability Schedule Name

This field contains the name of a schedule that determines whether or not the UTSC is available. When the schedule value is less than or equal to zero, the UTSC is always bypassed. When the schedule value is greater than zero, the UTSC is available and will be used when other conditions are met, such as outdoor air requested by mixer and preheating has been determined to be beneficial based on thermostatic control. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.39.9.1.4 Field: Inlet Node Name

This field contains the name of an air node that provides air into the UTSC. This node name should also be assigned to be an outdoor air node using the `OutdoorAir:NodeList` or `OutdoorAir:Node` objects. This node should also be named as the actuated node in a `Controller:OutdoorAir` object. If the UTSC is connected to more than one air system, then this field can be left blank and the `SolarCollector:UnglazedTranspired:Multisystem` object should be used to define the nodes.

#### 1.39.9.1.5 Field: Outlet Node Name

This field contains the name of an air node that is the outlet of the UTSC. This node name will typically be the inlet to the `OutdoorAir:Mixer` (if there is no other equipment on the outdoor air path). If the UTSC is connected to more than one air system, then this field can be left blank and the `SolarCollector:UnglazedTranspired:Multisystem` object should be used to define the nodes.

#### 1.39.9.1.6 Field: Setpoint Node Name

This field contains the name of an air node that has a setpoint manager controlling its temperature setpoint. This node name will typically be named as the control node in a `Controller:OutdoorAir` object. If the UTSC is connected to more than one air system, then this field can be left blank and the `SolarCollector:UnglazedTranspired:Multisystem` object should be used to define the nodes.

#### 1.39.9.1.7 Field: Zone Node Name

This field contains the name of an air node for a thermal zone that is ultimately connected to the air system. This node is used with the setpoint schedule, defined in the following field, to provide an added layer of thermostatic control for the UTSC without affecting the control of auxiliary heating. If there is a single air system that is connected to more than one zone, then a single zone should be selected based on where the thermostat might be located. If the UTSC is connected to more than one air system, then this field can be left blank and the `SolarCollector:UnglazedTranspired:Multisystem` object should be used to define the nodes.

**1.39.9.1.8 Field: Free Heating Setpoint Schedule Name**

This field contains the name of a temperature schedule defined elsewhere in the input file. This schedule should define temperatures *desired* in the zone, but not necessarily *required*. This secondary setpoint schedule is used to allow the UTSC to operate as if it has its own thermostat that is separate from the primary control mechanism. When the UTSC is used with auxiliary heating, the usual setpoint managers and temperature controllers will determine how the auxiliary heaters are controlled. This allows using a higher zone air temperature setpoint for controlling UTSC bypass than for the auxiliary heating system.

**1.39.9.1.9 Field: Diameter of Perforations in Collector**

This field is used to enter the effective diameter of the perforations in the collector surface. The diameter should be entered in meters. For perforations other than round, use an equivalent diameter for a round hole that would have the same area.

**1.39.9.1.10 Field: Distance Between Perforations in Collector**

This field is used to enter the pitch, or average, shortest distance between perforations.

**1.39.9.1.11 Field: Thermal Emissivity of Collector Surface**

This field is used to enter the thermal emissivity of the collector. This surface property is for longwave infrared radiation. The property is used for both sides of collector. Most painted materials have an emissivity of 0.9.

**1.39.9.1.12 Field: Solar Absorbtivity of Collector Surface**

This field is used to enter the solar absorbtivity of the collector. This surface property is for shortwave, solar radiation. The property is used for the front side of the collector that faces the environment. Darker colors have a higher absorbtivity. While black is the highest performance, other colors might be used to match the color scheme of the rest of the facade. The following table provides sample solar absorbtivities for different colors (source: Conserval Engineering Inc., Toronto, Ontario, Canada).

Color Name of Kynar(R) [[1]](#_ftn1) Paint	Solar Absorptivity
Black	0.94
Classic Bronze	0.91
Chocolate Brown	0.9
Hartford Green	0.9
Med. Bronze	0.89
Boysenberry	0.86
Rocky Grey	0.85
Regal Blue	0.85
Forest Green	0.84
Hemlock Green	0.82
Slate Blue	0.8
Redwood	0.79
Teal	0.79
Slate Grey	0.79
Patina Green	0.77

Color Name of Kynar(R) [[1]](#_ftn1) Paint	Solar Absorptivity
Mint Green	0.71
Dove Grey	0.69
Mission Red	0.69
Sierra Tan	0.65
Brite Red	0.59
Rawhide	0.57
Sandstone	0.54
Silversmith	0.53
Coppertone	0.51
Concord Cream	0.45
Ascot White	0.4
Bone White	0.3

([1] Kynar is a registered trademark of Elf Atochem North America, Inc.)

#### 1.39.9.1.13 Field: Effective Overall Height of Collector

This field is used to enter a nominal height for the collector. This value is used in the program to determine a length scale in the vertical direction for the buoyancy-driven portion of natural ventilation that occurs when the collector is inactive. (Note that most of the geometry information is obtained from the underlying surfaces.) The value entered here is adjusted inside the program to account for tilt of the collector. While the value here would generally correspond to the actual distance/height, its value is not critical and it can be used to adjust modeling the air exchange rates in passive mode. If the collector is horizontal, then the length scale is obtained from the following field.

#### 1.39.9.1.14 Field: Effective Gap Thickness of Plenum Behind Collector

This field is used to enter a nominal gap thickness for the collector. This distance value is only used when the collector is near horizontal to determine a length scale in the vertical direction for buoyancy calculations. For example, if the collector is mounted on a flat roof, its tilt-adjusted height is zero and the program will use this gap thickness as a length scale rather than the height from the previous field.

#### 1.39.9.1.15 Field: Effective Cross Section Area of Plenum Behind Collector

This field is used to enter the nominal cross sectional area of the gap behind the collector. This area is used to determine a velocity scale for surface convection heat transfer correlations when the collector is active. This value is generally the average gap thickness times the average width of the collector.

#### 1.39.9.1.16 Field: Hole Layout Pattern for Pitch

This field is used to describe the pattern of perforations in the collector surface. There are currently two choices available: Square and Triangle. Note that the hole layout pattern should be consistent with how the value for pitch was determined.

#### 1.39.9.1.17 Field: Heat Exchange Effectiveness Correlation

This field is used to select which correlation is used to model heat transfer from the collector surface to the incoming air when the collector is active. There are two choices available: Kutscher1994, and VanDeckerHollandsBrunger2001. See the Engineering Reference for details and references.

**1.39.9.1.18 Field: Ratio of Actual Collector Surface Area to Projected Surface Area**

This field is used to enter a factor that accounts for the extra surface area resulting from corrugations in the collector surface. Corrugations help stiffen the collector. The projected surface area is obtained by the program from the (flat) underlying surfaces. If the collector is flat then this ratio is 1.0. If the collector is corrugated, then this ratio will be greater than one. A typical value might be 1.165.

**1.39.9.1.19 Field: Roughness of Collector**

This field is used to describe the relative roughness of the collector material. This field is similar to one in the **Material** object. This parameter only influences the convection coefficients, more specifically the outside convection coefficient. A special keyword is expected in this field with the options being VeryRough , Rough , MediumRough , MediumSmooth , Smooth , and VerySmooth in order of roughest to smoothest options.

**1.39.9.1.20 Field: Collector Thickness**

This field is used to enter the thickness of the collector material. This value is only needed for the Van Decker Hollands Brunger 2001 correlation. The material thickness should be entered in meters.

**1.39.9.1.21 Field: Effectiveness for Perforations with Respect to Wind**

This field is used to enter a value for the coefficient used to determine natural air exchanges from wind, or Cv. When the collector is inactive, wind will cause exterior air to move in and out of the collector. Cv is an arbitrary coefficient used to model the effectiveness of openings and depends on opening geometry and the orientation with respect to the wind. Cv should probably be in the range 0.25 to 0.65. Increasing Cv will increase the amount of natural ventilation.

**1.39.9.1.22 Field: Discharge Coefficient for Openings with Respect to Buoyancy Driven Flow**

This field is used to enter a value for the coefficient used to determine natural air exchanges from buoyancy, or Cd. When the collector is inactive, stack or buoyancy effects will cause exterior air to move in and out of the collector. Cd is an arbitrary discharge coefficient that depends on the geometry of the opening. Cd should probably be in the range 0.4 to 1.0. Increasing Cd will increase the amount of natural ventilation.

**1.39.9.1.23 Field: Surface <#> Name**

The remaining fields are used to name the **BuildingSurface:Detailed** objects that are associated with the UTSC. These are the underlying heat transfer surfaces and are defined elsewhere in the input file. These other surfaces should all specify OtherSideConditionsModel as their exterior environment. The input object can currently accommodate up to ten surfaces, but it is extensible.

An example of this object follows.

### 1.39.9.2 Outputs

In addition to related output that can be obtained for air nodes and surfaces, these outputs are available for UTSC systems:

- HVAC,Average,Solar Collector Heat Exchanger Effectiveness []
- HVAC,Average,Solar Collector Leaving Air Temperature [C]
- HVAC,Average,Solar Collector Outside Face Suction Velocity [m/s]
- HVAC,Average,Solar Collector Surface Temperature [C]
- HVAC,Average,Solar Collector Plenum Air Temperature [C]
- HVAC,Average,Solar Collector Sensible Heating Rate [W]
- Zone,Meter,SolarAir:Facility [J]
- Zone,Meter,SolarAir:HVAC [J]
- Zone,Meter,HeatProduced:SolarAir [J]
- HVAC,Sum,Solar Collector Sensible Heating Energy [J]
- HVAC,Average,Solar Collector Natural Ventilation Air Change Rate [ACH]
- HVAC,Average,Solar Collector Natural Ventilation Mass Flow Rate [kg/s]
- HVAC,Average,Solar Collector Wind Natural Ventilation Mass Flow Rate [kg/s]
- HVAC,Average,Solar Collector Buoyancy Natural Ventilation Mass Flow Rate [kg/s]
- HVAC,Average,Solar Collector Incident Solar Radiation [W/m2]
- HVAC,Average,Solar Collector System Efficiency []
- HVAC,Average,Solar Collector Surface Efficiency []

**1.39.9.2.1 Solar Collector Heat Exchanger Effectiveness []**

The results from UTSC correlations defined by  $\varepsilon_{HX} = \frac{T_{a,HX} - T_{amb}}{T_{s,coll} - T_{amb}}$ .

**1.39.9.2.2 Solar Collector Leaving Air Temperature [C]**

The temperature of air entering the plenum after being heated by the collector. When there is no forced air flow or the collector is passive, then the condition of air entering the plenum or the collector leaving air is assumed to be that of outside air.

**1.39.9.2.3 Solar Collector Outside Face Suction Velocity [m/s]**

The bulk velocity of air approaching the collector.

**1.39.9.2.4 Solar Collector Surface Temperature [C]**

The surface temperature of the collector itself.

**1.39.9.2.5 Solar Collector Plenum Air Temperature [C]**

The temperature of air inside, and leaving, the plenum behind the collector. This plenum leaving air temperature depends on the mode of operation of the collector. When the collector is passive (no forced flow), then the passive model assumes the condition of air entering the plenum is that of outside air, or else when the collector is active, then the model sets the plenum entering air condition to transpired collector leaving air condition determined from the collector model.

**1.39.9.2.6 Solar Collector Sensible Heating Rate [W]**

The overall rate at which heat is being added to the outdoor air stream.

**1.39.9.2.7 SolarAir:Facility [J]**

A meter that includes the heating energy provided by the UTSC.

**1.39.9.2.8 SolarAir:HVAC [J]**

A meter that includes the heating energy provided by the UTSC.

**1.39.9.2.9 HeatProduced:SolarAir [J]**

A meter that includes the heating energy provided by the UTSC.

**1.39.9.2.10 Solar Collector Sensible Heating Energy [J]**

The overall sum of energy added to the outdoor air stream.

**1.39.9.2.11 Solar Collector Natural Ventilation Air Change Rate [ACH]**

The rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive in Air Changes per Hour.

**1.39.9.2.12 Solar Collector Natural Ventilation Mass Flow Rate [kg/s]**

The mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive.

**1.39.9.2.13 Solar Collector Wind Natural Ventilation Mass Flow Rate [kg/s]**

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to wind-driven forces.

**1.39.9.2.14 Solar Collector Buoyancy Natural Ventilation Mass Flow Rate [kg/s]**

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to buoyancy-driven forces.

**1.39.9.2.15 Solar Collector Incident Solar Radiation [W/m<sup>2</sup>]**

The intensity of solar radiation incident on the UTSC collector from all sources.

**1.39.9.2.16 Solar Collector System Efficiency []**

The overall efficiency of the UTSC system including collected solar energy and heat recovered from the underlying surface.

**1.39.9.2.17 Solar Collector Surface Efficiency []**

The efficiency of the UTSC solar collector.

**1.39.10 SolarCollector:UnglazedTranspired:Multisystem**

This object is used to model unglazed transpired solar collectors (UTSC) that are connected to multiple outdoor air systems. This object supplements the **SolarCollector:UnglazedTranspired** object and is only necessary if more than one air system is connected to a single transpired collector. After the name field, there are sets of four node names used to define the connections of each air system. Each set contains node names for inlet, outlet, control, and zone. If more than five air systems are needed, this object is extensible.

**1.39.10.1 Field: Solar Collector Name**

This field is used to identify the name of the **SolarCollector:UnglazedTranspired** object that needs to be connected to more than one air system. This field must match the name.

**1.39.10.2 Field Set: Inlet Node, Outlet Node, Mixed Air Node, Zone Node**

The following four fields form a repeating set of four fields. One set is used for each outdoor air system that is connected to the collector.

**1.39.10.3 Field: Outdoor Air System <#> Collector Inlet Node**

This field contains the name of an air node that provides air into the UTSC. This node name should also be assigned to be an outdoor air node using the **OutdoorAir:NodeList** and **OutdoorAir:Node** objects. This node is also be named as the actuator node in a **Controller:OutdoorAir** object.

**1.39.10.4 Field: Outdoor Air System <#> Collector Outlet Node**

This field contains the name of an air node that is the outlet of the UTSC. This node name will typically be the Outdoor Air Stream Node Name in the **OutdoorAir:Mixer** (if there is no other equipment on the outdoor air path).

**1.39.10.5 Field: Outdoor Air System <#> Mixed Air Node**

This field contains the name of an air node that has a setpoint manager controlling its temperature setpoint. This node name will typically be named as the mixed air node in a **Controller:OutdoorAir** object.

### 1.39.10.6 Field: Outdoor Air System <#> Zone Node

This field contains the name of an air node for a thermal zone that is ultimately connected to the air system. This node is used with the setpoint schedule, defined in the following field, to provide an added layer of thermostatic control for the UTSC without affecting the control of auxiliary heating. If there is a single air system that is connected to more than one zone, then a single zone should be selected based on where the thermostat might be located.

An example of this object follows.

```
SolarCollector:UnglazedTranspired:Multisystem,
OFFICE MultiSystem OA UTSC ,      ! Solar Collector Name
Outside Air Inlet Node ZN1,        ! Outdoor Air System 1 Collector Inlet Node
UTSC Outlet Node ZN1,              ! Outdoor Air System 1 Collector Outlet Node
Mixed Air Node ZN1,                ! Outdoor Air System 1 Mixed Air Node
ZN1 Node,                          ! Outdoor Air System 1 Zone Node
Outside Air Inlet Node ZN2,        ! Outdoor Air System 2 Collector Inlet Node
UTSC Outlet Node ZN2,              ! Outdoor Air System 2 Collector Outlet Node
Mixed Air Node ZN2,                ! Outdoor Air System 2 Mixed Air Node
ZN2 Node,                          ! Outdoor Air System 2 Zone Node
Outside Air Inlet Node ZN3,        ! Outdoor Air System 3 Collector Inlet Node
UTSC Outlet Node ZN3,              ! Outdoor Air System 3 Collector Outlet Node
Mixed Air Node ZN3,                ! Outdoor Air System 3 Mixed Air Node
ZN3 Node,                          ! Outdoor Air System 3 Zone Node
Outside Air Inlet Node ZN4,        ! Outdoor Air System 4 Collector Inlet Node
UTSC Outlet Node ZN4,              ! Outdoor Air System 4 Collector Outlet Node
Mixed Air Node ZN4,                ! Outdoor Air System 4 Mixed Air Node
ZN4 Node,                          ! Outdoor Air System 4 Zone Node
Outside Air Inlet Node ZN5,        ! Outdoor Air System 5 Collector Inlet Node
UTSC Outlet Node ZN5,              ! Outdoor Air System 5 Collector Outlet Node
Mixed Air Node ZN5,                ! Outdoor Air System 5 Mixed Air Node
ZN5 Node;                          ! Outdoor Air System 5 Zone Node
```

## 1.40 Group Pumps

EnergyPlus plant and condenser loops need pump components to drive liquid flow around the loop. There are various types of pump models available.

### 1.40.1 Pump:VariableSpeed

Pumps are needed in both plant and condenser loops. The syntax for a variable speed pump is given below.

#### 1.40.1.1 Inputs

##### 1.40.1.1.1 Field: Name

This alpha field contains the identifying a unique name for the pump.

##### 1.40.1.1.2 Field: Inlet Node Name

This alpha field contains the identifying name for the pump inlet node.

##### 1.40.1.1.3 Field: Outlet Node Name

This alpha field contains the identifying name for the pump outlet node.

##### 1.40.1.1.4 Field: Design Maximum Flow Rate

This numeric field contains the pump's design maximum volume flow rate in cubic meters per second. This field can be autosized.

**1.40.1.1.5 Field: Design Pump Head**

This numeric field contains the pump's design head pressure in Pascals. The default is 179352 Pa, or 60 ftH<sub>2</sub>O, and is for a fairly large building.

**1.40.1.1.6 Field: Design Power Consumption**

This numeric field contains the pump's design power consumption in Watts. If the user is performing a pressure simulation on the loop in which this pump is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically. This field can be autosized. When set to autosize the type of scaling factor is chosen in the input field Design Power Sizing Method.

**1.40.1.1.7 Field: Motor Efficiency**

This numeric field contains the pump motor's efficiency in decimal form (0 = 0%, 1 = 100%).

**1.40.1.1.8 Field: Fraction of Motor Inefficiencies to Fluid Stream**

This numeric field contains the pump motor's fraction of power loss to the fluid.

**1.40.1.1.9 Field: Coefficient 1 of the Part Load Performance Curve**

This numeric field contains the first coefficient in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$FractionFullLoadPower = C_1 + C_2PLR + C_3PLR^2 + C_4PLR^3 \quad (1.146)$$

where  $C_1, C_2, C_3,$  and  $C_4$  are Coefficients 1 4 (below) and PLR is the Part Load Ratio.

**1.40.1.1.10 Field: Coefficient 2 of the Part Load Performance Curve**

This numeric field contains the second coefficient in the part load ratio curve.

**1.40.1.1.11 Field: Coefficient 3 of the Part Load Performance Curve**

This numeric field contains the third coefficient in the part load ratio curve.

**1.40.1.1.12 Field: Coefficient 4 of the Part Load Performance Curve**

This numeric field contains the fourth coefficient in the part load ratio curve.

**1.40.1.1.13 Field: Design Minimum Flow Rate**

This field contains the minimum volume flow rate while operating in variable flow capacity rate in cubic meters per second. This field is autosizable. When set to autosize the value in the input field Design Minimum Flow Rate Sizing Factor is used to scale the minimum flow rate as a fraction of the Design Maximum Flow Rate.

**1.40.1.1.14 Field: Pump Control Type**

This is a choice field of Continuous or Intermittent. A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this control by forcing the pump to be on or off.

**1.40.1.1.15 Field: Pump Flow Rate Schedule Name**

The schedule values modify the value for Rated Flow Rate of the pump on a time basis. This essentially sets the maximum value available for the pump at a given time, **not the actual flow rate at that time**. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations. For additional control over pump flow, EMS actuators can be employed.

**1.40.1.1.16 Field: Pump Curve Name**

This references a pump curve to be used during pump flow-loop head resolution. This is only applicable for loop simulations which include pressure components on at least a single branch. More information regarding pressure system simulation is available in the engineering reference.

**1.40.1.1.17 Field: Impeller Diameter**

For pressure simulation cases, this is the impeller diameter used during calculations which is used in non-dimensionalizing the pump curve described in the previous field. The units of this value are meters.

**1.40.1.1.18 Field: VFD Control Type**

This string defines which type of VFD control type to perform. PressureSetPointControl is a realistic approach which requires inputs of pressure range schedules to control the pump rpm to maintain a certain pressure drop (head). ManualControl is an idealized control strategy in which the pump RPM is maintained at a scheduled value throughout the simulation, abiding by other flow restrictions in the loop.

**1.40.1.1.19 Field: Pump RPM Schedule Name**

For VFD Control Type = ManualControl, this defines the pump RPM schedule to use during the simulation. For VFD Control Type = PressureSetPointControl, this field is not interpreted. The value of the schedule is RPM.

**1.40.1.1.20 Field: Minimum Pressure Schedule**

For VFD Control Type = PressureSetPointControl, this field defines the minimum pressure range setpoint value, or the lower bound of pressure drop (head) to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is Pascals.

**1.40.1.1.21 Field: Maximum Pressure Schedule**

For VFD Control Type = PressureSetPointControl, this field defines the maximum pressure range setpoint value, or the upper bound of pressure drop (head) to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is Pascals.

**1.40.1.1.22 Field: Minimum RPM Schedule**

For VFD Control Type = PressureSetPointControl, this field defines the minimum allowable RPM, or the lower bound of pump speed to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is RPM.

**1.40.1.1.23 Field: Maximum RPM Schedule**

For VFD Control Type = PressureSetPointControl, this field defines the maximum allowable RPM, or the upper bound of pump speed to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is RPM.

**1.40.1.1.24 Field: Zone Name**

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

**1.40.1.1.25 Field: Skin Loss Radiative Fraction**

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

**1.40.1.1.26 Field: Design Power Sizing Method**

This field is optional. There are two choices PowerPerFlow and PowerPerFlowPerPressure. If PowerPerFlow is used the pump's Design Power Consumption will be calculated using the sizing factor from the input field Design Electric Power per Unit Flow Rate – with Design Power Consumption = Design Maximum Flow Rate \* scaling factor. If PowerPerFlowPerPressure is used the pump's Design Power Consumption will use the sizing factor from the input field Design Shaft Power per Unit Flow Rate Per Unit Head – with Design Power Consumption = Design Maximum Flow Rate \* Design Pump Head \* scaling factor / Motor Efficiency. If omitted the default method of PowerPerFlowPerPressure will be used.

**1.40.1.1.27 Field: Design Electric Power per Unit Flow Rate**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlow. It allows setting the efficiency the pumping system's power consumption using only the design flow rate. If omitted the default value of 348701.1 W/(m<sup>3</sup>/s) ( 22 W/gpm) will be used.

**1.40.1.1.28 Field: Design Shaft Power per Unit Flow Rate Per Unit Head**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlowPerPressure. It allows setting the efficiency of the impeller and drive assembly when calculating the pump power consumption for the design flow rate, motor efficiency, and pump head. If omitted the default value of 1.282051 W/((m<sup>3</sup>/s)-Pa) will be used.

**1.40.1.1.29 Field: Design Minimum Flow Rate Sizing Factor**

This field is optional. If omitted the default value of 0.0 will be used. This input is used when the input field Design Minimum Flow Rate is set to autosize. The minimum flow rate will be set to the product of this sizing factor and the Design Maximum Flow Rate.

**1.40.1.1.30 Field: End-Use Subcategory**

Allows you to specify a user-defined end-use subcategory, e.g., “Main Pumps”, etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the pump will be assigned to the “General” end-use subcategory.

Examples of this object in the IDF follow.

```
Pump:VariableSpeed,
  HW Circ Pump,           !- Name
  HW Supply Inlet Node,    !- Inlet Node Name
  HW Pump Outlet Node,     !- Outlet Node Name
  autosize,               !- Design Maximum Flow Rate {m3/s}
```

```

179352,                !- Design Pump Head {Pa}
autosize,              !- Design Power Consumption {W}
0.9,                  !- Motor Efficiency

---

### 1.40.1.2 Outputs

- HVAC,Average,Pump Electricity Rate [W]
- HVAC,Sum,Pump Electricity Energy [J]
- HVAC,Average,Pump Shaft Power [W]
- HVAC,Average,Pump Fluid Heat Gain Rate [W]
- HVAC,Sum,Pump Fluid Heat Gain Energy [J]
- HVAC,Average,Pump Outlet Temperature [C]
- HVAC,Average,Pump Mass Flow Rate [kg/s]
- HVAC,Average,Pump Zone Total Heating Rate [W]
- HVAC,Sum,Pump Zone Total Heating Energy [J]
- HVAC,Average,Pump Zone Convective Heating Rate [W]
- HVAC,Average,Pump Zone Radiative Heating Rate [W]

#### 1.40.1.2.1 Pump Electricity Rate [W]

#### 1.40.1.2.2 Pump Electricity Energy [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

#### 1.40.1.2.3 Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

**1.40.1.2.4 Pump Fluid Heat Gain Rate [W]****1.40.1.2.5 Pump Fluid Heat Gain Energy [J]**

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

**1.40.1.2.6 Pump Outlet Temperature [C]****1.40.1.2.7 Pump Mass Flow Rate [kg/s]**

These outputs are the water outlet temperature and mass flow rate.

**1.40.1.2.8 Pump Zone Total Heating Rate [W]****1.40.1.2.9 Pump Zone Total Heating Energy [J]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

**1.40.1.2.10 Pump Zone Convective Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

**1.40.1.2.11 Pump Zone Radiative Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

**1.40.2 Pump:ConstantSpeed**

Pumps may be found in both plant and condenser loops. The syntax for a constant speed pump is given below.

**1.40.2.1 Inputs****1.40.2.1.1 Field: Name**

This alpha field contains the identifying name for the pump.

**1.40.2.1.2 Field: Inlet Node Name**

This alpha field contains the identifying name for the pump inlet node.

**1.40.2.1.3 Field: Outlet Node Name**

This alpha field contains the identifying name for the pump outlet node.

**1.40.2.1.4 Field: Design Flow Rate**

This numeric field contains the pump's design volume flow rate in cubic meters per second. This field is autosizable.

#### 1.40.2.1.5 Field: Design Pump Head

This numeric field contains the pump's design head pressure in Pascals. The default is 179352 Pa, or 60 ftH<sub>2</sub>O, and is for a fairly large building.

#### 1.40.2.1.6 Field: Design Power Consumption

This numeric field contains the pump's design power consumption in Watts. If the user is performing a pressure simulation on the loop in which this pump is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically. This field can be autosized. When set to autosize the type of scaling factor is chosen in the input field Design Power Sizing Method.

#### 1.40.2.1.7 Field: Motor Efficiency

This numeric field contains the pump motor's efficiency in decimal form (0 = 0%, 1 = 100%).

#### 1.40.2.1.8 Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump motor's fraction of power loss to the fluid.

#### 1.40.2.1.9 Field: Pump Control Type

This is a choice field of Continuous or Intermittent. The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this control by forcing the pump to be on or off.

#### 1.40.2.1.10 Field: Pump Flow Rate Schedule Name

The schedule values modify the value for Rated Flow Rate of the pump on a time basis. This essentially sets the maximum value available for the pump at a given time, **not the actual flow rate at that time**. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations. For additional control over pump flow, EMS actuators can be employed.

#### 1.40.2.1.11 Field: Pump Curve Name

This field is only used if the user is performing a pressure-based simulation in the plant loop of the LoopFlowCorrection type (see [PlantLoop](#) section for how to enable this).

This field references a separate pressure head curve that the user has input separately in the input file. The pressure curve represents a non-dimensional regression of pressure-flow rate data. The equation should be of the following form:

$$\psi = C_4 \times \varphi^4 + C_3 \times \varphi^3 + C_2 \times \varphi^2 + C_1 \times \varphi + C_0. \quad (1.147)$$

In this equation, the two dimensionless parameters,  $\psi$  and  $\varphi$  are defined in terms of physical pump and flow parameters as:

$$\psi = \frac{\Delta P}{\rho N^2 D^2} \quad (1.148)$$

$$\varphi = \frac{\dot{m}}{\rho N D^3} \quad (1.149)$$

Where Delta P is the pressure drop,  $\dot{m}$  is the fluid mass flow rate,  $\rho$  is a representative fluid density, N is the rotational speed of the pump, and D is the pump impeller diameter.

Since the user may not need a full fourth order expansion of this, the user may use linear (first order), quadratic (second order), cubic (third order), or full quartic (fourth order). These are available in the objects **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**.

Once this curve is input properly (along with the following two fields), the pump will respond to the plant loop pressure drop when resolving the flow rate. Note that this simulation method will likely result in a plant loop that does not exactly hit the setpoint as the current simulation method does. This is due to the loop flow rate now being pressure-based and not decision-based .

#### 1.40.2.1.12 Field:Impeller Diameter

This field is only used if the user is performing a pressure-based simulation in the plant loop of the LoopFlowCorrection type (see **PlantLoop** section for how to enable this).

To re-dimensionalize the dimensionless pump curve, the impeller diameter must be known. This value is entered in meters.

#### 1.40.2.1.13 Field:Rotational Speed

This field is only used if the user is performing a pressure-based simulation in the plant loop of the LoopFlowCorrection type (see **PlantLoop** section for how to enable this).

To re-dimensionalize the dimensionless pump curve, the rotational speed must be known. This value is entered in RPM (revolutions per minute).

#### 1.40.2.1.14 Field: Zone Name

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

#### 1.40.2.1.15 Field: Skin Loss Radiative Fraction

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

#### 1.40.2.1.16 Field: Design Power Sizing Method

This field is optional. There are two choices PowerPerFlow and PowerPerFlowPerPressure. If omitted the default method of PowerPerFlowPerPressure will be used.

If PowerPerFlow is used the pump's Design Power Consumption will be calculated using the sizing factor from the input field Design Electrical Power per Unit Flow Rate – with Design Power Consumption = Design Maximum Flow Rate \* scaling factor.

If PowerPerFlowPerPressure is used the pump's Design Power Consumption will use the sizing factor from the input field Design Shaft Power per Unit Flow Rate Per Unit Head – with Design Power Consumption = Design Maximum Flow Rate \* Design Pump Head \* scaling factor / Motor Efficiency.

#### 1.40.2.1.17 Field: Design Electrical Power per Unit Flow Rate

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlow. It allows setting the efficiency the pumping system's power consumption using only the design flow rate. If omitted the default value of 348701.1 W/(m<sup>3</sup>/s) (22 W/gpm) will be used.

#### 1.40.2.1.18 Field: Design Shaft Power per Unit Flow Rate Per Unit Head

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlowPerPressure. It allows controlling the efficiency of the impeller and drive assembly when calculating the pump power consumption for the design flow rate, motor efficiency, and pump head. If omitted the default value of  $1.282051 \text{ W}/((\text{m}^3/\text{s})\text{-Pa})$  will be used.

#### 1.40.2.1.19 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Main Pumps”, etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the pump will be assigned to the “General” end-use subcategory.

An example of this object follows.

```
Pump:ConstantSpeed,
  Circ Pump,                !- Name
  CW Supply Inlet Node,      !- Inlet Node Name
  PumpChiller Node,         !- Outlet Node Name
  0.0011,                   !- Design Flow Rate
  300000,                   !- Design Pump Head
  700,                      !- Design Power Consumption
  0.87,                    !- Motor Efficiency
  0.0,                     !- Fraction of Motor Inefficiencies to Fluid Stream
  Intermittent;             !- Pump Control Type
```

### 1.40.2.2 Outputs

- HVAC,Average,Pump Electricity Rate [W]
- HVAC,Sum,Pump Electricity Energy [J]
- HVAC,Average,Pump Shaft Power [W]
- HVAC,Average,Pump Fluid Heat Gain Rate [W]
- HVAC,Sum,Pump Fluid Heat Gain Energy [J]
- HVAC,Average,Pump Outlet Temperature [C]
- HVAC,Average,Pump Mass Flow Rate [kg/s]
- HVAC,Average,Pump Zone Total Heating Rate [W]
- HVAC,Sum,Pump Zone Total Heating Energy [J]
- HVAC,Average,Pump Zone Convective Heating Rate [W]
- HVAC,Average,Pump Zone Radiative Heating Rate [W]

#### 1.40.2.2.1 Pump Electricity Rate [W]

#### 1.40.2.2.2 Pump Electricity Energy [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

**1.40.2.2.3 Pump Shaft Power [W]**

This is the shaft power delivered from the motor to the pump.

**1.40.2.2.4 Pump Fluid Heat Gain Rate [W]****1.40.2.2.5 Pump Fluid Heat Gain Energy [J]**

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

**1.40.2.2.6 Pump Outlet Temperature [C]****1.40.2.2.7 Pump Mass Flow Rate [kg/s]**

These outputs are the water outlet temperature and mass flow rate.

**1.40.2.2.8 Pump Zone Convective Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

**1.40.2.2.9 Pump Zone Radiative Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

**1.40.2.2.10 Pump Zone Total Heating Energy [J]****1.40.2.2.11 Pump Zone Total Heating Rate [W]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

**1.40.3 Pump:VariableSpeed:Condensate**

The Pump:VariableSpeed:Condensate object can only be used in steam system simulation for the condensate side of the loop. This is a variable speed pump, which pumps the condensate back to the steam boiler. The syntax for condensate pump is given below.

**1.40.3.1 Inputs****1.40.3.1.1 Field: Name**

This alpha field contains the identifying unique name for the pump.

**1.40.3.1.2 Field: Inlet Node Name**

This alpha field contains the identifying name for the pump inlet node.

**1.40.3.1.3 Field: Outlet Node Name**

This alpha field contains the identifying name for the pump outlet node.

**1.40.3.1.4 Field: Design Steam Volume Flow Rate**

This numeric field contains the pump's design volume flow rate in cubic meters per second. This field is autosizable. This is the volume flow rate of steam in expanded stated. The volume of condensate is calculated by the software from the steam density and is much lower.

**1.40.3.1.5 Field: Design Pump Head**

This numeric field contains the pump's design head in Pascals. The default is 179352 Pa, or 60 ftH<sub>2</sub>O, and is for a fairly large building.

**1.40.3.1.6 Field: Design Power Consumption**

This numeric field contains the pump's rated power consumption in Watts. If the user is performing a pressure simulation on the loop in which this pump is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically. This field can be autosized. When set to autosize the type of scaling factor is chosen in the input field Design Power Sizing Method.

**1.40.3.1.7 Field: Motor Efficiency**

This numeric field contains the pump motor's efficiency in decimal form (0 = 0%, 1 = 100%).

**1.40.3.1.8 Field: Fraction of Motor Inefficiencies to Fluid Stream**

This numeric field contains the pump motor's fraction of power loss to the fluid.

**1.40.3.1.9 Field: Coefficient 1 of the Part Load Performance Curve**

This numeric field contains the first coefficient in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$FractionFullLoadPower = C_1 + C_2PLR + C_3PLR^2 + C_4PLR^3 \quad (1.150)$$

where  $C_1, C_2, C_3,$  and  $C_4$  are Coefficients 1 4 (below) and PLR is the Part Load Ratio.

**1.40.3.1.10 Field: Coefficient 2 of the Part Load Performance Curve**

This numeric field contains the second coefficient in the part load ratio curve.

**1.40.3.1.11 Field: Coefficient 3 of the Part Load Performance Curve**

This numeric field contains the third coefficient in the part load ratio curve.

**1.40.3.1.12 Field: Coefficient 4 of the Part Load Performance Curve**

This numeric field contains the fourth coefficient in the part load ratio curve.

**1.40.3.1.13 Field: Pump Flow Rate Schedule Name**

The schedule values modify the value for Rated Flow Rate of the pump on a time basis. This essentially sets the maximum value available for the pump at a given time, **not the actual flow rate at that time**. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations. For additional control over pump flow, EMS actuators can be employed.

**1.40.3.1.14 Field: Zone Name**

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

**1.40.3.1.15 Field: Skin Loss Radiative Fraction**

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

**1.40.3.1.16 Field: Design Power Sizing Method**

This field is optional. There are two choices PowerPerFlow and PowerPerFlowPerPressure. If PowerPerFlow is used the pump's Design Power Consumption will be calculated using the sizing factor from the input field Design Electric Power per Unit Flow Rate – with Design Power Consumption = Design Maximum Flow Rate \* scaling factor. If PowerPerFlowPerPressure is used the pump's Design Power Consumption will use the sizing factor from the input field Design Shaft Power per Unit Flow Rate Per Unit Head – with Design Power Consumption = Design Maximum Flow Rate \* Design Pump Head \* scaling factor / Motor Efficiency. If omitted the default method of PowerPerFlowPerPressure will be used.

**1.40.3.1.17 Field: Design Electric Power per Unit Flow Rate**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlow. It allows setting the efficiency the pumping system's power consumption using only the design flow rate. If omitted the default value of 348701.1 W/(m<sup>3</sup>/s) ( 22 W/gpm) will be used.

**1.40.3.1.18 Field: Design Shaft Power per Unit Flow Rate Per Unit Head**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlowPerPressure. It allows setting the efficiency of the impeller and drive assembly when calculating the pump power consumption for the design flow rate, motor efficiency, and pump head. If omitted the default value of 1.282051 W/((m<sup>3</sup>/s)-Pa) will be used.

**1.40.3.1.19 Field: End-Use Subcategory**

Allows you to specify a user-defined end-use subcategory, e.g., “Main Pumps”, etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the pump will be assigned to the “General” end-use subcategory.

Examples of this object in the IDF follow.

```
Pump:VariableSpeed:Condensate,
  Steam Boiler Plant Steam Circ Pump,           !- Name
  Steam Boiler Plant Steam Supply Inlet Node, !- Inlet Node Name
  Steam Boiler Plant Steam Pump Outlet Node, !- Outlet Node Name

### 1.40.3.2 Outputs

- HVAC,Average,Pump Electricity Rate [W]
- HVAC,Sum,Pump Electricity Energy [J]
- HVAC,Average,Pump Shaft Power [W]
- HVAC,Average,Pump Fluid Heat Gain Rate [W]
- HVAC,Sum,Pump Fluid Heat Gain Energy [J]
- HVAC,Average,Pump Outlet Temperature [C]
- HVAC,Average,Pump Mass Flow Rate [kg/s]
- HVAC,Average, Pump Zone Total Heating Rate [W]
- HVAC, Sum, Pump Zone Total Heating Energy [J]
- HVAC, Average, Pump Zone Convective Heating Rate [W]
- HVAC, Average, Pump Zone Radiative Heating Rate [W]

#### 1.40.3.2.1 Pump Electricity Rate [W]

#### 1.40.3.2.2 Pump Electricity Energy [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

#### 1.40.3.2.3 Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

#### 1.40.3.2.4 Pump Fluid Heat Gain Rate [W]

#### 1.40.3.2.5 Pump Fluid Heat Gain Energy [J]

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

**1.40.3.2.6 Pump Outlet Temperature [C]****1.40.3.2.7 Pump Mass Flow Rate [kg/s]**

These outputs are the water outlet temperature and mass flow rate.

**1.40.3.2.8 Pump Zone Total Heating Rate [W]****1.40.3.2.9 Pump Zone Total Heating Energy [J]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

**1.40.3.2.10 Pump Zone Convective Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

**1.40.3.2.11 Pump Zone Radiative Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

**1.40.4 HeaderedPumps:ConstantSpeed**

Headered pumps are components with more than one identical pumps connected in parallel. The syntax for HeaderedPumps:ConstantSpeed is as follows.

**1.40.4.1 Inputs****1.40.4.1.1 Field: Name**

This alpha field contains the identifying name for the pump bank.

**1.40.4.1.2 Field: Inlet Node Name**

This alpha field contains the identifying name for the pump bank inlet node.

**1.40.4.1.3 Field: Outlet Node Name**

This alpha field contains the identifying name for the pump bank outlet node.

**1.40.4.1.4 Field: Total Design Flow Rate**

This numeric field contains the pump bank's rated volumetric flow rate in cubic meters per second. This is equal to the product of number of pumps and the flow rate of each individual pump. The field can be autosized.

**1.40.4.1.5 Field: Number of Pumps in Bank**

The numeric field specifies the number of pumps present in the pump bank. All these pumps are connected in parallel internally.

#### 1.40.4.1.6 Field: Flow Sequencing Control Scheme

The alpha field specifies the scheme for sequencing flow. Currently the only choice is Sequential, where a pump in the pump bank will be turned ON only after fully loading the previous pump.

#### 1.40.4.1.7 Field: Design Pump Head

This numeric field contains the pump's design head pressure in Pascals.

#### 1.40.4.1.8 Field: Design Power Consumption

This numeric field contains the pump bank's total power consumption in Watts. This field is equal to the product of number of pumps and the rated power consumption of each individual pump. If the user is performing a pressure simulation on the loop in which this pump bank is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically. This field can be autosized. When set to autosize the type of scaling factor is chosen in the input field Design Power Sizing Method.

#### 1.40.4.1.9 Field: Motor Efficiency

This numeric field contains the pump motor's efficiency in decimal form (0 = 0%, 1 = 100%).

#### 1.40.4.1.10 Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump motor's fraction of power loss to the fluid.

#### 1.40.4.1.11 Field: Pump Control Type

This is a choice field of Continuous or Intermittent. The operation of a constant speed pump bank is fairly straightforward. If the user designates a constant speed pump bank that is operating continuously, the pump bank will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump bank is constant speed and operates intermittently, the pump bank will run at its capacity if a load is sensed and will shut off if there is no load on the loop. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this control by forcing the pump to be on or off.

#### 1.40.4.1.12 Field: Pump Flow Rate Schedule Name

The schedule values modify the value for Rated Flow Rate of the pump on a time basis. This essentially sets the maximum value available for the pump at a given time, **not the actual flow rate at that time**. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations. For additional control over pump flow, EMS actuators can be employed.

#### 1.40.4.1.13 Field: Zone Name

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

#### 1.40.4.1.14 Field: Skin Loss Radiative Fraction

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

**1.40.4.1.15 Field: Design Power Sizing Method**

This field is optional. There are two choices `PowerPerFlow` and `PowerPerFlowPerPressure`. If `PowerPerFlow` is used the pump's Design Power Consumption will be calculated using the sizing factor from the input field Design Electric Power per Unit Flow Rate – with Design Power Consumption = Design Maximum Flow Rate \* scaling factor. If `PowerPerFlowPerPressure` is used the pump's Design Power Consumption will use the sizing factor from the input field Design Shaft Power per Unit Flow Rate Per Unit Head – with Design Power Consumption = Design Maximum Flow Rate \* Design Pump Head \* scaling factor / Motor Efficiency. If omitted the default method of `PowerPerFlowPerPressure` will be used.

**1.40.4.1.16 Field: Design Electric Power per Unit Flow Rate**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to `PowerPerFlow`. It allows setting the efficiency the pumping system's power consumption using only the design flow rate. If omitted the default value of 348701.1 W/(m<sup>3</sup>/s) ( 22 W/gpm) will be used.

**1.40.4.1.17 Field: Design Shaft Power per Unit Flow Rate Per Unit Head**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to `PowerPerFlowPerPressure`. It allows setting the efficiency of the impeller and drive assembly when calculating the pump power consumption for the design flow rate, motor efficiency, and pump head. If omitted the default value of 1.282051 W/((m<sup>3</sup>/s)-Pa) will be used.

**1.40.4.1.18 Field: End-Use Subcategory**

Allows you to specify a user-defined end-use subcategory, e.g., “Main Pumps”, etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the pump will be assigned to the “General” end-use subcategory.

An example for constant speed pump bank follows.

```
HeaderedPumps:ConstantSpeed,
  Chilled Water Headered Pumps,      !- Name
  CW Supply Inlet Node,              !- Inlet Node Name
  CW Pumps Outlet Node,              !- Outlet Node Name
  autosize,                          !- Total Design Flow Rate
  2,                                 !- Number of Pumps in Bank
  SEQUENTIAL,                       !- Flow Sequencing Control Scheme
  179352,                            !- Design Pump Head
  autosize,                         !- Design Power Consumption
  0.9,                              !- Motor Efficiency
  0.0,                              !- Fraction of Motor Inefficiencies to Fluid Stream
  INTERMITTENT,                     !- Pump Control Type
  CoolingPumpAvailSched;             !- Pump Flow Rate Schedule Name
```

**1.40.4.2 Outputs**

- HVAC,Average,Pump Electricity Rate [W]
- HVAC,Sum, Pump Electricity Energy [J]
- HVAC,Average,Pump Shaft Power [W]
- HVAC,Average, Pump Fluid Heat Gain Rate [W]
- HVAC,Sum, Pump Fluid Heat Gain Energy [J]

- HVAC,Average, Pump Outlet Temperature [C]

#### **1.40.4.2.5 Pump Fluid Heat Gain Energy [J]**

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

#### **1.40.4.2.6 Pump Outlet Temperature [C]**

#### **1.40.4.2.7 Pump Mass Flow Rate [kg/s]**

These outputs are the water outlet temperature and mass flow rate.

#### **1.40.4.2.8 Pump Operating Pumps Count []**

This output tells the number of pumps in the pump bank operating at any reporting frequency.

#### **1.40.4.2.9 Pump Zone Total Heating Rate [W]**

#### **1.40.4.2.10 Pump Zone Total Heating Energy [J]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

#### **1.40.4.2.11 Pump Zone Convective Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

#### 1.40.4.2.12 Pump Zone Radiative Heating Rate [W]

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

### 1.40.5 HeaderedPumps:VariableSpeed

Headered pumps are components with more than one identical pumps connected in parallel. Currently this object may be found only in plant loops. The syntax for a HeaderedPumps:VariableSpeed pump is given below.

#### 1.40.5.1 Inputs

##### 1.40.5.1.1 Field: Name

This alpha field contains the identifying unique name for the pump bank.

##### 1.40.5.1.2 Field: Inlet Node Name

This alpha field contains the identifying name for the pump bank inlet node.

##### 1.40.5.1.3 Field: Outlet Node Name

This alpha field contains the identifying name for the pump bank outlet node.

##### 1.40.5.1.4 Field: Total Design Flow Rate

This numeric field contains the pump bank's rated volume flow rate in cubic meters per second. This is equal to the product of number of pumps and the flow rate of each individual pump. The field can be autosized.

##### 1.40.5.1.5 Field: Number of Pumps in Bank

The numeric field specifies the number of pumps present in the pump bank. All these pumps are connected in parallel internally.

##### 1.40.5.1.6 Field: Flow Sequencing Control Scheme

The alpha field specifies the scheme for sequencing flow. Currently the only choice is Sequential, where a pump in the pump bank will be turned ON only after fully loading the previous pump.

##### 1.40.5.1.7 Field: Design Pump Head

This numeric field contains the pump's design head in Pascals.

##### 1.40.5.1.8 Field: Design Power Consumption

This numeric field contains the pump bank's total power consumption in Watts. This field is equal to the product of number of pumps and the design power consumption of each individual pump. If the user is performing a pressure simulation on the loop in which this pump bank is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically. This field can be autosized. When set to autosize the type of scaling factor is chosen in the input field Design Power Sizing Method.

**1.40.5.1.9 Field: Motor Efficiency**

This numeric field contains the motor's efficiency of the individual pump (which will be equivalent to pump bank efficiency) in decimal form (0 = 0%, 1 = 100%).

**1.40.5.1.10 Field: Fraction of Motor Inefficiencies to Fluid Stream**

This numeric field contains the individual pump's fraction of power loss to the fluid.

**1.40.5.1.11 Field: Coefficient 1 of the Part Load Performance Curve**

This numeric field contains the first coefficient ( $C_1$ ) in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$FractionFullLoadPower = C_1 + C_2PLR + C_3PLR^2 + C_4PLR^3 \quad (1.151)$$

where  $C_1, C_2, C_3,$  and  $C_4$  are Coefficients 1 4 (below) and PLR is the Part Load Ratio.

**1.40.5.1.12 Field: Coefficient 2 of the Part Load Performance Curve**

This numeric field contains the second coefficient ( $C_2$ ) in the part load ratio curve.

**1.40.5.1.13 Field: Coefficient 3 of the Part Load Performance Curve**

This numeric field contains the third coefficient ( $C_3$ ) in the part load ratio curve.

**1.40.5.1.14 Field: Coefficient 4 of the Part Load Performance Curve**

This numeric field contains the fourth coefficient ( $C_4$ ) in the part load ratio curve.

**1.40.5.1.15 Field: Minimum Flow Rate Fraction**

The numeric field specifies the minimum flow allowed for the pump bank as a fraction of the nominal flow. If the requested flow is less than minimum flow pump bank runs at minimum flow.

**1.40.5.1.16 Field: Pump Control Type**

This is a choice field of Continuous or Intermittent. A variable speed pump bank is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump bank is operating intermittently, then the bank can shutdown. For any other condition such as the loop having a load and the pump bank is operating intermittently or the pump bank is continuously operating (regardless of the loading condition), the bank will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump bank is running, it will try to meet the flow request made by demand side components. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this control by forcing the pump to be on or off.

**1.40.5.1.17 Field: Pump Flow Rate Schedule Name**

The schedule values modify the value for Rated Flow Rate of the pump on a time basis. This essentially sets the maximum value available for the pump at a given time, **not the actual flow rate at that time**. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations. For additional control over pump flow, EMS actuators can be employed.

**1.40.5.1.18 Field: Zone Name**

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

**1.40.5.1.19 Field: Skin Loss Radiative Fraction**

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

**1.40.5.1.20 Field: Design Power Sizing Method**

This field is optional. There are two choices PowerPerFlow and PowerPerFlowPerPressure. If PowerPerFlow is used the pump's Design Power Consumption will be calculated using the sizing factor from the input field Design Electric Power per Unit Flow Rate – with Design Power Consumption = Design Maximum Flow Rate \* scaling factor. If PowerPerFlowPerPressure is used the pump's Design Power Consumption will use the sizing factor from the input field Design Shaft Power per Unit Flow Rate Per Unit Head – with Design Power Consumption = Design Maximum Flow Rate \* Design Pump Head \* scaling factor / Motor Efficiency. If omitted the default method of PowerPerFlowPerPressure will be used.

**1.40.5.1.21 Field: Design Electric Power per Unit Flow Rate**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlow. It allows setting the efficiency the pumping system's power consumption using only the design flow rate. If omitted the default value of 348701.1 W/(m<sup>3</sup>/s) ( 22 W/gpm) will be used.

**1.40.5.1.22 Field: Design Shaft Power per Unit Flow Rate Per Unit Head**

This field is optional. This input is used when the input field Design Power Consumption is set to autosize and the Design Power Sizing Method is set to PowerPerFlowPerPressure. It allows setting the efficiency of the impeller and drive assembly when calculating the pump power consumption for the design flow rate, motor efficiency, and pump head. If omitted the default value of 1.282051 W/((m<sup>3</sup>/s)-Pa) will be used.

**1.40.5.1.23 Field: End-Use Subcategory**

Allows you to specify a user-defined end-use subcategory, e.g., “Main Pumps”, etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the pump will be assigned to the “General” end-use subcategory.

An example of this object follows.

```
HeaderedPumps:VariableSpeed,

### 1.40.5.2 Outputs

- HVAC,Average,Pump Electricity Rate [W]
- HVAC,Sum, Pump Electricity Energy [J]
- HVAC,Average,Pump Shaft Power [W]
- HVAC,Average, Pump Fluid Heat Gain Rate [W]
- HVAC,Sum, Pump Fluid Heat Gain Energy [J]
- HVAC,Average, Pump Outlet Temperature [C]
- HVAC,Average,Pump Mass Flow Rate [kg/s]
- HVAC,Average,Number of pumps operating []
- HVAC, Average, Pump Zone Total Heating Rate [W]
- HVAC, Sum, Pump Zone Total Heating Energy [J]
- HVAC, Average, Pump Zone Convective Heating Rate [W]
- HVAC, Average, Pump Zone Radiative Heating Rate [W]

#### 1.40.5.2.1 Pump Electricity Rate [W]

#### 1.40.5.2.2 Pump Electricity Energy [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

#### 1.40.5.2.3 Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

#### 1.40.5.2.4 Pump Fluid Heat Gain Rate [W]

#### 1.40.5.2.5 Pump Fluid Heat Gain Energy [J]

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

#### 1.40.5.2.6 Pump Outlet Temperature [C]

#### 1.40.5.2.7 Pump Mass Flow Rate [kg/s]

These outputs are the water outlet temperature and mass flow rate.

**1.40.5.2.8 Pump Operating Pumps Count []**

This output tells the number of pumps in the pump bank operating at any reporting frequency.

**1.40.5.2.9 Pump Zone Total Heating Rate [W]****1.40.5.2.10 Pump Zone Total Heating Energy [J]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

**1.40.5.2.11 Pump Zone Convective Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

**1.40.5.2.12 Pump Zone Radiative Heating Rate [W]**

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

## 1.41 Group Heating and Cooling Coils

Several different coils may be added to zone equipment and air loops. This includes simple heating (gas, electric, and hot water) and a simple water-cooling coil as well as a more detailed flat fin water-cooling coil model. In general, the heating coil description can be used for a heating coil, a reheat coil, or a preheat coil in the air loop simulation or for zone equipment. Figure 1.170 is an example of a heating and cooling coil in the air loop simulation in a dual duct system. This does show the basic node structure that will be referenced in the input description. The figure does show water coils since they are the most complex to input in the simulation compared to the Electric and Gas coils which only have air connections.

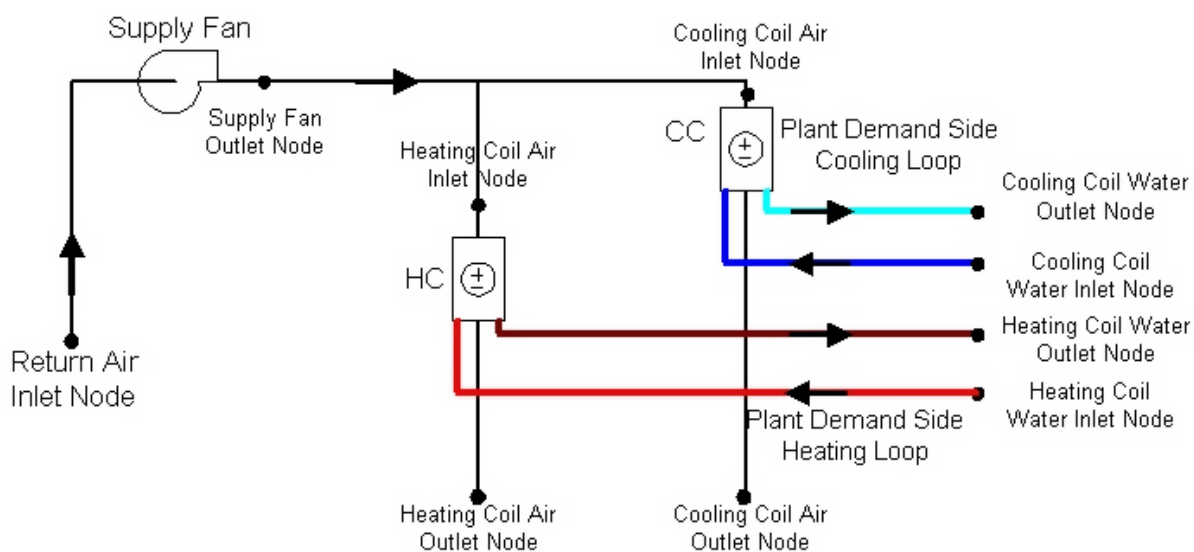

Figure 1.170: Example Air Loop Heating & Cooling Coil

### 1.41.1 Coil:Cooling:Water

The water cooling coil (Coil:Cooling:Water) has the ability to give detailed output with simplified inputs, inputting complicated coil geometry is not required by the user for this model instead the coil is sized in terms of auto-sizeable thermodynamic inputs. The coil requires thermodynamic inputs such as temperatures, mass flow rates and humidity ratios.

The coil is sized using auto-sized/user design input conditions and the UA values are calculated from the design conditions. A rough estimate of the coil area is provided along with percentage of surface wet and/or dry. This model uses the NTU-effectiveness approach to model heat transfer and has two types of flow arrangements cross-flow or counter-flow.

The basic underlying idea is - use auto sizeable thermodynamic design inputs, calculate the coil UA s, use these UA values and operating conditions from the nodes connections, calculate the outlet stream conditions, and calculate the heat transfer rates.

See section Cooling Coil Model in the EnergyPlus Engineering Document for further details regarding this model.

#### 1.41.1.1 Inputs

##### 1.41.1.1.1 Field: Name

A unique user-assigned name for an instance of a cooling coil. Any reference to this cooling coil by another object will use this name.

##### 1.41.1.1.2 Field:Availability Schedule Name

Schedule that defines when the coil is available. The name of the schedule (ref: Schedule) that denotes whether the cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off. If this field is blank, the schedule has a value of 1 for all time periods.

##### 1.41.1.1.3 Field: Design Water Flow Rate

The maximum possible water volume flow rate ( $\text{m}^3/\text{sec}$ ) through the coil. This is an auto sizeable design input.

##### 1.41.1.1.4 Field: Design Air Flow Rate

The maximum possible air volume flow rate ( $\text{m}^3/\text{sec}$ ) through the coil. This is an auto sizeable design input.

##### 1.41.1.1.5 Field: Design Inlet Water Temperature

The inlet water temperature for the design flow (C). This is an auto sizeable design input.

##### 1.41.1.1.6 Field: Design Inlet Air Temperature

The inlet air temperature for the design flow (C). This is an auto sizeable design input.

##### 1.41.1.1.7 Field: Design Outlet Air Temperature

The outlet air condition desired for design flow (C). This is an auto sizeable design input.

##### 1.41.1.1.8 Field: Design Inlet Air Humidity Ratio

The highest value of humidity ratio possible for the Design inlet air stream ( $\text{kgWater/kgDryAir}$ ). This is an auto sizeable input.

**1.41.1.1.9 Field: Design Outlet Air Humidity Ratio**

The value of humidity ratio for the Design outlet air stream (kgWater/kgDryAir), it is an auto sizable input.

**1.41.1.1.10 Field: Water Inlet Node Name**

The name of the water coil inlet from the chilled water loop, i.e. Cooling Coil Water Inlet Node. It is from this node the operating inputs for water are transferred to the coil.

**1.41.1.1.11 Field: Water Outlet Node Name**

The name of the water coil outlet from the chilled water loop, i.e. Cooling Coil Water Outlet Node. It is from this node the operating output for water are reported to the coil.

**1.41.1.1.12 Field: Air Inlet Node Name**

The name of the air inlet to the water coil, i.e. Cooling Coil Air Inlet Node. It is from this node the operating inputs for air are transferred to the coil.

**1.41.1.1.13 Field: Air Outlet Node Name**

The name of the air outlet from the water coil, i.e. Cooling Coil Air Outlet Node. It is from this node the operating output for airside is reported to the coil.

**1.41.1.1.14 Field: Type of Analysis**

The coil has two modes of operation, termed as **SimpleAnalysis** and **DetailedAnalysis**. The difference between the two modes being, the simple mode reports the value of surface area fraction wet of the coil as dry or wet. The detailed mode give the exact value, however the execution time in detailed mode is noticeably higher.

**1.41.1.1.15 Field: Heat Exchanger Configuration**

The coil is operable in two configurations: *CounterFlow* or *CrossFlow*. Chilled water coils are generally built as counter-flow. The default is CounterFlow. The detailed NTU-Effectiveness relationships for each flow setting are described in the Engineering Reference, Section ‘Effectiveness Equations’ in ‘Simulation Models - Encyclopedic Reference: Coil’ chapter.

**1.41.1.1.16 Field: Condensate Collection Water Storage Tank Name**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

**1.41.1.1.17 Field: Design Water Temperature Difference**

This input field is optional. If specified, it is used for sizing the *Design Water Flow Rate*. If blank or omitted, the *Loop Design Temperature Difference* value specified in *Sizing:Plant* object is used for sizing the *Design Water Flow Rate*.

Examples when auto sized in an IDF are as below:

```
Coil:Cooling:Water,
  Main Cooling Coil 1,      !- Coil Name
  CoolingCoilAvailSched,    !-Availability Schedule Name
  autosize,                 !- Design Water Volume Flow Rate of Coil {m3/s}
  autosize,                 !- Design Air Flow Rate of Coil {m3/s}
  autosize,                 !- Design Inlet Water Temperature {C}
  autosize,                 !- Design Inlet Air Temperature {C}
```

```

autosize,      !- Design Outlet Air Temperature {C}
autosize,      !- Design Inlet Air Humidity Ratio(kgWater/kgDryAir)
autosize,      !- Design Outlet Air Humidity Ratio(kgWater/kgDryAir)
Main Cooling Coil 1 Water Inlet Node,      !- Coil_Water_Inlet_Node
Main Cooling Coil 1 Water Outlet Node,      !- Coil_Water_Outlet_Node
Mixed Air Node 1,                          !- Coil_Air_Inlet_Node
Main Cooling Coil 1 Outlet Node;            !- Coil_Air_Outlet_Node

```

---

Examples when values (hard-sized) are input in an IDF are as below:

```

Coil:Cooling:Water,
Main Cooling Coil 1,      !- Coil Name
CoolingCoilAvailSched,    !-Availability Schedule Name
0.0022,                  !- Design Water Volume Flow Rate of Coil {m3/s}
1.45,                    !- Design Air Flow Rate of Coil {m3/s}
6.1,                     !- Design Inlet Water Temperature {C}
25,                       !- Design Inlet Air Temperature {C}
10,                       !- Design Outlet Air Temperature {C}
0.012,                   !- Design Inlet Air Humidity Ratio
0.008,                   !- Design Outlet Air Humidity Ratio
Main Cooling Coil 1 Water Inlet Node,      !- Coil_Water_Inlet_Node
Main Cooling Coil 1 Water Outlet Node,      !- Coil_Water_Outlet_Node
Mixed Air Node 1,                          !- Coil_Air_Inlet_Node
Main Cooling Coil 1 Outlet Node;            !- Coil_Air_Outlet_Node

```

---

### 1.41.1.2 Outputs

Following are the list of possible output variables from this coil model:

- HVAC,Sum,Cooling Coil Total Cooling Energy [J]
- HVAC,Sum,Cooling Coil Sensible Cooling Energy [J]
- HVAC,Average,Cooling Coil Total Cooling Rate [W]
- HVAC,Average,Cooling Coil Sensible Cooling Rate [W]
- HVAC,Average,Cooling Coil Wetted Area Fraction []
- HVAC,Average,Cooling Coil Condensate Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Coil Source Side Heat Transfer Energy [J]
- HVAC,Sum,Cooling Coil Condensate Volume [m3]

#### 1.41.1.2.1 Cooling Coil Total Cooling Energy (J)

Cooling Coil Total Cooling Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

#### 1.41.1.2.2 Cooling Coil Sensible Cooling Energy (J)

Cooling Coil Sensible Cooling Energy is the total amount of Sensible heat transfer taking place in the coil at the operating conditions. It only takes into account temperature difference in the inlet and outlet air streams at operating conditions.

#### 1.41.1.2.3 Cooling Coil Total Cooling Rate (W)

Cooling Coil Total Cooling Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

**1.41.1.2.4 Cooling Coil Sensible Cooling Rate (W)**

Cooling Coil Sensible Cooling Rate is the Rate of Sensible heat transfer taking place in the coil at the operating conditions.

**1.41.1.2.5 Cooling Coil Wetted Area Fraction []**

It defines the fraction of total surface area of coil which is wet due to moisture condensation on the surface of the coil. Value varies between 0.0 and 1.0.

In addition, if a Water Storage Tank is used to collect coil condensate, then the following outputs will be available.

**1.41.1.2.6 Cooling Coil Condensate Volume Flow Rate [m3/s]****1.41.1.2.7 Cooling Coil Condensate Volume [m3]**

These reports provide the rate and amount of condensate from the coil. Condensate is water condensed out of the air as a result of cooling. The condensate volume is also reported on the meter for OnSiteWater.

**1.41.1.2.8 Cooling Coil Source Side Heat Transfer Energy [J]**

This is the energy extracted from the chilled water serving the coil, in Joules.

**1.41.2 Coil:Heating:Water**

This simple heating coil model only does sensible heating of the air. The simple heating coil uses the Effectiveness-NTU algorithm and assumes a cross-flow heat exchanger.

**1.41.2.1 Inputs****1.41.2.1.1 Field: Name**

A unique identifying name for each coil.

**1.41.2.1.2 Field:Availability Schedule Name**

Schedule that defines when the coil is available. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off. If this field is blank, the schedule has a value of 1 for all time periods.

**1.41.2.1.3 Field: U-Factor Times Area Value**

The UA value for the coil needed for the Effectiveness-NTU heat exchanger model. An estimate of the UA can be obtained from:

$$q = UA \times (T_{water,avg} - T_{air,avg}) \quad (1.152)$$

where q is the heat transferred from water to the air in watts;  $T_{water,avg}$  is the average water temperature in degrees C; and  $T_{air,avg}$  is the average air temperature in degrees C. Or the LMTD temperature difference can be used. This field is used when *Performance Input Method = UFactorTimesAreaAndDesignWaterFlowRate*. This field is autosizable.

**1.41.2.1.4 Field: Maximum Water Flow Rate**

The maximum possible water flow rate (m<sup>3</sup>/sec) through the coil. This field is used when *Coil Performance Input Method = UFactorTimesAreaAndDesignWaterFlowRate*. This field is autosizable.

**1.41.2.1.5 Field: Water Inlet Node Name**

The name of the coil's water inlet node from the hot water loop.

**1.41.2.1.6 Field: Water Outlet Node Name**

The name of the coil's water outlet node from the hot water loop.

**1.41.2.1.7 Field: Air Inlet Node Name**

The name of the air inlet node to the water coil.

**1.41.2.1.8 Field: Air Outlet Node Name**

The name of the air outlet node from the water coil.

**1.41.2.1.9 Field: Performance Input Method**

The user can choose either *UFactorTimesAreaAndDesignWaterFlowRate* or *NominalCapacity*. If *UFactorTimesAreaAndDesignWaterFlowRate* is selected, the user must input values for UA of the Coil and Max Water FlowRate of the Coil (and Rated Capacity is ignored). If *NominalCapacity* is chosen, the user must input a Rated Capacity for the coil; UA of the Coil and Max Water FlowRate of the Coil will be ignored. Rated capacity is defined as the heating capacity in watts of the coil at the rating points (i.e., the rated inlet and outlet water/air temperatures defined in the input fields below). The rated capacity is used to calculate a water mass flow rate and a UA for the coil. The default is *NominalCapacity*.

To autosize the capacity, choose *UfactorTimesAreaAndDesignWaterFlowRate* and put autosize as the inputs for *U-Factor Times Area Value*, *Maximum Water Flow Rate*, and *Rated Capacity*. The program will use the Sizing inputs to size the coil. The rated temperatures (see below) are ignored in autosizing. These are used only when the user is specifying coil performance using the *NominalCapacity* input method.

**1.41.2.1.10 Field: Gross Rated Heating Capacity**

The heating capacity of the coil in watts at the rated inlet and outlet air and water temperatures. The gross rated heating capacity does not account for the effect of supply air fan heat. This field is used when the *Performance Input Method = Nominal Capacity*. This field is autosizable. The rating points are given in the four subsequent input fields.

**1.41.2.1.11 Field: Rated Inlet Water Temperature**

The inlet water temperature (degrees C) corresponding to the rated heating capacity. The default is 82.2 degrees C (180 degrees F).

**1.41.2.1.12 Field: Rated Inlet Air Temperature**

The inlet air temperature (degrees C) corresponding to the rated heating capacity. The default is 16.6 degrees C (60 degrees F).

**1.41.2.1.13 Field: Rated Outlet Water Temperature**

The outlet water temperature (degrees C) corresponding to the rated heating capacity. The default is 71.1 degrees C (160 degrees F).

**1.41.2.1.14 Field: Rated Outlet Air Temperature**

The outlet air temperature (degrees C) corresponding to the nominal heating capacity. The default is 32.2 degrees C (90 degrees F).

**1.41.2.1.15 Field: Rated Ratio for Air and Water Convection**

This is the ratio of convective heat transfers between air side and water side of the heating coil at the rated operating conditions. The default is .5. This ratio describes the geometry and the design of the coil and is defined by:

$$ratio = \frac{\eta_f(hA)_{air}}{(hA)_{water}} \quad (1.153)$$

where,

$\eta_f$  is the fin efficiency, (dimensionless)

$h$  is the surface convection heat transfer coefficient

$A$  is the surface area

**1.41.2.1.16 Field: Design Water Temperature Difference**

This input field is optional. If specified, it is used for sizing the *Design Water Flow Rate*. If blank or omitted, the *Loop Design Temperature Difference* value specified in *Sizing:Plant* object is used for sizing the *Design Water Flow Rate*.

An example input of the object is:

```
Coil:Heating:Water,
SPACE3-1 Zone Coil,      !- Coil Name
ReheatCoilAvailSched,    !- Availability Schedule Name
,                        !- UA of the Coil {W/K}
,                        !- Max Water Flow Rate of Coil {m3/s}
SPACE3-1 Zone Coil Water In Node, !- Coil_Water_Inlet_Node
SPACE3-1 Zone Coil Water Out Node, !- Coil_Water_Outlet_Node
SPACE3-1 Zone Coil Air In Node,    !- Coil_Air_Inlet_Node
SPACE3-1 In Node,                !- Coil_Air_Outlet_Node
NominalCapacity,                !- Coil Performance Input Method
10000.,                          !- Gross Rated Heating Capacity
0.55;                            !- Rated Ratio for Air and Water Convection
```

**1.41.2.2 Outputs**

- HVAC,Sum, Heating Coil Heating Energy [J]
- HVAC,Sum,Heating Coil Source Side Heat Transfer Energy [J]
- HVAC,Average,Heating Coil Heating Rate [W]
- HVAC,Average, Heating Coil U Factor Times Area Value [W/K]

**1.41.2.2.1 Heating Coil Heating Energy [J]**

Heating Coil Heating Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

**1.41.2.2.2 Heating Coil Heating Rate [W]**

Heating Coil Heating Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

**1.41.2.2.3 Heating Coil U Factor Times Area Value [W/K]**

This characterizes the overall heat transfer UA value, or U-factor times Area. The simple heating coil model adjusts UA value based on inlet temperatures and flow rates and this output contains the results from that adjustment.

#### 1.41.2.2.4 Heating Coil Source Side Heat Transfer Energy [J]

This is the same as the Heating Coil Heating Energy but it is also metered as a plant loop heating demand. This represents the heat in Joules extracted from the hot water serving the coil.

### 1.41.3 Coil:Heating:Steam

The simple steam to air heating coil model only does sensible heating of the air. The steam to air coils condense the steam and sub cool steam at loop pressure and discharge the condensate through steam traps at low pressure condensate line.

#### 1.41.3.1 Inputs

##### 1.41.3.1.1 Field: Name

A unique identifying name for each steam coil.

##### 1.41.3.1.2 Field:Availability Schedule Name

Schedule that defines when the coil is available. If the schedule's value is less than or equal to 0.0, then the coil is not available and flow will not be requested. If the schedule's value is  $> 0.0$  (usually 1 is used), the coil is available. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.41.3.1.3 Field: Maximum Steam Flow Rate

The maximum possible steam volumetric flow rate in  $\text{m}^3/\text{s}$  through the steam heating coil. The steam volumetric flow rate is calculated at 100C and 101325 Pa. This field is autosizable.

##### 1.41.3.1.4 Field: Degree of SubCooling

Ideally the steam trap located at the outlet of steam coil should remove all the condensate immediately, however there is a delay in this process in actual systems which causes the condensate to SubCool by certain degree in the coil before leaving the coil, this SubCool occurs in the steam coil and this SubCool-heat is added to the zone. The minimum value is 2 ° Celsius and default is 5 ° Celsius.

##### 1.41.3.1.5 Field: Degree of Loop SubCooling

This essentially represents the heat loss to the atmosphere due to uninsulated condensate return piping to the boiler. Condensate return piping operates at atmospheric pressure and is not insulated. The condensate sub cools to certain degree before it is pumped back to the boiler. The minimum value is 10 ° Celsius and default is 20 ° Celsius.

##### 1.41.3.1.6 Field: Water Inlet Node Name

The name of the steam coil inlet from the steam loop, i.e. Steam Coil steam inlet node.

##### 1.41.3.1.7 Field: Water Outlet Node Name

The name of the steam coil outlet to the condensate loop, i.e. Steam Coil condensate outlet node.

##### 1.41.3.1.8 Field: Air Inlet Node Name

The name of the air inlet to the steam coil, i.e. Steam Coil Air Inlet Node.

##### 1.41.3.1.9 Field: Air Outlet Node Name

The name of the air outlet from the steam coil, i.e. Steam Coil Air Outlet Node.

**1.41.3.1.10 Field:Coil Control Type**

Choice of either **ZoneLoadControl** steam coil or **TemperatureSetpointControl** steam coil. A zone coil is load controlled and an air loop steam coil is temperature controlled.

**1.41.3.1.11 Field: Temperature Setpoint Node Name**

If the coil is used in the air loop simulation and is temperature controlled using a Set Point Manager (i.e., the previous field is **TemperatureSetpointControl**), then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit, the coil is load controlled and a control node set point is not required (i.e., the previous field is **ZoneLoadControl**).

An example of a Steam Coil input statement (one each for Temperature Controlled and Load Controlled) from an IDF is given below:

```
Coil:Heating:Steam,
VAV SYS 1 Heating Coil,          !- Coil Name
ReheatCoilAvailSched,          !- Availability Schedule Name
0.06,                          !- Max Steam volume Flow rate
5.0,                           !- Deg of Subcooling Desired
15.0,                          !- Loop Subcooling Desired
VAV SYS 1 Heating Coil Steam Inlet, !- Coil Steam Inlet Node
VAV SYS 1 Heating Coil Steam Outlet, !- Coil Water Outlet Node
VAV SYS 1 Cooling Coil Outlet,      !- Coil Air Inlet Node
VAV SYS 1 Heating Coil Outlet,      !- Coil Air Outlet Node
TemperatureSetPointControl,        !- field Coil Control Type
VAV SYS 1 Heating Coil Outlet;      !- field Coil Temp Setpoint Node

Coil:Heating:Steam,
SPACE1-1 Reheat Coil,            !- Coil Name
ReheatCoilAvailSched,            !- Availability Schedule Name
autosize,                        !- Max Steam volume Flow rate
5.0,                             !- Deg of Subcooling Desired
15.0,                             !- Loop Subcooling Desired
SPACE1-1 Reheat Coil Steam Inlet, !- Coil Steam Inlet Node
SPACE1-1 Reheat Coil Steam Outlet, !- Coil Water Outlet Node
SPACE1-1 Damper Outlet,           !- Coil Air Inlet Node
SPACE1-1 Supply Inlet,            !- Coil Air Outlet Node
ZoneLoadControl;                  !- field Coil Control Type
```

**1.41.4 Heating Coil (Steam) Outputs:**

- HVAC,Sum, Heating Coil Heating Energy [J]
- HVAC,Average,Total Steam Coil Heating Rate [W]
- HVAC,Average,Heating Coil Steam Trap Loss Rate [W]
- HVAC, Average, Heating Coil Steam Inlet Temperature [C]
- HVAC, Average, Heating Coil Steam Outlet Temperature [C]
- HVAC, Average, Heating Coil Steam Mass Flow Rate [kg/s]

**1.41.4.1 Heating Coil Heating Energy [J]**

Heating Coil Heating Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

#### 1.41.4.2 Heating Coil Heating Rate [W]

Heating Coil Heating Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

#### 1.41.4.3 Heating Coil Steam Trap Loss Rate [W]

Loop losses represent the unavoidable loss due to degree of sub cooling in the condensate return piping back to the boiler and the loss occurring due to flashing of steam across the steam trap due to pressure differential between the steam and the condensate side.

#### 1.41.4.4 Heating Coil Steam Inlet Temperature [C]

#### 1.41.4.5 Heating Coil Steam Outlet Temperature [C]

#### 1.41.4.6 Heating Coil Steam Mass Flow Rate [kg/s]

These outputs are the Steam inlet and condensate outlet temperatures and steam flow rate for the boiler.

### 1.41.5 Coil:Heating:Electric

The electric heating coil is a simple capacity model with a user-inputted efficiency. In many cases, this efficiency for the electric coil will be 100%. This coil will be simpler than shown in Figure 1.170 since it will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled. If used in the air loop simulation it will be controlled to a specified temperature scheduled from the SetPoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand.

#### 1.41.5.1 Inputs

##### 1.41.5.1.1 Field: Name

A unique identifying name for each coil.

##### 1.41.5.1.2 Field:Availability Schedule Name

Schedule that defines when the coil is available. If the schedule's value is 0.0, then the coil is not available and flow will not be requested. If the schedule's value is  $> 0.0$  (usually 1 is used), the coil is available. If this field is blank, the schedule has values of 1 for all time periods. Schedule values must be  $> = 0$  and  $< = 1$ .

##### 1.41.5.1.3 Field: Efficiency

This is user-inputted efficiency (decimal units, not percent) and can account for any loss. In most cases for the electric coil, this will be 100%.

##### 1.41.5.1.4 Field: Nominal Capacity

This is the maximum capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

##### 1.41.5.1.5 Field: Air Inlet Node Name

The name of the air inlet to the electric coil, i.e. Heating Coil Air Inlet Node.

**1.41.5.1.6 Field: Air Outlet Node Name**

The name of the air outlet from the electric coil, i.e. Heating Coil Air Outlet Node.

**1.41.5.1.7 Field: Temperature Setpoint Node Name**

If the coil is used in the air loop simulation directly on a branch and is temperature controlled using a Set Point Manager, then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit or other parent object (ZoneHVAC: or AirloopHVAC:), the coil is controlled by the parent object and the temperature set point node name is not required.

An example of IDF usage:

---

```
Coil:Heating:Electric,
  AHU Reheater,           !- Name
  2,                      !- Availability Schedule Name
  0.99,                   !- Efficiency
  600000,                 !- Nominal Capacity {W}
  DOAS Supply Fan Outlet, !- Air Inlet Node Name
  AHU Reheater Outlet,    !- Air Outlet Node Name
  AHU Reheater Outlet;    !- Temperature Setpoint Node Name
```

---

**1.41.5.2 Outputs**

- HVAC,Sum,Heating Coil Heating Energy [J]
- HVAC,Average,Heating Coil Heating Rate [W]
- HVAC,Sum,Heating Coil Electricity Energy [J]
- HVAC,Average,Heating Coil Electricity Rate [W]

**1.41.5.2.1 Heating Coil Heating Energy (J)**

Heating Coil Heating Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

**1.41.5.2.2 Heating Coil Heating Rate [W]**

Heating Coil Heating Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

**1.41.5.2.3 Heating Coil Electricity Energy [J]**

Heating Coil electric consumption after the efficiency of the coil has been taken into account in Joules for the timestep reported.

**1.41.5.2.4 Heating Coil Electricity Rate [W]**

This field is the average Heating Coil electric power after the efficiency of the coil has been taken into account in Watts for the timestep reported.

**1.41.6 Coil:Heating:Electric:MultiStage**

The multi stage electric heating coil is a simple capacity model with a user-inputted efficiencies at different stages. In many cases, the efficiencies for the electric coil will be 100%. This coil will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled.

If used in the air loop simulation it will be controlled to a specified temperature scheduled from the SetPoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand. For the time being, this coil model can only be called by the parent object `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed`.

#### **1.41.6.1 Inputs**

##### **1.41.6.1.1 Field: Name**

A unique identifying name for each coil.

##### **1.41.6.1.2 Field:Availability Schedule Name**

Schedule that defines when the coil is available. If the schedule's value is 0.0, then the coil is not available and flow will not be requested. If the schedule's value is  $> 0.0$  (usually 1 is used), the coil is available. If this field is blank, the schedule has values of 1 for all time periods. Schedule values must be  $> 0$  and  $\leq 1$ .

##### **1.41.6.1.3 Field: Air Inlet Node Name**

The name of the air inlet to the electric coil, i.e. Heating Coil Air Inlet Node.

##### **1.41.6.1.4 Field: Air Outlet Node Name**

The name of the air outlet from the electric coil, i.e. Heating Coil Air Outlet Node.

##### **1.41.6.1.5 Field: Temperature Setpoint Node Name**

If the coil is used in the air loop simulation directly on a branch and is temperature controlled using a Set Point Manager, then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit or other parent object (ZoneHVAC: or AirloopHVAC:), the coil is controlled by the parent object and the temperature set point node name is not required. At present, the multistage electric heating coil does not model temperature setpoint control.

##### **1.41.6.1.6 Field: Stage 1 Efficiency**

This is stage 1 user-inputted efficiency (decimal units, not percent) and can account for any loss. In most cases for the electric coil, this will be 100%.

##### **1.41.6.1.7 Field: Stage 1 Nominal Capacity**

This is stage 1 capacity of the coil (W). This field is autosizable.

##### **1.41.6.1.8 Field: Stage 2 Efficiency**

This is stage 2 user-inputted efficiency (decimal units, not percent) and can account for any loss. In most cases for the electric coil, this will be 100%.

##### **1.41.6.1.9 Field: Stage 2 Nominal Capacity**

This is stage 2 capacity of the coil (W). This field is autosizable.

##### **1.41.6.1.10 Field: Stage 3 Efficiency**

This is stage 3 user-inputted efficiency (decimal units, not percent) and can account for any loss. In most cases for the electric coil, this will be 100%.

**1.41.6.1.11 Field: Stage 3 Nominal Capacity**

This is stage 3 capacity of the coil (W). This field is autosizable.

**1.41.6.1.12 Field: Stage 4 Efficiency**

This is stage 4 user-inputted efficiency (decimal units, not percent) and can account for any loss. In most cases for the electric coil, this will be 100%.

**1.41.6.1.13 Field: Stage 4 Nominal Capacity**

This is stage 4 capacity of the coil (W). This field is autosizable.

An example in IDF form:

```
Coil:Heating:Electric:MultiStage,
Heat Pump Heating Coil 1,          !- Name
FanAndCoilAvailSched,             !- Availability Schedule Name
Heating Coil Air Inlet Node,       !- Air Inlet Node Name
SuppHeating Coil Air Inlet Node,   !- Air Outlet Node Name
,                                  !- Temp Setpoint node name
3,                                 !- Number of Stages
1,                                 !- Stage 1 Efficiency
Autosize,                         !- Stage 1 Nominal Capacity {W}
1,                                 !- Stage 2 Efficiency
Autosize,                         !- Stage 2 Nominal Capacity {W}
1,                                 !- Stage 3 Efficiency
Autosize;                         !- Stage 3 Nominal Capacity {W}
```

**1.41.6.2 Outputs**

- HVAC,Sum,Heating Coil Heating Energy[J]
- HVAC,Average,Heating Coil Heating Rate[W]
- HVAC,Sum,Heating Coil Electric Consumption [J]
- HVAC,Average,Heating Coil Electricity Rate [W]

**1.41.6.2.1 Heating Coil Heating Energy (J)**

Heating Coil Heating Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

**1.41.6.2.2 Heating Coil Heating Rate[W]**

Heating Coil Heating Rate is the rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

**1.41.6.2.3 Heating Coil Electric Consumption [J]**

Heating Coil electric consumption after the efficiency of the coil has been taken into account in Joules for the timestep reported.

**1.41.6.2.4 Heating Coil Electricity Rate [W]**

This field is the average Heating Coil electric power after the efficiency of the coil has been taken into account in Watts for the timestep reported.

### 1.41.7 Coil:Heating:Desuperheater

A simplified approach is used to determine the performance of this air heating coil. The model assumes that the heating energy provided by this coil is reclaimed from the superheated refrigerant gas leaving a compressor (i.e., a desuperheating refrigerant-to-air heating coil) and does not impact the performance of the compressor. This coil can be used in air loop simulations but can't be used by certain compound objects (e.g., `AirLoopHVAC:UnitaryHeatPump:AirToAir`, `AirLoopHVAC:UnitaryHeatPump:WaterToAir`, or `Dehumidifier:Desiccant:NoFans`) or any air distribution equipment (e.g., `AirTerminal:SingleDuct:ConstantVolume:Reheat`, `AirTerminal:SingleDuct:VAV:Reheat`, or `AirTerminal:SingleDuct:SeriesPIU:Reheat`).

The desuperheater heating coil input requires a coil name, an availability schedule, and a heat reclaim recovery efficiency. The reclaim recovery efficiency determines the amount of heat available for use by this heating coil. Approximately 25-30% of the energy rejected by typical refrigeration system condensers is to reduce the superheated refrigerant vapor temperature to the condensing temperature. Recovery efficiencies higher than 30% may cause the refrigerant gas to condense which in turn impacts the performance of the refrigeration system. For this reason, the maximum heat reclaim recovery efficiency for this coil is 30% for most sources of waste heat, including refrigeration compressor racks. The one exception to this 30% limit is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 90% of the heat within the superheated region.

The next two input items for the desuperheater heating coil are the node names for the inlet and outlet air streams. The following two input fields define the source of heating energy for the coil. This desuperheater heating coil may only be used with direct expansion (DX) cooling or refrigeration equipment. The first of these two inputs is the heating source object type while the second defines the name of the heating source. For proper modeling, the desuperheater heating coil must be placed downstream of a DX cooling coil when reclaiming heat from that cooling coil. Desuperheating heating coil placement is unrestricted when reclaiming heat from a `Refrigeration:CompressorRack` or `Refrigeration:Condenser`.

The next input field is optional and defines the set point node name if the desuperheater heating coil is to be controlled based on temperature. When a load-based control scheme is used, this field is left blank. A final optional input is used to model parasitic electric energy use of auxiliary equipment associated with the desuperheater heating coil (e.g., solenoid valve).

#### 1.41.7.1 Inputs

##### 1.41.7.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a desuperheater heating coil. Any reference to this desuperheater heating coil by another object will use this name.

##### 1.41.7.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the desuperheater heating coil can run during a given time period. Schedule values must range from 0 to 1. A schedule value greater than 0 indicates that the coil can operate during the time period. A value equal to 0 denotes that the coil must be off for that time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.41.7.1.3 Field: Heat Reclaim Recovery Efficiency

This numeric field defines the ratio of recovered waste heat from the superheated refrigerant gas to the total rejected waste heat from the heating source (as if no heat reclaim occurred). Values can range

from 0.0 up to a maximum of 0.9 if the source is a refrigeration condenser and 0.3 for all other waste heat sources. If this input field is left blank, the default value is 0.8 for a refrigeration condenser source type and 0.25 for all other sources.

#### 1.41.7.1.4 Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the desuperheater heating coil draws its inlet air.

#### 1.41.7.1.5 Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the desuperheater heating coil sends its outlet air.

#### 1.41.7.1.6 Field: Heating Source Object Type

This alpha field defines the source of superheated refrigerant gas from which the desuperheater heating coil recovers energy. Valid choices are:

- Coil:Cooling:DX:SingleSpeed
- Coil:Cooling:DX:TwoSpeed
- Coil:Cooling:DX:TwoStageWithHumidityControlMode
- Coil:Cooling:DX:VariableSpeed
- Refrigeration:CompressorRack
- Refrigeration:Condenser:AirCooled
- Refrigeration:Condenser:EvaporativeCooled
- Refrigeration:Condenser:WaterCooled

When the heating coil source is a DX Coil, the air loop's supply air fan control mode may be auto fan (cycling fan cycling coil), constant fan, or variable volume. When the heating source is a compressor rack for refrigerated cases or a refrigeration condenser, the supply air fan control mode should be either variable volume or constant fan.

NOTE: Use of the desuperheater heating coil in variable air volume systems should be done with caution since the model assumption of a fixed heat reclaim recovery efficiency may not be valid if the air flow rate over the coil varies significantly.

#### 1.41.7.1.7 Field: Heating Source Name

This alpha field defines the name of the desuperheater heating coil source (e.g., the name of a specific valid coil (as mentioned in the previous field) which provides waste heat to this desuperheater heating coil).

NOTE: When the heating source is a Refrigeration Compressor rack, the heat rejection location in the **Refrigeration:CompressorRack** object must be Outdoors . If the compressor rack heat rejection location is Zone , the total amount of heat rejection available for reclaim (e.g., by this desuperheater heating coil) is set to zero by the compressor rack object and the simulation proceeds.

#### 1.41.7.1.8 Field: Temperature Setpoint Node Name

This optional alpha field defines the name of the HVAC system node used for temperature-based control (e.g., controlling the heating coil's outlet air dry-bulb temperature to a setpoint). If the desuperheater heating coil is temperature controlled through the use of a Set Point Manager, then the control node specified in the Set Point Manager will be entered here. If the desuperheater heating coil is controlled based on a certain heating load to be met (e.g., using this heating coil as part of **AirLoopHVAC:Unitary:Furnace:HeatCool** for high humidity control), this field should be left blank.

#### 1.41.7.1.9 Field: Parasitic Electric Load

This optional numeric field defines the parasitic electric load (in Watts) due to control valves or other devices specific to the desuperheater heating coil. The load is applied whenever the coil is heating the air. The model assumes that this electric load is small and does not contribute to heating the air.

Following is an example input for a desuperheater heating coil.

```
Coil:Heating:Desuperheater,
  DesuperheaterCoil,           !- Coil Name
  FanAndCoilAvailSched,       !- Availability Schedule
  0.3,                         !- Heat Reclaim Recovery Efficiency
  Cooling Coil Air Outlet Node, !- Coil Air Inlet Node Name
  Air Loop Outlet Node,       !- Coil Air Outlet Node Name
  Coil:Cooling:DX:SingleSpeed, !- Heating Source Type
  Furnace ACDXCoil 1,         !- Heating Source Name
  ,                           !- Coil Temperature Setpoint Node
  Name
  0.1;                        !- Parasitic Electric Load {W}
```

#### 1.41.7.2 Outputs

- HVAC,Average,Heating Coil Heating Rate [W]
- HVAC,Sum,Heating Coil Heating Energy [J]
- HVAC,Average,Heating Coil Electricity Rate [W]
- HVAC,Sum,Heating Coil Electric Consumption [J]
- HVAC,Average,Heating Coil Runtime Fraction []
- HVAC,Average,Heating Coil Heating Rate [W]
- HVAC,Sum,Heating Coil Heating Energy [J]
- HVAC,Average,Heating Coil Electricity Rate [W]
- HVAC,Sum,Heating Coil Electricity Energy [J]
- HVAC,Average,Heating Coil Runtime Fraction

##### 1.41.7.2.1 Heating Coil Heating Rate [W]

This output is the average heating rate to the air of the desuperheater heating coil in Watts over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.7.2.2 Heating Coil Heating Energy [J]**

This output is the total heating output to the air of the desuperheater heating coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Output:Meter objects).

**1.41.7.2.3 Heating Coil Electricity Rate [W]**

This output is the average electric consumption rate for the parasitic load associated with the desuperheater heating coil in Watts.

**1.41.7.2.4 Heating Coil Electricity Energy [J]**

This output is the electric consumption of the desuperheater heating coil parasitic load in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.7.2.5 Heating Coil Runtime Fraction []**

This is the runtime fraction of the desuperheater heating coil for the timestep being reported. Since the desuperheater heating coil can only provide heat when the heat source object is active, the runtime fraction of the desuperheater heating coil will always be less than or equal to the runtime fraction of the heat source object.

**1.41.8 Coil:Cooling:DX:VariableRefrigerantFlow**

The variable refrigerant flow (VRF) DX cooling coil model is nearly identical to the single-speed DX cooling coil model (Ref. [Coil:Cooling:DX:SingleSpeed](#)). For this reason, an adaptation of the single-speed DX cooling coil model is used to model the variable-speed compression system used in VRF AC systems. The model inputs are quite similar to the input requirements for the single-speed DX cooling coil model, however, the location of a majority of the inputs have been moved to the variable refrigerant flow air conditioner object since multiple DX cooling coils will use the same DX compression system (Ref. [AirConditioner:VariableRefrigerantFlow](#)).

**1.41.8.1 Inputs****1.41.8.1.1 Field: Coil Name**

This alpha field defines a unique user-assigned name for an instance of a VRF DX cooling coil. Any reference to this DX cooling coil by another object will use this name. This cooling coil name must be entered in the [AirConditioner:VariableRefrigerantFlow](#) object. No other system type uses this specific coil.

**1.41.8.1.2 Field: Availability Schedule Name**

This alpha field defines the name of the DX cooling coil availability schedule. Schedule values of 0 denote the DX cooling coil is off. A schedule value greater than 0 indicates that the coil can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.41.8.1.3 Field: Gross Rated Total Cooling Capacity**

This numeric field defines the gross rated total cooling capacity of the DX cooling coil in watts at a rating point of 19.44 C indoor wet-bulb temperature and 35 C outdoor dry-bulb temperature. The total cooling capacity should be a gross, i.e., the effect of supply air fan heat NOT accounted for.

**1.41.8.1.4 Field: Gross Ratio Sensible Heat Ratio**

This numeric field defines the gross sensible heat ratio (sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions. Both the sensible and total cooling capacities used to define the Rated SHR should be gross (i.e., the effect of supply air fan heat is NOT accounted for)

**1.41.8.1.5 Field: Rated Air Flow Rate**

The air volume flow rate, in  $\text{m}^3$  per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between  $0.00004027 \text{ m}^3/\text{s}$  and  $0.00006041 \text{ m}^3/\text{s}$  per watt of rated total cooling capacity (300 to 450 cfm/ton). The gross rated total cooling capacity and gross rated SHR should be performance information for the unit with at this rated air volume flow rate.

**1.41.8.1.6 Field: Cooling Capacity Ratio Modifier Function of Temperature Curve Name**

This alpha field defines the cooling capacity ratio modifier as a function of indoor wet-bulb temperature or indoor wet-bulb and outdoor dry-bulb temperatures. The curve is normalized to 1 at 19.44 C indoor wet-bulb temperature and if a biquadratic curve is used also at 35 C outdoor dry-bulb temperature. This curve is a linear, quadratic, or cubic curve if the cooling capacity is solely a function of indoor wet-bulb temperature (i.e., the indoor terminal units weighted average inlet air wet-bulb temperatures). Without specific manufacturers data indicating otherwise, the use of a single independent variable is recommended for this coil type. If, however, the user has reason to believe the cooling capacity is both a function of indoor wet-bulb temperature and outdoor dry-bulb temperature (and has manufacturers data to create the performance curve), a bi-quadratic equation using weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables may be used. See the Engineering Reference for more discussion on using this input field.

**1.41.8.1.7 Field: Cooling Capacity Modifier Curve Function of Flow Fraction Name**

This alpha field defines the name of a linear, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the gross rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

**1.41.8.1.8 Field: Coil Air Inlet Node Name**

This alpha field defines the name of the air inlet node entering the DX cooling coil.

**1.41.8.1.9 Field: Coil Air Outlet Node Name**

This alpha field defines the name of the air outlet node exiting the DX cooling coil.

**1.41.8.1.10 Field: Name of Water Storage Tank for Condensate Collection**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Following is an example input for a Coil:Cooling:DX:VariableRefrigerantFlow object.

### 1.41.8.2 Outputs

- HVAC,Average, Cooling Coil Total Cooling Rate [W]
- HVAC,Sum, Cooling Coil Total Cooling Energy [J]
- HVAC,Average, Cooling Coil Sensible Cooling Rate [W]
- HVAC,Sum, Cooling Coil Sensible Cooling Energy [J]
- HVAC,Average, Cooling Coil Latent Cooling Rate [W]
- HVAC,Sum, Cooling Coil Latent Cooling Energy [J]
- HVAC,Average, Cooling Coil Runtime Fraction []

Evaporative-cooled condenser:

- HVAC,Average,Cooling Coil Condensate Volume Flow Rate [m3/s]
- Zone,Meter,Condensate:OnSiteWater [m3]
- HVAC,Sum,Cooling Coil Condensate Volume [m3]

#### 1.41.8.2.1 Cooling Coil Total Cooling Rate [W]

This field is the total (sensible and latent) cooling rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.8.2.2 Cooling Coil Total Cooling Energy [J]

This is the total (sensible plus latent) cooling output of the DX coil in Joules over the time step being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (Ref. Output:Meter objects).

#### 1.41.8.2.3 Cooling Coil Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.8.2.4 Cooling Coil Sensible Cooling Energy [J]

This is the moist air sensible cooling output of the DX coil in Joules for the time step being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.8.2.5 Cooling Coil Latent Cooling Rate [W]

This is the latent cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.8.2.6 Cooling Coil Latent Cooling Energy [J]

This is the latent cooling output of the DX coil in Joules for the time step being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.8.2.7 Cooling Coil Runtime Fraction []

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the time step being reported.

#### 1.41.8.2.8 Cooling Coil Condensate Volume Flow Rate [m<sup>3</sup>/s]

#### 1.41.8.2.9 Cooling Coil Condensate Volume [m<sup>3</sup>]

These outputs are the rate and volume of water collected as condensate from the coil. These reports only appear if a water storage tank is named in the input object.

### 1.41.9 Coil:Heating:DX:VariableRefrigerantFlow

The variable refrigerant flow (VRF) DX heating coil model uses performance information at rated conditions along with performance curves for variations in total capacity, energy input ratio and part load fraction to determine performance at part-load conditions. The impacts of defrost operation is modeled based a combination of user inputs and empirical models taken from the air-to-air heat pump algorithms in DOE-2.1E.

The VRF DX heating coil input requires an availability schedule, the gross rated heating capacity and the rated air volume flow rate. The rated air volume flow rate should be between 0.00008056 m<sup>3</sup>/s and 0.00002684 m<sup>3</sup>/s per watt of gross rated heating capacity.

Two performance curves are required. The first performance curve defines the heating capacity as a function of indoor air dry-bulb and outdoor condenser entering air dry-bulb or wet-bulb temperature. The outdoor air temperature type is specified in the variable refrigerant flow air-to-air heat pump object. The second performance curve defines the change in heating capacity as a function of air flow fraction. Each of these performance curves are further discussed here.

#### 1) Heating capacity modifier curve (function of temperature, specified in Heat Pump)

The heating capacity modifier curve (function of temperature) can be a function of both the outdoor wet-bulb temperature and indoor air dry-bulb temperature. The curve is normalized to 1 at 21.11 C indoor dry-bulb temperature and if a biquadratic curve is used also at 6.11 C outdoor wet-bulb or 8.33 outdoor dry-bulb temperature. The outdoor air temperature type is specified in the variable refrigerant flow air-to-air heat pump object. Users have the choice of a bi-quadratic curve with two independent variables or a tri-quadratic curve with three independent variables. The tri-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the combined total capacity of all indoor units connected to the heat pump condenser and a more realistic output. The output of this curve is multiplied by the gross rated heating capacity to give the gross heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature) and the combination ratio of the installed system.

#### 2) Heating capacity modifier curve (function of flow fraction, specified in DX coil)

The heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the

actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the gross rated heating capacity and the heating capacity modifier curve (function of temperature) to give the gross heating capacity at the specific temperature and air flow conditions at which the coil is operating.

#### 1.41.9.1 Inputs

##### 1.41.9.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a VRF DX heating coil. Any reference to this DX heating coil by another object will use this name.

##### 1.41.9.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the DX heating coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.41.9.1.3 Field: Gross Rated Heating Capacity

This numeric field defines the total, full load gross heating capacity in watts of the DX coil unit at rated conditions (outside air dry-bulb temperature of 8.33 C, outside air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field rated air flow volume below). The value entered here must be greater than 0. The gross total heating capacity should not account for the effect of supply air fan heat.

##### 1.41.9.1.4 Field: Rated Air Flow Rate

This numeric field defines the volume air flow rate, in m<sup>3</sup> per second, across the DX heating coil at rated conditions. The value entered here must be greater than 0. The rated air volume flow rate should be between 0.00004027 m<sup>3</sup>/s and 0.00006041 m<sup>3</sup>/s per watt of gross rated heating capacity. The gross rated heating capacity and the gross rated COP should be performance information for the unit with outside air dry-bulb temperature of 8.33 C, outside air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and the rated air volume flow rate defined here.

##### 1.41.9.1.5 Field: Coil Air Inlet Node

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

##### 1.41.9.1.6 Field: Coil Air Outlet Node

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

##### 1.41.9.1.7 Field: Heating Capacity Ratio Modifier Function of Temperature Curve Name

This alpha field defines the heating capacity ratio modifier as a function of indoor dry-bulb temperature or indoor dry-bulb and outdoor wet-bulb temperatures. This curve is a linear, quadratic, or cubic curve if the heating capacity is solely a function of indoor dry-bulb temperature (i.e., the indoor terminal units weighted average inlet air dry-bulb temperatures). Without specific manufacturers data indicating

otherwise, the use of a single independent variable is recommended for this coil type. If, however, the user has reason to believe the heating capacity is both a function of indoor dry-bulb temperature and outdoor wet-bulb temperature (and has manufacturers data to create the performance curve), a bi-quadratic equation using weighted average indoor dry-bulb temperature and condenser entering air wet-bulb temperature as the independent variables may be used. See the Engineering Reference for more discussion on using this input field.

Note: The choice of using either outdoor dry-bulb temperature or outdoor wet-bulb temperature as the independent variable in this performance curve is set in the parent object AirConditioner: VariableRefrigerantFlow.

#### 1.41.9.1.8 Field: Heating Capacity Ratio Modifier Function of Flow Fraction Curve Name

This alpha field defines the name of a linear, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the gross rated heating capacity and the heating capacity modifier curve (function of temperature) to give the gross heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Following is an example input for the object.

```
COIL:Heating:DX:VariableRefrigerantFlow,

  autosize,                          !- Rated Air Flow Rate {m3/s}
  TU1 VRF DX CCoil Outlet Node,     !- Coil Air Inlet Node
  TU1 VRF DX HCoil Outlet Node,     !- Coil Air Outlet Node
  VRFTUHeatCapFT,                   !- Heating Capacity Ratio Modifier Function of Temperature Curve Name
  VRFACCoolCapFFF;                  !- Total heating capacity modifier curve Function of Flow Fraction
```

### 1.41.9.2 Outputs

- HVAC,Average, Heating Coil Heating Rate [W]
- HVAC,Sum, Heating Coil Heating Energy [J]
- HVAC,Average, Heating Coil Runtime Fraction []

#### 1.41.9.2.1 Heating Coil Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.9.2.2 Heating Coil Heating Energy [J]

This is the total heating output of the DX coil in Joules over the time step being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Output:Meter objects).

#### 1.41.9.2.3 Heating Coil Runtime Fraction []

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the time step being reported.

### 1.41.10 Coil:Cooling:DX:VariableRefrigerantFlow:FluidTemperatureControl

This coil object is specifically designed for the physics based VRF model applicable for Fluid Temperature Control (VRF-FluidTCtrl). It describes the performance of the indoor unit coil of the VRF system operating at cooling mode. The name of this object is entered as an input to the object *Zone-HVAC:TerminalUnit:VariableRefrigerantFlow*. The outdoor unit part of the VRF system is modeled separately (refer to *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object).

#### 1.41.10.1 Inputs

##### 1.41.10.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a VRF DX cooling coil. Any reference to this DX cooling coil by another object will use this name. This cooling coil name must be entered in the *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object. No other system type uses this specific coil.

##### 1.41.10.1.2 Field: Availability Schedule Name

This alpha field defines the name of the coil availability schedule. A name should be entered to define the availability of the coil. Schedule values of 0 denote the DX cooling coil is off. A schedule value greater than 0 indicates that the coil can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.41.10.1.3 Field: Coil Air Inlet Node

This alpha field defines the name of the air inlet node entering the DX cooling coil.

##### 1.41.10.1.4 Field: Coil Air Outlet Node

This alpha field defines the name of the air outlet node exiting the DX cooling coil.

##### 1.41.10.1.5 Field: Rated Total Cooling Capacity

This numeric field defines the gross rated total cooling capacity of the DX cooling coil in watts. The total cooling capacity should be a gross, i.e., the effect of supply air fan heat NOT accounted for. Note that if autosize is selected for this field, the cooling design supply air temperature provided in the *Sizing:Zone* object needs to be in accordance with the Indoor Unit Evaporating Temperature Function of Superheating Curve provided below in this object.

##### 1.41.10.1.6 Field: Rated Sensible Heat Ratio

This numeric field defines the gross sensible heat ratio (sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions. Both the sensible and total cooling capacities used to define the Rated SHR should be gross (i.e., the effect of supply air fan heat is NOT accounted for)

##### 1.41.10.1.7 Field: Indoor Unit Reference Superheating

This numeric field defines the reference superheating degrees of the indoor unit. If this field is blank, the default value of 5.0 C is used.

##### 1.41.10.1.8 Field: Indoor Unit Evaporating Temperature Function of Superheating Curve Name

This alpha field defines the name of a quadratic performance curve that parameterizes the variation of indoor unit evaporating temperature as a function of superheating degrees. The output of this curve is the temperature difference between the coil surface air temperature and the evaporating temperature.

#### 1.41.10.1.9 Field: Name of Water Storage Tank for Condensate Collection

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Following is an example input for a Coil:Cooling:DX:VariableRefrigerantFlow:FluidTemperatureControl object.

```
Coil:Cooling:DX:VariableRefrigerantFlow:FluidTemperatureControl,
TU1 VRF DX Cooling Coil, !- Name
VRFAvailSched,          !- Availability Schedule Name

This is the latent cooling output of the DX coil in Joules for the time step being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.10.2.7 Cooling Coil Runtime Fraction []**

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the time step being reported.

**1.41.10.2.8 Cooling Coil VRF Evaporating Temperature [C]**

This is the evaporating temperature of the VRF system operating at cooling mode. This value is manipulated by the VRF system considering the load conditions of all the zones it serves. It affects the cooling coil surface temperature and thus the cooling capacity of the coil.

**1.41.10.2.9 Cooling Coil VRF Super Heating Degrees [C]**

This is the super heating degrees of the VRF system operating at cooling mode. This value is manipulated by each VRF terminal unit to adjust the cooling capacity of the coil considering the load conditions of the zone. It affects the cooling coil surface temperature and thus the cooling capacity of the coil.

**1.41.10.2.10 Cooling Coil Condensate Volume Flow Rate [m3/s]**

This is the volumetric rate of water collected as condensate from the coil. This report only appears if a water storage tank is named in the input object.

**1.41.10.2.11 Cooling Coil Condensate Volume [m3]**

This is the volume of water collected as condensate from the coil. This report only appears if a water storage tank is named in the input object.

### 1.41.11 Coil:Heating:DX:VariableRefrigerantFlow:FluidTemperatureControl

This coil object is specifically designed for the physics based VRF model applicable for Fluid Temperature Control (VRF-FluidTCtrl). It describes the performance of the indoor unit coil of the VRF system operating at heating mode. The name of this object is entered as an input to the object *Zone-HVAC:TerminalUnit:VariableRefrigerantFlow*. The outdoor unit part of the VRF system is modeled separately (refer to *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object).

#### 1.41.11.1 Inputs

##### 1.41.11.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a VRF DX heating coil. Any reference to this DX heating coil by another object will use this name. This heating coil name must be entered in the *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object. No other system type uses this specific coil.

##### 1.41.11.1.2 Field: Availability Schedule

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the DX heating coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank the unit is always available.

##### 1.41.11.1.3 Field: Coil Air Inlet Node

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

##### 1.41.11.1.4 Field: Coil Air Outlet Node

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

##### 1.41.11.1.5 Field: Rated Total Heating Capacity

This numeric field defines the total, full load gross heating capacity in watts of the DX coil unit at rated conditions. The value entered here must be greater than 0. The gross total heating capacity should not account for the effect of supply air fan heat.

##### 1.41.11.1.6 Field: Indoor Unit Reference Subcooling

This numeric field defines the reference subcooling degrees of the indoor unit. If this field is blank, the default value of 5.0 C is used.

##### 1.41.11.1.7 Field: Indoor Unit Condensing Temperature Function of Subcooling Curve Name

This alpha field defines the name of a quadratic performance curve that parameterizes the variation of indoor unit condensing temperature as a function of subcooling degrees. The output of this curve is the temperature difference between the condensing temperature and the coil surface air temperature.

Following is an example input for a Coil:Heating:DX:VariableRefrigerantFlow:FluidTemperatureControl object.

```

### 1.41.11.2 Outputs

- HVAC,Average, Heating Coil Heating Rate [W]
- HVAC,Sum, Heating Coil Heating Energy [J]
- HVAC,Average, Heating Coil Runtime Fraction []
- Heating Coil VRF Condensing Temperature [C]
- Heating Coil VRF Subcooling Degrees [C]

#### 1.41.11.2.1 Heating Coil Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.11.2.2 Heating Coil Heating Energy [J]

This is the total heating output of the DX coil in Joules over the time step being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Output:Meter objects).

#### 1.41.11.2.3 Heating Coil Runtime Fraction []

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the time step being reported.

#### 1.41.11.2.4 Cooling Coil VRF Condensing Temperature [C]

This is the condensing temperature of the VRF system operating at heating mode. This value is manipulated by the VRF system considering the load conditions of all the zones it serves. It affects the heating coil surface temperature and thus the heating capacity of the coil.

#### 1.41.11.2.5 Cooling Coil VRF Subcooling Degrees [C]

This is the subcooling degrees of the VRF system operating at heating mode. This value is manipulated by each VRF terminal unit to adjust the heating capacity of the coil considering the load conditions of the zone. It affects the heating coil surface temperature and thus the heating capacity of the coil.

### 1.41.12 Coil:Heating:Fuel

The fuel heating coil is a simple capacity model with a user inputted gas burner efficiency. The default for the burner efficiency is 80%. This coil will be simpler than shown in Figure 1.170 since it will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled. If used in the air loop simulation it will be controlled to a specified temperature scheduled from the Setpoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand.

#### 1.41.12.1 Inputs

##### 1.41.12.1.1 Field: Name

A unique identifying name for each coil.

##### 1.41.12.1.2 Field: Availability Schedule Name

Schedule that defines when the coil is available. If the schedule's value is 0.0, then the coil is not available and flow will not be requested. If the schedule's value is  $> 0.0$  (usually 1 is used), the coil is available. If this field is blank, the schedule has values of 1 for all time periods. Schedule values must be  $> 0$  and  $\leq 1$ .

##### 1.41.12.1.3 Field: Fuel Type

This field designates the appropriate fuel type for the coil. Valid fuel types are: Gas, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, Steam, DistrictHeating, DistrictCooling, OtherFuel1 and OtherFuel2. The fuel type triggers the application of consumption amounts to the appropriate energy meters. NaturalGas is the default.

##### 1.41.12.1.4 Field: Burner Efficiency

This is user inputted gas burner efficiency (decimal, not percent) and is defaulted to 80%.

##### 1.41.12.1.5 Field: Nominal Capacity

This is the maximum capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

##### 1.41.12.1.6 Field: Air Inlet Node Name

The name of the air inlet to the coil, i.e. Heating Coil Air Inlet Node.

##### 1.41.12.1.7 Field: Air Outlet Node Name

The name of the air outlet from the coil, i.e. Heating Coil Air Outlet Node.

##### 1.41.12.1.8 Field: Temperature Setpoint Node Name

If the coil is used in the air loop simulation directly on a branch and is temperature controlled using a Set Point Manager, then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit or other parent object (ZoneHVAC: or AirloopHVAC:), the coil is controlled by the parent object and the temperature set point node name is not required.

**1.41.12.1.9 Field: Parasitic Electric Load**

This is the parasitic electric load associated with the coil operation, such as an inducer fan, etc. This will be modified by the PLR (or coil runtime fraction if a part-load fraction correlation is provided in the next input field) to reflect the time of operation in a simulation timestep.

**1.41.12.1.10 Field: Part Load Fraction Correlation Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of fuel consumption rate by the heating coil as a function of the part load ratio (PLR, sensible heating load/nominal capacity of the heating coil). For any simulation timestep, the nominal fuel consumption rate (heating load/burner efficiency) is divided by the part-load fraction (PLF) if a part-load curve has been defined. The part-load curve accounts for efficiency losses due to transient coil operation.

The part-load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the heating coil runs continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 <= \text{PLR} < 1$ ), the following rules apply:

$\text{PLF} >= 0.7$  and  $\text{PLF} >= \text{PLR}$

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the heating coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional gas heating coil (e.g., residential furnace) would be:

---

$$\text{PLF} = 0.8 + 0.2(\text{PLR})$$

---

**1.41.12.1.11 Field: Parasitic Fuel Load**

This numeric field is the parasitic fuel load associated with the coil's operation (Watts), such as a standing pilot light. The model assumes that this parasitic load is consumed only for the portion of the simulation timestep where the heating coil is not operating.

**1.41.12.2 Outputs**

- HVAC,Sum,Heating Coil Heating Energy [J]
- HVAC,Average,Heating Coil Heating Rate [W]
- HVAC,Sum,Heating Coil Gas Energy [J]
- HVAC,Average,Heating Coil <Fuel Type> Rate [W]
- HVAC,Sum,Heating Coil Electricity Energy [J]
- HVAC,Average,Heating Coil Electricity Rate [W]
- HVAC,Average,Heating Coil Runtime Fraction []
- HVAC,Sum,Heating Coil Ancillary <Fuel Type> Energy [J]
- HVAC,Average,Heating Coil Ancillary <Fuel Type> Rate [W]

**1.41.12.2.1 Heating Coil Heating Energy [J]**

This field is the total heating output of the coil to the air in Joules over the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Output:Meter objects).

**1.41.12.2.2 Heating Coil Heating Rate [W]**

This field is the average heating rate output of the coil to the air in Watts over the timestep being reported.

**1.41.12.2.3 Heating Coil <Fuel Type> Energy [J]**

This field is the fuel consumption of the heating coil in Joules over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified. This output is also added to a meter with Resource Type = Gas, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.12.2.4 Heating Coil <Fuel Type> Rate [W]**

This field is the average gas consumption rate of the coil in Watts over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified.

**1.41.12.2.5 Heating Coil Electricity Energy [J]**

This field is the electric consumption of the heating coil auxiliaries in Joules over the timestep being reported (e.g., inducer fan). This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.12.2.6 Heating Coil Electricity Rate [W]**

This field is the average electric consumption rate of the heating coil auxiliaries (e.g., inducer fan) in Watts over the timestep being reported.

**1.41.12.2.7 Heating Coil Runtime Fraction []**

This field is the runtime fraction of the coil over the timestep being reported.

**1.41.12.2.8 Heating Coil Ancillary <Fuel Type> Energy [J]**

This field is the parasitic fuel consumption of the heating coil in Joules over the timestep being reported (e.g., standing pilot light). The model assumes that the parasitic load is accumulated only for the portion of the simulation timestep where the gas heating coil is not operating. This output is also added to a meter with Resource Type = '<Fuel Type>', End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.12.2.9 Heating Coil Ancillary <Fuel Type> Rate [W]**

This field is the average parasitic gas consumption rate of the heating coil (e.g., standing pilot light) in Watts over the timestep being reported. The model assumes that the parasitic load is present only for the portion of the simulation timestep where the heating coil is not operating.

**1.41.13 Coil:Heating:Gas:MultiStage**

The multi stage gas heating coil is a simple capacity model with a user inputted gas burner efficiencies at different stages. This coil will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled. If used in the air loop simulation it will be controlled to a specified temperature scheduled from the Setpoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand. For the time being, this coil model can only be called by the parent object **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed**.

**1.41.13.1 Inputs****1.41.13.1.1 Field: Name**

A unique identifying name for each coil.

**1.41.13.1.2 Field: Availability Schedule Name**

Schedule that defines when the coil is available. If the schedule's value is 0.0, then the coil is not available and flow will not be requested. If the schedule's value is  $> 0.0$  (usually 1 is used), the coil is available. If this field is blank, the schedule has values of 1 for all time periods. Schedule values must be  $> = 0$  and  $< = 1$ .

**1.41.13.1.3 Field: Air Inlet Node Name**

The name of the air inlet to the gas coil, i.e. Heating Coil Air Inlet Node.

**1.41.13.1.4 Field: Air Outlet Node Name**

The name of the air outlet from the gas coil, i.e. Heating Coil Air Outlet Node.

**1.41.13.1.5 Field: Temperature Setpoint Node Name**

If the coil is used in the air loop simulation directly on a branch and is temperature controlled using a Set Point Manager, then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit or other parent object (ZoneHVAC: or AirloopHVAC:), the coil is controlled by the parent object and the temperature set point node name is not required. At present, the multistage gas heating coil does not model temperature setpoint control.

**1.41.13.1.6 Field: Part Load Fraction Correlation Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of gas consumption rate by the heating coil as a function of the part load ratio (PLR, sensible heating load/nominal capacity of the heating coil). For any simulation timestep, the nominal gas consumption rate (heating load/burner efficiency) is divided by the part-load fraction (PLF) if a part-load curve has been defined. The part-load curve accounts for efficiency losses due to transient coil operation.

The part-load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the heating coil runs continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 < = PLR < 1$ ), the following rules apply:

$PLF > = 0.7$  and  $PLF > = PLR$

If  $PLF < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the heating coil is defined a  $PLR/PLF$ . If  $PLF < PLR$ , then a warning message is issues and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional gas heating coil (e.g., residential furnace) would be:

---

$$PLF = 0.8 + 0.2(PLR)$$

---

**1.41.13.1.7 Field: Parasitic Gas Load**

This numeric field is the parasitic gas load associated with the gas coil's operation (Watts), such as a standing pilot light. The model assumes that this parasitic load is consumed only for the portion of the simulation timestep where the gas heating coil is not operating.

**1.41.13.1.8 Field: Stage 1 Gas Burner Efficiency**

This is user inputted stage 1 gas burner efficiency (decimal, not percent) and is defaulted to 80%.

**1.41.13.1.9 Field: Stage 1 Nominal Capacity**

This is the stage 1 capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

**1.41.13.1.10 Field: Stage 1 Parasitic Electric Load**

This is the stage 1 parasitic electric load associated with the gas coil operation, such as an inducer fan, etc. This will be modified by the PLR (or coil runtime fraction if a part-load fraction correlation is provided in the next input field) to reflect the time of operation in a simulation timestep.

**1.41.13.1.11 Field: Stage 2 Gas Burner Efficiency**

This is user inputted stage 2 gas burner efficiency (decimal, not percent) and is defaulted to 80%.

**1.41.13.1.12 Field: Stage 2 Nominal Capacity**

This is the stage 2 capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

**1.41.13.1.13 Field: Stage 2 Parasitic Electric Load**

This is the stage 2 parasitic electric load associated with the gas coil operation, such as an inducer fan, etc. This will be modified by the PLR (or coil runtime fraction if a part-load fraction correlation is provided in the next input field) to reflect the time of operation in a simulation timestep.

**1.41.13.1.14 Field: Stage 3 Gas Burner Efficiency**

This is user inputted stage 3 gas burner efficiency (decimal, not percent) and is defaulted to 80%.

**1.41.13.1.15 Field: Stage 3 Nominal Capacity**

This is the stage 3 capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

**1.41.13.1.16 Field: Stage 3 Parasitic Electric Load**

This is the stage 3 parasitic electric load associated with the gas coil operation, such as an inducer fan, etc. This will be modified by the PLR (or coil runtime fraction if a part-load fraction correlation is provided in the next input field) to reflect the time of operation in a simulation timestep.

**1.41.13.1.17 Field: Stage 4 Gas Burner Efficiency**

This is user inputted stage 4 gas burner efficiency (decimal, not percent) and is defaulted to 80%.

**1.41.13.1.18 Field: Stage 4 Nominal Capacity**

This is the stage 4 capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

### 1.41.13.1.19 Field: Stage 4 Parasitic Electric Load

This is the stage 4 parasitic electric load associated with the gas coil operation, such as an inducer fan, etc. This will be modified by the PLR (or coil runtime fraction if a part-load fraction correlation is provided in the next input field) to reflect the time of operation in a simulation timestep.

### 1.41.13.2 Outputs

- HVAC,Sum,Heating Coil Heating Energy[J]
- HVAC,Average,Heating Coil Heating Rate[W]
- HVAC,Sum,Heating Coil Gas Consumption [J]
- HVAC,Average,Heating Coil Gas Consumption Rate [W]
- HVAC,Sum,Heating Coil Electric Consumption [J]
- HVAC,Average,Heating Coil Electricity Rate [W]
- HVAC,Average,Heating Coil Runtime Fraction
- HVAC,Sum,Heating Coil Parasitic Gas Consumption [J]
- HVAC,Average,Heating Coil Parasitic Gas Consumption Rate [W]

#### 1.41.13.2.1 Heating Coil Heating Energy [J]

This field is the total heating output of the coil in Joules over the timestep being reported. This output is also added to an output meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Output:Meter objects).

#### 1.41.13.2.2 Heating Coil Heating Rate [W]

This field is the average heating rate output of the coil in Watts over the timestep being reported.

#### 1.41.13.2.3 Heating Coil Gas Consumption [J]

This field is the gas consumption of the heating coil in Joules over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified. This output is also added to an output meter with Resource Type = Gas, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.13.2.4 Heating Coil Gas Consumption Rate [W]**

This field is the average gas consumption rate of the coil in Watts over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified.

**1.41.13.2.5 Heating Coil Electric Consumption [J]**

This field is the electric consumption of the heating coil auxiliaries in Joules over the timestep being reported (e.g., inducer fan). This output is also added to an output meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.13.2.6 Heating Coil Electricity Rate [W]**

This field is the average electric consumption rate of the heating coil auxiliaries (e.g., inducer fan) in Watts over the timestep being reported.

**1.41.13.2.7 Heating Coil Parasitic Gas Consumption [J]**

This field is the parasitic gas consumption of the heating coil in Joules over the timestep being reported (e.g., standing pilot light). The model assumes that the parasitic load is accumulated only for the portion of the simulation timestep where the gas heating coil is not operating. This output is also added to an output meter with Resource Type = Gas, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.13.2.8 Heating Coil Parasitic Gas Consumption Rate [W]**

This field is the average parasitic gas consumption rate of the heating coil (e.g., standing pilot light) in Watts over the timestep being reported. The model assumes that the parasitic load is present only for the portion of the simulation timestep where the gas heating coil is not operating.

**1.41.14 Coil:Cooling:Water:DetailedGeometry**

This detailed flat fin coil model is for continuous plate fins. First, found in Type 12 from MODSIM, but now programmed directly from Elmahdy, A.H. and Mitalas, G.P. Then there was a discontinuity in their original model that was fixed in the EnergyPlus implementation. Now this model can be used in an interval halving solution technique for controlling this coil without the problems of non-convergence.

“A Model for Cooling and Dehumidifying Coils for Use in Energy Requirements for Buildings” ASHRAE Transactions, Vol. 83, Part 2, pp. 103-117 (1977). For fin efficiency see K.A. Gardner, “Efficiency of Extended,” Transactions ASME, Vol. 67, pp. 621-631, 1945.

The following figures illustrate the geometry and circuits in a cooling coil.

**1.41.14.1 Inputs****1.41.14.1.1 Field: Name**

A unique identifying name for each coil.

**1.41.14.1.2 Field:Availability Schedule Name**

Schedule that defines when the coil is available. If the schedule’s value is 0.0, then the coil is not available and flow will not be requested. If the schedule’s value is > 0.0 (usually 1 is used), the coil is available. If this field is blank, the schedule has values of 1 for all time periods.

**1.41.14.1.3 Field: Maximum Water Flow Rate**

The maximum possible water flow rate ( $\text{m}^3/\text{sec}$ ) through the coil.

Figure 1.171: Geometry of a Cooling Coil (CC)

**1.41.14.1.4 Field: Tube Outside Surface Area**

The outside surface area ( $\text{m}^2$ ) of the tubes that is exposed to air (i.e. the outside area of the unfinned tubes minus the area of tubes covered by the fins).

**1.41.14.1.5 Field: Total Tube Inside Area**

The total surface area ( $\text{m}^2$ ) inside the tubes (water side).

**1.41.14.1.6 Field: Fin Surface Area**

The total surface area ( $\text{m}^2$ ) of the fins attached to the coil.

**1.41.14.1.7 Field: Minimum Air Flow Area**

The minimum cross sectional area ( $\text{m}^2$ ) available for air passage. Frequently calculated as

$$A_{\min} = (A_{\min}/A_{fr}) \cdot A_{fr}$$

where  $A_{fr}$  is the frontal area of the heat exchanger, and  $(A_{\min}/A_{fr})$  is the ratio of the minimum airflow area to frontal area.

**1.41.14.1.8 Field: Coil Depth**

The distance (m) from the front of the coil to the back of the coil in the airflow direction. Also called the fin depth. Illustrated in the figure (Figure 1.171. Geometry of a Cooling Coil (CC)).

**1.41.14.1.9 Field: Fin Diameter**

The outside diameter (m) of the fins. Used instead of COIL HEIGHT

Figure 1.172: Number of Coolant Circuits (CCNCC)

**1.41.14.1.10 Field: Fin Thickness**

Thickness (m) of the air side fins.

**1.41.14.1.11 Field: Tube Inside Diameter**

The inside diameter (m) of the tubes.

**1.41.14.1.12 Field: Tube Outside Diameter**

The outside diameter (m) of the tubes.

**1.41.14.1.13 Field: Tube Thermal Conductivity**

The thermal conductivity (W/m-K) of the tube material.

**1.41.14.1.14 Field: Fin Thermal Conductivity**

The thermal conductivity (W/m-K) of the fin material.

**1.41.14.1.15 Field: Fin Spacing**

The spacing (m) of the fins, centerline to centerline.

**1.41.14.1.16 Field: Tube Depth Spacing**

The spacing (m) of the tube rows, centerline to centerline. Also called tube longitudinal spacing.

**1.41.14.1.17 Field: Number of Tube Rows**

The number of tube rows in the direction of the airflow.

**1.41.14.1.18 Field: Number of Tubes per Row**

The number of tubes per row. (NTPR in the above diagram)

**1.41.14.1.19 Field: Water Inlet Node Name**

The name of the water coil inlet from the chilled water loop, i.e. Cooling Coil Water Inlet Node.

**1.41.14.1.20 Field: Water Outlet Node Name**

The name of the water coil outlet from the chilled water loop, i.e. Cooling Coil Water Outlet Node.

**1.41.14.1.21 Field: Air Inlet Node Name**

The name of the air inlet to the water coil, i.e. Cooling Coil Air Inlet Node.

**1.41.14.1.22 Field: Air Outlet Node Name**

The name of the air outlet from the water coil, i.e. Cooling Coil Air Outlet Node.

**1.41.14.1.23 Field: Condensate Collection Water Storage Tank Name**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

**1.41.14.1.24 Field: Design Water Temperature Difference** This input field is optional. If specified, it is used for sizing the *Design Water Flow Rate*. If blank or omitted, the *Loop Design Temperature Difference* value specified in *Sizing:Plant* object is used for sizing the *Design Water Flow Rate*.

Examples of these statements in an IDF are:

```

## 1.41.14.2 Outputs

- HVAC,Sum,Cooling Coil Total Cooling Energy [J]
- HVAC,Sum,Cooling Coil Sensible Cooling Energy [J]
- HVAC,Average,Cooling Coil Total Cooling Rate [W]
- HVAC,Average,Cooling Coil Sensible Cooling Rate [W]
- HVAC,Average,Cooling Coil Condensate Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Coil Source Side Heat Transfer Energy [J]
- HVAC,Sum,Cooling Coil Condensate Volume [m3]

### 1.41.14.2.1 Cooling Coil Total Cooling Energy (J)

Cooling Coil Total Cooling Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

### 1.41.14.2.2 Cooling Coil Sensible Cooling Energy (J)

Cooling Coil Sensible Cooling Energy is the total amount of Sensible heat transfer taking place in the coil at the operating conditions. It only takes into account temperature difference in the inlet and outlet air streams at operating conditions.

### 1.41.14.2.3 Cooling Coil Total Cooling Rate (W)

Cooling Coil Total Cooling Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

**1.41.14.2.4 Cooling Coil Sensible Cooling Rate (W)**

Cooling Coil Sensible Cooling Rate is the Rate of Sensible heat transfer taking place in the coil at the operating conditions.

In addition, if a Water Storage Tank is used to collect coil condensate, then the following outputs will be available.

**1.41.14.2.5 Cooling Coil Condensate Volume Flow Rate [m3/s]****1.41.14.2.6 Cooling Coil Condensate Volume [m3]**

These reports provide the rate and amount of condensate from the coil. Condensate is water condensed out of the air as a result of cooling. The condensate volume is also reported on the meter for OnSiteWater.

**1.41.14.2.7 Cooling Coil Source Side Heat Transfer Energy [J]**

This is the energy extracted from the chilled water serving the cooling coil, in Joules.

**1.41.15 Coil:Cooling:DX:SingleSpeed**

This DX cooling coil input requires an availability schedule, the gross rated total cooling capacity, the gross rated SHR, the gross rated COP, and the rated air volume flow rate. The latter 4 inputs determine the coil performance at the rating point (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb and air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb). The rated air volume flow rate should be between .00004027 m<sup>3</sup>/s and .00006041 m<sup>3</sup>/s per watt of gross rated total cooling capacity (300 to 450 cfm/ton).

The rated volumetric air flow to total cooling capacity ratio for 100% dedicated outdoor air (DOAS) application DX cooling coils should be between 0.00001677 (m3/s)/W (125 cfm/ton) and 0.00003355 (m3/s)/W (250 cfm/ton).

Pumped refrigerant economizer integrated with the single speed DX cooling coil model will use exactly the same model except that performance curves use lookup table to cover the pumped refrigerant economizer and the compressor operating ranges. One or two independent variables may be used to represent the performance data.

This model requires 5 curves as follows:

1. The total cooling capacity modifier curve (function of temperature) is a curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 °C indoor wet-bulb temperature and 35 °C outdoor dry-bulb temperature. The output of this curve is multiplied by the gross rated total cooling capacity to give the gross total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). This curve is typically a biquadratic but any curve or table with two independent variables can be used.
2. The total cooling capacity modifier curve (function of flow fraction) is a curve or lookup table with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the gross rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. This curve is typically a quadratic or cubic but any curve or table with one independent variable can be used.

3. The energy input ratio (EIR) modifier curve (function of temperature) is a curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 C indoor wet-bulb temperature and 35 C outdoor dry-bulb temperature. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). This curve is typically a biquadratic but any curve or table with two independent variables can be used.
4. The energy input ratio (EIR) modifier curve (function of flow fraction) is a curve or lookup table with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating. This curve is typically a quadratic or cubic but any curve or table with one independent variable can be used.
5. The part load fraction correlation (function of part load ratio) is a curve or a lookup table with the independent variable being part load ratio (sensible cooling load / steady-state sensible cooling capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The curve should be normalized to a value of 1.0 when the part-load ratio equals 1.0 (i.e., the compressor(s) run continuously for the simulation timestep). This curve is typically a quadratic or cubic but any curve or table with one independent variable can be used.

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (see Performance Curves in this document).

The next four input fields are optional and relate to the degradation of latent cooling capacity when the supply air fan operates continuously while the cooling coil/compressor cycle on and off to meet the cooling load. The fan operating mode is determined in the parent object and is considered to either be constant (e.g. **CoilSystem:Cooling:DX**) or can be scheduled (e.g. **AirLoopHVAC:UnitaryHeatCool**). When scheduled, the schedule value must be greater than 0 to calculate degradation of latent cooling capacity. At times when the parent object's supply air fan operating mode schedule is 0, latent degradation will be ignored. When modeling latent capacity degradation, these next four input fields must all have positive values.

The next input specifies the outdoor air node used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor temperature entering the condenser is taken directly from the weather data. If this field is not blank, the node name specified must be listed in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an **OutdoorAir:NodeList** object where the outdoor temperature entering the condenser is taken directly from the weather data.

The next input describes the type of outdoor condenser coil used with the DX cooling coil (Air Cooled or Evap Cooled). The following three inputs are required when modeling an evaporative-cooled condenser: evaporative condenser effectiveness, evaporative condenser air volume flow rate, and the power consumed by the evaporative condenser pump. Crankcase heater capacity and cutout temperature are entered in the next two input fields. These two fields for this object define the name of the water storage tank for supply and condensate collection. See section DX Cooling Coil Model in the EnergyPlus Engineering Document for further details regarding this model.

The last two input fields following the Basin Heater Operating Schedule Name are the Sensible Heat Ratio (SHR) modifier curvenames for temperature and flow fraction. These two input fields are optional and used only when a user intends to override SHR calculated using the apparatus dew point (ADP) and bypass factor (BF) method. See section SHR Calculation Using User Specified SHR Modifier Curves in the EnergyPlus Engineering Document for further details.

### 1.41.15.1 Inputs

#### 1.41.15.1.1 Field: Name

A unique user-assigned name for an instance of a DX cooling coil. Any reference to this DX coil by another object will use this name.

#### 1.41.15.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.41.15.1.3 Field: Gross Rated Total Cooling Capacity

The total, full load gross cooling capacity (sensible plus latent) in watts of the DX coil unit at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb[1], and a cooling coil air flow rate defined by field rated air flow rate below). Capacity should be gross (i.e., the effect of supply air fan heat is NOT accounted for). When used in a heat pump, the gross rated total cooling capacity should be within 20% of the gross rated heating capacity, otherwise a warning message is issued.

#### 1.41.15.1.4 Field: Gross Rated Sensible Heat Ratio

The sensible heat ratio (SHR = gross sensible cooling capacity divided by gross total cooling capacity) of the DX cooling coil at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb), and a cooling coil air flow rate defined by field rated air flow rate below). Both the sensible and total cooling capacities used to define the Rated SHR should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

#### 1.41.15.1.5 Field: Gross Rated Cooling COP

The coefficient of performance is the ratio of the gross total cooling capacity in watts to electrical power input in watts of the DX cooling coil unit at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/ 23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air flow rate below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The gross COP should NOT account for the supply air fan. If this input field is left blank, the default value is 3.0.

#### 1.41.15.1.6 Field: Rated Air Flow Rate

The air volume flow rate, in m<sup>3</sup> per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m<sup>3</sup>/s and 0.00006041 m<sup>3</sup>/s per watt of gross rated total cooling capacity (300 to 450 cfm/ton). For DOAS applications the rated air volume flow rate should be between 0.00001677 m<sup>3</sup>/s and 0.00003355 m<sup>3</sup>/s per watt of gross rated total cooling capacity (125 to 250 cfm/ton). The gross rated total cooling capacity, gross rated SHR and gross rated COP should be performance information for the unit with air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb,

air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and the rated air volume flow rate defined here.

#### **1.41.15.1.7 Field: Rated Evaporator Fan Power Per Volume Flow Rate**

This field is the electric power for the evaporator (cooling coil) fan per air volume flow rate through the coil at the rated conditions in  $\text{W}/(\text{m}^3/\text{s})$ . The default value is 773.3  $\text{W}/(\text{m}^3/\text{s})$  (365  $\text{W}/1000 \text{ cfm}$ ) if this field is left blank. If a value is entered, it must be  $\geq 0.0$  and  $\leq 1250 \text{ W}/(\text{m}^3/\text{s})$ . This value is only used to calculate Seasonal Energy Efficiency Ratio (SEER), Energy Efficiency Ratio (EER), Integrated Energy Efficiency Ratio (IEER) and the Standard Rating (Net) Cooling Capacity which will be outputs in the EnergyPlus eio file (ref. EnergyPlus Engineering Reference, Single Speed DX Cooling Coil, Standard Ratings). This value is not used for modeling the evaporator (cooling coil) fan during simulations; instead, it is used for calculating SEER, EER, IEER and Standard Rating Cooling Capacity to assist the user in verifying their inputs for modeling this type of equipment.

#### **1.41.15.1.8 Field: Air Inlet Node Name**

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

#### **1.41.15.1.9 Field: Air Outlet Node Name**

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

#### **1.41.15.1.10 Field: Total Cooling Capacity Function of Temperature Curve Name**

The name of a performance curve (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the gross rated total cooling capacity to give the gross total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point. This curve is typically a biquadratic but any curve or table with two independent variables can be used.

#### **1.41.15.1.11 Field: Total Cooling Capacity Function of Flow Fraction Curve Name**

The name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the gross rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

#### **1.41.15.1.12 Field: Energy Input Ratio Function of Temperature Curve Name**

The name of a performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point. This curve is typically a biquadratic but any curve or table with two independent variables can be used.

**1.41.15.1.13 Field: Energy Input Ratio Function of Flow Fraction Curve Name**

The name of a performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This curve is typically a quadratic or cubic but any curve or table with one independent variable can be used.

**1.41.15.1.14 Field: Part Load Fraction Correlation Curve Name**

This alpha field defines the name of a performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. This curve is typically a quadratic or cubic but any curve or table with one independent variable can be used.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 < \text{PLR} < 1$ ), the following rules apply:

$$\text{PLF} \geq 0.7 \text{ and } \text{PLF} \geq \text{PLR}$$

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

**1.41.15.1.15 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation**

This numeric field defines the minimum outdoor air dry-bulb temperature where the cooling coil compressor turns off. If this input field is left blank, the default value is -25 °C.

**1.41.15.1.16 Field: Nominal Time for Condensate Removal to Begin**

The nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]), and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation.

#### 1.41.15.1.17 Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

Ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]); and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation.

#### 1.41.15.1.18 Field: Maximum Cycling Rate

The maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]); and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation.

#### 1.41.15.1.19 Field: Latent Capacity Time Constant

Time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; supply air fan operating mode must be continuous. That is, the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects (e.g., **AirloopHVAC:UnitaryHeatCool**), and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation.

#### 1.41.15.1.20 Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

#### 1.41.15.1.21 Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

#### 1.41.15.1.22 Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{condinlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o}) \quad (1.154)$$

where

$T_{condinlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

#### 1.41.15.1.23 Field: Evaporative Condenser Air Flow Rate

The air volume flow rate, in m<sup>3</sup> per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m<sup>3</sup>/s per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

#### 1.41.15.1.24 Field: Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = Air Cooled.

#### 1.41.15.1.25 Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump (Ref. [Air-LoopHVAC:UnitaryHeatPump:AirToAir](#) or PackageTerminal: HeatPump:AirToAir), the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. [Coil:Heating:DX:SingleSpeed](#)) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

**1.41.15.1.26 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C, and the default value is 10 °C.

**1.41.15.1.27 Field: Supply Water Storage Tank Name**

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling of its condenser. If blank or omitted, then the unit will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank. If a tank is specified, the unit will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the condenser needs, then the unit will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

**1.41.15.1.28 Field: Condensate Collection Water Storage Tank Name**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

**1.41.15.1.29 Field: Basin Heater Capacity**

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

**1.41.15.1.30 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2 °C, and the default value is 2 °C if this field is left blank.

**1.41.15.1.31 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

**1.41.15.1.32 Field: Sensible Heat Ratio Function of Temperature Curve Name**

The name of a biquadratic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of DX cooling coil entering air wet-bulb and dry-bulb

temperatures. The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of flow fraction) to give the SHR at the specific coil entering air temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 at the rated condition. This input field is optional.

#### 1.41.15.1.33 Field: Sensible Heat Ratio Function of Flow Fraction Curve Name

The name of a quadratic or cubic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of temperature) to give the SHR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This input field is optional.

#### 1.41.15.1.34 Field: Zone Name for Condenser Placement

This input field is name of a conditioned or unconditioned zone where the secondary coil (condenser) of DX system or a heat pump is to be placed. This is an optional input field specified only when user desires to reject the condenser heat into a zone. The heat rejected is modeled as sensible internal gain of a secondary zone.

Following is an example input for a Coil:Cooling:DX:SingleSpeed coil.

```
Coil:Cooling:DX:SingleSpeed,
Zone1WindACDXCoil,           ! Coil Name

```

### 1.41.16 Coil:Cooling:DX:TwoSpeed

This component models a two-speed (or variable speed) DX compressor and fan. The method is based on the model used for the cycling, single speed DX unit. The single speed unit is described by single full load capacity, SHR, COP, and air flow rate at rated conditions. Off rated full load performance is obtained by the use of 4 modifier curves. At partial load the unit cycles on/off and the cycling losses are described by a part load fraction curve.

The multispeed unit is described by specifying the performance at two states: high speed compressor, high speed fan; and low speed compressor, low speed fan. When the unit load is above the high speed capacity, the unit runs with high speed compressor and fan. When the load on the unit is below the high speed capacity but above the low speed capacity, the unit will run with performance intermediate between high speed and low speed. When the load is less than the low speed capacity, the unit will cycle on/off just like the single speed unit.

The multispeed unit model requires 2 full sets of performance data. There must be a high and low speed capacity, SHR, COP, and evaporator air flow rate; as well as high and low speed performance curves total cooling capacity modifier curve (function of temperature) and energy input ratio modifier curve (function of temperature).

The multispeed DX component should be used for all cases in which a DX VAV system is being simulated. Obviously this model in which performance is obtained by interpolating between 2 specified states - is an oversimplification of how real multi-speed and variable speed DX cooling units are controlled. But detailed descriptions of how actual units perform and are controlled are not available. This model should give a good average prediction of multispeed and variable speed DX cooling unit performance. The last four input fields following the Basin Heater Operating Schedule Name are the Sensible Heat Ratio (SHR) modifier curvenames for temperature and flow fraction for high and low speed DX cooling coils. These four input fields are optional and used only when a user intends to override SHR calculated using the apparatus dew point (ADP) and bypass factor (BF) method. See section SHR Calculation Using User Specified SHR Modifier Curves in the EnergyPlus Engineering Document for further details.

#### **1.41.16.1 Inputs**

##### **1.41.16.1.1 Field: Name**

A unique user-assigned name for an instance of a multispeed DX cooling coil. Any reference to this DX coil by another object will use this name.

##### **1.41.16.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### **1.41.16.1.3 Field: High Speed Gross Rated Total Cooling Capacity**

The total, full load gross cooling capacity (sensible plus latent) in watts of the DX coil unit for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air flow rate below). Capacity should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

##### **1.41.16.1.4 Field: High Speed Gross Rated Sensible Heat Ratio**

The sensible heat ratio (gross sensible capacity divided by gross total cooling capacity) of the DX cooling coil for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb[2], and a cooling coil air flow rate defined by field rated air flow rate below). Both the sensible and total cooling capacities used to define the Rated SHR should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

**1.41.16.1.5 Field: High Speed Gross Rated Cooling COP**

The coefficient of performance is the ratio of the gross total cooling capacity in watts to electrical power input in watts) of the DX cooling coil unit for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air flow rate below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The gross COP should NOT account for the supply air fan. If this input field is left blank, the default value is 3.0.

**1.41.16.1.6 Field: High Speed Rated Air Flow Rate**

The high speed air volume flow rate, in  $\text{m}^3$  per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027  $\text{m}^3/\text{s}$  and 0.00006041  $\text{m}^3/\text{s}$  per watt of gross rated total cooling capacity. For DOAS applications the rated air volume flow rate should be between 0.00001677  $\text{m}^3/\text{s}$  and 0.00003355  $\text{m}^3/\text{s}$  per watt of gross rated total cooling capacity (125 to 250 cfm/ton). The gross rated total cooling capacity, gross rated SHR and gross rated COP should be performance information for the unit with air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and the rated air volume flow rate defined here.

**1.41.16.1.7 Field: Unit Internal Static Air Pressure**

If this coil is used with a **Fan:VariableVolume** to model a packaged variable-air-volume unit, then ratings for standard rated net capacity, EER, and IEER will be calculated per ANSI/AHRI Standard 340/360-2007 with Addenda 1 and 2. This field is to specify the internal static air pressure, in units of Pascals, associated with the unit's supply air flow for rating purposes. This field does not affect the performance during operation. This field is optional. If this field is used, then the internal static air pressure is used with the associated fan characteristics when calculating standard rated net capacity, EER, and IEER. If this field is not used, then the standard ratings are still performed but use a default for specific fan power of 773.3 ( $\text{W}/(\text{m}^3/\text{s})$ ). The air pressure drop/rise input here should be internal in the sense that it is for the entire package of unitary equipment as it would be tested in a laboratory (including other non-cooling sections inside the package for filters, dampers, and or heating coils) but none of the external pressure drop for distributing supply air throughout the building. This is different from the input field called Pressure Rise in the fan object which includes both the external static pressure and the internal static pressure. The results of standard rating calculations are reported to the EIO file and to predefined output tables called DX Cooling Coils and VAV DX Cooling Standard Rating Details.

**1.41.16.1.8 Field: Air Inlet Node**

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

**1.41.16.1.9 Field: Air Outlet Node**

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

**1.41.16.1.10 Field: Total Cooling Capacity Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 °C indoor wet-bulb temperature and 35 °C outdoor dry-bulb temperature. The output of this curve is multiplied by the gross rated total cooling capacity to give the gross total cooling capacity at specific temperature

operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point. This curve is used for performance at the high speed compressor, high speed fan operating point.

#### **1.41.16.1.11 Field: Total Cooling Capacity Function of Flow Fraction Curve Name**

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of gross total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the gross rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. This curve is applied only at the high speed compressor, high speed fan operating point. There is no corresponding curve for the low speed operating point.

#### **1.41.16.1.12 Field: Energy Input Ratio Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 C indoor wet-bulb temperature and 35 C outdoor dry-bulb temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point. This curve is used for performance at the high speed compressor, high speed fan operating point.

#### **1.41.16.1.13 Field: Energy Input Ratio Function of Flow Fraction Curve Name**

The name of a quadratic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This curve is applied only at the high speed compressor, high speed fan operating point. There is no corresponding curve for the low speed operating point.

#### **1.41.16.1.14 Field: Part Load Fraction Correlation Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 \leq \text{PLR} < 1$ ), the following rules apply:

$\text{PLF} \geq 0.7$  and  $\text{PLF} \geq \text{PLR}$

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

#### 1.41.16.1.15 Field: Low Speed Gross Rated Total Cooling Capacity

The total, full load gross total cooling capacity (sensible plus latent) in watts of the DX coil unit for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air flow rate, low speed below). Capacity should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

#### 1.41.16.1.16 Field: Low Speed Gross Rated Sensible Heat Ratio

The sensible heat ratio (SHR = gross sensible capacity divided by gross total cooling capacity) of the DX cooling coil for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air flow rate, low speed below). Both the sensible and total cooling capacities used to define the Rated SHR should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

#### 1.41.16.1.17 Field: Low Speed Gross Rated Cooling COP

The coefficient of performance is the ratio of gross total cooling capacity in watts to electrical power input in watts) of the DX cooling coil unit for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air volume flow rate, low speed below). The input power includes power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The gross COP should NOT account for the supply air fan. If this input field is left blank, the default value is 3.0.

#### 1.41.16.1.18 Field: Low Speed Rated Air Flow Rate

The low speed volume air flow rate, in m<sup>3</sup> per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m<sup>3</sup>/s and 0.00006041 m<sup>3</sup>/s per watt of the gross rated total cooling capacity. For DOAS applications the rated air volume flow rate should be between 0.00001677 m<sup>3</sup>/s and 0.00003355 m<sup>3</sup>/s per watt of gross rated total cooling capacity (125 to 250 cfm/ton). The gross rated total cooling capacity, gross rated SHR and gross rated COP should be performance information for the unit with air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and the rated air volume flow rate defined here.

#### 1.41.16.1.19 Field: Low Speed Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the gross rated

total cooling capacity to give the gross total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point. This curve is used for performance at the low speed compressor, low speed fan operating point.

#### 1.41.16.1.20 Field: Low Speed Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wetbulb temperature of the air entering the cooling coil and the drybulb temperature of the air entering the air-cooled condenser (wetbulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point. This curve is used for performance at the low speed compressor, low speed fan operating point.

#### 1.41.16.1.21 Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

#### 1.41.16.1.22 Field: Condenser Type

The type of condenser used by the multi-speed DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

#### 1.41.16.1.23 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the cooling coil compressor turns off. If this input field is left blank, the value defaults to that specified in the IDD (e.g., -25 °C). If this field is not included in the input, the default value is -25 °C.

#### 1.41.16.1.24 Field: High Speed Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at high compressor/fan speed, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{condinlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness_{HighSpeed})(T_{db,o} - T_{wb,o}) \quad (1.155)$$

where

$T_{condinlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The

default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

#### 1.41.16.1.25 Field: High Speed Evaporative Condenser Air Flow Rate

The air volume flow rate, in m<sup>3</sup> per second, entering the evaporative condenser at high compressor/fan speed. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m<sup>3</sup>/s per watt of rated high-speed total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

#### 1.41.16.1.26 Field: High Speed Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts at high compressor/fan speed. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated high-speed total cooling capacity). This field is not used when Condenser Type = Air Cooled.

#### 1.41.16.1.27 Field: Low Speed Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at low compressor/fan speed, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{condinlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness_{LowSpeed}) (T_{db,o} - T_{wb,o}) \quad (1.156)$$

where

$T_{condinlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve, low speed (function of temperature) and the Energy Input Ratio Modifier Curve, low speed (function of

temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled. See field Evaporative Condenser Effectiveness, High Speed above for further information.

#### **1.41.16.1.28 Field: Low Speed Evaporative Condenser Air Flow Rate**

The air volume flow rate, in  $\text{m}^3$  per second, entering the evaporative condenser at low compressor/fan speed. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to  $0.000048 \text{ m}^3/\text{s}$  per watt of rated high-speed total cooling capacity [280 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

#### **1.41.16.1.29 Field: Low Speed Evaporative Condenser Pump Rated Power Consumption**

The rated power of the evaporative condenser water pump in Watts at low compressor/fan speed. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to  $0.001422 \text{ W}$  per watt [5 W/ton] of rated high-speed total capacity). This field is not used when Condenser Type = Air Cooled.

#### **1.41.16.1.30 Field: Supply Water Storage Tank Name**

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

#### **1.41.16.1.31 Field: Condensate Collection Water Storage Tank Name**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

#### **1.41.16.1.32 Field: Basin Heater Capacity**

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **1.41.16.1.33 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

**1.41.16.1.34 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

**1.41.16.1.35 Field: Sensible Heat Ratio Function of Temperature Curve Name**

The name of a biquadratic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of DX cooling coil entering air wet-bulb and dry-bulb temperatures. The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of flow fraction) to give the SHR at the specific coil entering air temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 at the rated condition. This input field is optional.

**1.41.16.1.36 Field: Sensible Heat Ratio Function of Flow Fraction Curve Name**

The name of a quadratic or cubic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of temperature) to give the SHR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This input field is optional.

**1.41.16.1.37 Field: Low Sensible Heat Ratio Function of Temperature Curve Name**

The name of a biquadratic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of DX cooling coil entering air wet-bulb and dry-bulb temperatures. The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of flow fraction) to give the SHR at the specific coil entering air temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 at the rated condition. This input field is optional.

**1.41.16.1.38 Field: Low Sensible Heat Ratio Function of Flow Fraction Curve Name**

The name of a quadratic or cubic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of temperature) to give the SHR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This input field is optional.

**1.41.16.1.39 Field: Zone Name for Condenser Placement**

This input field is name of a conditioned or unconditioned zone where the secondary coil (condenser) of DX system or a heat pump is to be placed. This is an optional input field specified only when user desires to reject the condenser heat into a zone. The heat rejected is modeled as sensible internal gain of a secondary zone.

Following are example inputs for the object.

### 1.41.17 Coil:Cooling:DX:TwoStageWithHumidityControlMode

The multimode DX coil is functionally equivalent to [Coil:Cooling:DX:SingleSpeed](#) but with multiple performance modes. It is capable of modeling two-stage DX units and units with an enhanced dehumidification mode such as coil bypass or subcool reheat. This object contains one-time specifications for the DX unit such as node names and crankcase heater specifications. It references one or more [CoilPerformance:DX:Cooling](#) objects which define the performance for each mode of operation. It can have up to 4 performance modes to accommodate a 2-stage 2-mode unit.

The multimode DX coil can be used only as a component of [AirLoopHVAC:UnitarySystem](#), [CoilSystem:Cooling:DX](#) or [AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass](#) (parent object). These parent objects pass a load and dehumidification mode to this coil. If the coil has 2 capacity stages, the multimode coil model determines the stage sequencing.

### 1.41.17.1 Inputs

#### 1.41.17.1.1 Field: Name

A unique user-assigned name for an instance of a DX cooling coil. Any reference to this DX coil by another object will use this name.

#### 1.41.17.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.41.17.1.3 Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

#### 1.41.17.1.4 Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

#### 1.41.17.1.5 Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump (Ref. [AirLoopHVAC:UnitarySystem](#) and [AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass](#)), the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. [Coil:Heating:DX:SingleSpeed](#)) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

#### 1.41.17.1.6 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C, and the default value is 10 °C.

#### 1.41.17.1.7 Field: Number of Capacity Stages

This integer field defines the number of capacity stages. The value for this input field must be either 1 or 2, and the default value is 1. Larger DX units often have two capacity stages, which are often two completely independent compressor/coil circuits with the evaporator coils arranged in parallel in the supply air stream. 2-stage operation affects cycling losses and latent degradation due to re-evaporation of moisture with continuous fan operation.

#### 1.41.17.1.8 Field: Number of Enhanced Dehumidification Modes

This integer field defines the number of enhanced dehumidification modes available. The value for this input field must be 0 or 1, and the default value is 0. If the DX unit can switch operating modes to increase dehumidification based on a humidistat signal, then set this to 1. This field just specified the availability of enhanced dehumidification. Actual control of the operating mode is handled by the coil's parent component.

**1.41.17.1.9 Field: Normal Mode Stage 1 Coil Performance Object Type****1.41.17.1.10 Field: Normal Mode Stage 1 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1 operation without enhanced dehumidification (normal mode). The only valid performance object type is **CoilPerformance:DX:Cooling**.

**1.41.17.1.11 Field: Normal Mode Stage 1+2 Coil Performance Object Type****1.41.17.1.12 Field: Normal Mode Stage 1+2 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1+2 operation (both stages active) without enhanced dehumidification (normal mode). The only valid performance object type is **CoilPerformance:DX:Cooling**.

**1.41.17.1.13 Field: Dehumidification Mode 1 Stage 1 Coil Performance Object Type****1.41.17.1.14 Field: Dehumidification Mode 1 Stage 1 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1 operation with enhanced dehumidification active. The only valid performance object type is **CoilPerformance:DX:Cooling**.

**1.41.17.1.15 Field: Dehumidification Mode 1 Stage 1+2 Coil Performance Object Type****1.41.17.1.16 Field: Dehumidification Mode 1 Stage 1+2 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1+2 operation (both stages active) with enhanced dehumidification active. The only valid performance object type is **CoilPerformance:DX:Cooling**.

**1.41.17.1.17 Field: Supply Water Storage Tank Name**

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

**1.41.17.1.18 Field: Condensate Collection Water Storage Tank Name**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

#### 1.41.17.1.19 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the cooling coil compressor turns off. If this input field is left blank, the value defaults to that specified in the IDD (e.g., -25 °C). If this field is not included in the input, the default value is -25 °C.

#### 1.41.17.1.20 Field: Basin Heater Capacity

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### 1.41.17.1.21 Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2 °C, and the default value is 2 °C if this field is left blank.

#### 1.41.17.1.22 Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

Following is an example IDF use of the object:

```

### 1.41.18 Coil:Cooling:DX:MultiSpeed

This component models a DX cooling unit with multiple discrete levels of cooling capacity. Depending on input choices, the user can model a single compressor with multiple operating speeds, or a unit with a single cooling coil fed by multiple compressors (e.g., row split or intertwined coil circuiting). Currently, this cooling coil can only be referenced by a `AirLoopHVAC:UnitarySystem` or `AirLoopHVAC:UnitaryHeatPump:AirToAir:Multispeed` object. Refer to `Coil:Cooling:DX:TwoStageWithHumidityControlMode` if the user wishes to model a cooling coil with discrete levels of cooling and the possibility of air bypass during low speed operation (e.g. face-split coil circuiting), or if cooling coil operation based on dehumidification requirements is desired.

The multispeed DX cooling coil can have from two to four operating speeds. When the coil operates at Speed 1 (the lowest speed), its performance is very similar to the single speed DX coil where the impacts of part-load ratio and latent capacity degradation can be included. When the coil operates at higher speeds (above Speed 1), the linear approximation methodology is applied. The coil outputs at two consecutive speeds are linearly interpolated to meet the required cooling capacity during an HVAC system timestep. When the coil performs above the lowest speed, the user can chose if they want to include part-load ratio and latent capacity degradation impacts at the higher speeds.

The multispeed unit is described by specifying the performance at different operating speeds. Each speed has its own set of input specifications: full load capacity, SHR, COP and air flow rate at rated conditions, along with modifier curves to determine performance when actual operating conditions are different from the rated conditions.

The coil operates to meet the sensible capacity being requested. When this requested capacity is above the sensible capacity of the highest operating speed, the coil runs continuously at the highest speed. When the requested capacity is between the sensible capacities of two consecutive speeds, the unit will operate a portion of the time at each speed to meet the request. When the requested capacity is less than the low speed (Speed 1) capacity, the unit will cycle on/off as needed.

#### 1.41.18.1 Inputs

##### 1.41.18.1.1 Field: Name

A unique user-assigned name for an instance of a multispeed DX cooling coil. Any reference to this DX coil by another object will use this name.

##### 1.41.18.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.41.18.1.3 Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

##### 1.41.18.1.4 Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

##### 1.41.18.1.5 Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the

node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

#### 1.41.18.1.6 Field: Condenser Type

The type of condenser used by the multispeed DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

#### 1.41.18.1.7 Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the evaporative cooler will obtain water directly from the mains. If the name of a **Water Storage Tank** object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as **StarvedWater**).

#### 1.41.18.1.8 Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of **Water Storage Tank** object defined elsewhere and the condensate will then be collected in that tank.

#### 1.41.18.1.9 Field: Apply Part Load Fraction to Speeds Greater than 1

This field determines whether part-load impacts on coil energy use are applied when the coil is operating at speeds greater than speed 1. The allowed choices are **Yes** or **No**, with the default being **No** if this field is left blank. Other input fields in this object allow the user to specify a part-load fraction correlation for each speed to account for compressor start up losses (cycle on/off). For the case of a single multi-speed compressor, the part load losses may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify **NO** for this input field to neglect part-load impacts on energy use at higher operating speeds. If part-load impacts on coil energy use are thought to be significant (e.g., intertwined cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify **YES** and the part-load fraction correlations specified for speeds 2 through 4 will be applied as appropriate. The selection for this input field does not affect part-load impacts when the compressor cycles between speed 1 and off (i.e., the part-load fraction correlation for speed 1 is always applied).

#### 1.41.18.1.10 Field: Apply Latent Degradation to Speeds Greater than 1

This field determines whether latent capacity degradation is applied when the coil is operating at speeds greater than speed 1. The allowed choices are **Yes** or **No**, with the default being **No** if this field is left blank. Other input fields in this object allow the user to specify latent capacity degradation at each speed.

The latent capacity degradation model only applies when the **ContinuousFanWithCyclingCompressor** supply air fan operating mode is specified, to account for moisture evaporation from the wet cooling coil when the compressor cycles off but the supply air fan continues to operate. For the case of a single multi-speed compressor, latent capacity degradation may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify **NO** for this input field to neglect latent capacity degradation impacts at higher operating speeds. If latent capacity

degradation is thought to be significant (e.g., intertwined or row-split cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify YES and the latent capacity degradation model will be applied for speeds 2 through 4 as appropriate. The selection for this input field does not affect latent capacity degradation between speed 1 and off.

#### **1.41.18.1.11 Field: Crankcase Heater Capacity**

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

#### **1.41.18.1.12 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C. If this input field is left blank, the default value is 10 °C.

#### **1.41.18.1.13 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation**

This numeric field defines the minimum outdoor air dry-bulb temperature where the cooling coil compressor turns off. If this input field is left blank, the value defaults to that specified in the IDD (e.g., -25 °C).

#### **1.41.18.1.14 Field: Basin Heater Capacity**

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **1.41.18.1.15 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2 °C, and the default value is 2 °C if this field is left blank.

#### **1.41.18.1.16 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

#### 1.41.18.1.17 Field: Fuel Type

This alpha field determines the type of fuel that this cooling coil uses. This field has seven choices: Electricity, NaturalGas, Propane, Coal, Diesel, Gasoline, FuelOilNo1, FuelOilNo2, OtherFuel1 and OtherFuel2. This is a required field with no default.

#### 1.41.18.1.18 Field: Number of Speeds

This field specifies the number of sets of data being entered for rated specifications, performance curves, evaporative condenser data, latent degradation data, and waste heat specifications for each cooling speed. The rated specifications consist of gross rated capacity, gross rated SHR, gross rated COP, and rated air flow rate. The performance curves consist of a total capacity modifier curve as a function of temperature, total capacity modifier curve as a function of flow fraction, energy input ratio modifier curve as a function of temperature, energy input ratio modifier curve as a function of flow fraction, and part load fraction correlation as a function of part load ratio. The evaporative condenser data consists of effectiveness, condenser air volume flow rate, and rated pump power consumption. The latent degradation data consists of nominal time for condensate removal to begin, ratio of initial moisture evaporation rate and steady-state latent capacity, maximum On/Off cycling rate, and latent capacity time constant. The latent degradation data are only applied if the supply air fan operation mode is specified as ContinuousFanWithCyclingCompressor. The waste heat specifications include the fraction of energy input to the cooling coil at the fully loaded and rated conditions, and a temperature modifier. The minimum number of speeds for cooling is 2 and the maximum number is 4. The number of speeds should be the same as the number of speeds for cooling defined in its parent object (`AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` or `[unitarysystem-performancemultispeed]UnitarySystemPerformance:Multispeed` used with `AirLoopHVAC:UnitarySystem`). The first set of performance inputs is for Speed 1 and should be for low speed, and the last set of performance inputs should be for high speed. For example, if only three cooling speeds are defined, the first set should be for low speed (Speed 1), the second set should be for medium speed (Speed 2), and the third set should be for high speed (Speed 3). In this example, any performance inputs for Speed 4 would be neglected (since this input field specifies that the coil only has three cooling speeds).

#### 1.41.18.1.19 Field Group: Rated Specification, Performance Curves, Latent Capacity Degradation Inputs, and Evaporative Cooled Condenser Data

The performance for each cooling speed must be specified as shown below. All inputs for Speed 1 are required first, followed by the inputs for Speed 2, Speed 3 and Speed 4.

#### 1.41.18.1.20 Field: Speed <x> Gross Rated Total Cooling Capacity

The total, full load gross cooling capacity (sensible plus latent) in watts of the DX coil unit for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb[3], and a cooling coil air flow rate defined by field Rated Air Flow Rate, Speed <x> below). Capacity should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

#### 1.41.18.1.21 Field: Speed <x> Gross Rated Sensible Heat Ratio

The sensible heat ratio (SHR = gross sensible capacity divided by gross total cooling capacity) of the DX cooling coil for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field Rated Air Flow Rate, Speed <x> below). Both the sensible and total cooling capacities used to define the Rated SHR should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

**1.41.18.1.22 Field: Speed <x> Gross Rated Cooling COP**

The coefficient of performance is the ratio of the gross total cooling capacity in watts to electrical power input in watts) of the DX cooling coil unit for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field Rated Air Flow Rate, Speed <x> below). The input power includes power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The gross COP should NOT account for the supply air fan. If this input field is left blank, the default value is 3.0.

**1.41.18.1.23 Field: Speed <x> Rated Air Flow Rate**

The volumetric air flow rate for Speed <x>, in m<sup>3</sup> per second, across the DX cooling coil at rated conditions. The rated air volume flow rate for Speed <x> should be between 0.00004027 m<sup>3</sup>/s and 0.00006041 m<sup>3</sup>/s per watt of the gross rated total cooling capacity for Speed <x>. The gross rated total cooling capacity, gross rated SHR and gross rated COP for Speed <x> should be performance information for the unit with air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and the rated air volume flow rate defined here.

**1.41.18.1.24 Field: Speed <X> Rated Evaporator Fan Power Per Volume Flow Rate**

This field is the electric power for the evaporator (cooling coil) fan per air volume flow rate through the coil at the rated conditions for Speed <x> in W/(m<sup>3</sup>/s). The default value is 773.3 W/(m<sup>3</sup>/s) (365 W/1000 cfm) if this field is left blank. If a value is entered, it must be  $\geq 0.0$  and  $\leq 1250$  W/(m<sup>3</sup>/s). This value is only used to calculate Seasonal Energy Efficiency Ratio (SEER), and the Standard Rating (Net) Cooling Capacity which will be outputs in the EnergyPlus eio file (ref. EnergyPlus Engineering Reference, Multi-Speed DX Cooling Coil, Standard Ratings). This value is not used for modeling the evaporator (cooling coil) fan during simulations; instead, it is used for calculating SEER and Standard Rating Cooling Capacity to assist the user in verifying their inputs for modeling this type of equipment.

**1.41.18.1.25 Field: Speed <x> Total Cooling Capacity Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity for Speed <x> as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 C indoor wet-bulb temperature and 35 C outdoor dry-bulb temperature. The output of this curve is multiplied by the gross rated total cooling capacity for Speed <x> to give the gross total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

**1.41.18.1.26 Field: Speed <x> Total Cooling Capacity Function of Flow Fraction Curve Name**

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity for Speed <x> as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate for Speed <x> (i.e., fraction of full load flow). The output of this curve is multiplied by the gross rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity for Speed <x> at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate for Speed <x>.

#### 1.41.18.1.27 Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) for Speed <x> as a function of the wetbulb temperature of the air entering the cooling coil and the drybulb temperature of the air entering the air-cooled condenser (wetbulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 C indoor wet-bulb temperature and 35 C outdoor dry-bulb temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR for Speed <x> (inverse of rated COP for Speed <x>) to give the EIR for Speed <x> at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).

#### 1.41.18.1.28 Field: Speed <x> Energy Input Ratio Function of Flow Fraction Curve Name

The name of a quadratic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) for Speed <x> as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate for Speed <x> (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR for Speed <x> at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate for Speed <x>.

#### 1.41.18.1.29 Field: Speed <x> Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity for Speed <x>). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep for Speed <x>. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 \leq \text{PLR} < 1$ ), the following rules apply:

---

$$\text{PLF} > = 0.7 \quad \text{and} \quad \text{PLF} > = \text{PLR}$$

---

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional DX cooling coil (Speed <x>) would be:

---

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

---

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

---

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

---

#### 1.41.18.1.30 Field: Speed <x> Nominal Time for Condensate Removal to Begin

For Speed <x>, the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent

degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]), and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation for Speed <x>.

#### 1.41.18.1.31 Field: Speed <x> Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

For Speed <x>, the ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) for Speed <x> at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]); and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation for Speed <x>.

#### 1.41.18.1.32 Field: Speed <x> Maximum Cycling Rate

For Speed <x>, the maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]); and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation for Speed <x>.

#### 1.41.18.1.33 Field: Speed <x> Latent Capacity Time Constant

For Speed <x>, the time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]), and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation for Speed <x>.

#### 1.41.18.1.34 Field: Speed <x> Rated Waste Heat Fraction of Power Input

The fraction of energy input to the cooling coil that is available as recoverable waste heat at full load and rated conditions for Speed <x>.

#### 1.41.18.1.35 Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of outdoor dry-bulb temperature and the entering coil dry-bulb temperature at Speed <x>. The output of this curve is multiplied by the rated waste heat fraction at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point. When the fuel type is electricity, this field can remain blank since it is ignored by the program in this instance. When the fuel type is not electricity and the parent object **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** does not require waste heat calculations, this field is ignored. If the field is blank, a warning will be issued and simulation continues. When the

fuel type is not electricity and the parent object **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** requires waste heat calculations, if this field is left blank, the program assumes a constant value of 1 to make simulation continue and a warning will be issued.

#### 1.41.18.1.36 Field: Speed <x> Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at Speed <x>, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{condinlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness_{Speed1})(T_{db,o} - T_{wb,o}) \quad (1.157)$$

where

$T_{condinlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify **AirCooled** in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves for Speed <x> must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

#### 1.41.18.1.37 Field: Speed <x> Evaporative Condenser Air Flow Rate

The air volume flow rate, in m<sup>3</sup> per second, entering the evaporative condenser at Speed <x>. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000114 m<sup>3</sup>/s per watt of rated total cooling capacity for Speed <x> [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

#### 1.41.18.1.38 Field: Speed <x> Rated Evaporative Condenser Pump Power Consumption

The rated power of the evaporative condenser water pump in Watts at Speed <x>. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total capacity for Speed <x>). This field is not used when Condenser Type = Air Cooled.

#### 1.41.18.1.39 Field: Zone Name for Condenser Placement

This input field is name of a conditioned or unconditioned zone where the secondary coil (condenser) of DX system or a heat pump is to be placed. This is an optional input field specified only when user desires to reject the condenser heat into a zone. The heat rejected is modeled as sensible internal gain of a secondary zone.

Following is an example input for this multispeed DX cooling coil.

- HVAC,Sum,DX Cooling Coil <Fuel Type> Consumption[J]

**1.41.18.2.1 Cooling Coil Total Cooling Rate [W]**

This field is the total (sensible and latent) cooling rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.18.2.2 Cooling Coil Total Cooling Energy [J]**

This is the total (sensible plus latent) cooling output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (Ref. Output:Meter objects).

**1.41.18.2.3 Cooling Coil Sensible Cooling Rate [W]**

This output is the moist air sensible cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.18.2.4 Cooling Coil Sensible Cooling Energy [J]**

This is the moist air sensible cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.18.2.5 Cooling Coil Latent Cooling Rate [W]**

This is the latent cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.18.2.6 Cooling Coil Latent Cooling Energy [J]**

This is the latent cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.18.2.7 Cooling Coil Electricity Rate [W]**

This output is the electricity consumption rate of the DX coil compressor and condenser fan(s) in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.18.2.8 Cooling Coil Electricity Energy [J]**

This is the electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

**1.41.18.2.9 Cooling Coil Runtime Fraction []**

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the timestep being reported.

**1.41.18.2.10 Cooling Coil Crankcase Heater Electricity Rate [W]**

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. If the DX Cooling Coil is used in a heat pump, the crankcase heater is reported only for the heating coil.

**1.41.18.2.11 Cooling Coil Crankcase Heater Electricity Energy [J]**

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects). This output variable appears only when the DX Cooling Coil is not used as part of a heat pump, otherwise the crankcase heater is reported only for the heating coil.

**1.41.18.2.12 Cooling Coil Condenser Inlet Temperature [C]**

This is the inlet air temperature to the condenser coil in degrees C. This value can represent the outdoor air dry-bulb temperature, wet-bulb temperature, or somewhere in between from the weather data being used, depending on the value used in the input field Evaporative Condenser Effectiveness . The temperature reported here is used in the various modifier curves related to temperature (e.g., Total Cooling Capacity Modifier Curve [function of temperature]). This output variable appears only when the DX Cooling Coil is not used as part of a heat pump, otherwise the crankcase heater is reported only for the heating coil.

**1.41.18.2.13 Cooling Coil Evaporative Condenser Water Volume [m3]**

This output is the amount of water used to evaporatively cool the condenser coil inlet air, in cubic meters. This output is also added to a meter with Resource Type = Water, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects). This output variable appears only when the DX Cooling Coil is evaporatively cooled.

**1.41.18.2.14 Cooling Coil Evaporative Condenser Mains Supply Water Volume [m3]**

This is the volume of water drawn from mains water service for the evaporatively cooled condenser.

**1.41.18.2.15 Cooling Coil Evaporative Condenser Pump Electricity Rate [W]**

This is the average electricity consumption rate of the evaporative condenser water pump in Watts for the timestep being reported. This output variable appears only when the DX Cooling Coil is evaporatively cooled.

**1.41.18.2.16 Cooling Coil Evaporative Condenser Pump Electricity Energy [J]**

This is the electricity consumption rate of the evaporative condenser water pump in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects). This output variable appears only when the DX Cooling Coil is evaporatively cooled.

**1.41.18.2.17 Cooling Coil Stage 2 Runtime Fraction []**

This is the runtime fraction of the stage 2 DX coil compressor and condenser fan(s) for the timestep being reported. Applicable only for COIL Coil:Cooling:DX:TwoStageWithHumidityControlMode when 2 capacity stages are specified. For 2-stage systems, Cooling Coil Runtime Fraction is the stage 1 runtime fraction. These runtime fractions overlap, because stage 2 will not run unless stage 1 is already running. For example, a system where stage 1 is 60% of total capacity is passed a load of 70%. The Cooling Coil Runtime Fraction (stage 1) will be 1.0, and the Cooling Coil Stage 2 Runtime Fraction will be 0.25  $[(70\%-60\%)/(100\%-60\%)]$ .

**1.41.18.2.18 Cooling Coil Dehumidification Mode []**

This is the dehumidification mode for the timestep being reported. Applicable only for Coil:Cooling:DX:TwoStageWithHumidityControlMode when enhanced dehumidification mode is

available. A value of 0 indicates normal mode (extra dehumidification not active). A value of 1 indicates dehumidification mode 1 is active. Note that this is an averaged variable, so fractional values are likely to be reported for reporting frequencies longer than “detailed”.

#### **1.41.18.2.19 Cooling Coil Condensate Volume Flow Rate [m3/s]**

#### **1.41.18.2.20 Cooling Coil Condensate Volume [m3]**

These outputs are the rate and volume of water collected as condensate from the coil. These reports only appear if a water storage tank is named in the input object.

#### **1.41.18.2.21 Cooling Coil Evaporative Condenser Mains Supply Water Volume [m3]**

This is the water consumed by the DX Cooling Coil evaporatively cooled condenser that is met by the mains water. This output variable appears only when the DX Cooling Coil is evaporatively cooled.

#### **1.41.18.2.22 Cooling Coil Basin Heater Electricity Rate [W]**

This is the average electricity consumption rate of the basin heater in Watts for the timestep being reported. This output variable appears only when the DX Cooling Coil is evaporatively cooled and the Basin Heater Capacity is greater than 0.

#### **1.41.18.2.23 Cooling Coil Basin Heater Electricity Energy [J]**

This is the electricity consumption rate of the basin heater in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects). This output variable appears only when the DX Cooling Coil is evaporatively cooled and the Basin Heater Capacity is greater than 0.

#### **1.41.18.2.24 Cooling Coil <Fuel Type> Power [W]**

This output variable appears only when using the Coil:Cooling:DX:Multispeed object and a fuel type other than electricity is used. This variable describes the input fuel type power for the cooling coil in Watts, averaged during the timestep being reported.

#### **1.41.18.2.25 Cooling Coil <Fuel Type> Energy [J]**

This output variable appears only when using the Coil:Cooling:DX:Multispeed object and a fuel type other than electricity is used. This variable describes the input fuel type consumption for the multispeed cooling coil in the unit of Joules, summed for the timestep being reported. The electric consumption is excluded..This output is added to a meter with Resource Type = <Fuel Type>, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

Note: <Fuel Type> in the above two output variables depends on the user specified input for the Fuel Type field. In addition to Electricity, valid fuel types are NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, OtherFuel1 and OtherFuel2.

### **1.41.19 Coil:Cooling:DX:VariableSpeed**

The Variable-Speed DX Cooling Coil is a collection of performance curves that represent the cooling coil at various speed levels. The performance curves should be generated from a Reference Unit data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. On the other hand, the model uses the bypass factor approach to calculate sensible heat transfer rate, similar to the one used in the single-speed DX coil. The number of speed levels can range from 1 to 10. The cooling coil

has two indoor air side connections, and one optional condenser air node connection. The user needs to specify a nominal speed level, at which the gross rated total cooling capacity, and rated volumetric air rate are sized. The rated capacity and rated volumetric flow rate represent the real situation in the air loop, and are used to determine and flow rates at various speed levels in the parent objects, e.g. of `AirLoopHVAC:UnitarySystem`, `AirLoopHVAC:UnitaryHeatCool`, `ZoneHVAC:PackagedTerminalAirConditioner`, `AirLoopHVAC:UnitaryHeatPump:AirToAir` and `ZoneHVAC:PackagedTerminalHeatPump`. It shall be mentioned that the performance correction curves, i.e. the temperature and flow fraction correction curves, should be normalized to the capacity and flow rate at each individual speed and at the rated conditions, similar to the performance curves used in the single-speed DX coil. However, the performance values, e.g. capacities, COPs, SHRs and flow rates at individual speed levels, should be given regarding a specific unit from the Reference Unit catalog data. In the following content, the statement started with Reference Unit means the actual Reference Unit catalog data. The rated conditions for obtaining the capacities, COPs and SHRs are at indoor dry-bulb temperature of 26.67 °C (80 °F), wet bulb temperature of 19.44 °C (67 °F), and the condenser entering air temperature of 35 °C (95 °F). Some equations are provided below to help explain the function of the various performance curves and data fields.

### 1.41.19.1 Inputs

#### 1.41.19.1.1 Field: Name

This alpha field contains the identifying name for the variable-speed cooling coil.

#### 1.41.19.1.2 Field: Air Inlet Node Name

This alpha field contains the cooling coil load side inlet node name.

#### 1.41.19.1.3 Field: Air Outlet Node Name

This alpha field contains the cooling coil load side outlet node name.

#### 1.41.19.1.4 Field: Number of Speeds

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, should be equal or higher than the maximum number. The performance inputs at higher speed levels are ignored.

#### 1.41.19.1.5 Field: Nominal Speed Level

This numeric field defines the nominal speed level, at which the rated capacity and rated air rate are correlated.

#### 1.41.19.1.6 Field: Gross Rated Total Cooling Capacity at Selected Nominal Speed Level

This numeric field contains the gross rated total cooling capacity at the nominal speed level. This field is autosizable. The gross rated total cooling capacity is used to determine a capacity scaling factor, as compared to the Reference Unit capacity at the nominal speed level.

$$\text{CapacityScaleFactor} = \frac{\text{GrossRatedTotalCoolingCapacity}}{\text{ReferenceUnitCapacity@NominalSpeedLevel}} \quad (1.158)$$

And then, this scaling factor is used to determine capacities at rated conditions for other speed levels, as below,

$$\begin{aligned} \text{GrossRatedCapacity@SpeedLevel}(x) = \\ \text{CapacityScaleFactor} \times \\ \text{ReferenceUnitCapacity@SpeedLevel}(x) \end{aligned} \quad (1.159)$$

#### 1.41.19.1.7 Field: Rated Air Flow Rate at Selected Nominal Speed Level

This numeric field contains the rated volumetric air flow rate on the load side of the DX unit, corresponding to the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the air flow rates in the parent objects. It is recommended that the ratio of the rated volumetric air flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\text{AirFlowScaleFactor} = \frac{\text{RatedVolumetricAirFlowRate}}{\text{ReferenceUnitVolAirFlowRate@NominalSpeedLevel} \times \text{CapacityScaleFactor}} \quad (1.160)$$

And the volumetric air flow rates in the parent objects are calculated as below,

$$\begin{aligned} \text{LoopVolumetricAirFlowRate@SpeedLevel}(x) = \\ \text{AirFlowScaleFactor} \times \\ \text{ReferenceUnitVolAirFlowRate@SpeedLevel}(x) \times \\ \text{CapacityScaleFactor} \end{aligned} \quad (1.161)$$

#### 1.41.19.1.8 Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

#### 1.41.19.1.9 Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

#### 1.41.19.1.10 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the unit as a function of the part load ratio (PLR, sensible or latent load/steady-state sensible or latent cooling capacity for Speed 1), in the case that the unit operates under the lowest speed, i.e. on/off. The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep for Speed 1. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep).

**1.41.19.1.11 Field: Condenser Air Inlet Node Name**

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

**1.41.19.1.12 Field: Condenser Type**

The type of condenser used by the DX cooling coil. Valid choices for this input field are AirCooled or EvaporativelyCooled. The default for this field is AirCooled.

**1.41.19.1.13 Field: Evaporative Condenser Pump Rated Power Consumption**

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = Air Cooled.

**1.41.19.1.14 Field: Crankcase Heater Capacity**

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air drybulb temperature is below the value specified in the input field Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump, the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. **Coil:Heating:DX:SingleSpeed**) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

**1.41.19.1.15 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C, and the default value is 10 °C.

**1.41.19.1.16 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation**

This numeric field defines the minimum outdoor air dry-bulb temperature where the cooling coil compressor turns off. If this input field is left blank, the value defaults to that specified in the IDD (e.g., -25 °C).

**1.41.19.1.17 Field: Supply Water Storage Tank Name**

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling of its condenser. If blank or omitted, then the unit will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, the unit will obtain its water from that tank. If a tank is specified, the unit will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the condenser needs, then the unit will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

**1.41.19.1.18 Field: Condensate Collection Water Storage Tank Name**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

**1.41.19.1.19 Field: Basin Heater Capacity**

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

**1.41.19.1.20 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

**1.41.19.1.21 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

**1.41.19.1.22 Field Group: Rated specification, performance curves**

The performance for each cooling speed must be specified as shown below. They should be directly given from the Reference Unit catalog data. All inputs for Speed 1 are required, followed by the optional inputs for other speeds.

**1.41.19.1.23 Field: Speed <x> Reference Unit Gross Rated Total Cooling Capacity**

This numeric field defines the total, full load gross cooling capacity in watts of the air-to-air cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. Capacity should not account for supply air fan heat.

**1.41.19.1.24 Field: Speed <x> Reference Unit Gross Rated Sensible Heat Ratio**

This numeric field defines sensible heat transfer ratio ( $\text{SHR} = \text{gross sensible cooling capacity} / \text{gross total cooling capacity}$ ) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0.0 and less than 1.0. This value should be obtained from the Reference Unit data.

**1.41.19.1.25 Field: Speed <x> Reference Unit Gross Rated Cooling COP**

This numeric field defines the coefficient of performance (COP = the gross total cooling capacity in watts divided by electrical power input in watts) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The input power includes power for the compressor(s), condenser fan and accessories, but does not include the supply air fan. The gross COP should Not account for the supply air fan.

**1.41.19.1.26 Field: Speed <x> Reference Unit Rated Air Flow Rate**

This numeric field defines the volumetric air flow rate, in m<sup>3</sup> per second, across the cooling coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given cooling capacity and COP at the speed, as above.

**1.41.19.1.27 Field: Speed <x> Reference Unit Rated Condenser Air Flow Rate**

This numeric field defines the condenser volumetric air flow rate, in m<sup>3</sup> per second, across the condenser coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data. This field is used to calculate water evaporation rate for an evaporatively-cooled condenser. For an air-cooled condenser, this input is not used.

**1.41.19.1.28 Field: Speed <x> Reference Unit Rated Pad Effectiveness of Evap Pre-cooling**

This numeric field defines the effectiveness of condenser evaporative precooling pad at rated condition. The values of effectiveness are given at individual speed levels, since varied condenser air flow rates impact the effectiveness.

**1.41.19.1.29 Field: Speed <x> Total Cooling Capacity Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the both the indoor wet-bulb and source side entering air temperature, from the Reference Unit. The output of this curve is multiplied by the gross rated total cooling capacity at the speed to give the gross total cooling capacity at specific temperature operating conditions (i.e., at an indoor air wet-bulb temperature or outdoor entering air temperature different from the rating point temperature). It should be noted that the curve is normalized to the cooling capacity at Speed<x> from the Reference Unit data, and have the value of 1.0 at the rating point.

**1.41.19.1.30 Field: Speed <x> Total Cooling Capacity Function of Air Flow Fraction Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow at Speed <x>, from the Reference Unit data). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the design air flow rate, at Speed <x>.

**1.41.19.1.31 Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor air wet-bulb and condenser entering air temperatures. The EIR is the inverse of the COP. The output of this

curve is multiplied by the rated EIR (inverse of rated COP at Speed <x> from the Reference Unit data) to give the EIR at specific temperature operating conditions (i.e., at an indoor air wet-bulb temperature or condenser entering air temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

#### 1.41.19.1.32 Field: Speed <x> Energy Input Ratio Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). The EIR is the inverse of the COP. This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

An example of this statement in an IDF is:

#### 1.41.19.2.1 Cooling Coil Electricity Rate [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

#### 1.41.19.2.2 Cooling Coil Total Cooling Rate [W]

The output variable is the average total cooling load provide by the heat pump which includes the sensible and latent load in Watts over the timestep being reported.

#### 1.41.19.2.3 Cooling Coil Sensible Cooling Rate [W]

The output variable is the average sensible cooling load provide by the heat pump in Watts over the timestep being reported.

#### 1.41.19.2.4 Cooling Coil Source Side Heat Transfer Rate [W]

The output variable is the average heat rejected to the water at the heat pump condenser in Watts over the timestep being reported.

#### 1.41.19.2.5 Cooling Coil Part Load Ratio []

This output variable is the ratio of the part-load capacity to the steady state capacity of the VSAir-toAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the VSAir-toAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

#### 1.41.19.2.6 Cooling Coil Runtime Fraction []

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The runtime fraction, or duty factor, accounts for efficiency losses due to compressor cycling.

#### 1.41.19.2.7 Cooling Coil Air Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate on the load side going through the heat pump over the timestep being reported.

#### 1.41.19.2.8 Cooling Coil Air Inlet Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

#### 1.41.19.2.9 Cooling Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

**1.41.19.2.10 Cooling Coil Air Outlet Temperature [C]**

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

**1.41.19.2.11 Cooling Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

**1.41.19.2.12 Cooling Coil Upper Speed Level []**

The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

**1.41.19.2.13 Cooling Coil Neighboring Speed Levels Ratio []**

The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

**1.41.19.2.14 Cooling Coil Electricity Energy [J]**

The output variable is the electric consumption of the heat pump in Joules over the timestep being reported.

**1.41.19.2.15 Cooling Coil Total Cooling Energy [J]**

The output variable is the total cooling output of the coil in Joules over the timestep being reported.

**1.41.19.2.16 Cooling Coil Sensible Cooling Energy [J]**

The output variable is the total sensible cooling output of the coil in Joules over the timestep being reported

**1.41.19.2.17 Cooling Coil Latent Cooling Energy [J]****1.41.19.2.18 Cooling Coil Latent Cooling Rate [W]**

These output variables are the total latent cooling output of the coil in Joules or Watts over the timestep being reported.

**1.41.19.2.19 Cooling Coil Source Side Heat Transfer Energy [J]**

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

**1.41.19.2.20 Cooling Coil Crankcase Heater Electricity Rate [W]**

The output variable is the average power used for crankcase heater, in Watts over the timestep being reported.

**1.41.19.2.21 Cooling Coil Crankcase Heater Electricity Energy [J]**

The output variable is the total electric energy usage of the coil for crankcase heater, in Joules over the timestep being reported.

**1.41.19.2.22 Cooling Coil Condensate Volume Flow Rate [m<sup>3</sup>/s]**

The output variable is the average water condensate volumetric flow rate from the cooling coil, in m<sup>3</sup>/s over the timestep being reported, if choosing to use CondensateToTank.

**1.41.19.2.23 Cooling Coil Condensate Volume [m3]**

The output variable is the total water condensate volume from the cooling coil, in m<sup>3</sup> over the timestep being reported.

**1.41.19.2.24 Cooling Coil Condenser Inlet Temperature [C]**

The output variable is the average air temperature entering the condenser coil, in °C over the timestep being reported.

**1.41.19.2.25 Cooling Coil Evaporative Condenser Water Volume [m3]**

The output variable is the total water volume consumed for condenser evaporative pre-cooling, in m<sup>3</sup> over the timestep being reported.

**1.41.19.2.26 Cooling Coil Evaporative Condenser Mains Water Volume [m3]**

The output variable is the total water volume for condenser evaporative pre-cooling, obtained from the Mains Water supply, in m<sup>3</sup> over the timestep being reported.

**1.41.19.2.27 Cooling Coil Evaporative Condenser Pump Electricity Rate [W]**

The output variable is the average power consumption rate of the evaporative condenser pump, in Watts over the timestep being reported.

**1.41.19.2.28 Cooling Coil Evaporative Condenser Pump Electricity Energy [J]**

The output variable is the total power consumption of the evaporative condenser pump, in Joules over the timestep being reported.

**1.41.19.2.29 Cooling Coil Basin Heater Electricity Rate [W]**

The output variable is the average power consumption rate by the basin heater, in Watts over the timestep being reported.

**1.41.19.2.30 Cooling Coil Basin Heater Electricity Energy [J]**

The output variable is the total power consumption by the basin heater, in Joules over the timestep being reported.

**1.41.20 CoilPerformance:DX:Cooling**

This coil performance object is used to specify DX coil performance for one mode of operation for a **Coil:Cooling:DX:TwoStageWithHumidityControlMode**. A single **Coil:Cooling:DX:TwoStageWithHumidityControlMode** object will reference one to four **CoilPerformance:DX:Cooling** objects depending on the number of available stages and dehumidification modes as specified in the two stage DX object. For example, a standard 2-stage DX system will use two of these performance objects, one to defined the capacity and performance for stage 1 operation, and a second one for stage 1+2 (both stages active) operation. In nearly all cases, the Rated Air Volume Flow Rate will be the same for all performance objects associated with a given multimode DX coil. If bypass is specified, the Rated Air Volume Flow Rate includes both the bypassed flow and the flow through the active coil.

This DX coil model is identical to **Coil:Cooling:DX:SingleSpeed** with addition of bypass and multi-stage capabilities. This DX cooling coil model and input are quite different from that for the heating and cooling water coils. The simple water coils use an NTU-effectiveness heat exchanger model. The single speed DX coil model uses performance information at rated conditions along with curve fits for

variations in total capacity, energy input ratio and part-load fraction to determine performance at part-load conditions. Sensible/latent capacity splits are determined by the rated sensible heat ratio (SHR) and the apparatus dewpoint/bypass factor (ADP/BF) approach. This approach is analogous to the NTU-effectiveness calculations used for sensible-only heat exchanger calculations, extended to a cooling and dehumidifying coil.

An alternative to ADP/BF method for sensible/latent capacity split is to use SHR modifier curves for temperature and flow fraction. These two optional input fields are used only when a user specified SHR calculation method desired over the (ADP/BF) method. Sensible heat ratio calculated using these two SHR modifier curves override the value calculated by ADP/BF method. See section SHR Calculation Using User Specified SHR Modifier Curves in the EnergyPlus Engineering Document for further details.

The DX cooling coil input requires the gross rated total cooling capacity, the gross rated SHR, the gross rated COP, the rated air volume flow rate, and the fraction of air flow which is bypassed around the coil. The first 4 inputs determine the coil performance at the rating point (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb and air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb). The rated air volume flow rate (less any bypassed fraction) should be between .00004027 m<sup>3</sup>/s and .00006041 m<sup>3</sup>/s per watt of gross rated total cooling capacity (300 to 450 cfm/ton). The rated volumetric air flow to gross total cooling capacity ratio for 100% dedicated outdoor air (DOAS) application DX cooling coils should be between 0.00001677 (m<sup>3</sup>/s)/W (125 cfm/ton) and 0.00003355 (m<sup>3</sup>/s)/W (250 cfm/ton).

This model requires 5 curves as follows:

1. The total cooling capacity modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 C indoor wet-bulb temperature and 35 C outdoor dry-bulb temperature. The output of this curve is multiplied by the gross rated total cooling capacity to give the gross total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
2. The total cooling capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the gross rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity at the specific temperature and air flow conditions at which the coil is operating.
3. The energy input ratio (EIR) modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 C indoor wet-bulb temperature and 35 C outdoor dry-bulb temperature. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
4. The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.

5. The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible cooling load / steady-state sensible cooling capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The curve should be normalized to a value of 1.0 when the part-load ratio equals 1.0 (i.e., the compressor(s) run continuously for the simulation timestep).

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (see Performance Curves in this document).

The next four input fields are optional and relate to the degradation of latent cooling capacity when the supply air fan operates continuously while the cooling coil/compressor cycle on and off to meet the cooling load. The fan operating mode is either considered to be constant (e.g. **CoilSystem:Cooling:DX**) or can be scheduled in the parent object (e.g. **AirLoopHVAC:UnitaryHeatCool**). When scheduled, the schedule value must be greater than 0 to calculate degradation of latent cooling capacity. At times when the parent object's supply air fan operating mode schedule is 0, latent degradation will be ignored. When used, these next four input fields must all have positive values in order to model latent capacity degradation.

The next input specifies the outdoor air node used to define the conditions of the air entering the outdoor condenser. If this field is not blank, the node name specified must be listed in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an **OutdoorAir:NodeList** object where the outdoor temperature entering the condenser is taken directly from the weather data. This field may also be left blank, if this is the case then the outdoor temperature entering the condenser is taken directly from the weather data.

The next input describes the type of outdoor condenser coil used with the DX cooling coil (Air Cooled or Evap Cooled). The following three inputs are required when modeling an evaporative-cooled condenser: evaporative condenser effectiveness, evaporative condenser air volume flow rate, and the power consumed by the evaporative condenser pump. See section DX Cooling Coil Model in the EnergyPlus Engineering Document for further details regarding this model.

### 1.41.20.1 Inputs

#### 1.41.20.1.1 Field: Name

This alpha field is a unique user-assigned name for an instance of DX cooling coil performance. Any reference to this DX coil performance object by another object will use this name.

#### 1.41.20.1.2 Field: Gross Rated Total Cooling Capacity

The total, full load gross cooling capacity (sensible plus latent) in watts of the DX coil unit at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb[4], and a cooling coil air flow rate defined by field rated air flow rate below). Capacity should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

#### 1.41.20.1.3 Field: Gross Rated Sensible Heat Ratio

The sensible heat ratio (SHR = gross sensible capacity divided by gross total cooling capacity) of the DX cooling coil at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air flow rate below). Both the sensible and total cooling capacities used to define the Rated SHR should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

#### 1.41.20.1.4 Field: Gross Rated Cooling COP

The coefficient of performance is the ratio of the gross total cooling capacity in watts to electrical power input in watts) of the DX cooling coil unit at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/ 23.9 °C wetbulb, and a cooling coil air flow rate defined by field rated air flow rate below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. If this input field is left blank, the default value is 3.0.

#### 1.41.20.1.5 Field: Rated Air Flow Rate

The air volume flow rate, in m<sup>3</sup> per second, across the DX cooling coil at rated conditions. The gross rated total cooling capacity, gross rated SHR and gross rated COP should be performance information for the unit with air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb, air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb, and the rated air volume flow rate defined here.

#### 1.41.20.1.6 Field: Fraction of Air Flow Bypassed Around Coil

This numeric field specifies the fraction of the Rated Air Volume Flow Rate which bypasses the active cooling coil for this performance mode. The remaining portion of the flow should be between 0.00004027 m<sup>3</sup>/s and .00006041 m<sup>3</sup>/s per watt of gross rated total cooling capacity (300 to 450 cfm/ton) for this performance mode. For DOAS applications the remaining portion of rated air volume flow rate should be between 0.00001677 m<sup>3</sup>/s and 0.00003355 m<sup>3</sup>/s per watt of gross rated total cooling capacity (125 to 250 cfm/ton). This is used to model face-split coils on multi-stage units or bypass dampers. If total flow rate varies during simulation, the same fraction is bypassed. This input may range from 0.0 to <1.0. The default is 0.0. For a multi-stage face-split coil in which stage 1 is 60% of total capacity, this field would be set to 0.4 for the Stage 1 performance and set to 0.0 for the Stage 1+2 performance. For a DX system which activates a bypass damper for improved dehumidification, this field would be set to 0.0 for normal mode performance and set to something greater than zero for enhanced dehumidification mode performance.

#### 1.41.20.1.7 Field: Total Cooling Capacity Function of Temperature Curve Name

The name of a **biquadratic** performance curve (ref: Performance Curves) that parameterizes the variation of the total gross cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the gross rated total cooling capacity to give the gross total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

#### 1.41.20.1.8 Field: Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a **quadratic** or **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the gross rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

#### 1.41.20.1.9 Field: Energy Input Ratio Function of Temperature Curve Name

The name of a **biquadratic** performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering

the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point.

#### 1.41.20.1.10 Field: Energy Input Ratio Function of Flow Fraction Curve Name

The name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

#### 1.41.20.1.11 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 \leq \text{PLR} < 1$ ), the following rules apply:

$\text{PLF} \geq 0.7$  and  $\text{PLF} \geq \text{PLR}$

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

---

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

---

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

---

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

---

#### 1.41.20.1.12 Field: Nominal Time for Condensate Removal to Begin

The nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]), and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation.

#### 1.41.20.1.13 Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

Ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]); and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation.

#### 1.41.20.1.14 Field: Maximum Cycling Rate

The maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]); and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation.

#### 1.41.20.1.15 Field: Latent Capacity Time Constant

Time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., **CoilSystem:Cooling:DX**) or can be scheduled in other objects [e.g., **AirloopHVAC:UnitaryHeatCool**]), and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation.

#### 1.41.20.1.16 Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

#### 1.41.20.1.17 Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

#### 1.41.20.1.18 Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{condinlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o}) \quad (1.162)$$

where

$T_{condinlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

#### 1.41.20.1.19 Field: Evaporative Condenser Air Flow Rate

The air volume flow rate, in  $\text{m}^3$  per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to  $0.000144 \text{ m}^3/\text{s}$  per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

#### 1.41.20.1.20 Field: Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to  $0.004266 \text{ W}$  per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = AirCooled.

#### 1.41.20.1.21 Field: Sensible Heat Ratio Function of Temperature Curve Name

The name of a biquadratic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of DX cooling coil entering air wet-bulb and dry-bulb temperatures. The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of flow fraction) to give the SHR at the specific coil entering air temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 at the rated condition. This input field is optional.

#### 1.41.20.1.22 Field: Sensible Heat Ratio Function of Flow Fraction Curve Name

The name of a quadratic or cubic normalized curve (Ref: Performance Curves) that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of temperature) to give the SHR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This input field is optional.

Following is an example input for a **Coil:Cooling:DX:TwoStageWithHumidityControlMode** with 2 capacity stages and one enhanced dehumidification mode so it requires four CoilPerformance:DX:Cooling objects.

### 1.41.20.2 Outputs

The CoilPerformance:DX:Cooling object does not have specific output variables. To request reports, use the parent object Coil:Cooling:DX:TwoStageWithHumidityControlMode output variable options (ref. DX

Cooling Coil Outputs). When requesting specific output variables by name, use the name of the parent object as the Key Value for Output:Variable reporting objects (ref. Output:Variable object). The name of the CoilPerformance:DX:Cooling object cannot be used as a Key Value in the Output:Variable object.

### 1.41.21 Coil:Heating:DX:SingleSpeed

The single speed heating DX coil model uses performance information at rated conditions along with curve fits for variations in total capacity, energy input ratio and part load fraction to determine performance at part-load conditions. The impacts of various defrost strategies (reverse cycle, resistive, timed or on-demand) are modeled based on a combination of user inputs and empirical models taken from the air-to-air heat pump algorithms in DOE-2.1E.

The single speed heating DX coil input requires an availability schedule, the gross rated heating capacity, the gross rated COP and the rated air volume flow rate. The latter 3 inputs determine the coil performance at the rating point (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, coil entering air dry-bulb temperature of 21.11 C, coil entering air wet-bulb temperature of 15.55 C). The rated air volume flow rate should be between .00004027 m<sup>3</sup>/s and .00006041 m<sup>3</sup>/s per watt of gross rated heating capacity.

Up to 6 curves are required depending on the defrost strategy selected.

- 1) The heating capacity modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The curve is normalized to 1 at 8.33 outdoor dry-bulb temperature and if a biquadratic curve is used also at 21.11 C indoor dry-bulb temperature. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the gross rated heating capacity to give the gross heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 2) The heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the gross rated heating capacity and the heating capacity modifier curve (function of temperature) to give the gross heating capacity at the specific temperature and air flow conditions at which the coil is operating.
- 3) The energy input ratio (EIR) modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The curve is normalized to 1 at 8.33 outdoor dry-bulb temperature and if a biquadratic curve is used also at 21.11 C indoor dry-bulb temperature. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 4) The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the

rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.

- 5) The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible heating load / steady-state heating capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the effective EIR for a given simulation timestep. The part load fraction correlation accounts for efficiency losses due to compressor cycling.
- 6) The defrost energy input ratio (EIR) modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: the heating coil entering air wet-bulb temperature (variable x) and the outdoor air dry-bulb temperature (variable y). The output of this curve is multiplied by the heating coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the coil is operating. This curve is only required when a reverse-cycle defrost strategy is specified.

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (ref. Performance Curves).

The next input item for the coil is the supply air fan operation mode. Either the supply air fan runs continuously while the DX coil cycles on/off, or the fan and coil cycle on/off together. The next two inputs define the minimum outdoor dry-bulb temperature that the heat pump compressor will operate and the maximum outdoor dry-bulb temperature for defrost operation. Crankcase heater capacity and cutout temperature are entered in the following two inputs. The final four inputs cover the type of defrost strategy (reverse-cycle or resistive), defrost control (timed or on-demand), the fractional defrost time period (timed defrost control only), and the resistive defrost heater capacity if a resistive defrost strategy is selected.

### 1.41.21.1 Inputs

#### 1.41.21.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a DX heating coil. Any reference to this DX heating coil by another object will use this name.

#### 1.41.21.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the DX heating coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.41.21.1.3 Field: Gross Rated Heating Capacity

This numeric field defines the total, full load gross heating capacity in watts of the DX coil unit at rated conditions (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field rated air flow volume below). The value entered here must be greater than 0. Capacity should not account for supply air fan heat. The gross rated heating capacity should be within 20% of the gross rated total cooling capacity, otherwise a warning message is issued. The gross heating capacity should NOT include the effect of supply air fan heat.

#### 1.41.21.1.4 Field: Gross Rated Heating COP

This numeric field defines the coefficient of performance ( $\text{COP} = \text{the gross heating capacity in watts divided by electrical power input in watts}$ ) of the DX heating coil unit at rated conditions (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, coil entering air dry-bulb temperature of 21.11 C, coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field rated air flow volume rate below). The value entered here must be greater than 0. The input power includes power for the compressor(s) and outdoor fan(s) but does not include the power consumption of the indoor supply air fan. The gross COP should NOT account for the supply air fan.

#### 1.41.21.1.5 Field: Rated Air Flow Rate

This numeric field defines the volume air flow rate, in  $\text{m}^3$  per second, across the DX heating coil at rated conditions. The value entered here must be greater than 0. The rated air volume flow rate should be between  $0.00004027 \text{ m}^3/\text{s}$  and  $0.00006041 \text{ m}^3/\text{s}$  per watt of the gross rated heating capacity. The gross rated heating capacity and gross rated COP should be performance information for the unit with outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and the rated air volume flow rate defined here.

#### 1.41.21.1.6 Field: Rated Evaporator Fan Power Per Volume Flow Rate

This field is the electric power for the evaporator (heating coil) fan per air volume flow rate through the coil at the rated conditions in  $\text{W}/(\text{m}^3/\text{s})$ . The default value is  $773.3 \text{ W}/(\text{m}^3/\text{s})$  ( $365 \text{ W}/1000 \text{ cfm}$ ) if this field is left blank. If a value is entered, it must be  $\geq 0.0$  and  $\leq 1250 \text{ W}/(\text{m}^3/\text{s})$ . This value is only used to calculate High Temperature Heating Standard (Net) Rating Capacity, Low Temperature Heating Standard (Net) Rating Capacity and Heating Seasonal Performance Factor (HSPF) which will be outputs in the EnergyPlus eio file (ref. EnergyPlus Engineering Reference, Single Speed DX Heating Coil, Standard Ratings). This value is not used for modeling the evaporator (heating coil) fan during simulations; instead, it is used for calculating the above standard ratings to assist the user in verifying their inputs for modeling this type of equipment.

#### 1.41.21.1.7 Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

#### 1.41.21.1.8 Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

#### 1.41.21.1.9 Field: Heating Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the gross rated heating capacity to give the gross total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

**1.41.21.1.10 Field: Heating Capacity Function of Flow Fraction Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the gross rated heating capacity and the heating capacity modifier curve (function of temperature) to give the gross heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

**1.41.21.1.11 Field: Energy Input Ratio Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

**1.41.21.1.12 Field: Energy Input Ratio Function of Flow Fraction Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

**1.41.21.1.13 Field: Part Load Fraction Correlation Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 \leq \text{PLR} < 1$ ), the following rules apply:

$$\text{PLF} \geq 0.7 \text{ and } \text{PLF} \geq \text{PLR}$$

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

---

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

---

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

---

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

---

**1.41.21.1.14 Field: Defrost Energy Input Ratio Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the wet-bulb temperature of the air entering the indoor coil (variable x) and the outdoor air dry-bulb temperature (variable y). The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse-cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

**1.41.21.1.15 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation****1.41.21.1.16 Field: Outdoor Dry-Bulb Temperature to Turn On Compressor**

This numeric field defines the outdoor air dry-bulb temperature when the compressor is automatically turned back on following an automatic shut off because of low outdoor temperature. This field is only used for the calculation heating seasonal performance factor (HSPF) of heating coil. If this field is not provided, outdoor bin temperature is always considered to be greater than this temperature and Minimum Outdoor dry-bulb Temperature for Compressor Operation field described above.

**1.41.21.1.17 Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

**1.41.21.1.18 Field: Crankcase Heater Capacity**

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation (described below), the crankcase heater is enabled during the time that the compressor is not running. If this heating coil is used as part of an air-to-air heat pump (Ref. [AirLoopHVAC:UnitaryHeatPump:AirToAir](#) or [ZoneHVAC:PackagedTerminalHeatPump](#)), the crankcase heater defined for this DX heating coil is enabled during the time that the compressor is not running for either heating or cooling (and the crankcase heater power defined in the DX cooling coil object is disregarded in this case). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

**1.41.21.1.19 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 C. If this input field is left blank, the default value is 10 C.

**1.41.21.1.20 Field: Defrost Strategy**

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a

resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle.

#### 1.41.21.1.21 Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field Defrost Time Period Fraction described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field Maximum Outdoor Dry-bulb Temperature for Defrost Operation described above. If this input field is left blank, the default defrost control is timed.

#### 1.41.21.1.22 Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to timed defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

#### 1.41.21.1.23 Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is resistive (see input field Defrost Strategy above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

#### 1.41.21.1.24 Field: Region Number

This optional numeric field defines the region number which is used to calculate HSPF of heating coil. The value for this input field must be between 1 and 6. If this input field is left blank, the default value is 4.

#### 1.41.21.1.25 Field: Evaporator Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor evaporator. If this field is left blank, the outdoor air temperature entering the evaporator is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data.

#### 1.41.21.1.26 Field: Zone Name for Evaporator Placement

This input field is name of a conditioned or unconditioned zone where the secondary coil (evaporator) of a heat pump is installed. This is an optional input field specified only when user desires to extract heat from the zone via secondary coil. Heat extracted is modeled as internal gain. If the primary DX system is a heat pump, then the zone name should be the same as the zone name specified for placing the secondary cooling DX coil.

**1.41.21.1.27 Field: Secondary Coil Air Flow Rate**

This input value is the secondary coil (evaporator) air flow rate when the heat pump is working in heating mode or the secondary coil (condenser) air flow rate when the heat pump is working in cooling mode. This input field is auto-sizable.

**1.41.21.1.28 Field: Secondary Coil Fan Flow Scaling Factor**

This input field is scaling factor for autosizing the secondary DX coil fan flow rate. The secondary air flow rate is determined by multiplying the primary DX coil rated air flow rate by the fan flow scaling factor. Default value is 1.25. If the secondary coil fan flow rate is not autosized, then the secondary coil fan flow scaling factor is set to 1.0.

**1.41.21.1.29 Field: Nominal Sensible Heat Ratio of Secondary Coil**

This input value is the nominal sensible heat ratio used to split the heat extracted by a secondary DX coil (evaporator) of a heat pump into sensible and latent components. This is an optional input field. If this input field is left blank, then pure sensible internal heat gain is assumed, i.e., sensible heat ratio of 1.0.

**1.41.21.1.30 Field: Sensible Heat Ratio Modifier Function of Temperature Curve Name**

This input field is name of sensible heat ratio modifier biquadratic curve. The value of this curve modifies the nominal sensible heat ratio for current time step depending on the secondary zone air node wet-bulb temperature and the heating DX coil entering air dry-bulb temperature. This is an optional input field. If this input field is left blank, then the nominal sensible heat ratio modifier curve value for temperature is set to 1.0.

**1.41.21.1.31 Field: Sensible Heat Ratio Modifier Function of Flow Fraction Curve Name**

This input field is name of sensible heat ratio modifier curve as function of secondary air flow fraction. The value of this curve modifies the nominal sensible heat ratio for current time step depending on the secondary coil air flow fraction. This is an optional input field. If this input field is left blank, then the sensible heat ratio modifier curve value for flow fraction is set to 1.0.

Following is an example input for the object.

### 1.41.21.2 Outputs

- HVAC,Average,Heating Coil Heating Rate [W]
- HVAC,Sum,Heating Coil Heating Energy [J]
- HVAC,Average,Heating Coil Electricity Rate [W]
- HVAC,Sum,Heating Coil Electricity Energy [J]
- HVAC,Average,Heating Coil Defrost Electricity Rate [W]
- HVAC,Sum,Heating Coil Defrost Electricity Energy [J]
- HVAC,Average,Heating Coil Crankcase Heater Electricity Rate [W]
- HVAC,Sum,Heating Coil Crankcase Heater Electricity Energy [J]
- HVAC,Average,Heating Coil Runtime Fraction []

#### 1.41.21.2.1 Heating Coil Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.21.2.2 Heating Coil Heating Energy [J]

This is the total heating output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (ref. Output:Meter objects).

#### 1.41.21.2.3 Heating Coil Electricity Rate [W]

This output is the electricity consumption rate of the DX coil compressor and outdoor fan(s) in Watts. This rate is applicable when the unit is providing heating to the conditioned zone(s), and excludes periods when the unit is in reverse-cycle defrost mode.

#### 1.41.21.2.4 Heating Coil Electricity Energy [J]

This is the electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This consumption is applicable when the unit is providing heating to the conditioned zone(s), and excludes periods when the unit is in reverse-cycle defrost mode. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

#### 1.41.21.2.5 Heating Coil Defrost Electricity Rate [W]

This is the electricity consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle or resistive).

#### 1.41.21.2.6 Heating Coil Defrost Electricity Energy [J]

This is the electricity consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive).

#### 1.41.21.2.7 Heating Coil Crankcase Heater Electricity Rate [W]

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported.

#### 1.41.21.2.8 Heating Coil Crankcase Heater Electricity Energy [J]

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Miscellaneous, Group Key = System (ref. Output:Meter objects).

#### 1.41.21.2.9 Heating Coil Runtime Fraction []

This is the runtime fraction of the DX heating coil compressor and outdoor fan(s) for the timestep being reported.

### 1.41.22 Coil:Heating:DX:MultiSpeed

This component models a DX heating unit with multiple discrete levels of heating capacity. Currently, this heating coil can only be referenced by a `AirLoopHVAC:UnitarySystem` or `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` compound object. The multispeed DX heating coil can have from two to four operating speeds. When the coil operates at Speed 1 (the lowest speed), its performance is very similar to the `Coil:Heating:DX:SingleSpeed` object where the impacts of part-load ratio can be included. When the coil operates at higher speeds (above Speed 1), the linear approximation methodology is applied. The coil outputs at two consecutive speeds are linearly interpolated to meet the required heating capacity during an HVAC system timestep. When the coil performs above the lowest speed, the user can choose if they want to include part-load ratio impacts at the higher speeds.

The multispeed unit is described by specifying the performance at different operating speeds. Each speed has its own set of input specifications: full load capacity, COP and air flow rate at rated conditions, along with modifier curves to determine performance when actual operating conditions are different from the rated conditions.

The coil operates to meet the sensible capacity being requested. When this requested capacity is above the sensible capacity of the highest operating speed, the coil runs continuously at the highest speed. When the requested capacity is between the sensible capacities of two consecutive speeds, the unit will operate a portion of the time at each speed to meet the request. When the requested capacity is less than the low speed (Speed 1) capacity, the unit will cycle on/off as needed.

The next input defines the minimum outdoor dry-bulb temperature where the compressor will operate. The followed two inputs are related to crankcase heater operation: capacity and maximum outdoor dry-bulb temperature for crankcase heater operation. The next six inputs cover defrost operation: defrost EIR modifier curve, the maximum outdoor dry-bulb temperature for defrost operation, the type of defrost strategy (reverse-cycle or resistive), defrost control (timed or on-demand), the fractional defrost time period (timed defrost control only), and the resistive defrost heater capacity if a resistive defrost strategy is selected. The activation of defrost is dependent on outdoor conditions. The capacity reduction and energy use modification are independent of speed. The defrost EIR modifier is described below:

The defrost energy input ratio (EIR) modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: the heating coil entering air wet-bulb temperature (variable x) and the outdoor air dry-bulb temperature (variable y). The output of this curve is multiplied by the heating coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost

power at the specific temperatures at which the coil is operating. This curve is only required when a reverse-cycle defrost strategy is specified.

The next input allows the user to choose whether to apply the part load fraction correlation to speeds greater than 1 or not. The following input is the type of fuel.

Then the number of speed for heating is entered. The rest of inputs are speed dependent. Each set of data consists of gross rated heating capacity, gross rated COP, and the rated air volume flow rate. These three inputs determine the coil performance at the rating point (outdoor air dry-bulb temperature of 8.33 °C, outdoor air wet-bulb temperature of 6.11 °C, coil entering air dry-bulb temperature of 21.11 °C, coil entering air wet-bulb temperature of 15.55 °C). The rated air volume flow rate should be between .00004027 m<sup>3</sup>/s and .00006041 m<sup>3</sup>/s per watt of gross rated heating capacity. The rated waste heat fraction is needed to calculate how much waste heat is available at the rated conditions. In addition, up to 6 modifier curves are required per speed.

- 1) The heating capacity modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The curve is normalized to 1 at 8.33 outdoor dry-bulb temperature and if a biquadratic curve is used also at 21.11 C indoor dry-bulb temperature. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the gross rated heating capacity to give the gross total heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 2) The heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the gross rated heating capacity and the heating capacity modifier curve (function of temperature) to give the gross heating capacity at the specific temperature and air flow conditions at which the coil is operating.
- 3) The energy input ratio (EIR) modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The curve is normalized to 1 at 8.33 outdoor dry-bulb temperature and if a biquadratic curve is used also at 21.11 C indoor dry-bulb temperature. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 4) The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.

- 5) The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible heating load / steady-state heating capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the effective EIR for a given simulation timestep. The part load fraction correlation accounts for efficiency losses due to compressor cycling.
- 6) The waste heat modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: outdoor air dry-bulb temperature and the heating coil entering air dry-bulb temperature. The output of this curve is multiplied by the heating input energy, the waste heat fraction of heat input to give the recoverable waste heat.

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (ref. Performance Curves).

### 1.41.22.1 Inputs

#### 1.41.22.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a multispeed DX heating coil. Any reference to this DX heating coil by another object will use this name. The only allowed parent is **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed**.

#### 1.41.22.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the multispeed DX heating coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.41.22.1.3 Field: Air Inlet Node name

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

#### 1.41.22.1.4 Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

#### 1.41.22.1.5 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the heating coil compressor turns off. If this input field is left blank, the default value is -8 °C.

#### 1.41.22.1.6 Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

**1.41.22.1.7 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C. If this input field is left blank, the default value is 10 °C.

**1.41.22.1.8 Field: Defrost Energy Input Ratio Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the wet-bulb temperature of the air entering the indoor coil (variable x) and the outdoor air dry-bulb temperature (variable y). The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse-cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

**1.41.22.1.9 Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 °C and less than or equal to 7.22 °C. If this input field is left blank, the default value is 5 °C.

**1.41.22.1.10 Field: Defrost Strategy**

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle.

**1.41.22.1.11 Field: Defrost Control**

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field Defrost Time Period Fraction described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field Maximum Outdoor Dry-bulb Temperature for Defrost Operation described above. If this input field is left blank, the default defrost control is timed.

**1.41.22.1.12 Field: Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to timed defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

**1.41.22.1.13 Field: Resistive Defrost Heater Capacity**

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is resistive (see input field Defrost Strategy above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

**1.41.22.1.14 Field: Apply Part Load Fraction to Speeds Greater than 1**

This field determines whether part-load impacts on coil energy use are applied when the coil is operating at speeds greater than speed 1. The allowed choices are Yes or No, with the default being No if this field is left blank. Other input fields in this object allow the user to specify a part-load fraction correlation for each speed to account for compressor start up losses (cycle on/off). For the case of a single multi-speed compressor, the part load losses may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify **No** for this input field to neglect part-load impacts on energy use at higher operating speeds. If part-load impacts on coil energy use are thought to be significant (e.g., intertwined cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify **Yes** and the part-load fraction correlations specified for speeds 2 through 4 will be applied as appropriate. The selection for this input field does not affect part-load impacts when the compressor cycles between speed 1 and off (i.e., the part-load fraction correlation for speed 1 is always applied).

**1.41.22.1.15 Field: Fuel Type**

This alpha field determines the type of fuel that the chiller uses. This field has seven choices: Electricity, NaturalGas, Propane, Coal, Diesel, Gasoline, FuelOilNo1, FuelOilNo2, OtherFuel1 and OtherFuel2. This is a required field with no default.

**1.41.22.1.16 Field: Number of Speeds**

This field specifies the number of sets of data being entered for rated specifications, performance curves, and waste heat specifications for each cooling speed. The rated specifications consist of gross rated capacity, gross rated COP, and rated air flow rate. The performance curves consist of a total capacity modifier curve as a function of temperature, total capacity modifier curve as a function of flow fraction, energy input ratio modifier curve as a function of temperature, energy input ratio modifier curve as a function of flow fraction, and part load fraction correlation as a function of part load ratio. The waste heat specifications include the fraction of energy input to the heating coil at the fully loaded and rated conditions, and a temperature modifier. The minimum number of speeds for heating is 2 and the maximum number is 4. The number of speeds should be the same as the number of speeds for heating defined in its parent object (**AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed**). The first set of performance inputs is for Speed 1 and should be for low speed, and the last set of performance inputs should be for high speed. For example, if only three heating speeds are defined, the first set should be for low speed (Speed 1), the second set should be for medium speed (Speed 2), and the third set should be for high speed (Speed 3). In this example, any performance inputs for Speed 4 would be neglected (since this input field specifies that the coil only has three heating speeds).

**1.41.22.1.17 Field Group: Rated Specification, Performance Curves, and Waste Heat Data**

The performance for each heating speed must be specified as shown below. All inputs for Speed 1 are required first, followed by the inputs for Speed 2, Speed 3 and Speed 4.

**1.41.22.1.18 Field: Speed <x> Gross Rated Heating Capacity**

This numeric field defines the total, full load gross heating capacity in watts of the DX coil unit at rated conditions for Speed <x> operation (outdoor air dry-bulb temperature of 8.33 °C, outdoor air wet-bulb temperature of 6.11 °C, heating coil entering air dry-bulb temperature of 21.11 °C, heating coil entering air wet-bulb temperature of 15.55 °C, and a heating coil air flow rate defined by field Rated Air Flow Rate, Speed <x> below). The value entered here must be greater than 0. The gross heating capacity should not account for the effect of supply air fan heat.

**1.41.22.1.19 Field: Speed <x> Gross Rated Heating COP**

This numeric field defines the coefficient of performance (COP = gross heating capacity in watts divided by electrical power input in watts) of the DX heating coil unit at rated conditions for Speed <x> operation (outdoor air dry-bulb temperature of 8.33 °C, outdoor air wet-bulb temperature of 6.11 °C, coil entering air dry-bulb temperature of 21.11 °C, coil entering air wet-bulb temperature of 15.55 °C, and a heating coil air flow rate defined by field Speed <x> Rated Air Flow Rate below). The value entered here must be greater than 0. The input power includes power for the compressor(s) and outdoor fan(s) but does not include the power consumption of the indoor supply air fan. The gross heating capacity is the value entered above in the field Gross Rated Heating Capacity . The gross COP should NOT account for the supply air fan.

**1.41.22.1.20 Field: Speed <x> Rated Air Flow Rate**

This numeric field defines the volume air flow rate, in m<sup>3</sup> per second, across the DX heating coil at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The rated air volume flow rate should be between 0.00004027 m<sup>3</sup>/s and 0.00006041 m<sup>3</sup>/s per watt of gross rated heating capacity. The gross rated heating capacity and gross rated COP should be performance information for the unit with outdoor air dry-bulb temperature of 8.33 °C, outdoor air wet-bulb temperature of 6.11 °C, heating coil entering air dry-bulb temperature of 21.11 °C, heating coil entering air wet-bulb temperature of 15.55 °C, and the rated air volume flow rate defined here.

**1.41.22.1.21 Field: Speed <x> Heating Capacity Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the gross rated heating capacity to give the gross total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

**1.41.22.1.22 Field: Speed <x> Heating Capacity Function of Flow Fraction Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the gross rated heating capacity and the gross heating capacity modifier curve (function of temperature) to give the gross heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

#### 1.41.22.1.23 Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

#### 1.41.22.1.24 Field: Speed <x> Energy Input Ratio Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

#### 1.41.22.1.25 Field: Speed <x> Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 \leq \text{PLR} < 1$ ), the following rules apply:

---

$$\text{PLF} > = 0.7 \quad \text{and} \quad \text{PLF} > = \text{PLR}$$

---

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional DX heating coil (Speed <x>) would be:

---

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

---

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

---

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

---

#### 1.41.22.1.26 Field: Speed <x> Rated Waste Heat Fraction of Power Input

The fraction of heat input to heating that is available as recoverable waste heat at full load and rated conditions for Speed <x> operation.

**1.41.22.1.27 Field: Speed <x> Waste Heat Function of Temperature Curve Name**

The name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of outdoor dry-bulb temperature and the entering coil dry-bulb temperature for Speed <x>. The output of this curve is multiplied by the rated recoverable waste heat at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point. When the fuel type is electricity, the field is either left blank or ignored by the program. When the fuel type is not electricity and the parent object **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** does not require waste heat calculations, this field is ignored. If the field is blank, a warning will be issued and simulation continues. When the fuel type is not electricity and the parent object **AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed** requires waste heat calculations, if this field is left blank, the program assumes a constant value of 1 to make simulation continue and a warning will be issued.

**1.41.22.1.28 Field: Zone Name for Evaporator Placement**

This input field is name of a conditioned or unconditioned zone where the secondary coil (evaporator) of a heat pump is installed. This is an optional input field specified only when user desires to extract heat from the zone via secondary coil. Heat extracted is modeled as internal gain. If the primary DX system is a heat pump, then the zone name should be the same as the zone name specified for placing the secondary cooling DX coil.

**1.41.22.1.29 Field: Speed <x> Secondary Coil Air Flow Rate**

This input value is the secondary coil (evaporator) air flow rate when the heat pump is working in heating mode or the secondary coil (condenser) air flow rate when the heat pump is working in cooling mode. This input field is auto-sizable.

**1.41.22.1.30 Field: Speed <x> Secondary Coil Fan Flow Scaling Factor**

This input field is scaling factor for autosizing the secondary DX coil fan flow rate. The secondary air flow rate is determined by multiplying the primary DX coil rated air flow rate by the fan flow scaling factor. Default value is 1.25. If the secondary coil fan flow rate is not autosized, then the secondary coil fan flow scaling factor is set to 1.0.

**1.41.22.1.31 Field: Speed <x> Nominal Sensible Heat Ratio of Secondary Coil**

This input value is the nominal sensible heat ratio used to split the heat extracted by a secondary DX coil (evaporator) of a heat pump into sensible and latent components. This is an optional input field. If this input field is left blank, then pure sensible internal heat gain is assumed, i.e., sensible heat ratio of 1.0.

**1.41.22.1.32 Field: Speed <x> Sensible Heat Ratio Modifier Function of Temperature Curve Name**

This input field is name of sensible heat ratio modifier biquadratic curve. The value of this curve modifies the nominal sensible heat ratio for current time step depending on the secondary zone air node wet-bulb temperature and the heating DX coil entering air dry-bulb temperature. This is an optional input field. If this input field is left blank, then the nominal sensible heat ratio modifier curve value for temperature is set to 1.0.

**1.41.22.1.33 Field: Speed <x> Sensible Heat Ratio Modifier Function of Flow Fraction Curve Name**

This input field is name of sensible heat ratio modifier curve as function of secondary air flow fraction. The value of this curve modifies the nominal sensible heat ratio for current time step depending on the secondary coil air flow fraction. This is an optional input field. If this input field is left blank, then the sensible heat ratio modifier curve value for flow fraction is set to 1.0.

Following is an example input for a multi-speed heating DX coil.

```

- HVAC,Sum,Heating Coil Defrost Gas Energy [J]
- HVAC,Average,Heating Coil Crankcase Heater Electricity Rate [W]
- HVAC,Sum,Heating Coil Crankcase Heater Electricity Energy [J]
- HVAC,Average,Heating Coil Runtime Fraction []

If Fuel Type is not Electricity:

- HVAC,Average, Heating Coil <Fuel Type> Rate [W]
- HVAC,Sum, Heating Coil <Fuel Type> Energy [J]

**1.41.22.2.1 Heating Coil Heating Rate [W]**

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.22.2.2 Heating Coil Heating Energy [J]**

This is the total heating output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoil, Group Key = System (ref. Output:Meter objects).

**1.41.22.2.3 Heating Coil Electricity Rate [W]**

This output variable is the input fuel type power for the heating coil in the unit of Watts, averaged during the report period. If Fuel Type is not Electricity, the value is zero.

**1.41.22.2.4 Cooling Coil Electricity Energy [J]**

This output variable is the input fuel type consumption for the multispeed heating coil in the unit of Joules, summed during the report period. This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects). If Fuel Type is not Electricity, the value is zero.

**1.41.22.2.5 Heating Coil Defrost Electricity Rate [W]**

This is the electricity consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle or resistive). The variable is available when the defrost mode is resistive or the fuel type is electricity.

**1.41.22.2.6 Heating Coil Defrost Electricity Energy [J]**

This is the electricity consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive). The variable is available when the defrost mode is resistive or the fuel type is electricity.

**1.41.22.2.7 Heating Coil Defrost <Fuel Type> Rate [W]**

This is the fuel consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle). The variable is available when the defrost mode is reverse-cycle and the fuel type is non-electricity.

**1.41.22.2.8 Heating Coil Defrost <Fuel Type> Energy [J]**

This is the fuel consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle). The variable is available when the defrost mode is reverse-cycle and the fuel type is non-electricity.

**1.41.22.2.9 Heating Coil Crankcase Heater Electricity Rate [W]**

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. When a companion cooling coil exits, the crankcase heater power of the companion cool coil is also reported in this variable.

**1.41.22.2.10 Heating Coil Crankcase Heater Electricity Energy [J]**

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects). When a companion cooling coil exits, the crankcase heater power of the companion cool coil is also reported in this variable.

**1.41.22.2.11 Heating Coil Runtime Fraction []**

This is the runtime fraction of the DX heating coil compressor and outdoor fan(s) for the timestep being reported. When the heating speed is above 1, this output is the run time fraction for the higher speed.

**1.41.22.2.12 Heating Coil <Fuel Type> Rate [W]**

This output variable is the input fuel type power for the heating coil in the unit of Watts, averaged during the report period. The electric power is excluded. If Fuel Type is Electricity, this output variable is not reported.

**1.41.22.2.13 Cooling Coil <Fuel Type> Energy [J]**

This output variable is the input fuel type consumption for the multispeed heating coil in the unit of Joules, summed during the report period. The electric consumption is excluded. This output is also added to a meter with Resource Type = <Fuel Type>, End Use Key = Heating, Group Key = System (ref. Output:Meter objects). If Fuel Type is Electricity, this output variable is not reported.

Note: The Fuel Type defined in the above two output variables depends on the input in the fuel type field. In addition to Electricity, Valid fuel types are NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, OtherFuel1 and OtherFuel2.

### 1.41.23 Coil:Heating:DX:VariableSpeed

The Variable-Speed Air-to-Air Heating DX Coil is a collection of performance curves that represent the heating coil at various speed levels. The performance curves should be generated from the heat pump Reference Unit catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The number of speed levels can range from 1 to 10. The heating coil has two air side node connections. The user needs to specify a nominal speed level, at which the gross rated capacity and rated volumetric air flow rate are sized. The gross rated capacity and rated volumetric flow rate represent the real situation in the air loop, and are used to determine the flow rates at various speed levels in the parent objects, e.g. `AirLoopHVAC:UnitarySystem` or `AirLoopHVAC:UnitaryHeatPump:AirToAir`, `ZoneHVAC:PackagedTerminalHeatPump`, etc. It shall be mentioned that the performance correction curves, i.e. the temperature and flow fraction correction curves, should be normalized to the capacity and flow rate at each individual speed and at the rated operating conditions, similar to the performance curves used in the single-speed DX coil. On the other hand, the performance values at individual speed levels, e.g. capacities, COPs and flow rates, should be given regarding a specific unit from the Reference Unit catalog data. In the following content, the statement started with Reference Unit means the actual Reference Unit catalog data. The rated conditions for obtaining the capacities and COPs are at indoor dry-bulb temperature of 21.1 °C (70 °F) and the source side entering air temperature of 8.3 °C (47 °F). Some equations are provided below to help explain the function of the various performance curves and data fields.

#### 1.41.23.1 Inputs

##### 1.41.23.1.1 Field: Name

This alpha field contains the identifying name for the variable speed heating coil.

##### 1.41.23.1.2 Field: Air Inlet Node Name

This alpha field contains the heating coil load side inlet node name.

##### 1.41.23.1.3 Field: Air Outlet Node Name

This alpha field contains the heating coil load side outlet node name.

##### 1.41.23.1.4 Field: Number of Speeds

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, has to be equal to or higher than the maximum number. The performance inputs at higher speeds are ignored.

##### 1.41.23.1.5 Field: Nominal Speed Level

This numeric field defines the nominal speed level, at which the rated capacity, rated air and volumetric flow rate are correlated.

##### 1.41.23.1.6 Field: Gross Rated Heating Capacity at Selected Nominal Speed Level

This numeric field contains the rated capacity at the nominal speed level. This field is autosizable. The gross rated heating capacity is used to determine a capacity scaling factor, as compared to the Reference Unit capacity at the nominal speed level.

$$\text{CapacityScaleFactor} = \frac{\text{GrossRatedTotalHeatingCapacity}}{\text{ReferenceUnitCapacity@NominalSpeedLevel}} \quad (1.163)$$

And then, this scaling factor is used to determine capacities at rated conditions for other speed levels, as below,

$$\begin{aligned} \text{GrossRatedCapacity@SpeedLevel}(x) = \\ \text{CapacityScaleFactor} \times \\ \text{ReferenceUnitCapacity@SpeedLevel}(x) \end{aligned} \quad (1.164)$$

#### 1.41.23.1.7 Field: Rated Volumetric Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump corresponding to the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the air flow rates in the parent objects. It is recommended that the ratio of the rated volumetric air flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\text{AirFlowScaleFactor} = \frac{\text{RatedVolumetricAirFlowRate}}{\text{ReferenceUnitVolAirFlowRate@NominalSpeedLevel} \times \text{CapacityScaleFactor}} \quad (1.165)$$

And the volumetric air flow rates in the parent objects are calculated as below,

$$\begin{aligned} \text{LoopVolumetricAirFlowRate@SpeedLevel}(x) = \\ \text{AirFlowScaleFactor} \times \\ \text{ReferenceUnitVolAirFlowRate@SpeedLevel}(x) \times \\ \text{CapacityScaleFactor} \end{aligned} \quad (1.166)$$

#### 1.41.23.1.8 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the unit as a function of the part load ratio (PLR, heating load/steady-state heating capacity for Speed 1), in the case that the unit operates under the lowest speed, i.e. on/off. The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep for Speed 1. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep).

#### 1.41.23.1.9 Field: Defrost Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the wet-bulb temperature of the air entering the indoor coil (variable x) and the outdoor air dry-bulb temperature (variable y). The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity at the maximum speed level, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

#### 1.41.23.1.10 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the heating coil compressor turns off. If this input field is left blank, the default value is -8 °C.

#### **1.41.23.1.11 Field: Outdoor Dry-Bulb Temperature to Turn On Compressor**

This numeric field defines the outdoor temperature when the compressor is automatically turned back on following an automatic shut off because of low outdoor dry-bulb temperature. This field is only used for the calculation of HSPF. If this field is not provided, then outdoor bin temperature used in the HSPF calculation is always considered to be greater than this temperature and ‘Minimum Outdoor Dry-Bulb Temperature for Compressor Operation’ field described above. This assumption is based on AHRI standard 210/240 (2008) and can introduce significant error in the final value of HSPF.

#### **1.41.23.1.12 Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 °C and less than or equal to 7.22 °C. If this input field is left blank, the default value is 5 °C.

#### **1.41.23.1.13 Field: Crankcase Heater Capacity**

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air drybulb temperature is below the value specified in the input field Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

#### **1.41.23.1.14 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature above which the compressor’s crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C. If this input field is left blank, the default value is 10 °C.

#### **1.41.23.1.15 Field: Defrost Strategy**

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse cycle.

#### **1.41.23.1.16 Field: Defrost Control**

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field Defrost Time Period Fraction described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field Maximum Outdoor Dry-bulb Temperature for Defrost Operation described above. If this input field is left blank, the default defrost control is timed.

**1.41.23.1.17 Field: Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to timed defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

**1.41.23.1.18 Field: Resistive Defrost Heater Capacity**

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is resistive (see input field Defrost Strategy above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

**1.41.23.1.19 Field Group: Rated specification and performance curves**

The performance for each heating speed must be specified as shown below. They should be directly given from the Reference Unit data. All inputs for Speed 1 are required, followed by the optional inputs for other speeds.

**1.41.23.1.20 Field: Speed <x> Reference Unit Gross Rated Heating Capacity**

This numeric field defines the total, full load gross heating capacity in watts of the air-to-air heating coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The gross heating capacity should not account for the effects of supply air fan heat.

**1.41.23.1.21 Field: Speed <x> Reference Unit Gross Rated Heating COP**

This numeric field defines the coefficient of performance ( $COP = \text{gross heating capacity in watts} / \text{electrical power input in watts}$ ) of the heating coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The input power includes power for the compressor(s), the outdoor coil fan and accessories, but does not include the power consumption of the indoor supply air fan. The gross COP should NOT account for the supply air fan.

**1.41.23.1.22 Field: Speed <x> Reference Unit Rated Air Flow Rate**

This numeric field defines the volume air flow rate, in  $\text{m}^3$  per second, across the heating coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given gross rated heating capacity and gross rated heating COP at the speed, as above.

**1.41.23.1.23 Field: Speed <x> Heating Capacity Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the indoor dry-bulb and source side entering air temperature, from the Reference Unit. The output of this curve is multiplied by the gross rated heating capacity at the speed to give the gross heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or entering air temperature different from the rating point temperature). It should be noted that the curve is normalized to the heating capacity at Speed<x> from the Reference Unit data, and have the value of 1.0 at the rating point.

#### 1.41.23.1.24 Field: Speed <x> Heating Capacity Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the gross heating capacity as a function of the ratio of actual air flow rate across the heating coil to the design air flow rate (i.e., fraction of full load flow), at Speed <x> from the Reference Unit data. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the design air flow rate at Speed <x>.

#### 1.41.23.1.25 Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor air dry-bulb and entering air temperatures. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP at Speed <x> from the Reference Unit data) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry bulb temperature or entering air temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

#### 1.41.23.1.26 Field: Speed <x> Energy Input Ratio Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the design air flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). The EIR is the inverse of the COP. This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

An example of this statement in an IDF is:

#### 1.41.23.2.1 Heating Coil Electricity Rate [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

#### 1.41.23.2.2 Heating Coil Heating Rate [W]

The output variable is the average total heating capacity provide by the heat pump in Watts over the timestep being reported.

#### 1.41.23.2.3 Heating Coil Sensible Heating Rate [W]

The output variable is the average sensible heating capacity provide by the heat pump in Watts over the timestep being reported. For heating mode, the sensible capacity is equal to the total capacity.

#### 1.41.23.2.4 Heating Coil Source Side Heat Transfer Rate [W]

The output variable is the average heat absorbed at the heat pump evaporator in Watts over the timestep being reported.

**1.41.23.2.5 Heating Coil Part Load Ratio []**

This output variable is the ratio of the part-load capacity to the steady state capacity of the heating coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the heating coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

**1.41.23.2.6 Heating Coil Runtime Fraction []**

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

**1.41.23.2.7 Heating Coil Air Mass Flow Rate [kg/s]**

The output variable is the average air mass flow rate on the load side going through the heat pump over the timestep being reported.

**1.41.23.2.8 Heating Coil Air Inlet Temperature [C]**

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

**1.41.23.2.9 Heating Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average entering air dry humidity ratio over the timestep being reported.

**1.41.23.2.10 Heating Coil Air Outlet Temperature [C]**

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

**1.41.23.2.11 Heating Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

**1.41.23.2.12 Heating Coil Upper Speed Level []**

The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

**1.41.23.2.13 Heating Coil Neighboring Speed Levels Ratio []**

The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

**1.41.23.2.14 Heating Coil Electricity Energy [J]**

The output variable is the total electric consumption of the heat pump in Joules over the timestep being reported.

**1.41.23.2.15 Heating Coil Heating Energy [J]**

The output variable is the total heating output of the coil in Joules over the timestep being reported.

**1.41.23.2.16 Heating Coil Source Side Heat Transfer Energy [J]**

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

**1.41.23.2.17 Heating Coil Defrost Electricity Rate [W]**

The output variable is the average electric power used for defrosting, in Watts over the timestep being reported.

**1.41.23.2.18 Heating Coil Defrost Electricity Energy [J]**

The output variable is the total electric defrosting energy usage of the coil in Joules over the timestep being reported.

**1.41.23.2.19 Heating Coil Crankcase Heater Electricity Rate [W]**

The output variable is the average power used for crankcase heater, in Watts over the timestep being reported.

**1.41.23.2.20 Heating Coil Crankcase Heater Electricity Energy [J]**

The output variable is the total electric energy usage of the coil for crankcase heater, in Joules over the timestep being reported.

**1.41.24 Coil:WaterHeating:Desuperheater**

A simplified approach is used to determine the performance of this water heating coil. The model assumes that the heating energy provided by this coil is reclaimed from the superheated refrigerant gas leaving a compressor (i.e., a desuperheating refrigerant-to-water heating coil) and does not impact the performance of the compressor. This coil must be used with a water heater tank (e.g., **WaterHeater:Mixed**) which can supply heated potable water and/or hot water for use in a plant loop (e.g., hydronic air reheat coils).

Except for detailed refrigeration system models, the amount of available superheat is simply a percentage of the total heat being rejected by the DX system's condenser. Approximately 25-30% of the energy rejected by typical refrigeration system condensers is to reduce the superheated refrigerant vapor temperature to the condensing temperature. Recovery efficiencies higher than 30% may cause the refrigerant gas to condense which in turn impacts the performance of the refrigeration system. For this reason, the maximum heat reclaim recovery efficiency for this coil is 30% for most sources of waste heat, including refrigeration compressor racks. The one exception to this 30% limit is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 90% of the heat within the superheated region.

The model includes the ability to modify the heat reclaim recovery efficiency based on variations in inlet water temperature and outdoor air dry-bulb temperature.

This coil model performs the following major functions:

- calculates the amount of heat delivered to the water tank
- calculates the electricity consumption of the integral water pump and on/off-cycle parasitic loads
- reflects the reduction of heat transfer in the HVAC condenser plant loop if the source coil is water-cooled

The input fields for this object are described below in detail:

### 1.41.24.1 Inputs

#### 1.41.24.1.1 Field: Name

This alpha field contains a unique user-assigned name for an instance of a desuperheater water heating coil. Any reference to this desuperheater coil by another object will use this name.

#### 1.41.24.1.2 Field: Availability Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that denotes whether the desuperheater coil is available to operate during a given time period. A schedule value equal to 0 denotes that the desuperheater coil is off for that time period. A value other than 0 denotes that the desuperheater coil is available to operate during that time period. During times when the desuperheater coil is scheduled off, the heater (element or burner) in the water tank object operates based on its tank set point temperature schedule and the desuperheater coil's parasitic electric power is also off for that time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.41.24.1.3 Field: Setpoint Temperature Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that specifies the set point (or cut-out ) temperature for the desuperheater coil. Temperature values used in this schedule should be in degrees Celsius. The desuperheater coil turns off when the tank water reaches this set point temperature. Once the desuperheater coil is off, the tank water temperature floats downward until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the cut-in temperature). At this point, the desuperheater coil turns on and remains on until the desuperheater coil set point temperature is reached.

#### 1.41.24.1.4 Field: Dead Band Temperature Difference

This numeric field contains the dead band temperature difference in degrees Celsius. The desuperheater coil cut-in temperature is defined as the desuperheater coil set point temperature defined above minus this dead band temperature difference. The desuperheater coil turns on when the water temperature in the tank falls below the cut-in temperature. The desuperheater coil remains on until the water temperature in the tank rises above the desuperheater coil set point ( cut-out ) temperature defined above. The dead band temperature difference must be greater than 0 °C and less than or equal to 20 °C. If this field is left blank, the default value is 5 °C.

Desuperheater water heating coils are typically used to offset energy consumption by the water tank's heater (element or burner). Therefore, the cut-in temperature for the desuperheater coil (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point temperature is greater than the cut-in temperature of the desuperheater coil, the model disables the desuperheater coil and the tank's heater is used to heat the water.

#### 1.41.24.1.5 Field: Rated Heat Reclaim Recovery Efficiency

This numeric field defines the ratio of recovered waste heat from the superheated refrigerant gas to the total rejected waste heat from the heating source (as if no heat reclaim occurred). Input values must be greater than 0 up to a maximum value is 0.3 (with a defaults of 0.25) for most sources of waste heat, including refrigeration compressor racks. The one exception to this 0.3 limit is a source that is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 0.9. with a default value is 0.8.

**1.41.24.1.6 Field: Rated Inlet Water Temperature**

This numeric field defines the coil inlet water temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. Also see field Heat Reclaim Efficiency Modifier Curve Name (function of temperature) below.

**1.41.24.1.7 Field: Rated Outdoor Air Temperature**

This numeric field defines the outdoor air dry-bulb temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. The outdoor air dry-bulb temperature impacts the desuperheater coil refrigerant temperature and the amount of heat available for reclaim. Also see field Heat Reclaim Efficiency Modifier Curve Name(function of temperature) below.

**1.41.24.1.8 Field: Maximum Inlet Water Temperature for Heat Reclaim**

This numeric field defines the maximum coil inlet water temperature in degrees Celsius. Any time the inlet water temperature to the desuperheater coil is above this maximum allowed temperature, heat reclaim is restricted so that the tank water does not exceed this temperature.

**1.41.24.1.9 Field: Heat Reclaim Efficiency Function of Temperature Curve Name**

This alpha field specifies the name of a bi-quadratic curve object (ref: Performance Curves) that defines the variation in heat reclaim efficiency as a function of inlet fluid (air and water) temperatures. The bi-quadratic curve uses the coil inlet water temperature and outdoor air dry-bulb temperature (entering the DX coil condenser) as the independent variables. The output of this curve is multiplied by the rated heat reclaim recovery efficiency to give the heat reclaim efficiency at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heat reclaim efficiency remains constant (curve value assumed to be 1.0 for all conditions). The model restricts the product of the output of this curve and the rated heat reclaim recovery efficiency to a maximum of 0.9 for refrigeration condenser sources and 0.3 for all other sources..

**1.41.24.1.10 Field: Water Inlet Node Name**

This alpha field defines the name of the water node from which the desuperheater heating coil draws its inlet water. This node name must also match the source side outlet node name for the water heater tank used with this coil (ref. Water Heaters).

**1.41.24.1.11 Field: Water Outlet Node Name**

This alpha field defines the name of the water node to which the desuperheater heating coil sends its outlet water. This node name must also match the source side inlet node name for the water heater tank used with this coil (ref. Water Heaters).

**1.41.24.1.12 Field: Tank Object Type**

This alpha (choice) field contains the types of water heater tank used by this desuperheater heating coil. The valid choices are:

- **WaterHeater:Mixed**
- **WaterHeater:Stratified**

**1.41.24.1.13 Field: Tank Name**

This alpha field contains the name of the specific water heater tank (**WaterHeater:Mixed** or **WaterHeater:Stratified** object) used by this desuperheater heating coil.

**1.41.24.1.14 Field: Heating Source Object Type**

This alpha (choice) field defines the source of superheated refrigerant gas from which the desuperheater water heating coil recovers energy through heat reclaim. Valid choices are:

- Coil:Cooling:DX:SingleSpeed
- Coil:Cooling:DX:TwoSpeed
- Coil:Cooling:DX:TwoStageWithHumidityControlMode
- Coil:Cooling:DX:VariableSpeed
- Coil:Cooling:WaterToAirHeatPump:EquationFit
- Refrigeration:CompressorRack
- Refrigeration:Condenser:AirCooled
- Refrigeration:Condenser:EvaporativeCooled
- Refrigeration:Condenser:WaterCooled

**1.41.24.1.15 Field: Heating Source Name**

This alpha field defines the name of the desuperheater coil's heat source (e.g., the name of a specific coil of the type mentioned in the previous field which provides waste heat to this desuperheater water heating coil).

**1.41.24.1.16 Field: Water Flow Rate**

This numeric field defines the desuperheater coil's water flow rate in cubic meters per second. The model assumes that this flow rate is constant (throughout the simulation period) when the desuperheater coil operates, and that it corresponds to the heat reclaim recovery efficiency performance specified by the user. This water flow rate must be greater than zero.

**1.41.24.1.17 Field: Water Pump Power**

This numeric field defines the coil's water circulation pump power in Watts. This is the operating pump power as installed. Values must be greater than or equal to 0. If this field is left blank, the default value is 0. A warning message will be issued if the ratio of water pump power to desuperheater water volumetric flow rate exceeds  $7.9264\text{E}6 \text{ W/m}^3/\text{s}$ , but the simulation will continue using the user-defined values. The model assumes that this integral pump (i.e., no need to define a separate pump object) cycles on and off with the desuperheater heating coil.

**1.41.24.1.18 Field: Fraction of Pump Heat to Water**

This numeric field defines the fraction of water circulation pump heat that is transferred to the water. The pump is assumed to be downstream of the desuperheater water heating coil, and this field is used to determine the desuperheater water outlet temperature. Values must be greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

**1.41.24.1.19 Field: On-Cycle Parasitic Electric Load**

This optional numeric field contains the on-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

**1.41.24.1.20 Field: Off-Cycle Parasitic Electric Load**

This optional numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is available but is not operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Following is an example input for a desuperheater water heating coil.

**1.41.24.2 Outputs**

- HVAC,Average,Water Heater Part Load Ratio
- HVAC,Average,Water Heater Heating Rate [W]
- HVAC,Sum,Water Heater Heating Energy [J]
- HVAC,Average,Water Heater Pump Electricity Rate [W]
- HVAC,Sum,Water Heater Pump Electricity Energy [J]
- HVAC,Average,Water Heater Heat Reclaim Efficiency Modifier Multiplier []
- HVAC,Average,Water Heater On Cycle Parasitic Electricity Rate [W]
- HVAC,Sum,Water Heater On Cycle Parasitic Electricity Energy [J]

- HVAC,Average,Water Heater Off Cycle Parasitic Electricity Rate [W]
- HVAC,Sum,Water Heater Off Cycle Parasitic Electricity Energy [J]

Water Heater Part Load Ratio [] This output field contains the part load ratio of the desuperheater heating coil for the timestep being reported. This ratio represents the fraction of the timestep that the desuperheater heating coil is operating.

#### **1.41.24.2.1 Water Heater Heating Rate [W]**

This output field contains the average heating rate output of the desuperheater heating coil in Watts for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

#### **1.41.24.2.2 Water Heater Heating Energy [J]**

This output field contains the total heating output of the desuperheater heating coil in Joules for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

#### **1.41.24.2.3 Water Heater Pump Electricity Rate [W]**

This output field contains the average electricity consumption rate for the water circulation pump in Watts for the timestep being reported.

#### **1.41.24.2.4 Water Heater Pump Electricity Energy [J]**

This output field contains the electricity consumption of the water circulation pump in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

#### **1.41.24.2.5 Water Heater Heat Reclaim Efficiency Modifier Multiplier []**

This output field contains the average output of the Heat Reclaim Efficiency Modifier Curve (function of temperature) for the timestep being reported.

#### **1.41.24.2.6 Water Heater On Cycle Parasitic Electricity Rate [W]**

#### **1.41.24.2.7 Water Heater On Cycle Parasitic Electricity Energy [J]**

#### **1.41.24.2.8 Water Heater Off Cycle Parasitic Electricity Rate [W]**

#### **1.41.24.2.9 Water Heater Off Cycle Parasitic Electricity Energy [J]**

These outputs are the parasitic electric power and consumption associated with the desuperheater water heating coil. Specific outputs represent parasitic electrical usage during the coil on and off cycles. These outputs represent electronic controls or other electric component. The model assumes that the parasitic power does not contribute to heating the water nor does it impact the zone air heat balance. The parasitic electric consumption outputs are also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

### 1.41.25 CoilSystem:Cooling:DX

The CoilSystem:Cooling:DX object is a virtual container component that consists of a DX cooling coil component and its associated controls, as shown in the Figure below. This control object supports several different types of DX cooling coils (see field Cooling Coil Object Type).

This component may be used as a cooling coil in constant volume or variable volume systems, as blow through or draw through, with or without humidity controls. Unlike AirLoopHVAC:Unitary system types, this component controls only the DX coil, not the supply fan. CoilSystem:Cooling:DX is added to a system by placing it in an air loop branch (see Branch object) or in an [AirLoopHVAC:OutdoorAirSystem:EquipmentList](#) or in a [ZoneHVAC:OutdoorAirUnit:EquipmentList](#). It requires one or more setpoint manager (see SetpointManager:\*) objects to specify temperature and/or humidity setpoints (unless it is used in a [ZoneHVAC:OutdoorAirUnit](#) which has its own temperature setpoints). This object is the one that is listed in the Branch or equipment list object rather than the coil itself. A constant volume or variable volume fan is modeled separately from this cooling system. These are the only fan types allowed for this system type (ref. [Fan:ConstantVolume](#) and [Fan:VariableVolume](#)). Cycling fan operation is not available with this model. The CoilSystem:Cooling:DX object can also be placed on dedicated outdoor air system (DOAS) airloop branches or in airloop branches where the air flow to capacity ratio range is between 100 300 cfm/ton. 100% DOAS DX cooling coils operate in lower flow to capacity ratio range compared to regular DX cooling coils. The CoilSystem:Cooling:DX is selected to operate in DOAS application or in low flow to capacity ratio range by specifying YES to the input field Use Outdoor Air DX Cooling Coil. If this optional input field is left blank or specified as NO, then the coil is modeled as regular DX cooling coil. If the CoilSystem:Cooling:DX object is in an [AirLoopHVAC:OutdoorAirSystem:EquipmentList](#) or in a [ZoneHVAC:OutdoorAirUnit:EquipmentList](#) then it is treated as 100% DOAS DX cooling coil only if the choice input field Use Outdoor Air DX Cooling Coil is set too YES. All the control options of the regular DX cooling coils are available to DOAS DX coils as well. Heating DX coils in DOAS airloop operate at the same flow to capacity ratio limits as the DOAS DX cooling coils.

#### 1.41.25.1 Inputs

##### 1.41.25.1.1 Field: Name

This alpha field contains the identifying name for this component.

##### 1.41.25.1.2 Field: Availability Schedule Name

This alpha field contains the schedule name that contains information on the availability of the DX coil to operate. A schedule value of 0 indicates that the coil is off for that time period. A schedule value greater than 0 indicates that the coil can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.41.25.1.3 Field: DX Cooling Coil System Inlet Node Name

This alpha field contains the identifying name given to the DX cooling coil inlet node, as specified in the DX cooling coil object.

##### 1.41.25.1.4 Field: DX Cooling Coil System Outlet Node Name

This alpha field contains the identifying name given to the DX cooling coil outlet node, as specified in the cooling coil object.

##### 1.41.25.1.5 Field: DX Cooling Coil System Sensor Node Name

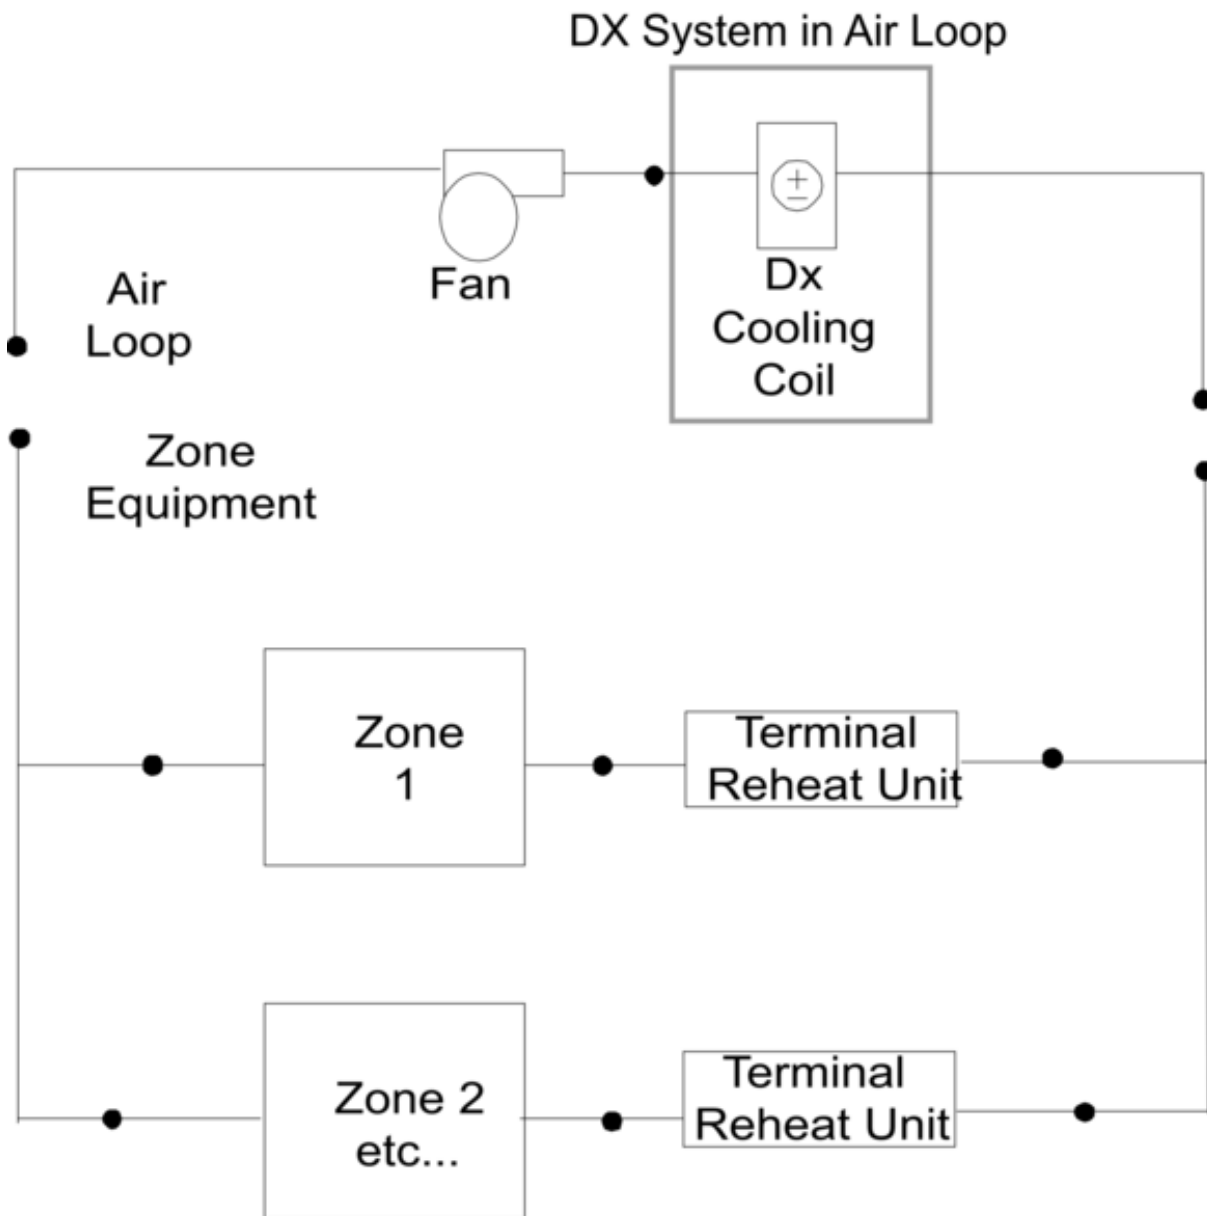

Figure 1.173: Schematic of CoilSystem:Cooling:DX Object in an Air Loop for a Blow Through Application

This alpha field contains the identifying name given to the DX cooling coil control node, this is the node at which the temperature set point is specified by the set point manager.

#### 1.41.25.1.6 Field: Cooling Coil Object Type

This alpha field specifies the type of DX cooling coil. The valid choices for this field are:

- **Coil:Cooling:DX:SingleSpeed**
- **CoilSystem:Cooling:DX:HeatExchangerAssisted**
- **Coil:Cooling:DX:TwoSpeed**
- **Coil:Cooling:DX:TwoStageWithHumidityControlMode**
- **Coil:Cooling:DX:VariableSpeed**
- **Coil:Cooling:DX:SingleSpeed:ThermalStorage**

#### 1.41.25.1.7 Field: Cooling Coil Name

This alpha field contains the identifying name of the DX cooling coil.

As shown in the example below, correct specification of this system requires specification of the DX Cooling Coil object in addition to the CoilSystem:Cooling:DX object.

#### 1.41.25.1.8 Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

**None** - meet sensible load only, no active dehumidification control

**MultiMode** - activate enhanced dehumidification mode as needed and operate to meet the sensible load. If a sensible load exists, the system will operate to meet that sensible load and may not meet the latent load. If no sensible load exists, and Run on Latent Load = Yes, the system will operate to meet the entire latent load. This option is used to model DX equipment with a switchable option such as subcool reheat. It is valid only with Cooling coil type = **Coil:Cooling:DX:TwoStageWithHumidityControlMode** or **CoilSystem:Cooling:DX:HeatExchangerAssisted**. If the Run on Latent Load option below is set to Yes, this option may require the use of a heating coil and heating coil outlet air temperature set point manager downstream of this cooling coil to maintain the temperature set point.

**CoolReheat** - cool beyond the dry-bulb setpoint as required to meet the humidity setpoint. It is valid only with Cooling coil type = **Coil:Cooling:DX:TwoStageWithHumidityControlMode**. This option requires the use of a heating coil and heating coil outlet air temperature set point manager downstream of this cooling coil to maintain the temperature set point.

The default is **None**. For all dehumidification controls, the max humidity setpoint on the control node is used. This must be set using a **ZoneControl:Humidistat** **ZoneControl:Humidistat** and one of:

- **SetpointManager:SingleZone:Humidity:Maximum**
- **SetpointManager:MultiZone:Humidity:Maximum**
- **SetpointManager:MultiZone:MaximumHumidity:Average**

objects and **SetpointManager:OutdoorAirPretreat** (optional) objects. When extra dehumidification is required, the equipment may not be able to meet the humidity setpoint if its full capacity is not adequate.

#### 1.41.25.1.9 Field: Run on Sensible Load

This alpha field specifies if the unit will operate to meet a sensible load as determined by the inlet node dry-bulb temperature and the dry-bulb temperature setpoint on the control node. There are two valid choices, **Yes** or **No**. If **Yes**, unit will run if there is a sensible load. If **No**, unit will not run if there is only a sensible load. The default is **Yes**.

#### 1.41.25.1.10 Field: Run on Latent Load

This alpha field specifies if the unit will operate to meet a latent load as determined by the inlet node humidity ratio and the max humidity setpoint on the control node. There are two valid choices, **Yes** or **No**. If **Yes**, unit will run if there is a latent load. If both a sensible and latent load exist, the system will operate to maintain the temperature set point. When only a latent load exists, the system will operate to meet the humidity ratio set point and requires the use of a heating coil and heating coil outlet air temperature set point manager downstream of this cooling coil to maintain the temperature set point. If **No**, unit will not run if there is only a latent load. The default is **No**.

#### 1.41.25.1.11 Field: Use Outdoor Air DX Cooling Coil

This input field enables the Coil System DX Coil to be used for low air flow to capacity ratio range ( 100 300 cfm/ton). This flow to capacity ratio range is common in 100% dedicated outdoor air system (DOAS) applications. Other airloop or zone HVAC systems may use this input field if they operate at such a low flow to capacity ratio range. There are two valid choices, **Yes** or **No**. If **Yes**, the DX cooling coil is forced to operate in this flow to capacity ratio range or runs as 100% DOAS DX coil. If **No**, DX coil is used as regular DX coil. This input field is optional.

#### 1.41.25.1.12 Field: Outdoor Air DX Cooling Coil Leaving Minimum Air Temperature

This input field is the DX cooling coil leaving supply air minimum temperature specified for frost control. The DX cooling coil leaving air temperature is not allowed to exceed this minimum coil leaving air temperature. The DX cooling coil frost controller adjusts or limits the desired coil outlet air setpoint temperature when the coil outlet temperature exceeds this minimum temperature limit specified. This input field is optional and only used along with in the input field above. The minimum and maximum values of this input field are 0.0 °C and 7.2 °C, and the default value is 2.0 °C.

### 1.41.25.2 Outputs

#### *All DX Coils:*

- HVAC,Average,Coil System Frost Control Status

*Coil Type = Coil:Cooling:DX:TwoStageWithHumidityControlMode & Coil:Cooling:DX:VariableSpeed*

- HVAC,Average,Coil System Cycling Ratio
- HVAC,Average,Coil System Compressor Speed Ratio

*Coil:Cooling:DX:VariableSpeed*

- HVAC,Average,Coil System Compressor Speed Number

*Coil types = Coil:Cooling:DX:SingleSpeed & CoilSystem:Cooling:DX:HeatExchangerAssisted*

- HVAC,Average,Coil System Part Load Ratio

#### 1.41.25.2.1 Coil System Cycling Ratio

The system may operate for the entire system timestep, but to meet the load the compressor can cycle on and off. This reports the fraction of the system timestep that the compressor is operating. (1.0 is continuous, 0.0 is off). For Coil:Cooling:VariableSpeed this description is true when compressor speed = 1. At higher compressor speeds Coil System Cycling Ratio = 1.

#### 1.41.25.2.2 Coil System Compressor Speed Ratio

This is the ratio of time in a system timestep that the compressor is at rated speed. The compressor speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep. This report is a duplicate of the report in Coil:Cooling:DX:VariableSpeed named Cooling Coil Neighboring Speed Levels Ratio.

#### 1.41.25.2.3 Coil System Compressor Speed Number

This is the stage number that the compressor is operating at in a system timestep. The compressor speed number (from 1 to number of speeds) is reported and averaged over the timestep. This report is a duplicate of the report in Coil:Cooling:DX:VariableSpeed named Cooling Coil Upper Speed Level.

#### 1.41.25.2.4 Coil System Part Load Ratio

The DX system can operate with a cycling compressor or a varying speed compressor. This variable reports the fraction of the Full Load that is met during the system timestep. This can differ from the cycling part load ratio or the compressor speed ratio. (1.0 is Full Load and 0.0 is no load)

#### 1.41.25.2.5 Coil System Frost Control Status

This is a flag indicating whether frost control is active at current time step or not. Frost control is activated or enforced when the sensible load control requires DX cooling coil outlet air temperature below the user specified minimum temperature or when the dehumidification load control requires DX cooling coil outlet air humidity ratio below the saturation humidity ratio corresponding to the user specified minimum temperature for frost control. Frost control status of zero means no active frost control, a value of 1 or 2 indicates that frost control is active. If frost control status is 1, then the frost control was enforced when the cooling coil is run to meet sensible load. If the frost control status value is 2, then the control was enforced when the cooling coil is run to meet latent load. When frost control is active the DX cooling coil setpoint value is modified based on user specified limit.

### 1.41.26 CoilSystem:Heating:DX

The CoilSystem:Heating:DX object is a virtual container component for a DX heating coil that provides the controls needed to operate the coil. Only single speed DX air-to-air heating coils are supported.

This component may be used as a heating coil in constant volume or variable volume air handlers. It can also be used in an outside air system (by including it in an [AirLoopHVAC:OutdoorAirSystem:EquipmentList](#) object) or in a zone outdoor air unit (by including it in an [ZoneHVAC:OutdoorAirUnit:EquipmentList](#) object). This object is the one that is listed in the Branch or equipment list object rather than the coil itself.

The inlet and outlet nodes for the DX heat pump system are defined in the heating coil object. The control node is always the outlet node of the coil. This DX heat pump heating system requires that a (drybulb) temperature setpoint be placed on the outlet node using either a setpoint manager or the energy management system. The coil is controlled to attempt to meet that setpoint using a part load ratio modeling approach.

This model only supports continuous fan and cycling compressor operation – cycling fan modeling is not available with this model.

#### 1.41.26.1 Inputs

##### 1.41.26.1.1 Field: Name

This alpha field contains the identifying name for this component.

##### 1.41.26.1.2 Field: Availability Schedule Name

This alpha field contains the schedule name that contains information on the availability of the DX coil to operate. A schedule value of 0 indicates that the coil is off for that time period. A schedule value greater than 0 indicates that the coil can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.41.26.1.3 Field: Heating Coil Object Type

This alpha field specifies the type of DX heating coil. This model currently supports only single speed DX heat pump heating coils and the only options for this field are [Coil:Heating:DX:SingleSpeed](#) and [Coil:Heating:DX:VariableSpeed](#).

##### 1.41.26.1.4 Field: Heating Coil Name

This alpha field specifies the unique name of the DX heating coil. This field references the name of a [Coil:Heating:DX:SingleSpeed](#) that needs to be defined elsewhere in the input file.

An example of a DX heating coil system follows.

```

CoilSystem:Heating:DX,

```

## 1.41.26.2 Outputs

### 1.41.26.2.1 Coil System Part Load Ratio

The DX system can operate with a cycling compressor or a varying speed compressor, This variable reports the fraction of the Full Load that is met during the system timestep. This can differ from the cycling part load ratio or the compressor speed ratio. (1.0 is Full Load and 0.0 is no load)

## 1.41.27 CoilSystem:Cooling:DX:HeatExchangerAssisted

The heat exchanger-assisted DX cooling coil is a virtual component consisting of a direct expansion (DX) cooling coil and an air-to-air heat exchanger as shown in Figure 1.174 below. The air-to-air heat exchanger pre-conditions the air entering the cooling coil, and reuses this energy to post-condition the supply air leaving the cooling coil. This heat exchange process improves the latent removal performance of the cooling coil by allowing it to dedicate more of its cooling capacity toward dehumidification (lower sensible heat ratio).

This compound object models the basic operation of an air-to-air heat exchanger in conjunction with a cooling coil. The heat exchanger-assisted DX cooling coil does not have an operating schedule of its own; its operating schedule is governed by the availability schedules for the DX cooling coil and the air-to-air heat exchanger. This compound object is used in the same way as a DX cooling coil object. It cannot be used directly on a branch. It must be contained within a parent object such as CoilSystem:Cooling:DX or AirloopHVAC:UnitarySystem and others which list CoilSystem:Cooling:DX:HeatExchangerAssisted as a valid cooling coil option.

To model a heat exchanger-assisted DX cooling coil, the input data file should include the following objects:

- CoilSystem:Cooling:DX:HeatExchangerAssisted object
- Air-to-air heat exchanger object such as:
  - HeatExchanger:AirToAir:FlatPlate
  - HeatExchanger:AirToAir:SensibleAndLatent
  - HeatExchanger:Desiccant:BalancedFlow
- DX cooling coil object (Coil:Cooling:DX:SingleSpeed or Coil:Cooling:DX:VariableSpeed)

In terms of controlling the operation of the heat exchanger, the heat exchanger is assumed to always provide its heat transfer when the associated DX cooling coil is operating and no high humidity control mechanism is specified. However, the heat exchanger's energy transfer may be controlled (i.e., turned on and off) based on a zone air humidity level using either a humidistat (ref. AirLoopHVAC:UnitarySystem, AirLoopHVAC:Unitary:Furnace:HeatCool or AirLoopHVAC:UnitaryHeatCool) or a humidistat and a maximum humidity set point manager to place a humidity ratio set point on the appropriate control node (ref. CoilSystem:Cooling:DX). This model may also be used with the unitary changeover bypass system and the unitary air-to-air heat pump system (ref. AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass and AirLoopHVAC:UnitaryHeatPump:AirToAir); however, the heat exchanger is assumed to always provide its heat transfer when the cooling coil operates and cannot be turned on and off based on a zone air humidity set point. Two zone air conditioners may also use this model for improved dehumidification. The first type is the packaged terminal heat pump (ref. ZoneHVAC:PackagedTerminalHeatPump) where the heat exchanger's heat transfer is always active whenever the cooling coil operates. The second type is the window air conditioner (ref. ZoneHVAC:WindowAirConditioner) where the heat exchanger's heat transfer is always active when the cooling coil operates and no high humidity control mechanism is specified, OR the heat exchanger's heat transfer may be controlled based on zone air humidity level if a humidistat and high humidity set point manager are specified (maximum humidity ratio set point placed on the heat exchanger's exhaust air outlet node, ref. Figure 1.174).

Links to the cooling coil and air-to-air heat exchanger specifications are provided in the input data syntax for this compound object. A description of each input field for this compound object is provided below.

NOTE: Node naming shown in Figure 1.174 is representative for HeatExchanger:AirToAir:SensibleAndLatent. For HeatExchanger:AirToAir:FlatPlate, the exhaust air nodes are referred to as secondary air nodes. For HeatExchanger:Desiccant:BalancedFlow, the supply air nodes are referred to as regeneration air nodes and the exhaust air nodes as process air nodes.

### 1.41.27.1 Inputs

#### 1.41.27.1.1 Field: Name

A unique user-assigned name for the heat exchanger-assisted DX cooling coil. Any reference to this compound component by another object will use this name.

#### 1.41.27.1.2 Field: Heat Exchanger Object Type

This alpha field denotes the type of heat exchanger being modeled. Valid choices are:

- HeatExchanger:AirToAir:FlatPlate
- HeatExchanger:AirToAir:SensibleAndLatent
- HeatExchanger:Desiccant:BalancedFlow

Figure 1.174: Schematic of the CoilSystem:Cooling:DX:HeatExchangerAssisted compound object

**1.41.27.1.3 Field: Heat Exchanger Name**

This alpha field denotes the name of the air-to-air heat exchanger being modeled.

**1.41.27.1.4 Field: Cooling Coil Object Type**

This alpha field denotes the type of DX cooling coil being modeled. The only valid choices are `Coil:Cooling:DX:SingleSpeed` or `Coil:Cooling:DX:VariableSpeed`.

**1.41.27.1.5 Field: Cooling Coil Name**

This alpha field denotes the name of the DX cooling coil being modeled.

Following is an example input for this compound object:

```
CoilSystem:Cooling:DX:HeatExchangerAssisted,
HeatExchangerAssistedCoolingCoil,           ! Name of the heat exchanger assisted cooling coil

---

### 1.41.27.2 Outputs

No variables are reported for this compound object. However, outputs are provided by the cooling coil and heat exchanger that are specified.

## 1.41.28 CoilSystem:IntegratedHeatPump:AirSource

CoilSystem:IntegratedHeatPump:AirSource is a collection of all the working modes in an air-source integrated heat pump, including space cooling (SC), space heating (SH), dedicated water heating (DWH), combined space cooling and water heating with full condensing (SCWH), combined space cooling and water heating with desuperheating (SCDWH), combined space heating and water heating with desuperheating (SHDWH). These working modes should also be referred to in other related air loop or water loop parent objects, for example, [AirLoopHVAC:UnitarySystem](#) and [WaterHeater:HeatPump:PumpedCondenser](#), to represent the air side and water side node connections, and facilitate iterating the speed to match the space conditioning or water heating load. In addition, CoilSystem:IntegratedHeatPump:AirSource contains a series of criteria for selecting a working mode at the beginning of each timestep.

### 1.41.28.1 Inputs

#### 1.41.28.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of an air-source integrated heat pump.

#### 1.41.28.1.2 Field: Supply Water Monitoring Node Name

This alpha field defines a water side node to monitor the supply water amount after the water heating operation of the integrated heat pump is turned on.

#### 1.41.28.1.3 Field: Space Cooling Mode Coil Name

This alpha field defines the space cooling (SC) mode in an ASIHP, which must be given. The SC mode refers to the name of a [Coil:Cooling:DX:VariableSpeed](#) object, which contains all the performance curves and rated values to describe the space cooling operation.

**1.41.28.1.4 Field: Space Heating Mode Coil Name**

This alpha field defines the space heating (SH) mode in the ASIHP, which must be given. The SH mode refers to the name of a **Coil:Heating:DX:VariableSpeed** object, which contains all the performance curves and rated values to describe the space heating operation.

**1.41.28.1.5 Field: Water Heating Mode Coil Name**

This alpha field defines the dedicated water heating (DWH) mode in the ASIHP, which must be given. The DWH mode refers to the name of a **Coil:WaterHeating:AirToWaterHeatPump:–VariableSpeed** object, which contains all the performance curves and rated values to describe the water heating operation with outdoor air source.

**1.41.28.1.6 Field: SCWH Mode Coil Name**

This alpha field defines the combined space cooling and water heating with full condensing (SCWH) in an ASIHP, which must be given. The SCWH mode refers to the name of a **Coil:WaterHeating:AirToWaterHeatPump:VariableSpeed** object, which contains all the performance curves and rated values to describe the water heating operation with an indoor air source. The SCWH mode is connected to the same **WaterHeater:HeatPump:PumpedCondenser** as the DWH mode, and the same air side node connections as the SC mode.

**1.41.28.1.7 Field: SCDWH Mode Cooling Coil Name**

This alpha field defines the cooling operation in the combined space cooling and water heating with desuperheating (SCDWH) mode in an ASIHP, which must be given. These should be a different object from the SC mode. It should be noted that the rated power and power correction curves are contained in the **Coil:Cooling:DX:VariableSpeed** object. That means the power consumption at each speed level of the SCDWH mode is accounted for by the cooling coil part.

**1.41.28.1.8 Field: SCDWH Mode Water Heating Coil Name**

This alpha field defines the water heating operation in the combined space cooling and water heating with desuperheating (SCDWH) mode in an ASIHP, which must be given. The power values and curves in the **Coil:WaterHeating:AirToWaterHeatPump:VariableSpeed** are not used. That means the power consumption at each speed level of the SCDWH mode is accounted for by the cooling coil part.

**1.41.28.1.9 Field: SHDWH Mode Heating Coil Name**

This alpha field defines the heating operation in the combined space heating and water heating with desuperheating (SHDWH) mode in an ASIHP, which must be given. This should be a different object from the SH mode. It should be noted that the rated power and power correction curves are contained in the **Coil:Heating:DX:VariableSpeed** object. That means the power consumption at each speed level of the SHDWH mode is accounted for by the cooling coil part.

**1.41.28.1.10 Field: SHDWH Mode Water Heating Coil Name**

This alpha field defines the water heating operation in the combined space heating and water heating with desuperheating (SHDWH) mode in an ASIHP, which must be given. The power values and curves in the **Coil:WaterHeating:AirToWaterHeatPump:VariableSpeed** are not used. That means the power consumption at each speed level of the SHDWH mode is accounted for by the heating coil part.

**1.41.28.1.11 Field: SCWH Mode Minimum Indoor Temperature to Allow Overcooling**

This numeric field defines an indoor air temperature [C] above which indoor overcooling is allowed in the cooling operation, i.e., allowing running the SCWH mode to cool down the indoor air below the thermostat setting temperature, and iterate the compressor speed to match the water heating load. It has to be noted that both the indoor temperature and ambient temperature lower bound settings have to be satisfied when allowing indoor overcooling by running the SCWH mode.

#### **1.41.28.1.12 Field: SCWH Mode Minimum Outdoor Temperature to Allow Overcooling**

This numeric field defines an ambient air temperature above which indoor overcooling is allowed in the cooling operation, i.e., allowing running the SCWH mode to cool down the indoor air below the thermostat setting temperature, and iterate the compressor speed to match the water heating load. It has to be noted that both the indoor temperature and ambient temperature lower bound settings have to be satisfied when allowing overcooling the indoor by running the SCWH mode.

#### **1.41.28.1.13 Field: Minimum Indoor Temperature to Ignore Space Heating Call**

This numeric field defines an indoor air temperature [C] above which the water heating request has the higher priority and the space heating call can be ignored. The ASIHP will run the DWH mode to match the water heating load regardless of space heating call. It has to be noted that both the indoor temperature and ambient temperature lower bound settings have to be satisfied when a space heating call can be ignored.

#### **1.41.28.1.14 Field: Minimum Outdoor Temperature to Ignore Space Heating Call**

This numeric field defines an ambient air temperature [C] above which the water heating request has the higher priority and the space heating call can be ignored. The ASIHP will run the DWH mode to match the water heating load regardless of space heating call. It has to be noted that both the indoor temperature and ambient temperature lower bound settings have to be satisfied when a space heating call can be ignored.

#### **1.41.28.1.15 Field: SCWH Mode Load Matching Type**

This choice field specifies the control in the SCWH mode. The choices are CoolingLoad or WaterHeatingLoad. During the SCWH operation when both the space cooling and water heating calls exist, if the field is CoolingLoad, it means that the compressor speed is iterated to match the space cooling load, and the water heating energy is a byproduct. If this field is WaterHeatingLoad, it means that the speed is altered to match the water heating load, and the space cooling energy is a byproduct.

#### **1.41.28.1.16 Field: SCWH Mode Minimum Speed**

This numeric field defines a minimum speed level for running the SCWH; i.e., the compressor speed will be altered between the minimum speed specified and top speed, responding to the simultaneous space cooling and water heating calls. If there is only a water heating call, this input will not be used.

#### **1.41.28.1.17 Field: SCDWH Mode Maximum Heated Water Vol Before Switching to SCWH**

This numeric field defines an accumulative, heated water volume [m3] before switching from SCDWH to SCWH mode. When there are simultaneous space cooling and water heating calls, the ASIHP will run SCDWH first to satisfy a small water heating load. If the water volume heated by the heat pump goes beyond the limit, it means that the SCDWH, which uses a desuperheater, cannot provide enough capacity for the water heating request, and thus the SCWH mode will be turned on.

**1.41.28.1.18 Field: SCDWH Mode Minimum Speed**

This numeric field defines a minimum speed level for running the SCDWH; i.e., the compressor speed will be altered between the minimum speed specified and top speed to match the space cooling load, and the water heating energy is a byproduct.

**1.41.28.1.19 Field: SHDWH Mode Time Limit Before Turning on Electric Water Heating Element**

This numeric field defines the running time [s] of the SHDWH mode before electric heating elements in the connected water tank are turned on if the water heating request cannot be satisfied on time. When there are simultaneous space heating and water heating calls, the ASIHP will run SHDWH mode first to satisfy a small water heating load. If the running time goes beyond the time limit, it means that the SHDWH mode, which uses a desuperheater, cannot provide enough capacity for the water heating request, and thus the electric elements in the water tank will be turned on to supplement the heating capacity.

**1.41.28.1.20 Field: SHDWH Mode Minimum Speed**

This numeric field defines a minimum speed level for running the SHDWH mode; i.e., the compressor speed will be altered between the minimum speed and top speed to match the space heating load. Consequently, the water heating capacity is the byproduct.

**1.41.28.1.21 An IDF example:**

**1.41.28.2 Outputs**

The output variables that are available for this air source integrated heat pump are shown below:

- HVAC, Average, Integrated Heat Pump Air Loop Mass Flow Rate [kg/s]
- HVAC, Average, Integrated Heat Pump Condenser Water Mass Flow Rate [kg/s]
- HVAC, Average, Integrated Heat Pump Air Total Cooling Rate [W]
- HVAC, Average, Integrated Heat Pump Air Heating Rate [W]
- HVAC, Average, Integrated Heat Pump Water Heating Rate [W]

- HVAC, Average, Integrated Heat Pump Electricity Rate [W]
- HVAC, Average, Integrated Heat Pump Air Latent Cooling Rate [W]
- HVAC, Average, Integrated Heat Pump Source Heat Transfer Rate [W]
- HVAC, Average, Integrated Heat Pump COP []
- HVAC, Sum, Integrated Heat Pump Electricity Energy [J]
- HVAC, Sum, Integrated Heat Pump Air Total Cooling Energy [J]
- HVAC, Sum, Integrated Heat Pump Air Heating Energy [J]
- HVAC, Sum, Integrated Heat Pump Water Heating Energy [J]
- HVAC, Sum, Integrated Heat Pump Air Latent Cooling Energy [J]
- HVAC, Sum, Integrated Heat Pump Source Heat Transfer Energy [J]

**1.41.28.2.1 Integrated Heat Pump Air Loop Mass Flow Rate [kg/s]** The output variable is the air mass flow rate in the indoor air loop, over the timestep being reported.

**1.41.28.2.2 Integrated Heat Pump Condenser Water Mass Flow Rate [kg/s]**

The output variable is the hot water mass flow rate through the condenser of the heat pump water heater, over the timestep being reported.

**1.41.28.2.3 Integrated Heat Pump Air Total Cooling Rate [W]**

The output variable is the average total cooling load provided by the integrated heat pump, which includes the sensible and latent load in watts over the timestep being reported.

**1.41.28.2.4 Integrated Heat Pump Air Heating Rate [W]**

The output variable is the average total heating load provided by the integrated heat pump in watts over the timestep being reported.

**1.41.28.2.5 Integrated Heat Pump Water Heating Rate [W]**

The output variable is the average total water heating load provided by the integrated heat pump in watts over the timestep being reported.

**1.41.28.2.6 Integrated Heat Pump Electricity Rate [W]**

The output variable is the average total electric power consumed by the integrated heat pump in watts over the timestep being reported.

**1.41.28.2.7 Integrated Heat Pump Air Latent Cooling Rate [W]**

The output variable is the average latent cooling load provided by the integrated heat pump in watts over the timestep being reported.

**1.41.28.2.8 Integrated Heat Pump Source Heat Transfer Rate [W]**

The output variable is the average total source energy rate absorbed or discharged to the outdoor air by the integrated heat pump in watts over the timestep being reported.

**1.41.28.2.9 Integrated Heat Pump COP []**

The output variable is the average total COP (using the total delivered load divided by the electric power) by the integrated heat pump in watts over the timestep being reported. The total delivered load includes all the incurred space cooling, water heating, and space heating loads.

**1.41.28.2.10 Integrated Heat Pump Electricity Energy [J]**

The output variable is the electric consumption of the integrated heat pump in joules over the timestep being reported.

**1.41.28.2.11 Integrated Heat Pump Air Total Cooling Energy [J]** The output variable is the total space cooling output of the integrated heat pump in joules over the timestep being reported.

**1.41.28.2.12 Integrated Heat Pump Air Heating Energy [J]**

The output variable is the total space heating output of the integrated heat pump in joules over the timestep being reported.

**1.41.28.2.13 Integrated Heat Pump Water Heating Energy[J]** The output variable is the total water heating output of the integrated heat pump in joules over the timestep being reported.

**1.41.28.2.14 Integrated Heat Pump Air Latent Cooling Energy [J]** The output variable is the total latent cooling output of the integrated heat pump in joules over the timestep being reported.

**1.41.28.2.15 Integrated Heat Pump Source Heat Transfer Energy [J]** The output variable is the total source energy output of the integrated heat pump in joules, absorbed or discharged to the outdoor air, over the timestep being reported.

**1.41.29 CoilSystem:Cooling:Water:HeatExchangerAssisted**

The heat exchanger-assisted water cooling coil is a virtual component consisting of a chilled-water cooling coil and an air-to-air heat exchanger as shown in Figure 1.175 below. The air-to-air heat exchanger precools the air entering the cooling coil, and reuses this energy to reheat the supply air leaving the cooling coil. This heat exchange process improves the latent removal performance of the cooling coil by allowing it to dedicate more of its cooling capacity toward dehumidification (lower sensible heat ratio).

Note: Node naming shown in Figure 1.175 is representative for **HeatExchanger:AirToAir:SensibleAndLatent**. For **HeatExchanger:AirToAir:FlatPlate**, the exhaust air nodes are referred to as secondary air nodes.

This compound object models the basic operation of an air-to-air heat exchanger in conjunction with a chilled-water cooling coil. The heat exchanger-assisted water cooling coil does not have an operating schedule of its own; its operating schedule is governed by the availability schedules for the chilled-water cooling coil and the air-to-air heat exchanger. Heat exchange will occur whenever the heat exchanger is available to operate (via its availability schedule) and a temperature difference exists between the two air streams – there is currently no method to enable or disable heat exchange based on zone air humidity level. This compound object is used in place of where a chilled-water cooling coil object would normally be used by itself.

To model a heat exchanger-assisted water cooling coil, the input data file should include the following objects:

- CoilSystem:Cooling:Water:HeatExchangerAssisted compound object
- Air-to-air heat exchanger object (**HeatExchanger:AirToAir:FlatPlate** or **HeatExchanger:AirToAir:SensibleAndLatent**)

Figure 1.175: Schematic of the CoilSystem:Cooling:Water:HeatExchangerAssisted compound object

- Chilled-water cooling coil object ([Coil:Cooling:Water](#) or [Coil:Cooling:Water:DetailedGeometry](#))

Links to the cooling coil and air-to-air heat exchanger specifications are provided in the input data syntax for this compound object. A description of each input field for this compound object is provided below.

### 1.41.29.1 Inputs

#### 1.41.29.1.1 Field: Name

A unique user-assigned name for the heat exchanger-assisted water cooling coil. Any reference to this compound component by another object (e.g., [ZoneHVAC:UnitVentilator](#), [ZoneHVAC:FourPipeFanCoil](#), component in an air loop Branch object) will use this name.

#### 1.41.29.1.2 Field: Heat Exchanger Object Type

This alpha field denotes the type of heat exchanger being modeled. Valid choices are:

[HeatExchanger:AirToAir:FlatPlate](#)

[HeatExchanger:AirToAir:SensibleAndLatent](#)

#### 1.41.29.1.3 Field: Heat Exchanger Name

This alpha field denotes the name of the air-to-air heat exchanger being modeled.

#### 1.41.29.1.4 Field: Cooling Coil Object Type

This alpha field denotes the type of chilled-water cooling coil being modeled. Valid choices are:

[Coil:Cooling:Water](#)

[Coil:Cooling:Water:DetailedGeometry](#)

### 1.41.29.1.5 Field: Cooling Coil Name

This alpha field denotes the name of the chilled-water cooling coil being modeled.

Following is an example input for this compound object:

```
CoilSystem:Cooling:Water:HeatExchangerAssisted,
Heat Exchanger Assisted Cooling Coil 1, !- Name of the heat exchanger assisted cooling coil
HeatExchanger:AirToAir:FlatPlate,      !- Heat exchanger type
Heat Exchanger Assisting Cooling Coil,  !- Heat exchanger name
Coil:Cooling:Water:DetailedGeometry,    !- Cooling coil type
Main Cooling Coil 1;                     !- Cooling coil name

HeatExchanger:AirToAir:FlatPlate,
Heat Exchanger Assisting Cooling Coil,  !- Name

```

### 1.41.29.2 Outputs

No variables are reported for this compound object. However, outputs are provided by the cooling coil and heat exchanger that are specified.

### 1.41.30 Coil:WaterHeating:AirToWaterHeatPump:Pumped

EnergyPlus can model a heat pump water heater (HPWH) consisting of a water heater tank (e.g., `WaterHeater:Mixed`), a direct expansion (DX) coil (i.e., an air-to-water DX compression system which includes a water heating coil, air coil, compressor, and water pump), and a fan to provide air flow across the air coil associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source. From the air-side heat transfer perspective, the water-heater receives heating energy from air. Thus it is considered as a cooling coil, and the output variable names are using "Cooling Coil".

The `WaterHeater:HeatPump:PumpedCondenser` compound object, water heater tank object (e.g., `WaterHeater:Mixed`), and fan object (e.g., `Fan:OnOff`) are defined elsewhere in this reference document. `Coil:WaterHeating:AirToWaterHeatPump:Pumped` object described here models an air-to-water DX compression system to determine its air-side and water-side performance. This DX coil object calculates the air-side sensible and latent cooling capacity at the specific operating conditions for each simulation timestep, as well as the condenser's water-side temperature difference at a given condenser water flow rate.

The heat pump water heater DX coil model performs the following major functions:

- calculates the electric consumption of the DX compressor and water pump
- calculates the amount of heat delivered to the water tank
- calculates the electric consumption of the compressor's crankcase heater
- calculates the air-side performance of the DX coil

The input fields for this object are described below in detail:

#### 1.41.30.1 Inputs

##### 1.41.30.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a heat pump water heater DX coil. Any reference to this coil by another object (e.g., `WaterHeater:HeatPump:PumpedCondenser`) will use this name.

##### 1.41.30.1.2 Field: Rated Heating Capacity

This numeric field defines the DX coil heating capacity in Watts at the rated evaporator inlet air temperatures, rated condenser inlet water temperature, rated evaporator air flow rate, and rated condenser water flow rate specified below. Values must be greater than 0. This value represents water heating capacity, and it may or may not include the impact of condenser pump heat (see field Condenser Pump Heat Included in Rated Heating Capacity below).

##### 1.41.30.1.3 Field: Rated COP

This numeric field defines the DX coil's water heating coefficient of performance ( $COP = \text{water heating capacity in watts} / \text{electrical power input in watts}$ ) at rated conditions (rated inlet temperatures and flow rates specified below). This input not only determines the electric energy use of the heat pump DX coil, but also the amount of total air cooling provided by the evaporator. The rated COP includes compressor power, and may or may not include condenser pump power or evaporator fan power (see field Evaporator Fan Power Included in Rated COP and field Condenser Pump Power Included in Rated COP). Values must be greater than 0. If this field is left blank, the default value is 3.2.

**1.41.30.1.4 Field: Rated Sensible Heat Ratio**

This numeric field defines the air-side sensible heat ratio ( $SHR = \text{sensible cooling capacity} / \text{total cooling capacity}$ ) of the DX coil at rated conditions (rated inlet temperatures and flow rates specified below). This value should not include the effect of evaporator fan heat. Values must be greater than or equal to 0.5, and less than or equal to 1.0. The default value is 0.85.

**1.41.30.1.5 Field: Rated Evaporator Inlet Air Dry-Bulb Temperature**

This numeric field defines the evaporator inlet air dry-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5 °C. If this field is left blank, the default value is 19.7 °C.

**1.41.30.1.6 Field: Rated Evaporator Inlet Air Wet-Bulb Temperature**

This numeric field defines the evaporator inlet air wet-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5 °C. If this field is left blank, the default value is 13.5 °C.

**1.41.30.1.7 Field: Rated Condenser Inlet Water Temperature**

This numeric field defines the condenser inlet water temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 25 °C. If this field is left blank, the default value is 57.5 °C.

**1.41.30.1.8 Field: Rated Evaporator Air Flow Rate**

This numeric field defines the evaporator air volume flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = **autocalculate**), the default value is  $5.035\text{E-}5 \text{ m}^3/\text{s}/\text{W}$  (31.25 cfm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated evaporator air volumetric flow rate, a zone sizing object is not required.

**1.41.30.1.9 Field: Rated Condenser Water Flow Rate**

This numeric field defines the condenser water volumetric flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = **autocalculate**), the default value is  $4.487\text{E-}8 \text{ m}^3/\text{s}/\text{W}$  (0.208 gpm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated condenser water volumetric flow rate, a zone sizing object is not required. A warning message will be issued if the ratio of Rated Condenser Water Volumetric Flow Rate to Rated Heating Capacity is less than  $1.79405\text{E-}8 \text{ m}^3/\text{s}/\text{W}$  (0.083 gpm/MBH) or greater than  $8.97024\text{E-}8 \text{ m}^3/\text{s}/\text{W}$  (0.417 gpm/MBH), but the simulation will continue.

**1.41.30.1.10 Field: Evaporator Fan Power Included in Rated COP**

This choice field specifies if evaporator fan power is included in the rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep. If Yes is selected, the evaporator fan power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. If No is selected, it is assumed that the total heating power does not include evaporator fan power. If this field is left blank, the default is Yes. See the Engineering Reference section for `Coil:WaterHeating:AirToWaterHeatPump:\*` for further details.

**1.41.30.1.11 Field: Condenser Pump Power Included in Rated COP**

This choice field specifies if condenser pump power is included in the rated COP defined above. This input impacts the calculation of compressor electric power which then impacts the total air cooling provided

by the evaporator for each simulation timestep. If Yes is selected, the condenser pump power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. If No is selected, it is assumed that the total heating power does not include the condenser pump. If this field is left blank, the default is No. See Engineering Reference section for `Coil:WaterHeating:AirToWaterHeatPump:\*` for further details.

#### **1.41.30.1.12 Field: Condenser Pump Heat Included in Rated Heating Capacity and Rated COP**

This choice field specifies if condenser pump heat is included in the rated heating capacity and rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep. If Yes is selected, the condenser pump heat is already included in the rated heating capacity and rated COP. If No is selected, it is assumed that the rated heating capacity and rated COP do not include the condenser pump heat, and pump heat is added to the total water heating capacity based on the Condenser Water Pump Power and Fraction of Condenser Pump Heat to Water fields below. If this field is left blank, the default is No. See Engineering Reference section for `Coil:WaterHeating:AirToWaterHeatPump:\*` for further details.

#### **1.41.30.1.13 Field: Condenser Water Pump Power**

This numeric field defines the DX coil's condenser pump power in Watts. This is the operating pump power as installed. Values must be greater than or equal to 0. If this field is left blank, the default value is 0. A warning message will be issued if the ratio of Condenser Water Pump Power to Rated Heating Capacity exceeds 0.1422 W/W (41.67 Watts/MBH), but the simulation will continue.

#### **1.41.30.1.14 Field: Fraction of Condenser Pump Heat to Water**

This numeric field defines the fraction of condenser pump heat that is transferred to the condenser water. The pump is assumed to be downstream of the condenser water coil, and this field is used to determine the water temperature at the condenser outlet node when the field Condenser Pump Power Included in Rated Heating Capacity is set to No. Values must be greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

#### **1.41.30.1.15 Field: Evaporator Air Inlet Node Name**

This alpha field defines the name of the air node from which the evaporator coil draws its inlet air.

#### **1.41.30.1.16 Field: Evaporator Air Outlet Node Name**

This alpha field defines the name of the air node to which the evaporator coil sends its outlet air.

#### **1.41.30.1.17 Field: Condenser Water Inlet Node Name**

This alpha field defines the name of the node from which the DX coil condenser draws its inlet water. This node name must also match the source side outlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

#### **1.41.30.1.18 Field: Condenser Water Outlet Node Name**

This alpha field defines the name of the node to which the heat pump condenser sends its outlet water. This node name must also match the source side inlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

**1.41.30.1.19 Field: Crankcase Heater Capacity**

This numeric field defines the compressor's crankcase heater capacity in Watts. The crankcase heater only operates when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation specified below.

**1.41.30.1.20 Field: Maximum Ambient Temperature for Crankcase Heater Operation**

This numeric field defines the maximum ambient temperature for crankcase heater operation in degree Celsius. The crankcase heater only operates when the air surrounding the compressor is below this maximum temperature value and the compressor is off. The ambient temperature surrounding the compressor is set by the Heat Pump:Water Heater parent object (field Compressor Location).

**1.41.30.1.21 Field: Evaporator Air Temperature Type for Curve Objects**

This choice field specifies the air temperature type used for the heating capacity and COP modifier curve objects below. The valid selections are Dry-bulb Temperature and Wet-bulb Temperature. If dry-bulb temperature is selected, the inlet air dry-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If wet-bulb temperature is selected, the inlet air wet-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If this field is left blank and the following curve names are defined, the default value is wet-bulb temperature. If the following curve names are not defined, this field is not used.

**1.41.30.1.22 Field: Heating Capacity Function of Temperature Curve Name**

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated heating capacity to give the heating capacity at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all conditions).

**1.41.30.1.23 Field: Heating Capacity Function of Air Flow Fraction Curve Name**

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated heating capacity and the heating capacity modifier curve (function of temperature) to give the DX coil heating capacity at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all air flow rates).

**1.41.30.1.24 Field: Heating Capacity Function of Water Flow Fraction Curve Name**

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate. The output of this curve is multiplied

by the rated heating capacity and the output from the two other heating capacity modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating capacity at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all water flow rates).

#### 1.41.30.1.25 Field: Heating COP Function of Temperature Curve Name

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated COP to give the heating COP at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the COP remains constant (curve value assumed to be 1.0 for all conditions).

#### 1.41.30.1.26 Field: Heating COP Function of Air Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated COP and the heating COP modifier curve (function of temperature) to give the heating COP at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all air flow rates).

#### 1.41.30.1.27 Field: Heating COP Function of Water Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate.. The output of this curve is multiplied by the rated COP and the output from the two other heating COP modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating COP at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all water flow rates).

#### 1.41.30.1.28 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 < \text{PLR} < 1$ ), the following rules apply:

$\text{PLF} > = 0.7$  and  $\text{PLF} > = \text{PLR}$

If  $PLF < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $PLR/PLF$ . If  $PLF < PLR$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Following is an example input for the `Coil:WaterHeating:AirToWaterHeatPump:Pumped` object:

### 1.41.30.2 Outputs

- HVAC,Average,Heating Coil Total Heating Rate [W]
- HVAC,Sum,Heating Coil Total Heating Energy [J]
- HVAC,Average,Heating Coil Runtime Fraction []
- HVAC,Average,Heating Coil Crankcase Heater Electricity Rate [W]
- HVAC,Sum,Heating Coil Crankcase Heater Electricity Energy [J]
- HVAC,Average,Heating Coil Total Water Heating Rate [W]
- HVAC,Sum,Heating Coil Total Water Heating Energy [J]
- HVAC,Average,Heating Coil Water Heating Electricity Rate [W]
- HVAC,Sum,Heating Coil Water Heating Electricity Energy [J]

**1.41.30.2.1 Heating Coil Total Heating Rate [W]**

This output field is the average total heating rate output of the DX coil in Watts for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.30.2.2 Heating Coil Total Heating Energy [J]**

This output field is the total heating output of the DX coil in Joules for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.30.2.3 Heating Coil Runtime Fraction []**

This output field is the average runtime fraction of the DX coil compressor for the timestep being reported. This also represents the runtime fraction of the condenser water pump.

**1.41.30.2.4 Heating Coil Crankcase Heater Electricity Rate [W]**

This output field is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. The crankcase heater operates only when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation, otherwise this output variable is set equal to 0.

**1.41.30.2.5 Heating Coil Crankcase Heater Electricity Energy [J]**

This output field is the total electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

**1.41.30.2.6 Heating Coil Total Water Heating Rate [W]**

This output field is the average water heating rate output of the DX coil (condenser coil plus condenser water pump) in Watts for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

**1.41.30.2.7 Heating Coil Total Water Heating Energy [J]**

This output field is the total water heating output of the DX coil (condenser coil plus condenser water pump) in Joules for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

**1.41.30.2.8 Heating Coil Water Heating Electricity Rate [W]**

This output field is the average electricity consumption rate of the DX coil compressor and condenser pump in Watts for the timestep being reported.

**1.41.30.2.9 Heating Coil Water Heating Electricity Energy [J]**

This output field is the electricity consumption of the DX coil compressor and condenser pump in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

**1.41.31 Coil:WaterHeating:AirToWaterHeatPump:Wrapped**

EnergyPlus can model a heat pump water heater (HPWH) consisting of a water heater tank (e.g., `WaterHeater:Stratified`), a direct expansion (DX) coil (i.e., an air-to-water DX compression system which includes a water heating coil, air coil, compressor, and water pump), and a fan to provide air flow across the air coil

associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source. From the air-side heat transfer perspective, the water-heater receives heating energy from the air. Thus it is considered as a cooling coil, and the output variable names are using "Cooling Coil".

The `WaterHeater:HeatPump:WrappedCondenser` compound object, water heater tank object (e.g., `WaterHeater:Mixed`), and fan object (e.g., `Fan:OnOff`) are defined elsewhere in this reference document. `Coil:WaterHeating:AirToWaterHeatPump:Wrapped` object described here models an air-to-water DX compression system to determine its air-side and water-side performance. This DX coil object calculates the air-side sensible and latent cooling capacity at the specific operating conditions for each simulation timestep, as well as the condenser's water-side temperature difference at a given condenser water flow rate.

The heat pump water heater DX coil model performs the following major functions:

- calculates the electric consumption of the DX compressor
- calculates the amount of heat delivered to the water tank
- calculates the electric consumption of the compressor's crankcase heater
- calculates the air-side performance of the DX coil

#### 1.41.31.1 Inputs

##### 1.41.31.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a heat pump water heater DX coil. Any reference to this coil by another object (e.g., `WaterHeater:HeatPump:WrappedCondenser`) will use this name.

##### 1.41.31.1.2 Field: Rated Heating Capacity

This numeric field defines the DX coil heating capacity in Watts at the rated evaporator inlet air temperatures, rated condenser inlet water temperature, rated evaporator air flow rate, and rated condenser water flow rate specified below. Values must be greater than 0. This value represents water heating capacity, and it may or may not include the impact of condenser pump heat (see field Condenser Pump Heat Included in Rated Heating Capacity below).

##### 1.41.31.1.3 Field: Rated COP

This numeric field defines the DX coil's water heating coefficient of performance ( $COP = \text{water heating capacity in watts} / \text{electrical power input in watts}$ ) at rated conditions (rated inlet temperatures and flow rates specified below). This input not only determines the electric energy use of the heat pump DX coil, but also the amount of total air cooling provided by the evaporator. The rated COP includes compressor power, and may or may not include condenser pump power or evaporator fan power (see field Evaporator Fan Power Included in Rated COP and field Condenser Pump Power Included in Rated COP). Values must be greater than 0. If this field is left blank, the default value is 3.2.

##### 1.41.31.1.4 Field: Rated Sensible Heat Ratio

This numeric field defines the air-side sensible heat ratio ( $SHR = \text{sensible cooling capacity} / \text{total cooling capacity}$ ) of the DX coil at rated conditions (rated inlet temperatures and flow rates specified below). This value should not include the effect of evaporator fan heat. Values must be greater than or equal to 0.5, and less than or equal to 1.0. The default value is 0.85.

**1.41.31.1.5 Field: Rated Evaporator Inlet Air Dry-Bulb Temperature**

This numeric field defines the evaporator inlet air dry-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5 °C. If this field is left blank, the default value is 19.7 °C.

**1.41.31.1.6 Field: Rated Evaporator Inlet Air Wet-Bulb Temperature**

This numeric field defines the evaporator inlet air wet-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5 °C. If this field is left blank, the default value is 13.5 °C.

**1.41.31.1.7 Field: Rated Condenser Water Temperature**

This numeric field defines the condenser inlet water temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 25 °C. If this field is left blank, the default value is 57.5 °C.

**1.41.31.1.8 Field: Rated Evaporator Air Flow Rate**

This numeric field defines the evaporator air volume flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = **autocalculate**), the default value is  $5.035\text{E-}5 \text{ m}^3/\text{s}/\text{W}$  (31.25 cfm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated evaporator air volumetric flow rate, a zone sizing object is not required.

**1.41.31.1.9 Field: Evaporator Fan Power Included in Rated COP**

This choice field specifies if evaporator fan power is included in the rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep. If Yes is selected, the evaporator fan power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. If No is selected, it is assumed that the total heating power does not include evaporator fan power. If this field is left blank, the default is Yes. See the Engineering Reference section for `Coil:WaterHeating:AirToWaterHeatPump:\*` for further details.

**1.41.31.1.10 Field: Evaporator Air Inlet Node Name**

This alpha field defines the name of the air node from which the evaporator coil draws its inlet air.

**1.41.31.1.11 Field: Evaporator Air Outlet Node Name**

This alpha field defines the name of the air node to which the evaporator coil sends its outlet air.

**1.41.31.1.12 Field: Crankcase Heater Capacity**

This numeric field defines the compressor's crankcase heater capacity in Watts. The crankcase heater only operates when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation specified below.

**1.41.31.1.13 Field: Maximum Ambient Temperature for Crankcase Heater Operation**

This numeric field defines the maximum ambient temperature for crankcase heater operation in degree Celsius. The crankcase heater only operates when the air surrounding the compressor is below this maximum temperature value and the compressor is off. The ambient temperature surrounding the compressor is set by the Heat Pump:Water Heater parent object (field Compressor Location).

**1.41.31.1.14 Field: Evaporator Air Temperature Type for Curve Objects**

This choice field specifies the air temperature type used for the heating capacity and COP modifier curve objects below. The valid selections are Dry-bulb Temperature and Wet-bulb Temperature. If dry-bulb temperature is selected, the inlet air dry-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If wet-bulb temperature is selected, the inlet air wet-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If this field is left blank and the following curve names are defined, the default value is wet-bulb temperature. If the following curve names are not defined, this field is not used.

**1.41.31.1.15 Field: Heating Capacity Function of Temperature Curve Name**

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated heating capacity to give the heating capacity at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all conditions).

**1.41.31.1.16 Field: Heating Capacity Function of Air Flow Fraction Curve Name**

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated heating capacity and the heating capacity modifier curve (function of temperature) to give the DX coil heating capacity at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all air flow rates).

**1.41.31.1.17 Field: Heating COP Function of Temperature Curve Name**

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated COP to give the heating COP at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the COP remains constant (curve value assumed to be 1.0 for all conditions).

**1.41.31.1.18 Field: Heating COP Function of Air Flow Fraction Curve Name**

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated COP and the heating COP modifier curve (function of temperature) to give the heating COP at

the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all air flow rates).

#### 1.41.31.1.19 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 <= \text{PLR} < 1$ ), the following rules apply:

$\text{PLF} >= 0.7$  and  $\text{PLF} >= \text{PLR}$

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Following is an example input for the `Coil:WaterHeating:AirToWaterHeatPump:Wrapped` object:

```

#### 1.41.31.2 Outputs

- HVAC,Average,Heating Coil Total Heating Rate [W]
- HVAC,Sum,Heating Coil Total Heating Energy [J]
- HVAC,Average, Heating Coil Runtime Fraction []

- HVAC,Average,Heating Coil Crankcase Heater Electricity Rate [W]
- HVAC,Sum, Heating Coil Crankcase Heater Electricity Energy [J]
- HVAC,Average,Heating Coil Total Water Heating Rate [W]
- HVAC,Sum,Heating Coil Total Water Heating Energy [J]
- HVAC,Average,Heating Coil Water Heating Electricity Rate [W]
- HVAC,Sum,Heating Coil Water Heating Electricity Energy [J]

#### 1.41.31.2.1 Heating Coil Total Heating Rate [W]

This output field is the average total heating rate output of the DX coil in Watts for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.31.2.2 Heating Coil Total Heating Energy [J]

This output field is the total heating output of the DX coil in Joules for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

#### 1.41.31.2.3 Heating Coil Runtime Fraction []

This output field is the average runtime fraction of the DX coil compressor for the timestep being reported. This also represents the runtime fraction of the condenser water pump.

#### 1.41.31.2.4 Heating Coil Crankcase Heater Electricity Rate [W]

This output field is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. The crankcase heater operates only when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation, otherwise this output variable is set equal to 0.

#### 1.41.31.2.5 Heating Coil Crankcase Heater Electricity Energy [J]

This output field is the total electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

#### 1.41.31.2.6 Heating Coil Total Water Heating Rate [W]

This output field is the average water heating rate output of the DX coil (condenser coil plus condenser water pump) in Watts for the timestep being reported.

#### 1.41.31.2.7 Heating Coil Total Water Heating Energy [J]

This output field is the total water heating output of the DX coil (condenser coil plus condenser water pump) in Joules for the timestep being reported.

#### 1.41.31.2.8 Heating Coil Water Heating Electricity Rate [W]

This output field is the average electricity consumption rate of the DX coil compressor in Watts for the timestep being reported.

#### 1.41.31.2.9 Heating Coil Water Heating Electricity Energy [J]

This output field is the electricity consumption of the DX coil compressor in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

### 1.41.32 Coil:WaterHeating:AirToWaterHeatPump:VariableSpeed

`Coil:WaterHeating:AirToWaterHeatPump:VariableSpeed` object described here models an air-to-water DX compression system to determine its air-side and water-side performance. Unlike the `WaterHeater:HeatPump:PumpedCondenser` it has multiple, and up to 10, speeds.

It can be used in `CoilSystem:IntegratedHeatPump:AirSource` OR `Coil:WaterHeating:AirToWaterHeatPump:Pumped` which are defined elsewhere in this document.

This DX coil object calculates the air-side sensible and latent cooling capacity at the specific operating conditions for each simulation timestep, as well as the condenser's water-side temperature difference at a given condenser water flow rate.

This coil draws heating energy from air to the heater. Thus it is regarded as a cooling coil, as shown in the output variable names.

The heat pump water heater DX coil model performs the following major functions:

- calculates the electric consumption of the DX compressor and water pump
- calculates the amount of heat delivered to the water tank
- calculates the electric consumption of the compressor's crankcase heater
- calculates the air-side performance of the DX coil

The input fields for this object are described below in detail:

#### 1.41.32.0.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a heat pump water heater Variable Speed DX coil. Any reference to this coil by another object (e.g., `WaterHeater:HeatPump:PumpedCondenser` OR `CoilSystem:IntegratedHeatPump:AirSource`) will use this name.

#### 1.41.32.0.2 Field: Number of Speeds

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, should be equal or higher than the maximum number. The performance inputs at higher speed levels are ignored. This must be greater or equal to 1, and lesser or equal to 10.

#### 1.41.32.0.3 Field: Nominal Speed Level

This numeric field defines the nominal speed level, at which the rated capacity, rated air and water volumetric flow rates are correlated.

#### 1.41.32.0.4 Field: Rated Water Heating Capacity

This numeric field defines the DX coil heating capacity in Watts at the rated evaporator inlet air temperatures, rated condenser inlet water temperature, rated evaporator air flow rate, and rated condenser water flow rate specified below. Values must be greater than 0. This value represents water heating capacity, and it may or may not include the impact of condenser pump heat (see field Condenser Pump Heat Included in Rated Heating Capacity below).

**1.41.32.0.5 Field: Rated Evaporator Inlet Air Dry-Bulb Temperature**

This numeric field defines the evaporator inlet air dry-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5 °C. If this field is left blank, the default value is 19.7 °C.

**1.41.32.0.6 Field: Rated Evaporator Inlet Air Wet-Bulb Temperature**

This numeric field defines the evaporator inlet air wet-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5 °C. If this field is left blank, the default value is 13.5 °C.

**1.41.32.0.7 Field: Rated Condenser Inlet Water Temperature**

This numeric field defines the condenser inlet water temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 25 °C. If this field is left blank, the default value is 57.5 °C.

**1.41.32.0.8 Field: Rated Evaporator Air Flow Rate**

This numeric field defines the evaporator air volume flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = `autocalculate`), the default value is  $5.035 \times 10^{-5} \text{ (m}^3\text{/s)}/\text{W}$  (31.25 CFM/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated evaporator air volumetric flow rate, a zone sizing object is not required.

**1.41.32.0.9 Field: Rated Condenser Water Flow Rate**

This numeric field defines the condenser water volumetric flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = `autocalculate`), the default value is  $4.487 \times 10^{-8} \text{ (m}^3\text{/s)}/\text{W}$  (0.208 gpm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated condenser water volumetric flow rate, a zone sizing object is not required. A warning message will be issued if the ratio of Rated Condenser Water Volumetric Flow Rate to Rated Heating Capacity is less than  $1.79405 \times 10^{-8} \text{ (m}^3\text{/s)}/\text{W}$  (0.083 gpm/MBH) or greater than  $8.97024 \times 10^{-8} \text{ (m}^3\text{/s)}/\text{W}$  (0.417 gpm/MBH), but the simulation will continue.

**1.41.32.0.10 Field: Evaporator Fan Power Included in Rated COP**

This choice field specifies if evaporator fan power is included in the rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep.

- If **Yes** is selected, the evaporator fan power is subtracted from the total electric heating power when calculating total evaporator cooling capacity.
- If **No** is selected, it is assumed that the total heating power does not include evaporator fan power.

If this field is left blank, the default is **Yes**. See the Engineering Reference section for `Coil:WaterHeating:AirToWaterHeatPump:\*` for further details.

**1.41.32.0.11 Field: Condenser Pump Power Included in Rated COP**

This choice field specifies if condenser pump power is included in the rated COP defined above. This input impacts the calculation of compressor electric power which then impacts the total air cooling provided by the evaporator for each simulation timestep.

- If **Yes** is selected, the condenser pump power is subtracted from the total electric heating power when calculating total evaporator cooling capacity.
- If **No** is selected, it is assumed that the total heating power does not include the condenser pump.

If this field is left blank, the default is **No**. See Engineering Reference section for `Coil:WaterHeating:AirToWaterHeatPump:\*` for further details.

#### **1.41.32.0.12 Field: Condenser Pump Heat Included in Rated Heating Capacity and Rated COP**

This choice field specifies if condenser pump heat is included in the rated heating capacity and rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep.

- If **Yes** is selected, the condenser pump heat is already included in the rated heating capacity and rated COP.
- If **No** is selected, it is assumed that the rated heating capacity and rated COP do not include the condenser pump heat, and pump heat is added to the total water heating capacity based on the Condenser Water Pump Power and Fraction of Condenser Pump Heat to Water fields below.

If this field is left blank, the default is **No**. See Engineering Reference section for `Coil:WaterHeating:AirToWaterHeatPump:\*` for further details.

#### **1.41.32.0.13 Field: Fraction of Condenser Pump Heat to Water**

This numeric field defines the fraction of condenser pump heat that is transferred to the condenser water. The pump is assumed to be downstream of the condenser water coil, and this field is used to determine the water temperature at the condenser outlet node when the field Condenser Pump Power Included in Rated Heating Capacity is set to No. Values must be greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

#### **1.41.32.0.14 Field: Evaporator Air Inlet Node Name**

This alpha field defines the name of the air node from which the evaporator coil draws its inlet air.

#### **1.41.32.0.15 Field: Evaporator Air Outlet Node Name**

This alpha field defines the name of the air node to which the evaporator coil sends its outlet air.

#### **1.41.32.0.16 Field: Condenser Water Inlet Node Name**

This alpha field defines the name of the node from which the DX coil condenser draws its inlet water. This node name must also match the source side outlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

#### **1.41.32.0.17 Field: Condenser Water Outlet Node Name**

This alpha field defines the name of the node to which the heat pump condenser sends its outlet water. This node name must also match the source side inlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

#### **1.41.32.0.18 Field: Crankcase Heater Capacity**

This numeric field defines the compressor's crankcase heater capacity in Watts. The crankcase heater only operates when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation specified below.

**1.41.32.0.19 Field: Maximum Ambient Temperature for Crankcase Heater Operation**

This numeric field defines the maximum ambient temperature for crankcase heater operation in degree Celsius. The crankcase heater only operates when the air surrounding the compressor is below this maximum temperature value and the compressor is off. The ambient temperature surrounding the compressor is set by the Heat Pump:Water Heater parent object (field Compressor Location). The default is 10 °C.

**1.41.32.0.20 Field: Evaporator Air Temperature Type for Curve Objects**

This choice field specifies the air temperature type used for the heating capacity and COP modifier curve objects below (for each speed). The valid selections are Dry-bulb Temperature and Wet-bulb Temperature. If dry-bulb temperature is selected, the inlet air dry-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If wet-bulb temperature is selected, the inlet air wet-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If this field is left blank and the following curve names are defined, the default value is **WetBulbTemperature**.

**1.41.32.0.21 Field: Part Load Fraction Correlation Curve Name**

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep).

Use a `Curve:Quadratic` with coefficients of {1, 0, 0} (constant curve) or leave this field blank when neglecting performance impacts due to variations in part load ratio.

**1.41.32.0.22 Field Group: rated specification, performance curves**

The performance for each speed must be specified as shown below. All inputs for Speed 1 are required, followed by the optional inputs for other speeds.

**Speeds should be ordered from lower capacity to higher capacity/airflow rate, or a Fatal error will be thrown.**

**1.41.32.0.23 Field: Rated Water Heating Capacity at Speed <x>**

This numeric field defines the DX coil heating capacity in Watts at the rated evaporator inlet air temperatures, rated condenser inlet water temperature, rated evaporator air flow rate, and rated condenser water flow rate specified below for this speed.

Values must be greater than 0. This value represents water heating capacity, and it may or may not include the impact of condenser pump heat (see field Condenser Pump Heat Included in Rated Heating Capacity above).

**1.41.32.0.24 Field: Rated Water Heating COP at Speed <x>**

This numeric field defines the DX coil's water heating coefficient of performance (COP = water heating capacity in watts divided by electrical power input in watts) at rated conditions (rated inlet temperatures and flow rates specified below). This input not only determines the electric energy use of the heat pump DX coil, but also the amount of total air cooling provided by the evaporator. The rated COP includes compressor power, and may or may not include condenser pump power or evaporator fan power (see field

Evaporator Fan Power Included in Rated COP and field Condenser Pump Power Included in Rated COP). Values must be greater than 0. If this field is left blank, the default value is 3.2.

#### 1.41.32.0.25 Field: Rated Sensible Heat Ratio at Speed <x>

This numeric field defines the gross air-side sensible heat ratio ( $SHR = \text{gross sensible cooling capacity} / \text{gross total cooling capacity}$ ) of the DX coil at rated conditions (rated inlet temperatures and flow rates specified below). This value should not include the effect of evaporator fan heat, only sensible cooling and dehumidification by the coil alone. Values must be greater than or equal to 0.5, and less than or equal to 1.0. The default value is 0.85.

**1.41.32.0.26 Field: Speed <x> Reference Unit Rated Air Flow Rate** This numeric field contains the reference volumetric air flow rate on the evaporator at this specific speed level in  $\text{m}^3/\text{s}$ . Values must be greater than or equal to 0.

**1.41.32.0.27 Field: Speed <x> Reference Unit Rated Water Flow Rate** This numeric field contains the reference volumetric water flow rate on the condenser at this specific speed level in  $\text{m}^3/\text{s}$ . Values must be greater than or equal to 0.

#### 1.41.32.0.28 Field: Speed <x> Reference Unit Water Pump Input Power At Rated Conditions

This numeric field defines the DX coil's condenser pump power in Watts. This is the operating pump power at this specific speed's reference conditions. Values must be greater than or equal to 0.

#### 1.41.32.0.29 Field: Speed <x> Total WH Capacity Function of Temperature Curve Name

This alpha field specifies the name of a **biquadratic** performance curve object (ref: Performance Curves) (or any Bivariate function) that defines the variation in DX coil heating capacity as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The output of this curve is multiplied by the rated heating capacity at this speed to give the heating capacity at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all conditions).

#### 1.41.32.0.30 Field: Speed <x> Total WH Capacity Function of Air Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated heating capacity at this specific speed and the heating capacity modifier curve (function of temperature) to give the DX coil heating capacity at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all air flow rates).

**1.41.32.0.31 Field: Speed <x> Total WH Capacity Function of Water Flow Fraction Curve Name**

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate. The output of this curve is multiplied by the rated heating capacity at this specific speed and the output from the two other heating capacity modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating capacity at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all water flow rates).

**1.41.32.0.32 Field: Speed <x> COP Function of Temperature Curve Name**

This alpha field specifies the name of a **biquadratic** performance curve object (ref: Performance Curves) (or any Bivariate function) that defines the variation in DX coil heating COP as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The output of this curve is multiplied by the rated COP at this specific speed to give the heating COP at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the COP remains constant (curve value assumed to be 1.0 for all conditions).

**1.41.32.0.33 Field: Speed <x> COP Function of Air Flow Fraction Curve Name**

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated COP at this specific speed and the heating COP modifier curve (function of temperature) to give the heating COP at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all air flow rates).

**1.41.32.0.34 Field: Speed <x> COP Function of Water Flow Fraction Curve Name**

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate. The output of this curve is multiplied by the rated COP at this specific speed and the output from the two other heating COP modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating COP at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all water flow rates).

**1.41.32.1.1 HVAC,Average,Cooling Coil Total Cooling Rate [W]** This output field is the average total (sensible and latent) cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.32.1.2 HVAC,Sum,Cooling Coil Cooling Energy [J]** This output field is the total (sensible plus latent) cooling output of the DX coil in Joules for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.32.1.3 HVAC,Average,Cooling Coil Sensible Cooling Rate [W]** This output field is the average moist air sensible cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.32.1.4 HVAC,Sum,Cooling Coil Sensible Cooling Energy [J]** This output field is the moist air sensible cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.32.1.5 HVAC,Average,Cooling Coil Latent Cooling Rate [W]** This output field is the average latent cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.32.1.6 HVAC,Sum,Cooling Coil Latent Cooling Energy [J]** This output field is the latent cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

**1.41.32.1.7 HVAC,Average,Cooling Coil Runtime Fraction []** This output field is the average runtime fraction of the DX coil compressor for the timestep being reported. This also represents the runtime fraction of the condenser water pump.

**1.41.32.1.8 HVAC,Average,Cooling Coil Crankcase Heater Electricity Rate [W]** This output field is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. The crankcase heater operates only when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation, otherwise this output variable is set equal to 0.

**1.41.32.1.9 HVAC,Sum,Cooling Coil Crankcase Heater Electricity Energy [J]** This output field is the total electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

**1.41.32.1.10 HVAC,Average,Cooling Coil Total Water Heating Rate [W]** This output field is the average water heating rate output of the DX coil (condenser coil plus condenser water pump) in Watts for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

**1.41.32.1.11 HVAC,Sum,Cooling Coil Water Side Heat Transfer Energy [J]** This output field is the total water heating output of the DX coil (condenser coil plus condenser water pump) in Joules for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

**1.41.32.1.12 HVAC,Average,Cooling Coil Water Heating Electricity Rate [W]** This output field is the average electricity consumption rate of the DX coil compressor and condenser pump in Watts for the timestep being reported.

**1.41.32.1.13 HVAC,Sum,Cooling Coil Electricity Energy [J]** This output field is the electricity consumption of the DX coil compressor and condenser pump in Joules for the timestep being reported. nThis output is also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

**1.41.32.1.14 HVAC,Average,Cooling Coil Part Load Ratio []** This output variable is the ratio of the part-load capacity to the steady state capacity of the DX coil.

**1.41.32.1.15 HVAC,Average,Cooling Coil Air Mass Flow Rate [kg/s]** The output variable is the average air mass flow rate going through the evaporator over the timestep being reported.

**1.41.32.1.16 HVAC,Average,Cooling Coil Air Inlet Temperature [C]** The output variable is the average entering air dry-bulb temperature over the timestep being reported.

**1.41.32.1.17 HVAC,Average,Cooling Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]** The output variable is the average entering air dry humidity ratio over the timestep being reported.

**1.41.32.1.18 HVAC,Average,Cooling Coil Air Outlet Temperature [C]** The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

**1.41.32.1.19 HVAC,Average,Cooling Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]** The output variable is the average leaving air dry humidity ratio over the timestep being reported.

**1.41.32.1.20 HVAC,Average,Cooling Coil Water Mass Flow Rate [kg/s]** The output variable is the average water mass flow rate going through the condenser over the timestep being reported.

**1.41.32.1.21 HVAC,Average,Cooling Coil Water Inlet Temperature [C]** The output variable is the average entering water temperature over the timestep being reported.

**1.41.32.1.22 HVAC,Average,Cooling Coil Water Outlet Temperature [C]** The output variable is the average leaving water temperature over the timestep being reported.

**1.41.32.1.23 HVAC,Average,Cooling Coil Upper Speed Level []** The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

**1.41.32.1.24 HVAC,Average,Cooling Coil Neighboring Speed Levels Ratio []** The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

**1.41.32.1.25 HVAC,Average,Cooling Coil Water Heating Pump Electricity Rate [W]** This output field is the average electricity consumption rate of the DX coil condenser water circulation pump in Watts for the timestep being reported.

**1.41.32.1.26 HVAC,Sum,Cooling Coil Water Heating Pump Electricity Energy [J]** This output field is the electricity consumption of the DX coil condenser water circulation pump in Joules for the timestep being reported.

### 1.41.33 Coil:Cooling:WaterToAirHeatPump:ParameterEstimation

The **Coil:Cooling:WaterToAirHeatPump:ParameterEstimation** coil is a deterministic model that requires parameters to describe the operating conditions of the heat pump's components. The parameters are generated from the manufacturer catalog data using multi-variable optimization method. In addition, the cooling coil model can be used for 3 type of compressors: **reciprocating**, **rotary** and **scroll**. Descriptions and strength of each respective model is available in the following references:

Jin, Hui. 2002. Parameter Estimation Based Models of Water Source Heat Pumps. Phd. Thesis, Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Tang,C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

#### 1.41.33.1 Inputs

##### 1.41.33.1.1 Field: Name

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., **AirLoopHVAC:UnitarySystem** or **AirLoopHVAC:UnitaryHeatPump:WaterToAir**) will use this name.

##### 1.41.33.1.2 Field: Compressor Type

Type of compressor mode used for the heat pump. Choices available are reciprocating, rotary and scroll compressor. Note that the parameters vary for different compressor.

##### 1.41.33.1.3 Field: Refrigerant Type

This alpha field contains the type of refrigerant used by the heat pump.

##### 1.41.33.1.4 Field: Design Source Side Flow Rate

This numeric field defines the water flow rate through the coil in m<sup>3</sup>/sec

##### 1.41.33.1.5 Field: Nominal Cooling Coil Capacity

This numeric field defines the nominal cooling capacity for the WaterToAirHP cooling coil in Watts.

**1.41.33.1.6 Field: Nominal Time for Condensate Removal to Begin**

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

**1.41.33.1.7 Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity**

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

**1.41.33.1.8 Field: High Pressure Cutoff**

This numeric field defines the compressor's maximum allowable pressure in Pascal (N/m<sup>2</sup>)

**1.41.33.1.9 Field: Low Pressure Cutoff**

This numeric field defines the compressor's minimum allowable pressure in Pascal (N/m<sup>2</sup>)

**1.41.33.1.10 Field: Water Inlet Node Name**

This alpha field contains the cooling coil source side inlet node name.

**1.41.33.1.11 Field: Water Outlet Node Name**

This alpha field contains the cooling coil source side outlet node name.

**1.41.33.1.12 Field: Air Inlet Node Name**

This alpha field contains the cooling coil air inlet node name.

**1.41.33.1.13 Field: Air Outlet Node Name**

This alpha field contains the cooling coil air outlet node name.

**1.41.33.1.14 Cooling Coil Parameters**

Depending on the type of compressor and the source side fluid specified, the type of parameters and values also differs. An Excel Spreadsheet is developed to estimate the parameters based on the manufacturer data. The general parameters are listed first followed by specific parameters required by the respective compressor model. Lastly, parameters are listed based on the type of source side fluid used.

**1.41.33.1.15 Field: Load Side Total Heat Transfer Coefficient**

This numeric field defines the estimated parameter **load side total heat transfer coefficient** in W/K. This field was previously known as Parameter 1.

**1.41.33.1.16 Field: Load Side Outside Surface Heat Transfer Coefficient**

This numeric field defines the estimated parameter **load side outside surface heat transfer coefficient** in W/K. This field was previously known as Parameter 2.

**1.41.33.1.17 Field: Superheat Temperature at the Evaporator Outlet**

This numeric field defines the estimated parameter **superheat temperature** at the evaporator outlet in °C. This field was previously known as Parameter 3.

**1.41.33.1.18 Field: Compressor Power Losses**

This numeric field defines the estimated parameter **compressor power losses**, which accounts for the loss of work due to mechanical and electrical losses in the compressor in Watts. This field was previously known as Parameter 4.

**1.41.33.1.19 Field: Compressor Efficiency**

This numeric field defines the estimated parameter of the **compressor's efficiency**. The compressor efficiency is formulated as the equation below:

$$\eta = \frac{\dot{W}_{Theoretical}}{\dot{W}_{CompInput} - \dot{W}_{Loss}} \quad (1.167)$$

This field was previously know as Parameter 5.

**1.41.33.1.20 Field: Compressor Piston Displacement**

This numeric field defines the estimated parameter **piston displacement of the compressor** in m<sup>3</sup>/s. This field was part of what was previously known as Parameter 6. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

**1.41.33.1.21 Field: Compressor Suction/Discharge Pressure Drop**

This numeric field defines the estimated parameter **pressure drop** at the compressor suction and discharge in Pascals (N/m<sup>2</sup>). This field was part of what was previously known as Parameter 7. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

**1.41.33.1.22 Field: Compressor Clearance Factor**

This numeric field defines the estimated parameter **clearance factor of the compressor**. This parameter is dimensionless. This field was part of what was previously known as Parameter 8. It should only be used when the Compressor type is Reciprocating. The field should be left blank when Compressor type is Scroll or Rotary.

**1.41.33.1.23 Field: Refrigerant Volume Flow Rate**

This numeric field defines the **refrigerant volume flow rate** at the beginning of the compression [m<sup>3</sup>/s]. This field was part of what was previously known as Parameter 6. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

**1.41.33.1.24 Field: Volume Ratio**

This numeric field defines the built-in-**volume ratio**. This field was part of what was previously known as Parameter 7. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

#### 1.41.33.1.25 Field: Leak Rate Coefficient

This numeric field defines the **leak rate coefficient** for the relationship between pressure ratio and leakage rate. This field was part of what was previously known as Parameter 8. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

#### 1.41.33.1.26 Field: Source Side Heat Transfer Coefficient

This numeric field defines the estimated parameter **source side heat transfer coefficient** in W/K. This field was part of what was previously known as Parameter 9. It should only be used when the Source Side Fluid Name is Water.

#### 1.41.33.1.27 Field: Source Side Heat Transfer Resistance1

This numeric field defines the estimated parameter **source side heat transfer resistance 1**. Unit is dimensionless. This field was part of what was previously known as Parameter 9. It should only be used when the Source Side Fluid Name is an antifreeze.

#### 1.41.33.1.28 Field: Source Side Heat Transfer Resistance2

This numeric field defines the estimated parameter **source side heat transfer resistance 2**. Unit is W/K. This field was previously known as Parameter 10. It should only be used when the Source Side Fluid Name is an antifreeze.

### 1.41.34 Coil:Cooling:WaterToAirHeatPump:EquationFit

The **Coil:Cooling:WaterToAirHeatPump:EquationFit** is a simple curve-fit model that requires coefficients generated from the heat pump catalog data. This is an equation-fit model that resembles a black box with

no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data. Description of the equation-fit model is available in the following reference:

Tang, C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

### 1.41.34.1 Inputs

#### 1.41.34.1.1 Field: Name

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., **AirLoopHVAC:UnitarySystem** or **AirLoopHVAC:UnitaryHeatPump:WaterToAir**) will use this name.

#### 1.41.34.1.2 Field: Water Inlet Node Name

This alpha field contains the cooling coil source side inlet node name.

#### 1.41.34.1.3 Field: Water Outlet Node Name

This alpha field contains the cooling coil source side outlet node name.

#### 1.41.34.1.4 Field: Air Inlet Node Name

This alpha field contains the cooling coil air inlet node name.

#### 1.41.34.1.5 Field: Air Outlet Node Name

This alpha field contains the cooling coil air outlet node name.

#### 1.41.34.1.6 Field: Rated Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump in m<sup>3</sup>/s. This field is autosizable.

#### 1.41.34.1.7 Field: Rated Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump in m<sup>3</sup>/s. This field is autosizable.

#### 1.41.34.1.8 Field: Gross Rated Total Cooling Capacity

This numeric field contains the gross rated total cooling capacity of the heat pump in W. This field is autosizable. The gross rated total cooling capacity should be within 20% of the gross rated heating capacity, otherwise a warning message is issued. The gross rated total cooling capacity should not account for the effect of supply air fan heat.

#### 1.41.34.1.9 Field: Gross Rated Sensible Cooling Capacity

This numeric field contains the gross rated sensible capacity of the heat pump in W. This field is autosizable. The gross rated sensible cooling capacity should not account for the effect of supply air fan heat.

#### 1.41.34.1.10 Field: Rated Cooling Coefficient of Performance

This numeric field contains the rated cooling coefficient of performance of the heat pump.

**1.41.34.1.11 Field: Total Cooling Capacity Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the heat pump total cooling capacity. The Single Speed Equation-Fit Model for Unitary Water-To-Air Heat Pump under the Air System Compound Component Groups in the Engineering Reference document contains more explanation regarding this.

**1.41.34.1.12 Field: Sensible Cooling Capacity Curve Name**

This alpha field specifies the name of a **quintlinear** performance curve object (ref: Performance Curves) for the heat pump sensible cooling capacity. The Single Speed Equation-Fit Model for Unitary Water-To-Air Heat Pump under the Air System Compound Component Groups in the Engineering Reference document contains more explanation regarding this.

**1.41.34.1.13 Field: Cooling Power Consumption Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the heat pump power consumption. The Single Speed Equation-Fit Model for Unitary Water-To-Air Heat Pump under the Air System Compound Component Groups in the Engineering Reference document contains more explanation regarding this.

**1.41.34.1.14 Field: Nominal Time for Condensate Removal to Begin**

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

**1.41.34.1.15 Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity**

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

### 1.41.34.2 Outputs

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation and Coil:Cooling:WaterToAirHeatPump:EquationFit have the same output variables listed as follows;

- HVAC, Average, Cooling Coil Electricity Rate [W]
- HVAC, Average, Cooling Coil Total Cooling Rate [W]
- HVAC, Average, Cooling Coil Sensible Cooling Rate [W]
- HVAC, Average, Cooling Coil Source Side Heat Transfer Rate [W]

- HVAC, Average, Cooling Coil Part Load Ratio []
- HVAC, Average, Cooling Coil Runtime Fraction []
- HVAC, Average, Cooling Coil Air Mass Flow Rate [kg/s]
- HVAC, Average, Cooling Coil Air Inlet Temperature [C]
- HVAC, Average, Cooling Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]
- HVAC, Average, Cooling Coil Air Outlet Temperature [C]
- HVAC, Average, Cooling Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]
- HVAC, Average, Cooling Coil Source Side Mass Flow Rate [kg/s]
- HVAC, Average, Cooling Coil Source Side Inlet Temperature [C]
- HVAC, Average, Cooling Coil Source Side Outlet Temperature [C]
- HVAC, Sum, Cooling Coil Electricity Energy [J]
- HVAC, Sum, Cooling Coil Total Cooling Energy [J]
- HVAC, Sum, Cooling Coil Sensible Cooling Energy [J]
- HVAC, Sum, Cooling Coil Latent Cooling Energy [J]
- HVAC, Average, Cooling Coil Latent Cooling Rate [W]
- HVAC, Sum, Cooling Coil Source Side Heat Transfer Energy [J]

#### 1.41.34.2.1 Cooling Coil Electricity Rate [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

#### 1.41.34.2.2 Cooling Coil Total Cooling Rate [W]

The output variable is the average total cooling load provide by the heat pump which includes the sensible and latent load in Watts over the timestep being reported.

#### 1.41.34.2.3 Cooling Coil Sensible Cooling Rate [W]

The output variable is the average sensible cooling load provide by the heat pump in Watts over the timestep being reported.

#### 1.41.34.2.4 Cooling Coil Source Side Heat Transfer Rate [W]

The output variable is the average heat rejected to the water at the heat pump condenser in Watts over the timestep being reported.

#### 1.41.34.2.5 Cooling Coil Part Load Ratio []

This output variable is the ratio of the part-load capacity to the steady state capacity of the Water-to-AirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the Water-to-AirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

**1.41.34.2.6 Cooling Coil Runtime Fraction []**

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

**1.41.34.2.7 Cooling Coil Air Mass Flow Rate [kg/s]**

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

**1.41.34.2.8 Cooling Coil Air Inlet Temperature [C]**

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

**1.41.34.2.9 Cooling Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average entering air dry humidity ratio over the timestep being reported.

**1.41.34.2.10 Cooling Coil Air Outlet Temperature [C]**

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

**1.41.34.2.11 Cooling Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

**1.41.34.2.12 Cooling Coil Source Side Mass Flow Rate [kg/s]**

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

**1.41.34.2.13 Cooling Coil Source Side Inlet Temperature [C]**

The output variable is the average entering water temperature over the timestep being reported.

**1.41.34.2.14 Cooling Coil Source Side Outlet Temperature [C]**

The output variable is the average leaving water temperature over the timestep being reported.

**1.41.34.2.15 Cooling Coil Electricity Energy [J]**

The output variable is the electric consumption of the heat pump in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

**1.41.34.2.16 Cooling Coil Total Cooling Energy [J]**

The output variable is the total cooling output of the coil in Joules over the timestep being reported. Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (ref. Output:Meter objects).

**1.41.34.2.17 Cooling Coil Sensible Cooling Energy [J]**

The output variable is the total sensible cooling output of the coil in Joules over the timestep being reported

**1.41.34.2.18 Cooling Coil Latent Cooling Energy [J]**

#### 1.41.34.2.19 Cooling Coil Latent Cooling Rate [W]

These output variables are the total latent cooling output of the coil in Joules or Watts over the timestep being reported.

#### 1.41.34.2.20 Cooling Coil Source Side Heat Transfer Energy [J]

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported

### 1.41.35 Coil:Cooling:WaterToAirHeatPump:VariableSpeedEquationFit

The Variable-Speed Water-to-Air Cooling Equation Fit Coil is a collection of performance curves that represent the cooling coil at various speed levels. The performance curves should be generated from the heat pump Reference Unit data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. On the other hand, the model uses the bypass factor approach to calculate sensible heat transfer rate, similar to the one used in the single-speed DX coil. The number of speed levels can range from 2 to 10. The cooling coil has four node connections, i.e. two air sides and two water sides. The user needs to specify a nominal speed level, at which the gross rated total cooling capacity, rated volumetric air and water flow rates are sized. The rated capacity, rated volumetric flow rates represent the real situation in the air and water loops, and are used to determine and flow rates at various speed levels in the parent objects, e.g. `AirLoopHVAC:UnitarySystem`, `AirLoopHVAC:UnitaryHeatPump:WaterToAir` and `ZoneHVAC:WaterToAirHeatPump`. It shall be mentioned that the performance correction curves, i.e. the temperature and flow fraction correction curves, should be normalized to the capacity and flow rates at each individual speed and at the rated conditions, similar to the performance curves used in the DX coils. However, the performance values, e.g. gross capacities, gross COPs, gross SHR and flow rates at individual speed levels, should be given regarding a specific unit from the Reference Unit catalog data. In the following content, the statement started with Reference Unit means the actual Reference Unit catalog data. The rated conditions for obtaining the capacities, COPs and SHRs are at indoor dry-bulb temperature of 26.67 °C (80 °F), wet bulb temperature of 19.44 °C (67 °F), and the source side entering water temperature of 29.4 °C (85 °F). Some equations are provided below to help explain the function of the various performance curves and data fields. For a detailed description of the algorithm and how the curves are used in the calculations, please see the Engineering Reference.

#### 1.41.35.1 Inputs

##### 1.41.35.1.1 Field: Name

This alpha field contains the identifying name for the variable speed cooling coil. Any reference to this coil by another object (e.g., `AirLoopHVAC:UnitarySystem` or `AirLoopHVAC:UnitaryHeatPump:WaterToAir`) will use this name.

**1.41.35.1.2 Field: Water Inlet Node Name**

This alpha field contains the cooling coil source side inlet node name.

**1.41.35.1.3 Field: Water Outlet Node Name**

This alpha field contains the cooling coil source side outlet node name.

**1.41.35.1.4 Field: Air Inlet Node Name**

This alpha field contains the cooling coil load side inlet node name.

**1.41.35.1.5 Field: Air Outlet Node Name**

This alpha field contains the cooling coil load side outlet node name.

**1.41.35.1.6 Field: Number of Speeds**

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, should be equal or higher than the maximum number. The performance inputs at higher speed levels are ignored.

**1.41.35.1.7 Field: Nominal Speed Level**

This numeric field defines the nominal speed level, at which the rated capacity, rated air and water volumetric flow rates are correlated.

**1.41.35.1.8 Field: Gross Rated Total Cooling Capacity at Selected Nominal Speed Level**

This numeric field contains the gross rated total cooling capacity at the nominal speed level. This field is autosizable. The gross rated total cooling capacity is used to determine a capacity scaling factor, as compared to the Reference Unit capacity at the nominal speed level.

$$CapacityScaleFactor = \frac{GrossRatedTotalCoolingCapacity}{ReferenceUnitCapacity@NominalSpeedLevel} \quad (1.168)$$

And then, this scaling factor is used to determine capacities at rated conditions for other speed levels, as below,

$$\begin{aligned} GrossRatedCapacity@SpeedLevel(x) = CapacityScaleFactor \\ \times ReferenceUnitCapacity@SpeedLevel(x) \end{aligned} \quad (1.169)$$

**1.41.35.1.9 Field: Rated Volumetric Air Flow Rate**

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump corresponding to the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the air flow rates in the parent objects. It is recommended that the ratio of the rated volumetric air flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\begin{aligned} AirFlowScaleFactor = \\ \frac{RatedVolumetricAirFlowRate}{ReferenceUnitVolAirFlowRate@NominalSpeedLevel \times CapacityScaleFactor} \end{aligned} \quad (1.170)$$

And the volumetric air flow rates in the parent objects are calculated as below,

$$\begin{aligned} \text{LoopVolumetricAirFlowRate@SpeedLevel}(x) &= \text{AirFlowScaleFactor} \\ &\times \text{ReferenceUnitVolAirFlowRate@SpeedLevel}(x) \\ &\times \text{CapacityScaleFactor} \end{aligned} \quad (1.171)$$

#### 1.41.35.1.10 Field: Rated Volumetric Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump at the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the water flow rates in the water loop. It is recommended that the ratio of the rated volumetric water flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\begin{aligned} \text{WaterFlowScaleFactor} &= \\ &\frac{\text{RatedVolumetricWaterFlowRate}}{\text{ReferenceUnitVolWaterFlowRate@NominalSpeedLevel} \times \text{CapacityScaleFactor}} \end{aligned} \quad (1.172)$$

And the required volumetric water flow rates at the speed levels in the parent objects, other than the nominal speed, are calculated as below,

$$\begin{aligned} \text{LoopVolumetricWaterFlowRate@SpeedLevel}(x) &= \text{WaterFlowScaleFactor} \\ &\times \text{ReferenceUnitVolWaterFlowRate@SpeedLevel}(x) \\ &\times \text{CapacityScaleFactor} \end{aligned} \quad (1.173)$$

#### 1.41.35.1.11 Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

#### 1.41.35.1.12 Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

#### 1.41.35.1.13 Field: Flag for Using Hot Gas Reheat, 0 or 1

This numeric field dictates whether to use the recoverable waste heat for reheating the supply air, downstream of the coil. The value 1 means using the hot gas reheating, and 0 means not using. If the hot gas reheating is turned on, the recoverable waste heat is subtracted from both the total cooling capacity and the sensible cooling capacity. The default value for this field is zero.

#### 1.41.35.1.14 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the unit as a function of the part load ratio (PLR, sensible or latent load/steady-state sensible or latent cooling capacity for Speed 1), in the case that the unit operates under the lowest speed, i.e. on/off. The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep for

Speed 1. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 < = PLR < 1$ ), the following rules apply:

PLF  $> = 0.7$  and PLF  $> = PLR$

If PLF  $< 0.7$ , the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF. If PLF  $< PLR$ , the runtime fraction of the coil is limited to 1.0. A typical part load fraction correlation would be:

$$PLF = 0.85 + 0.15 \times PLR \quad (1.174)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 0.85 + 0.0 \times PLR \quad (1.175)$$

#### **1.41.35.1.15 Field Group: rated specification, performance curves, and waste heat data**

The performance for each cooling speed must be specified as shown below. They should be directly given from the Reference Unit catalog data. All inputs for Speed 1 are required, followed by the optional inputs for other speeds.

##### **1.41.35.1.16 Field: Speed <x> Reference Unit Gross Rated Total Cooling Capacity**

This numeric field defines the total, full load cooling capacity in watts of the water-to-air cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The gross rated total capacity should not account for the effect of supply air fan heat.

##### **1.41.35.1.17 Field: Speed <x> Reference Unit Gross Rated Sensible Heat Ratio**

This numeric field defines sensible heat transfer ratio (SHR = gross sensible cooling capacity divided by gross total cooling capacity) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0.0 and less than 1.0. This value should be obtained from the Reference Unit data. The gross rated SHR should not account for the effect of supply air fan heat.

##### **1.41.35.1.18 Field: Speed <x> Reference Unit Gross Rated Cooling COP**

This numeric field defines the coefficient of performance (COP = gross total cooling capacity in watts divided by electrical power input in watts) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The input power includes power for the compressor(s) and accessories, but does not include the power consumptions of the indoor supply air fan and water pump. The gross COP should not account for the supply air fan.

##### **1.41.35.1.19 Field: Speed <x> Reference Unit Rated Air Flow Rate**

This numeric field defines the volumetric air flow rate, in m<sup>3</sup>per second, across the cooling coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given gross rated total cooling capacity and gross rated cooling COP at the speed, as above.

**1.41.35.1.20 Field: Speed <x> Reference Unit Rated Water Flow Rate**

This numeric field defines the volumetric water flow rate, in m<sup>3</sup>per second, flowing at the source side of the cooling coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given gross rated total cooling capacity and gross rated cooling COP at the speed, as above.

**1.41.35.1.21 Field: Speed <x> Total Cooling Capacity Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the both the indoor wet-bulb and source side entering water temperature, from the Reference Unit. The output of this curve is multiplied by the gross rated total cooling capacity at the speed to give the gross total cooling capacity at specific temperature operating conditions (i.e., at an indoor air wet-bulb temperature or entering water temperature different from the rating point temperature). It should be noted that the curve is normalized to the cooling capacity at Speed<x> from the Reference Unit data, and have the value of 1.0 at the rating point.

**1.41.35.1.22 Field: Speed <x> Total Cooling Capacity Function of Air Flow Fraction Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow at Speed <x>, from the Reference Unit data). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the design air flow rate, at Speed <x>.

**1.41.35.1.23 Field: Speed <x> Total Cooling Capacity Function of Water Flow Fraction Curve Name**

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the gross total cooling capacity as a function of the ratio of actual water flow rate across the cooling coil to the design water flow rate (i.e., fraction of full load flow), at Speed <x>, from the Reference Unit data. The curve is normalized to have the value of 1.0 when the actual water flow rate equals the design air flow rate, at Speed <x>.

The actual total cooling capacity at Speed <x>, considering variations in temperatures, air and water flow rates is calculated as below:

$$\begin{aligned}
 \text{ActualCapacity@SpeedLevel}(x) &= \text{CapacityScaleFactor} \\
 &\times \text{ReferenceUnitCapacity@SpeedLevel}(x) \\
 &\times \text{TotCapTempModFac@SpeedLevel}(x) \\
 &\times \text{TotCapAirFlowModFac@SpeedLevel}(x) \\
 &\times \text{TotCapWaterFlowModFac@SpeedLevel}(x)
 \end{aligned}
 \tag{1.176}$$

**1.41.35.1.24 Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor air wet-bulb and entering water temperatures. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP at Speed <x> from the Reference Unit data) to give the EIR at specific temperature operating conditions (i.e., at an indoor

air wet-bulb temperature or entering water temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

#### 1.41.35.1.25 Field: Speed <x> Energy Input Ratio Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). The EIR is the inverse of the COP. This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

#### 1.41.35.1.26 Field: Speed <x> Energy Input Ratio Function of Water Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual water flow rate across the cooling coil to the design water flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

The actual EIR at Speed <x>, considering variations in temperatures, air and water flow rates is calculated as below:

$$\begin{aligned} ActualEIR@SpeedLevel(x) &= \frac{1.0}{ReferenceUnitCOP@SpeedLevel(x)} \\ &\times EIRTempModFac@SpeedLevel(x) \\ &\times EIRAirFlowModFac@SpeedLevel(x) \\ &\times EIRWaterFlowModFac@SpeedLevel(x) \end{aligned} \quad (1.177)$$

And, the actual power consumption is calculated:

$$\begin{aligned} ActualPower@SpeedLevel(x) &= ActualCapacity@SpeedLevel(x) \\ &\times ActualEIR@SpeedLevel(x) \end{aligned} \quad (1.178)$$

#### 1.41.35.1.27 Field: Speed <x> Reference Unit Waste Heat Fraction of Power Input

The fraction of heat input to cooling that is available as recoverable waste heat at full load and rated conditions for Speed <x> operation. The part of heat is not discharged to the water loop. And it can be used for hot gas reheating during dehumidification operation, by setting 1 to Flag for Using Hot Gas Reheat.

#### 1.41.35.1.28 Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of indoor wet-bulb temperature and the entering water temperature for Speed <x> from the Reference Unit data. The output of this curve is multiplied by the design recoverable waste heat at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point.

The actual recoverable waste heat at Speed <x> is calculated as below:

$$\begin{aligned}
 ActualWasteHeat@SpeedLevel(x) &= ActualPower@SpeedLevel(x) \\
 &\times WasteHeatFrac@SpeedLevel(x) \\
 &\times WasteHeatTempModFac@SpeedLevel(x)
 \end{aligned}
 \tag{1.179}$$

An example of this statement in an IDF is:

- HVAC, Sum, Cooling Coil Source Side Heat Transfer Energy [J]

#### 1.41.35.2.1 Cooling Coil Electricity Rate [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

#### 1.41.35.2.2 Cooling Coil Total Cooling Rate [W]

The output variable is the average total cooling load provide by the heat pump which includes the sensible and latent load in Watts over the timestep being reported.

#### 1.41.35.2.3 Cooling Coil Sensible Cooling Rate [W]

The output variable is the average sensible cooling load provide by the heat pump in Watts over the timestep being reported.

#### 1.41.35.2.4 Cooling Coil Source Side Heat Transfer Rate [W]

The output variable is the average heat rejected to the water at the heat pump condenser in Watts over the timestep being reported.

**1.41.35.2.5 Cooling Coil Part Load Ratio []**

This output variable is the ratio of the part-load capacity to the steady state capacity of the VSWa-tertoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the VSWa-tertoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

**1.41.35.2.6 Cooling Coil Runtime Fraction []**

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or runtime fraction accounts for efficiency losses due to compressor cycling.

**1.41.35.2.7 Cooling Coil Air Mass Flow Rate [kg/s]**

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

**1.41.35.2.8 Cooling Coil Air Inlet Temperature [C]**

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

**1.41.35.2.9 Cooling Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average entering air dry humidity ratio over the timestep being reported.

**1.41.35.2.10 Cooling Coil Air Outlet Temperature [C]**

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

**1.41.35.2.11 Cooling Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

**1.41.35.2.12 Cooling Coil Source Side Mass Flow Rate [kg/s]**

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

**1.41.35.2.13 Cooling Coil Source Side Inlet Temperature [C]**

The output variable is the average entering water temperature over the timestep being reported.

**1.41.35.2.14 Cooling Coil Source Side Outlet Temperature [C]**

The output variable is the average leaving water temperature over the timestep being reported.

**1.41.35.2.15 Cooling Coil Upper Speed Level []**

The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

**1.41.35.2.16 Cooling Coil Neighboring Speed Levels Ratio []**

The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

**1.41.35.2.17 Cooling Coil Recoverable Heat Transfer Rate [W]**

This output variable is the average recoverable waste heat rate of the heat pump in Watts over the timestep being reported.

**1.41.35.2.18 Cooling Coil Electricity Energy [J]**

The output variable is the electric consumption of the heat pump in Joules over the timestep being reported.

**1.41.35.2.19 Cooling Coil Total Cooling Energy [J]**

The output variable is the total cooling output of the coil in Joules over the timestep being reported.

**1.41.35.2.20 Cooling Coil Sensible Cooling Energy [J]**

The output variable is the total sensible cooling output of the coil in Joules over the timestep being reported

**1.41.35.2.21 Cooling Coil Latent Cooling Energy [J]****1.41.35.2.22 Cooling Coil Latent Cooling Rate [W]**

These output variables are the total latent cooling output of the coil in Joules or Watts over the timestep being reported.

**1.41.35.2.23 Cooling Coil Source Side Heat Transfer Energy [J]**

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

**1.41.36 Coil:Heating:WaterToAirHeatPump:ParameterEstimation**

The Water to Air heat pump heating coil is a deterministic model that requires parameters to describe the operating conditions of the heat pump's components. The parameters are generated from the manufacturer catalog data using multi-variable optimization method. However, the parameters required for WatertoAirHP heating coil is similar to WatertoAirHP cooling except (source side outside heat transfer coefficient) parameter is not required for heating. In addition, the heating coil model can be used for 3 type of compressors which are **reciprocating**, **rotary** and **scroll**.

**1.41.36.1 Inputs****1.41.36.1.1 Field: Name**

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., **AirLoopHVAC:UnitarySystem** or **AirLoopHVAC:UnitaryHeatPump:WaterToAir**) will use this name.

**1.41.36.1.2 Field: Compressor Type**

Type of compressor mode used for the heat pump. Choices available are reciprocating, rotary and scroll compressor. Note that the parameters vary for different compressor.

**1.41.36.1.3 Field: Refrigerant Type**

This alpha field contains the type of refrigerant used by the heat pump.

**1.41.36.1.4 Field: Design Source Side Flow Rate**

This numeric field defines the water flow rate through the coil in m3/sec

**1.41.36.1.5 Field: Gross Rated Heating Capacity**

This numeric field defines the gross heating capacity for the WatertoAirHP heating coil at the rated condition in Watts. The gross heating capacity should Not include the effect of supply air fan heat.

**1.41.36.1.6 Field: High Pressure Cutoff**

This numeric field defines the compressor's maximum allowable pressure in Pascal (N/m<sup>2</sup>)

**1.41.36.1.7 Field: Low Pressure Cutoff**

This numeric field defines the compressor's minimum allowable pressure in Pascal (N/m<sup>2</sup>)

**1.41.36.1.8 Field: Water Inlet Node Name**

This alpha field contains the heating coil source side inlet node name.

**1.41.36.1.9 Field: Water Outlet Node Name**

This alpha field contains the heating coil source side outlet node name.

**1.41.36.1.10 Field: Air Inlet Node Name**

This alpha field contains the heating coil air inlet node name.

**1.41.36.1.11 Field: Air Outlet Node Name**

This alpha field contains the heating coil air outlet node name.

**1.41.36.1.12 Heating Coil Parameters**

Depending on the type of compressor specified, the type of parameters and values also differs. An Excel Spreadsheet is in the final stage of development that is capable of estimating the parameters based on the manufacturer data. The general parameters are listed first followed by specific parameters required by the respective compressor model. Lastly, parameters are listed based on the type of source side fluid used.

**1.41.36.1.13 Field: Load Side Total Heat Transfer Coefficient**

This numeric field defines the estimated parameter **load side total heat transfer coefficient** in W/K. This field was previously known as Parameter 1.

**1.41.36.1.14 Field: Superheat Temperature at the Evaporator Outlet**

This numeric field defines the estimated parameter **superheat temperature** at the evaporator outlet in °C. This field was previously known as Parameter 2.

**1.41.36.1.15 Field: Compressor Power Losses**

This numeric field defines the estimated parameter **compressor power losses**, which accounts for the loss of work due to mechanical and electrical losses in the compressor in Watts. This field was previously known as Parameter 3.

**1.41.36.1.16 Field: Compressor Efficiency**

This numeric field defines the estimated parameter of the **compressor's efficiency**. The compressor efficiency is formulated as the equation below:

$$\eta = \frac{\dot{W}_{Theoretical}}{\dot{W}_{CompInput} - \dot{W}_{Loss}} \quad (1.180)$$

This field was previously know as Parameter 4.

**1.41.36.1.17 Field: Compressor Piston Displacement**

This numeric field defines the estimated parameter **piston displacement of the compressor** in m3/s. This field was part of what was previously known as Parameter 5. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

**1.41.36.1.18 Field: Compressor Suction/Discharge Pressure Drop**

This numeric field defines the estimated parameter **pressure drop at the compressor suction** and discharge in Pascals (N/m2). This field was part of what was previously known as Parameter 6. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

**1.41.36.1.19 Field: Compressor Clearance Factor**

This numeric field defines the estimated parameter **clearance factor of the compressor**. This parameter is dimensionless. This field was part of what was previously known as Parameter 7. It should only be used when the Compressor type is Reciprocating. The field should be left blank when Compressor type is Scroll or Rotary.

**1.41.36.1.20 Field: Refrigerant Volume Flow Rate**

This numeric field defines the **refrigerant volume flow rate** at the beginning of the compression [m3/s]. This field was part of what was previously known as Parameter 6. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

**1.41.36.1.21 Field: Volume Ratio**

This numeric field defines the **built-in-volume ratio**. This field was part of what was previously known as Parameter 6. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

**1.41.36.1.22 Field: Leak Rate Coefficient**

This numeric field defines the coefficient for the relationship between **pressure ratio and leakage rate**. This field was part of what was previously known as Parameter 7. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

**1.41.36.1.23 Field: Source Side Heat Transfer Coefficient**

This numeric field defines the estimated parameter **source side heat transfer coefficient** in W/K. This field was part of what was previously known as Parameter 8. It should only be used when the Source Side Fluid Name is Water.

#### 1.41.36.1.24 Field: Source Side Heat Transfer Resistance1

This numeric field defines the estimated parameter **source side heat transfer resistance 1**. Unit is dimensionless. This field was part of what was previously known as Parameter 8. It should only be used when the Source Side Fluid Name is an antifreeze.

#### 1.41.36.1.25 Field: Source Side Heat Transfer Resistance2

This numeric field defines the estimated **parameter source side heat transfer resistance 2**. Unit is W/K. This field was previously known as Parameter 9. It should only be used when the Source Side Fluid Name is an antifreeze.

Following is an example input for Coil:WatertoAirHP:ParameterEstimation:Heating

### 1.41.37 Coil:Heating:WaterToAirHeatPump:EquationFit

The Water to Air Heating Equation Fit Coil is a simple curve-fit model that requires coefficients generated from the heat pump catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data.

#### 1.41.37.1 Inputs

##### 1.41.37.1.1 Field: Name

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., [AirLoopHVAC:UnitarySystem](#) or [AirLoopHVAC:UnitaryHeatPump:WaterToAir](#)) will use this name.

##### 1.41.37.1.2 Field: Water Inlet Node Name

This alpha field contains the heating coil source side inlet node name.

##### 1.41.37.1.3 Field: Water Outlet Node Name

This alpha field contains the heating coil source side outlet node name.

**1.41.37.1.4 Field: Air Inlet Node Name**

This alpha field contains the heating coil air inlet node name.

**1.41.37.1.5 Field: Air Outlet Node Name**

This alpha field contains the heating coil air outlet node name.

**1.41.37.1.6 Field: Rated Air Flow Rate**

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump in m<sup>3</sup>/s. This field is autosizable.

**1.41.37.1.7 Field: Rated Water Flow Rate**

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump in m<sup>3</sup>/s. This field is autosizable.

**1.41.37.1.8 Field: Gross Rated Heating Capacity**

This numeric field contains the gross heating capacity of the heat pump at the rated condition in W. The gross heating capacity should not account for the effect of supply air fan heat. This field is autosizable.

**1.41.37.1.9 Field: Gross Rated Heating COP**

This numeric field contains the gross rated heating coefficient of performance of the heat pump. The gross rated COP of the heat pump should not account for the effect of supply air fan heat.

**1.41.37.1.10 Field: Heating Capacity Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the heat pump capacity. The Single Speed Equation-Fit Model for Unitary Water-To-Air Heat Pump under the Air System Compound Component Groups in the Engineering Reference document contains more explanation regarding these coefficients.

**1.41.37.1.11 Field: Heating Power Consumption Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the heat pump power consumption. The Single Speed Equation-Fit Model for Unitary Water-To-Air Heat Pump under the Air System Compound Component Groups in the Engineering Reference document contains more explanation regarding this.

**1.41.37.2 Outputs**

Coil:Heating:WaterToAirHeatPump:ParameterEstimation and Coil:Heating:WaterToAirHeatPump:EquationFit have the same output variables listed as follows;

- HVAC, Average, Heating Coil Electricity Rate [W]
- HVAC, Average, Heating Coil Heating Rate [W]
- HVAC, Average, Heating Coil Sensible Heating Rate [W]
- HVAC, Average, Heating Coil Source Side Heat Transfer Rate [W]
- HVAC, Average, Heating Coil Part Load Ratio
- HVAC, Average, Heating Coil Runtime Fraction []

- HVAC, Average, Heating Coil Air Mass Flow Rate [kg/s]
- HVAC, Average, Heating Coil Air Inlet Temperature [C]
- HVAC, Average, Heating Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]
- HVAC, Average, Heating Coil Air Outlet Temperature [C]
- HVAC, Average, Heating Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]
- HVAC, Average, Heating Coil Source Side Mass Flow Rate [kg/s]
- HVAC, Average, Heating Coil Source Side Inlet Temperature [C]
- HVAC, Average, Heating Coil Source Side Outlet Temperature [C]
- HVAC, Sum, Heating Coil Electricity Energy [J]
- HVAC, Sum, Heating Coil Heating Energy [J]
- HVAC, Sum, Heating Coil Source Side Heat Transfer Energy [J]

#### **1.41.37.2.1 Heating Coil Electricity Rate [W]**

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

#### **1.41.37.2.2 Heating Coil Heating Rate [W]**

The output variable is the average total heating capacity provide by the heat pump which includes the sensible and latent capacity in Watts over the timestep being reported.

#### **1.41.37.2.3 Heating Coil Sensible Heating Rate [W]**

The output variable is the average sensible heating capacity provide by the heat pump in Watts over the timestep being reported. For heating mode, the sensible capacity is equal to the total capacity.

#### **1.41.37.2.4 Heating Coil Source Side Heat Transfer Rate [W]**

The output variable is the average heat absorbed at the heat pump evaporator in Watts over the timestep being reported.

#### **1.41.37.2.5 Heating Coil Part Load Ratio []**

This output variable is the ratio of the part-load capacity to the steady state capacity of the Water-to-AirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the Water-to-AirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

#### **1.41.37.2.6 Heating Coil Runtime Fraction []**

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

#### **1.41.37.2.7 Heating Coil Air Mass Flow Rate [kg/s]**

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

**1.41.37.2.8 Heating Coil Air Inlet Temperature [C]**

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

**1.41.37.2.9 Heating Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average entering air dry humidity ratio over the timestep being reported.

**1.41.37.2.10 Heating Coil Air Outlet Temperature [C]**

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

**1.41.37.2.11 Heating Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

**1.41.37.2.12 Heating Coil Source Side Mass Flow Rate [kg/s]**

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

**1.41.37.2.13 Heating Coil Source Side Inlet Temperature [C]**

The output variable is the average entering water temperature over the timestep being reported.

**1.41.37.2.14 Heating Coil Source Side Outlet Temperature [C]**

The output variable is the average leaving water temperature over the timestep being reported.

**1.41.37.2.15 Heating Coil Electricity Energy [J]**

The output variable is the total electric consumption of the heat pump in Joules over the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.41.37.2.16 Heating Coil Heating Energy [J]**

The output variable is the heating output of the coil in Joules over the timestep being reported. Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Output:Meter objects).

**1.41.37.2.17 Heating Coil Source Side Heat Transfer Energy [J]**

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

**1.41.38 Coil:Heating:WaterToAirHeatPump:VariableSpeedEquationFit**

The Variable-Speed Water-to-Air Heating Equation Fit Coil is a collection of performance curves that represent the heating coil at various speed levels. The performance curves should be generated from the heat pump Reference Unit catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The number of speed levels can range from 2 to 10. The heating coil has four node connections, i.e. two air sides and two water sides. The user needs to specify a nominal speed level, at which the rated capacity, rated volumetric air and water flow rates are sized. The rated capacity, rated volumetric flow rates represent the real situation in the air and water loops, and are used to determine the flow rates at various speed levels in the parent objects, e.g. [AirLoopHVAC:UnitarySystem](#), [AirLoopHVAC:UnitaryHeatPump:WaterToAir](#) and [ZoneHVAC:WaterToAirHeatPump](#). It shall be mentioned that the performance correction curves, i.e. the temperature and flow fraction correction curves,

should be normalized to the capacity and flow rates at each individual speed and at the rated operating conditions, similar to the performance curves used in the DX coils. On the other hand, the performance values at individual speed levels, e.g. capacities, COPs and flow rates, should be given regarding a specific unit from the Reference Unit catalog data. In the following content, the statement started with Reference Unit means the actual Reference Unit catalog data. The rated conditions for obtaining the capacities and COPs are at indoor dry-bulb temperature of 21.1 °C (70 °F) and the source side entering water temperature of 21.1 °C (70 °F). Some equations are provided below to help explain the function of the various performance curves and data fields. For a detailed description of the algorithm and how the curves are used in the calculations, please see the Engineering Reference.

### 1.41.38.1 Inputs

#### 1.41.38.1.1 Field: Name

This alpha field contains the identifying name for the variable speed heating coil. Any reference to this coil by another object (e.g., **AirLoopHVAC:UnitarySystem** or **AirLoopHVAC:UnitaryHeatPump:WaterToAir**) will use this name.

#### 1.41.38.1.2 Field: Water Inlet Node Name

This alpha field contains the heating coil source side inlet node name.

#### 1.41.38.1.3 Field: Water Outlet Node Name

This alpha field contains the heating coil source side outlet node name.

#### 1.41.38.1.4 Field: Air Inlet Node Name

This alpha field contains the heating coil load side inlet node name.

#### 1.41.38.1.5 Field: Air Outlet Node Name

This alpha field contains the heating coil load side outlet node name.

#### 1.41.38.1.6 Field: Number of Speeds

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, has to be equal to or higher than the maximum number. The performance inputs at higher speeds are ignored.

#### 1.41.38.1.7 Field: Nominal Speed Level

This numeric field defines the nominal speed level, at which the rated capacity, rated air and water volumetric flow rates are correlated.

#### 1.41.38.1.8 Field: Gross Rated Heating Capacity at Selected Nominal Speed Level

This numeric field contains the gross rated capacity at the nominal speed level. This field is autosizable. The gross rated heating capacity is used to determine a capacity scaling factor, as compared to the Reference Unit capacity at the nominal speed level.

$$CapacityScaleFactor = \frac{GrossRatedHeatingCapacity}{ReferenceUnitCapacity@NominalSpeedLevel} \quad (1.181)$$

And then, this scaling factor is used to determine capacities at rated conditions for other speed levels, as below,

$$\begin{aligned} \text{GrossRatedCapacity@SpeedLevel}(x) = \\ \text{CapacityScaleFactor} \times \text{ReferenceUnitCapacity@SpeedLevel}(x) \end{aligned} \quad (1.182)$$

#### 1.41.38.1.9 Field: Rated Volumetric Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump corresponding to the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the air flow rates in the parent objects. It is recommended that the ratio of the rated volumetric air flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\begin{aligned} \text{AirFlowScaleFactor} = \\ \frac{\text{RatedVolumetricAirFlowRate}}{\text{ReferenceUnitVolAirFlowRate@NominalSpeedLevel} \times \text{CapacityScaleFactor}} \end{aligned} \quad (1.183)$$

And the volumetric air flow rates in the parent objects are calculated as below,

$$\begin{aligned} \text{LoopVolumetricAirFlowRate@SpeedLevel}(x) = \\ \text{AirFlowScaleFactor} \\ \times \text{ReferenceUnitVolAirFlowRate@SpeedLevel}(x) \\ \times \text{CapacityScaleFactor} \end{aligned} \quad (1.184)$$

#### 1.41.38.1.10 Field: Rated Volumetric Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump at the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the water flow rates at other speed levels. It is recommended that the ratio of the rated volumetric water flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\begin{aligned} \text{WaterFlowScaleFactor} = \frac{\text{RatedVolumetricWaterFlowRate}}{\text{ReferenceUnitVolWaterFlowRate@NominalSpeedLevel} \times \text{CapacityScaleFactor}} \end{aligned} \quad (1.185)$$

And the required volumetric water flow rates in the water loop are calculated as below,

$$\text{LoopVolumetricWaterFlowRate@SpeedLevel}(x) = \text{WaterFlowScaleFactor} \times \text{ReferenceUnitVolWaterFlowRate@SpeedLevel}(x) \quad (1.186)$$

#### 1.41.38.1.11 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the unit as a function of the part load ratio (PLR, heating load/steady-state heating capacity for Speed 1), in the case that the unit operates under the lowest speed, i.e. on/off. The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep for Speed 1. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 < \text{PLR} < 1$ ), the following rules apply:

PLF  $> = 0.7$  and PLF  $> = \text{PLR}$

If  $PLF < 0.7$ , the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $PLR/PLF$ . If  $PLF < PLR$ , the runtime fraction of the coil is limited to 1.0. A typical part load fraction correlation would be:

$$PLF = 0.85 + 0.15 \times PLR \quad (1.187)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 0.85 + 0.0 \times PLR \quad (1.188)$$

#### **1.41.38.1.12 Field Group: Rated Specification, Performance Curves, and Waste Heat Data**

The performance for each heating speed must be specified as shown below. They should be directly given from the Reference Unit data. All inputs for Speed 1 are required, followed by the optional inputs for other speeds.

##### **1.41.38.1.13 Field: Speed <x> Reference Unit Gross Rated Heating Capacity**

This numeric field defines the total, full load gross heating capacity in watts of the water-to-air heating coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. Capacity should not account for the effect of supply air fan heat.

##### **1.41.38.1.14 Field: Speed <x> Reference Unit Gross Rated Heating COP**

This numeric field defines the coefficient of performance ( $COP = \text{gross heating capacity in watts} / \text{electrical power input in watts}$ ) of the heating coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The input power includes power for the compressor(s) and accessories, but does not include the power consumption of the indoor supply air fan and water pump. The gross COP should not account for the supply air fan.

##### **1.41.38.1.15 Field: Speed <x> Reference Unit Rated Air Flow Rate**

This numeric field defines the volume air flow rate, in  $\text{m}^3$  per second, across the heating coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given gross rated heating capacity and gross rated heating COP at the speed, as above.

##### **1.41.38.1.16 Field: Speed <x> Reference Unit Rated Water Flow Rate**

This numeric field defines the volume water flow rate, in  $\text{m}^3$  per second, flowing at the source side of the heating coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given gross rated heating capacity and gross rated heating COP at the speed, as above.

##### **1.41.38.1.17 Field: Speed <x> Heating Capacity Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the indoor dry-bulb and source side entering water temperature, from the Reference Unit. The output of this curve is multiplied by the gross rated heating capacity at the speed to give the gross total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or entering water temperature different from the rating point temperature). It should be noted that the curve is normalized

to the heating capacity at Speed<x> from the Reference Unit data, and have the value of 1.0 at the rating point.

#### 1.41.38.1.18 Field: Speed <x> Heating Capacity Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the gross total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the design air flow rate (i.e., fraction of full load flow), at Speed <x> from the Reference Unit data. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the design air flow rate at Speed <x>.

#### 1.41.38.1.19 Field: Speed <x> Heating Capacity Function of Water Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual water flow rate across the heating coil to the design water flow rate (i.e., fraction of full load flow), at Speed <x> from the Reference Unit data. The curve is normalized to have the value of 1.0 when the actual water flow rate equals the design air flow rate at Speed <x>.

The actual total heating capacity at Speed <x>, considering variations in temperatures, air and water flow rates is calculated as below:

$$\begin{aligned}
 ActualCapacity@SpeedLevel(x) = & CapacityScaleFactor \\
 & \times ReferenceUnitCapacity@SpeedLevel(x) \\
 & \times TotCapTempModFac@SpeedLevel(x) \\
 & \times TotCapAirFlowModFac@SpeedLevel(x) \\
 & \times TotCapWaterFlowModFac@SpeedLevel(x)
 \end{aligned}
 \tag{1.189}$$

#### 1.41.38.1.20 Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor air dry-bulb and entering water temperatures. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP at Speed <x> from the Reference Unit data) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry bulb temperature or entering water temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

#### 1.41.38.1.21 Field: Speed <x> Energy Input Ratio Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the design air flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). The EIR is the inverse of the COP. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

#### 1.41.38.1.22 Field: Speed <x> Energy Input Ratio Function of Water Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual water flow rate across the heating coil to the rated water flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

The actual EIR at Speed <x>, considering variations in temperatures, air and water flow rates is calculated as below:

$$\begin{aligned} ActualEIR@SpeedLevel(x) = & \frac{1.0}{ReferenceUnitCOP@SpeedLevel(x)} \\ & \times EIRTempModFac@SpeedLevel(x) \\ & \times EIRAirFlowModFac@SpeedLevel(x) \\ & \times EIRWaterFlowModFac@SpeedLevel(x) \end{aligned} \quad (1.190)$$

And, the actual power consumption is calculated:

$$\begin{aligned} ActualPower@SpeedLevel(x) = & ActualCapacity@SpeedLevel(x) \\ & \times ActualEIR@SpeedLevel(x) \end{aligned} \quad (1.191)$$

#### 1.41.38.1.23 Field: Speed <x> Rated Waste Heat Fraction of Power Input

The fraction of heat input to heating that is available as recoverable waste heat at full load and rated conditions for Speed <x> operation. The part of heat is not delivered to the indoor side.

#### 1.41.38.1.24 Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of indoor dry-bulb temperature and the entering water temperature for Speed <x> from the Reference Unit data. The output of this curve is multiplied by the rated recoverable waste heat at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point.

The actual recoverable waste heat at Speed <x> is calculated as below:

$$\begin{aligned} ActualWasteHeat@SpeedLevel(x) = & ActualPower@SpeedLevel(x) \\ & \times WasteHeatFrac@SpeedLevel(x) \\ & \times WasteHeatTempModFac@SpeedLevel(x) \end{aligned} \quad (1.192)$$

An example of this statement in an IDF is:

#### 1.41.38.2.1 Heating Coil Electricity Rate [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

#### 1.41.38.2.2 Heating Coil Heating Rate [W]

The output variable is the average total heating capacity provide by the heat pump in Watts over the timestep being reported.

#### 1.41.38.2.3 Heating Coil Sensible Heating Rate [W]

The output variable is the average sensible heating capacity provide by the heat pump in Watts over the timestep being reported. For heating mode, the sensible capacity is equal to the total capacity.

#### 1.41.38.2.4 Heating Coil Source Side Heat Transfer Rate [W]

The output variable is the average heat absorbed at the heat pump evaporator in Watts over the timestep being reported.

#### 1.41.38.2.5 Heating Coil Part Load Ratio []

This output variable is the ratio of the part-load capacity to the steady state capacity of the VSWa-tertoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the VSWa-tertoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

**1.41.38.2.6 Heating Coil Runtime Fraction []**

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

**1.41.38.2.7 Heating Coil Air Mass Flow Rate [kg/s]**

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

**1.41.38.2.8 Heating Coil Air Inlet Temperature [C]**

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

**1.41.38.2.9 Heating Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average entering air dry humidity ratio over the timestep being reported.

**1.41.38.2.10 Heating Coil Air Outlet Temperature [C]**

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

**1.41.38.2.11 Heating Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

**1.41.38.2.12 Heating Coil Source Side Mass Flow Rate [kg/s]**

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

**1.41.38.2.13 Heating Coil Source Side Inlet Temperature [C]**

The output variable is the average entering water temperature over the timestep being reported.

**1.41.38.2.14 Heating Coil Source Side Outlet Temperature [C]**

The output variable is the average leaving water temperature over the timestep being reported.

**1.41.38.2.15 Heating Coil Upper Speed Level []**

The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

**1.41.38.2.16 Heating Coil Neighboring Speed Levels Ratio []**

The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

**1.41.38.2.17 Heating Coil Recoverable Heat Transfer Rate [W]**

This output variable is the average recoverable waste heat rate of the heat pump in Watts over the timestep being reported.

**1.41.38.2.18 Heating Coil Electricity Energy [J]**

The output variable is the total electric consumption of the heat pump in Joules over the timestep being reported.

**1.41.38.2.19 Heating Coil Heating Energy [J]**

The output variable is the total heating output of the coil in Joules over the timestep being reported.

**1.41.38.2.20 Heating Coil Source Side Heat Transfer Energy [J]**

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

**1.41.39 Coil:Cooling:DX:SingleSpeed:ThermalStorage**

This object models a special direct expansion (DX) cooling coil that includes methods of storing thermal energy within the cooling coil package. This packaged thermal storage cooling coil model includes all of the equipment needed to charge and discharge and the Thermal Energy Storage (TES) tank itself. This coil object is used with **CoilSystem:Cooling:DX** object and a constant volume supply fan, but all other subcomponents are contained within the package.

Some types of devices may have a process air cooling section that actually has two coils, one an evaporator and the second some other kind of coil that cools by discharging the TES tank. There may also be two separate heat engines inside the package with two compressors. The model wraps these complexities inside of the model which considers just one process air cooling section that combines both types of coils and one heat rejection condenser section that rejects heat from both engines. The operating modes that are likely to have two heat engines offer dual sets of rating points and performance curves to model the energy and capacity implications separately.

The model offers various modes of operation that can be controlled over time using either a schedule or EMS actuators. The user can choose which of the five operating modes are present in the device. Each of the modes has its own separate set of performance characteristics and curves and the model can change abruptly from one mode to the next. For example when using the schedule control, the TES coil can be put into Charge Only Mode for some number of hours at night, operated in Cooling Only Mode during the mild morning hours, and run in Discharge Only Mode during the hottest part of the day. Custom control routines can be programmed using EMS to obtain a dynamic, supervisory control algorithm.

- Off Mode. This mode is always present. Although the coil will not do any cooling, the state of the TES tank is still modeled since it can continue to exchange heat with the surrounding ambient air.
- Cooling Only Mode. This mode is where the coil cools air at the evaporator using a model that is very similar to the regular, single speed DX cooling coil. The same five performance curves are used to describe cooling capacity and electric power use. The sensible heat ratio is described using two performance curves in the same as is available for 100% outdoor air coils. The TES tank is neither charged or discharged but it continues to exchange heat with the surrounding ambient air.
- Cooling And Charge Mode. This mode is where the coil both cools air at the evaporator and cools the TES tank at the same time. The model supports separate performance characteristics when there two separate heat engines, one for evaporator cooling and one for charging the TES tank.
- Cooling and Discharge Mode. This mode is where the coil cools process air and heat is rejected to both the condenser section and the TES tank at the same time. The model supports separate performance characteristics when there two separate heat engines, one for evaporator cooling and one for TES cooling.
- Charge Only Mode. This mode is where the coil charges the TES tank but does not provide any cooling at the process air cooling section.
- Discharge Only Mode. This mode is where the coil cools process air by discharging the TES tank.

This cooling coil can be autosized. The cooling capacity for the cooling only mode is sized to meet the air system's final design cooling capacity. The cooling capacity for the other modes, and the storage capacity, can all be scaled relative to that one capacity using sizing factors that can be input by the user.

### 1.41.39.1 Inputs

#### 1.41.39.1.1 Field: Name

A unique name for this TES coil object, assigned by user.

#### 1.41.39.1.2 Field: Availability Schedule Name

The name of a schedule that determines whether the TES coil is available for cooling during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that unit must be in off mode. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.41.39.1.3 Field: Operating Mode Control Method

This field determines how the TES coil is to be controlled in terms of which operating mode is in effect for a given time period. There are two choices, `ScheduledModes` or `EMSControlled`. Choosing `ScheduledModes` indicates that the operating mode is determined by the values in a schedule that is named in the following input field. Choosing `EMSControlled` indicates that the operating mode is determined by the state of an EMS actuator called `Coil:Cooling:DX:SingleSpeed:ThermalStorage` with the control type `Operating Mode`.

#### 1.41.39.1.4 Field: Operation Mode Control Schedule Name

This field is used (and required) if the operating model control method is set to `ScheduledModes` in the previous input field. The control schedule consists of a series of integer values that indicate what mode the TES coil should operate in for a given time period. The values for various operating modes have been programmed to be as follows:

0. Off Mode
1. Cooling Only Mode
2. Cooling And Charge Mode
3. Cooling And Discharge Mode
4. Charge Only Mode
5. Discharge Only Mode

#### 1.41.39.1.5 Field: Storage Type

This field is used to determine what type of material is used for thermal storage. There are two basic types of thermal storage material, fluid or ice. For fluid tanks, the material can be water or a user-defined fluid such as a glycol and the storage of thermal energy accompanies changes in the temperature of the fluid in the tank. For ice tanks, the material is water ice and the storage of thermal energy accompanies changes in the fraction of ice. This input field has three possible choices: **Water**, **UserDefinedFluidType**, Or **Ice**. Choose **Water** for a fluid tank TES based on water. Choose **UserDefinedFluidType** for a fluid tank TES based on custom or glycol type fluid. Choose **Ice** for ice-based TES tank.

#### 1.41.39.1.6 Field: User Defined Fluid Type

This field is used to declare what type of user defined fluid is contained in the TES tank. This input field is only used (and required) if the previous field is set to `UserDefinedFluidType`. Water, EthyleneGlycol, and PropyleneGlycol have fluid properties built-in to EnergyPlus. Using a `FluidProperties:GlycolConcentration` object allows specifying a mixture of water and a glycol and the name of one can be entered here. For

other types of fluids, a complete set of fluid property data is needed, see [FluidProperties:Name](#), [FluidProperties:Temperature](#), etc.

#### 1.41.39.1.7 Field: Fluid Storage Volume [m<sup>3</sup>]

This field is used to describe the size of fluid-based TES tank, in m<sup>3</sup>. The storage volume can be automatically calculated based on the cooling capacity and sizing factor.

#### 1.41.39.1.8 Field: Ice Storage Capacity [GJ]

This field is used to describe the size of ice-based TES tank, in GJ. The storage capacity can be automatically calculated based on the cooling capacity and a sizing factor.

#### 1.41.39.1.9 Field: Storage Capacity Sizing Factor [hr]

This field is used if one of the previous two fields is set to autocalculate. The value entered here is a time duration, in hours. This time period is used for calculating a storage capacity. The basic idea is that storage be sized such that the TES can provide cooling at rated capacity for this amount of time. The rated capacity used in the sizing calculation is the Discharge Only Mode Rated Storage Discharging Capacity unless the Discharge Only mode is not available in which case it is the Cooling Only Mode Rated Total Evaporator Cooling Capacity. This sizing factor approach allows scaling the storage size relative to the TES coil's capacity. The sizing factor is applied for an ice-based TES by simply multiplying the rated capacity by the time duration (converted to seconds). For fluid-based TES, a change in fluid temperature of 10 °C is assumed to calculate the tank volume.

#### 1.41.39.1.10 Field: Storage Tank Ambient Temperature Node Name

This field is used to assign the environmental conditions surrounding the TES coil. The thermal storage tank exchanges heat with its surroundings and the boundary conditions for those surrounding are taken from this node named in this field. Typically this is the name of a node declared to be an outdoor air node. This field is required.

#### 1.41.39.1.11 Field: Storage Tank to Ambient U-value Times Area Heat Transfer Coefficient [W/K]

This field is used to characterize the rate at which heat is exchanged between the TES tank and the surrounding ambient conditions, in W/K. This is an overall UA value for the tank where the U-factor and surface area are combined into one coefficient. Heat loss or gain to the TES tank is modeled using  $\dot{Q} = (UA)_{Tank} (T_{TES} - T_{Amb})$ . This field is required.

#### 1.41.39.1.12 Field: Fluid Storage Tank Rating Temperature [C]

This field is used to define what temperature is used for rating conditions when using a fluid storage tank. This field is only used for Storage Type of Water or UserDefinedFluidType. The temperature here is used for declaring the state of the TES fluid tank that corresponds to Rated conditions. The temperature entered here is used to define fluid properties and to characterize the performance curves that depend on the state of the TES.

#### 1.41.39.1.13 Field: Rated Evaporator Air Flow Rate [m<sup>3</sup>/s]

This field is the air volume flow rate through the coil, in m<sup>3</sup>/s, at rating conditions. This is the rated air flow rate through the evaporator (and any other air cooling devices that are in series with the main evaporator). The coil can be operated with a different flow rate than this rated flow rate and the performance of the unit scales accordingly using the curves that are of the type Function of Flow Fraction

Curve. All of the other rated values for capacity, COP, and SHR values, for all the various modes, should be determined at the same air flow rate used here. This field can be autosized.

#### **1.41.39.1.14 Field: Evaporator Air Inlet Node Name**

This field is the name of an HVAC system node that the coil draws in as its inlet air. This for the evaporator's connection to air system but it may include other air cooling devices that are in series with the evaporator and contained within the packaged TES coil. This node must be unique across the model. This field is required.

#### **1.41.39.1.15 Field: Evaporator Air Outlet Node Name**

This field is the name of an HVAC system node that the coils sends its outlet air. This for the evaporator's connection to air system but it may include other air cooling devices that are in series with the evaporator and contained within the packaged TES coil. This node must be unique across the model. This field is required.

#### **1.41.39.1.16 Field: Cooling Only Mode Available**

This field is used to indicate if the packaged TES coil includes a mode with only cooling and no equipment is interacting with TES tank to charge or discharge it. The choices are Yes or No. This field is required.

#### **1.41.39.1.17 Field: Cooling Only Mode Rated Total Evaporator Cooling Capacity [W]**

This field is used to specify the total, full load cooling capacity (sensible plus latent), in Watts, of the TES coil at rated conditions, while operating in Cooling Only Mode. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb and air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, and the air flow rate specified in Rated Evaporator Air Flow Rate. Capacity should be gross (i.e. supply air fan heat is NOT included). This total cooling capacity is a central value for TES coil in the sense that it is the basis for various autocalculated sizes for the rest of the model which can be scaled off of this one value. This field is required if Cooling Only Mode is available or if another operating mode's capacity, or storage capacity, will be autocalculated from this value. This field is autosizable.

#### **1.41.39.1.18 Field: Cooling Only Mode Rated Sensible Heat Ratio**

This field is used to specify the sensible heat ratio (SHR) at rating conditions while operating in Cooling Only Mode. SHR is the sensible cooling capacity divided by the total (sensible plus latent) cooling capacity and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, and cooling coil air flow rate specified in Rated Evaporator Air Flow Rate. Both the sensible and total cooling capacities used to define the rated SHR should be gross and not include supply fan heat. The packaged TES coil model uses SHR curves to modify the rated SHR as conditions move away from the rating conditions. This field is only used if Cooling Only Mode is available. If this input is left blank, the default is 0.7.

#### **1.41.39.1.19 Field: Cooling Only Mode Rated COP**

This field is used to specify the coefficient of performance (COP) at rating conditions while operating in Cooling Only Mode. COP is the total cooling power output in watts divided by the electric power input in watts and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, and cooling coil air flow rate specified in Rated Evaporator Air Flow Rate. The electric input power includes power

for the compressor(s), condenser fan(s), and internal controls but does not include the electric power for the supply fan (which is modeled separately in EnergyPlus). The total cooling power output is the same as the value for the Cooling Only Mode Rated Total Evaporator Cooling Capacity and is gross cooling without the fan heat. This field is only used if Cooling Only Mode is available. If this input is left blank, the default is 3.0.

#### 1.41.39.1.20 Field: Cooling Only Mode Total Evaporator Cooling Capacity Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the total cooling capacity as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil and (2) the drybulb temperature of the air entering the condenser section. The performance curve can be any curve or table based on two independent variables, x and y, including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The x values for the performance curve are the wetbulb temperature of air entering the evaporator section. The y values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 19.4$  °C and  $y = 35.0$  °C. The result of the curve is multiplied by Cooling Only Mode Rated Total Evaporator Cooling Capacity to model capacity at temperatures away from the rating point. This field is required if Cooling Only Mode is available.

#### 1.41.39.1.21 Field: Cooling Only Mode Total Evaporator Cooling Capacity Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable, x, including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling Only Mode Rated Total Evaporator Cooling Capacity to model capacity at air flow rates away from the rating point. This field is required if Cooling Only Mode is available.

#### 1.41.39.1.22 Field: Cooling Only Mode Energy Input Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil and (2) the drybulb temperature of the air entering the condenser section. The performance curve can be any curve or table based on two independent variables, x and y, including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The x values for the performance curve are the wetbulb temperature of air entering the evaporator section. The y values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 19.4$  °C and  $y = 35.0$  °C. The result of this curve is multiplied by the inverse of the Cooling Only Mode Rated COP to model electric energy consumption at temperatures away from the rating point. This field is required if Cooling Only Mode is available.

#### 1.41.39.1.23 Field: Cooling Only Mode Energy Input Ratio Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the inverse of the Cooling Only Mode Rated COP to model electric energy consumption at air flow rates away from the rating point. This field is required if Cooling Only Mode is available.

#### 1.41.39.1.24 Field: Cooling Only Mode Part Load Fraction Correlation Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) as a function of the part load ratio (PLR). PLR is the ratio of current cooling load to the current cooling capacity. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is the part load fraction (PLF) and the runtime fraction of the coil is defined as PLR divided by PLF. The runtime fraction is then multiplied by the energy input ratio to model electric energy consumption at part load to account for inefficiencies because of compressor cycling. This field is required if Cooling Only Mode is available.

#### 1.41.39.1.25 Field: Cooling Only Mode Sensible Heat Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil and (2) the drybulb temperature of the air entering the evaporator section. The performance curve can be any curve or table based on two independent variables,  $x$  and  $y$ , including: `Curve:Biquadratic`, `Table:Lookup`, `Curve:Bicubic`, and `Curve:QuadraticLinear`. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the evaporator section. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$  and  $y = 26.7\text{ }^{\circ}\text{C}$ . The result of the curve is multiplied by the Cooling Only Mode Rated Sensible Heat Ratio to model the SHR at coil entering temperatures that differ from the rating point. This field is required if Cooling Only Mode is available.

#### 1.41.39.1.26 Field: Cooling Only Mode Sensible Heat Ratio Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`,

Curve:RectangularHyperbola2, Curve:ExponentialDecay, Curve:DoubleExponentialDecay, and Table:Lookup. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling Only Mode Rated Sensible Heat Ratio to model the SHR at coil air flow rates that differ from the rating point. This field is required if Cooling Only Mode is available.

#### 1.41.39.1.27 Field: Cooling And Charge Mode Available

This field is used to indicate if the packaged TES coil includes a mode with both cooling at the coil and charging of the TES tank at the same time. The choices are Yes or No. This field is required.

#### 1.41.39.1.28 Field: Cooling And Charge Mode Rated Total Evaporator Cooling Capacity [W]

This field is used to specify the total, full load cooling capacity (sensible plus latent), in Watts, of the TES coil at rated conditions, while operating in Cooling And Charge Mode. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb and air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, the air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Capacity should be gross (i.e. supply air fan heat is NOT included). The Cooling and Charge Mode has two capacities, this first one is for cooling and would typically be for a heat engine operating between the condenser and the evaporator. This field is required if Cooling And Charge Mode is available.

This field is autocalculatable. When autocalculating the capacity, the following sizing factor field is used to scale this capacity relative to the Cooling Only Mode Rated Total Evaporator Cooling Capacity.

#### 1.41.39.1.29 Field: Cooling And Charge Mode Capacity Sizing Factor

This field is used if the previous input field is set to autocalculate. This sizing factor is multiplied by the Cooling Only Mode Rated Total Evaporator Cooling Capacity to obtain a scaled value for Cooling and Charge Mode Rated Total Evaporator Cooling Capacity, in Watts. If this field is left blank the default values is 0.5.

#### 1.41.39.1.30 Field: Cooling And Charge Mode Rated Storage Charging Capacity [W]

This field is used to specify the total, full load charging capacity, in Watts, of the TES coil at rated conditions, while operating in Cooling And Charge Mode. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb and air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, the air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Capacity should be net (i.e. any ancillary equipment inside the package needed for charging is included). The Cooling and Charge Mode has two capacities, this second one is for charging and would typically be for a heat engine operating between the condenser and the TES tank. This field is required if Cooling And Charge Mode is available.

This field is autocalculatable. When autocalculating the capacity, the following sizing factor field is used to scale this capacity relative to the Cooling Only Mode Rated Total Evaporator Cooling Capacity.

#### 1.41.39.1.31 Field: Cooling And Charge Mode Storage Capacity Sizing Factor

This field is used if the previous input field is set to autocalculate. This sizing factor is multiplied by the Cooling Only Mode Rated Total Evaporator Cooling Capacity to obtain a scaled value for Cooling and

Charge Mode Rated Storage Charging Capacity, in Watts. If this field is left blank the default values is 0.5.

#### **1.41.39.1.32 Field: Cooling And Charge Mode Rated Sensible Heat Ratio**

This field is used to specify the sensible heat ratio (SHR) at rating conditions while operating in Cooling And Charge Mode. SHR is the sensible cooling capacity divided by the total (sensible plus latent) cooling capacity and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, and cooling coil air flow rate specified in Rated Evaporator Air Flow Rate. Both the sensible and total cooling capacities used to define the rated SHR should be gross and not include supply fan heat. The packaged TES coil model uses SHR curves to modify the rated SHR as conditions move away from the rating conditions. This field is only used if Cooling And Charge Mode is available. If this input is left blank, the default is 0.7.

#### **1.41.39.1.33 Field: Cooling And Charge Mode Cooling Rated COP**

This field is used to specify the coefficient of performance (COP) at rating conditions while operating in Cooling And Charge Mode to cool air at the evaporator. COP is the total cooling power output in watts divided by the electric power input in watts and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, cooling coil air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). The electric input power includes power for the compressor(s), condenser fan(s), and internal controls but does not include the electric power for the supply fan (which is modeled separately in EnergyPlus). The total cooling power output is the same as the value for the Cooling And Charge Mode Rated Total Evaporator Cooling Capacity and is gross cooling without the fan heat. The Cooling And Charge Mode has two COP values and this first COP is for cooling and would typically be for a heat engine operating between the condenser and the evaporator. This field is only used if Cooling And Charge Mode is available. If this input is left blank, the default is 3.0.

#### **1.41.39.1.34 Field: Cooling And Charge Mode Charging Rated COP**

This field is used to specify the coefficient of performance (COP) at rating conditions while operating in Cooling And Charge Mode to charge the TES. COP is the total cooling power output in watts divided by the electric power input in watts and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, cooling coil air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). The electric input power includes power for the compressor(s), condenser fan(s), and internal controls. The charging power output is the same as the value for the Cooling And Charge Mode Rated Storage Charging Capacity and is net charging including any internal equipment. The Cooling And Charge Mode has two COP values and this second COP is for charging and would typically be for a heat engine operating between the condenser and the TES tank. This field is only used if Cooling And Charge Mode is available. If this input is left blank, the default is 3.0.

#### **1.41.39.1.35 Field: Cooling And Charge Mode Total Evaporator Cooling Capacity Function of Temperature Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the total cooling capacity as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the

state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables, x, y, and z, including: **Curve:Triquadratic** and **Table:Lookup**. The x values for the performance curve are the wetbulb temperature of air entering the evaporator section. The y values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The z values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 35.0\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of the curve is multiplied by Cooling And Charge Mode Rated Total Evaporator Cooling Capacity to model capacity at temperatures away from the rating point. This field is required if Cooling And Charge Mode is available.

#### **1.41.39.1.36 Field: Cooling And Charge Mode Total Evaporator Cooling Capacity Function of Flow Fraction Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable, x, including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling And Charge Mode Rated Total Evaporator Cooling Capacity to model capacity at air flow rates away from the rating point. This field is required if Cooling And Charge Mode is available.

#### **1.41.39.1.37 Field: Cooling And Charge Mode Evaporator Energy Input Ratio Function of Temperature Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for evaporator cooling as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables, x, y, and z, including: **Curve:Triquadratic** and **Table:Lookup**. The x values for the performance curve are the wetbulb temperature of air entering the evaporator section. The y values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The z values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 35.0\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The performance curve is normalized to have the value of 1.0 at the rating point. The result of this curve is multiplied by the inverse of the Cooling And Charge Mode Cooling Rated COP to model electric energy consumption at temperatures away from the rating point. This field is required if Cooling And Charge Mode is available.

#### **1.41.39.1.38 Field: Cooling And Charge Mode Evaporator Energy Input Ratio Function of Flow Fraction Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for evaporator cooling as a function of the ratio of actual air flow

rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the inverse of the Cooling And Charge Mode Cooling Rated COP to model electric energy consumption at air flow rates away from the rating point. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.39 Field: Cooling And Charge Mode Evaporator Part Load Fraction Correlation Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) (for evaporator cooling) as a function of the part load ratio (PLR). PLR is the ratio of current cooling load to the current cooling capacity. The performance curve can be any curve or table based on one independent variable,  $x$ , including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is the part load fraction (PLF) and the runtime fraction of the coil is defined as PLR divided by PLF. The runtime fraction is then multiplied by the energy input ratio to model electric energy consumption at part load to account for inefficiencies because of compressor cycling. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.40 Field: Cooling And Charge Mode Storage Charge Capacity Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the storage charging capacity as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: **Curve:Triquadratic** and **Table:Lookup**. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 35.0\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or **UserDefinedFluidType**. The result of the curve is multiplied by Cooling And Charge Mode Rated Storage Charging Capacity to model capacity at temperatures away from the rating point. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.41 Field: Cooling And Charge Mode Storage Charge Capacity Function of Total Evaporator PLR Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the storage charging capacity as a function of part load ratio (PLR) at the evaporator. PLR is the ratio of current evaporator cooling load to the current evaporator cooling capacity. This curve allows increasing the storage charging capacity when loads at the evaporator are low. The performance curve can be any curve or table based on one independent variable,  $x$ , including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**,

`Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by Cooling And Charge Mode Rated Storage Charging Capacity to model capacity at evaporator PLR less than 1.0. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.42 Field: Cooling And Charge Mode Storage Energy Input Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for charging as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: `Curve:Triquadratic` and `Table:Lookup`. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 35.0\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or `UserDefinedFluidType`. The result of this curve is multiplied by the inverse of the Cooling And Charge Mode Charging Rated COP to model electric energy consumption at temperatures away from the rating point. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.43 Field: Cooling And Charge Mode Storage Energy Input Ratio Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for charging as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the inverse of the Cooling And Charge Mode Charging Rated COP to model electric energy consumption at air flow rates away from the rating point. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.44 Field: Cooling And Charge Mode Storage Energy Part Load Fraction Correlation Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) (for storage charging) as a function of the part load ratio (PLR). PLR is the ratio of current cooling load to the current cooling capacity (at the evaporator). The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is the part load fraction (PLF) and the runtime fraction is defined as PLR divided by PLF. The runtime fraction is then multiplied

by the energy input ratio to model electric energy consumption at part load to account for inefficiencies because of compressor cycling. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.45 Field: Cooling And Charge Mode Sensible Heat Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of temperature and optionally state of TES tank. The user can enter the name of a curve or table object that has either two or three independent variables.

For a curve or table with two independent variables the SHR is a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil and (2) the drybulb temperature of the air entering the evaporator section. The performance curve can be any curve or table based on two independent variables,  $x$  and  $y$ , including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the evaporator section.

For a curve or table with three independent variables the SHR is a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the evaporator section and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: **Curve:Triquadratic** and **Table:Lookup**. The  $x$  and  $y$  values for the curve are the same as for two independent variables while the  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types.

The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 26.7\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of the curve is multiplied by the Cooling And Charge Mode Rated Sensible Heat Ratio to model the SHR at coil entering temperatures that differ from the rating point. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.46 Field: Cooling And Charge Mode Sensible Heat Ratio Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectuangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling And Charge Mode Rated Sensible Heat Ratio to model the SHR at coil air flow rates that differ from the rating point. This field is required if Cooling And Charge Mode is available.

#### 1.41.39.1.47 Field: Cooling And Discharge Mode Available

This field is used to indicate if the packaged TES coil includes a mode with both cooling at the coil and discharging of the TES tank at the same time. The choices are Yes or No. This field is required.

#### 1.41.39.1.48 Field: Cooling And Discharge Mode Rated Total Evaporator Cooling Capacity [W]

This field is used to specify the total, full load cooling capacity (sensible plus latent), in Watts, of the TES evaporator coil at rated conditions, while operating in Cooling And Discharge Mode. The rating

conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb and air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, the air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Capacity should be gross (i.e. supply air fan heat is NOT included). The Cooling and Discharge Mode has two capacities (and may have two separate cooling coils contained within), this first one is for Evaporator cooling and would typically be for a heat engine operating between the condenser and the evaporator. This field is required if Cooling And Discharge Mode is available.

This field is autocalculatable. When autocalculating the capacity, the following sizing factor field is used to scale this capacity relative to the Cooling Only Mode Rated Total Evaporator Cooling Capacity.

#### **1.41.39.1.49 Field: Cooling And Discharge Mode Evaporator Capacity Sizing Factor**

This field is used if the previous input field is set to autocalculate. This sizing factor is multiplied by the Cooling Only Mode Rated Total Evaporator Cooling Capacity to obtain a scaled value for Cooling and Discharge Mode Rated Total Evaporator Cooling Capacity, in Watts. If this field is left blank the default values is 1.0.

#### **1.41.39.1.50 Field: Cooling And Discharge Mode Rated Storage Discharging Capacity**

This field is used to specify the total, full load discharging capacity, in Watts, of the TES coil at rated conditions, while operating in Cooling And Discharge Mode. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb and air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, the air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Capacity should be net (i.e. any ancillary equipment inside the package needed for discharging is included). The Cooling and Discharge Mode has two capacities, this second one is for discharging and would typically be for a heat transfer loop operating between the TES tank and a coil in series with the evaporator. This field is required if Cooling And Discharge Mode is available.

This field is autocalculatable. When autocalculating the capacity, the following sizing factor field is used to scale this capacity relative to the Cooling Only Mode Rated Total Evaporator Cooling Capacity.

#### **1.41.39.1.51 Field: Cooling And Discharge Mode Storage Discharge Capacity Sizing Factor**

This field is used if the previous input field is set to autocalculate. This sizing factor is multiplied by the Cooling Only Mode Rated Total Evaporator Cooling Capacity to obtain a scaled value for Cooling and Discharge Mode Rated Storage Discharging Capacity, in Watts. If this field is left blank the default value is 1.0.

#### **1.41.39.1.52 Field: Cooling And Discharge Mode Rated Sensible Heat Ratio**

This field is used to specify the sensible heat ratio (SHR) at rating conditions while operating in Cooling And Discharge Mode. SHR is the sensible cooling capacity divided by the total (sensible plus latent) cooling capacity and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, cooling coil air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Both the sensible and total cooling capacities used to define the rated SHR

should be gross and not include supply fan heat. The packaged TES coil model uses SHR curves to modify the rated SHR as conditions move away from the rating conditions. Cooling and discharge mode may have two separate coils in series all contained within the package and this SHR should be for the combined performance of the entire package. This field is only used if Cooling And Discharge Mode is available. If this input is left blank, the default is 0.7.

#### **1.41.39.1.53 Field: Cooling And Discharge Mode Cooling Rated COP**

This field is used to specify the coefficient of performance (COP) at rating conditions while operating in Cooling And Discharge Mode to cool air at the evaporator. COP is the total cooling power output in watts divided by the electric power input in watts and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, cooling coil air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). The electric input power includes power for the compressor(s), condenser fan(s), and internal controls but does not include the electric power for the supply fan (which is modeled separately in EnergyPlus). The total cooling power output is the same as the value for the Cooling And Discharge Mode Rated Total Evaporator Cooling Capacity and is gross cooling without the fan heat. The Cooling And Discharge Mode has two COP values and this first COP is for evaporator cooling and would typically be for a heat engine operating between the condenser and the evaporator. This field is only used if Cooling And Discharge Mode is available. If this input is left blank, the default is 3.0.

#### **1.41.39.1.54 Field: Cooling And Discharge Mode Discharging Rated COP**

This field is used to specify the coefficient of performance (COP) at rating conditions while operating in Cooling And Discharge Mode to discharge the TES. COP is the total cooling power output in watts divided by the electric power input in watts and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb, cooling coil air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). The electric input power includes power for the compressor or circulation pumps and internal controls. The discharging power output is the same as the value for the Cooling And Discharge Mode Rated Storage Discharging Capacity and is net discharging including any internal equipment. The Cooling And Discharge Mode has two COP values and this second COP is for discharging and would typically be for a heat transfer loop operating between the TES tank and a coil in series with the evaporator. This field is only used if Cooling And Discharge Mode is available. If this input is left blank, the default is 3.0.

#### **1.41.39.1.55 Field: Cooling And Discharge Mode Total Evaporator Cooling Capacity Function of Temperature Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the total cooling capacity as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables, x, y, and z, including: **Curve:Triquadratic** and **Table:Lookup**. The x values for the performance curve are the wetbulb temperature of air entering the evaporator section. The y values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The z values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is

normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 35.0\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or `UserDefinedFluidType`. The result of the curve is multiplied by Cooling And Discharge Mode Rated Total Evaporator Cooling Capacity to model capacity at temperatures away from the rating point. This field is required if Cooling And Discharge Mode is available.

#### **1.41.39.1.56 Field: Cooling And Discharge Mode Total Evaporator Cooling Capacity Function of Flow Fraction Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling And Discharge Mode Rated Total Evaporator Cooling Capacity to model capacity at air flow rates away from the rating point. This field is required if Cooling And Discharge Mode is available.

#### **1.41.39.1.57 Field: Cooling And Discharge Mode Evaporator Energy Input Ratio Function of Temperature Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for evaporator cooling as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: `Curve:Triquadratic` and `Table:Lookup`. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 35.0\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or `UserDefinedFluidType`. The result of this curve is multiplied by the inverse of the Cooling And Discharge Mode Cooling Rated COP to model electric energy consumption at temperatures away from the rating point. This field is required if Cooling And Discharge Mode is available.

#### **1.41.39.1.58 Field: Cooling And Discharge Mode Evaporator Energy Input Ratio Function of Flow Fraction Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for evaporator cooling as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the inverse of the Cooling And Discharge Mode Cooling Rated COP to model electric energy consumption at air flow rates away from the rating point. This field is required if Cooling And discharge Mode is available.

#### 1.41.39.1.59 Field: Cooling And Discharge Mode Evaporator Part Load Fraction Correlation Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) (for evaporator cooling) as a function of the part load ratio (PLR). PLR is the ratio of current cooling load to the current cooling capacity. The performance curve can be any curve or table based on one independent variable,  $x$ , including: [Curve:Linear](#), [Curve:Quadratic](#), [Curve:Cubic](#), [Curve:Quartic](#), [Curve:Exponent](#), [Curve:ExponentialSkewNormal](#), [Curve:Sigmoid](#), [Curve:RectangularHyperbola1](#), [Curve:RectangularHyperbola2](#), [Curve:ExponentialDecay](#), [Curve:DoubleExponentialDecay](#), and [Table:Lookup](#). The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is the part load fraction (PLF) and the runtime fraction of the coil is defined as PLR divided by PLF. The runtime fraction is then multiplied by the energy input ratio to model electric energy consumption at part load to account for inefficiencies because of compressor cycling. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.60 Field: Cooling And Discharge Mode Storage Discharge Capacity Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the storage discharging capacity as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: [Curve:Triquadratic](#) and [Table:Lookup](#). The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 35.0\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of the curve is multiplied by Cooling And Discharge Mode Rated Storage Discharging Capacity to model capacity at temperatures away from the rating point. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.61 Field: Cooling And Discharge Mode Storage Discharge Capacity Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the storage discharge capacity as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: [Curve:Linear](#), [Curve:Quadratic](#), [Curve:Cubic](#), [Curve:Quartic](#), [Curve:Exponent](#), [Curve:ExponentialSkewNormal](#), [Curve:Sigmoid](#), [Curve:RectangularHyperbola1](#), [Curve:RectangularHyperbola2](#), [Curve:ExponentialDecay](#), [Curve:DoubleExponentialDecay](#), and [Table:Lookup](#). The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling And Discharge Mode Rated Storage Discharging Capacity to model capacity at air flow rates away from the rating point. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.62 Field: Cooling And Discharge Mode Storage Discharge Capacity Function of Total Evaporator PLR Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the storage discharging capacity as a function of part load ratio (PLR) at the evaporator. PLR is

the ratio of current evaporator cooling load to the current evaporator cooling capacity. This curve allows varying the storage discharging capacity based on loads at the evaporator. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by Cooling And Discharge Mode Rated Storage Discharging Capacity to model capacity at different evaporator PLR values. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.63 Field: Cooling And Discharge Mode Storage Energy Input Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for discharging as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the condenser section, and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: `Curve:Triquadratic` and `Table:Lookup`. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4$  °C,  $y = 35.0$  °C, and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or `UserDefinedFluidType`. The result of this curve is multiplied by the inverse of the Cooling And Discharge Mode Discharging Rated COP to model electric energy consumption at temperatures away from the rating point. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.64 Field: Cooling And Discharge Mode Storage Energy Input Ratio Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for discharging as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the inverse of the Cooling And Discharge Mode Discharging Rated COP to model electric energy consumption at air flow rates away from the rating point. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.65 Field: Cooling And Discharge Mode Storage Energy Part Load Fraction Correlation Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) (for storage discharging) as a function of the part load ratio (PLR). PLR is the ratio of current cooling load to the current cooling capacity (at the evaporator). The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`,

**Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is the part load fraction (PLF) and the runtime fraction is defined as PLR divided by PLF. The runtime fraction is then multiplied by the energy input ratio to model electric energy consumption at part load to account for inefficiencies because of compressor cycling. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.66 Field: Cooling And Discharge Mode Sensible Heat Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of temperature and optionally state of TES tank. The user can enter the name of a curve or table object that has either two or three independent variables.

For a curve or table with two independent variables the SHR is a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil and (2) the drybulb temperature of the air entering the evaporator section. The performance curve can be any curve or table based on two independent variables,  $x$  and  $y$ , including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the evaporator section.

For a curve or table with three independent variables the SHR is a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the evaporator section and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: **Curve:Triquadratic** and **Table:Lookup**. The  $x$  and  $y$  values for the curve are the same as for two independent variables while the  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types.

The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 26.7\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of the curve is multiplied by the Cooling And Discharge Mode Rated Sensible Heat Ratio to model the SHR at coil entering temperatures that differ from the rating point. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.67 Field: Cooling And Discharge Mode Sensible Heat Ratio Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling And Discharge Mode Rated Sensible Heat Ratio to model the SHR at coil air flow rates that differ from the rating point. This field is required if Cooling And Discharge Mode is available.

#### 1.41.39.1.68 Field: Charge Only Mode Available

This field is used to indicate if the packaged TES coil includes a mode with only charging of the TES tank. The choices are Yes or No. This field is required.

#### 1.41.39.1.69 Field: Charge Only Mode Rated Storage Charging Capacity [W]

This field is used to specify the total, full load charging capacity, in Watts, of the TES coil at rated conditions, while operating in Charge Only Mode. The rating conditions are air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Capacity should be net (i.e. any ancillary equipment inside the package needed for charging is included). The Charge Only Mode capacity would typically be for a heat engine operating between the condenser and the TES tank. This field is required if Charge Only Mode is available.

This field is autocalculatable. When autocalculating the capacity, the following sizing factor field is used to scale this capacity relative to the Cooling Only Mode Rated Total Evaporator Cooling Capacity.

#### **1.41.39.1.70 Field: Charge Only Mode Capacity Sizing Factor**

This field is used if the previous input field is set to autocalculate. This sizing factor is multiplied by the Cooling Only Mode Rated Total Evaporator Cooling Capacity to obtain a scaled value for Charge Only Mode Rated Storage Charging Capacity, in Watts. If this field is left blank the default value is 1.0.

#### **1.41.39.1.71 Field: Charge Only Mode Charging Rated COP**

This field is used to specify the coefficient of performance (COP) at rating conditions while operating in Charge Only Mode to charge the TES. COP is the total cooling power output in watts divided by the electric power input in watts and is dimensionless. The rating conditions are air entering the outdoor condenser section at 35 °C drybulb and 23.9 °C wetbulb and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). The electric input power includes power for the compressor(s), condenser fan(s), and internal controls. The charging power output is the same as the value for the Charge Only Mode Rated Storage Charging Capacity and is net charging including any internal equipment. This field is only used if Charge Only Mode is available. If this input is left blank, the default is 3.0.

#### **1.41.39.1.72 Field: Charge Only Mode Storage Charge Capacity Function of Temperature Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the storage charging capacity as a function of (1) the drybulb temperature of the air entering the condenser section, and (2) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on two independent variables, x and y, including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The x values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The y values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 35.0$  °C, and  $y = 0.5$  for Ice storage type or  $y = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of the curve is multiplied by Charge Only Mode Rated Storage Charging Capacity to model capacity at temperatures away from the rating point. This field is required if Charge Only Mode is available.

#### **1.41.39.1.73 Field: Charge Only Mode Storage Energy Input Ratio Function of Temperature Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for charging as a function of (1) the drybulb temperature of the air entering the condenser section, and (2) the state of TES tank (in C or fraction). The performance curve can

be any curve or table based on two independent variables,  $x$  and  $y$ , including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The  $x$  values for the performance curve are the drybulb temperature of air entering the condenser section (which if using evaporatively-cooled condenser the temperature will be adjusted to approach the wetbulb temperature depending on effectiveness). The  $y$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 35.0$  °C, and  $y = 0.5$  for Ice storage type or  $y = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of this curve is multiplied by the inverse of the Charge Only Mode Charging Rated COP to model electric energy consumption at temperatures away from the rating point. This field is required if Charge Only Mode is available.

#### **1.41.39.1.74 Field: Discharge Only Mode Available**

This field is used to indicate if the packaged TES coil includes a mode with only discharging of the TES tank. The choices are Yes or No. This field is required.

#### **1.41.39.1.75 Field: Discharge Only Mode Rated Storage Discharging Capacity [W]**

This field is used to specify the total, full load discharging capacity, in Watts, of the TES coil at rated conditions, while operating in Discharge Only Mode. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, the air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Capacity should be net (i.e. any ancillary equipment inside the package needed for discharging is included) with regard to TES discharge, and gross with regard to supply fan heat. Discharge Only Mode would typically be for a heat transfer loop operating between the TES tank and a coil in series with the evaporator. This field is required if Discharge Only Mode is available.

This field is autocalculatable. When autocalculating the capacity, the following sizing factor field is used to scale this capacity relative to the Cooling Only Mode Rated Total Evaporator Cooling Capacity.

#### **1.41.39.1.76 Field: Discharge Only Mode Capacity Sizing Factor**

This field is used if the previous input field is set to autocalculate. This sizing factor is multiplied by the Cooling Only Mode Rated Total Evaporator Cooling Capacity to obtain a scaled value for Discharge Only Mode Rated Storage Discharging Capacity, in Watts. If this field is left blank the default value is 1.0.

#### **1.41.39.1.77 Field: Discharge Only Mode Rated Sensible Heat Ratio**

This field is used to specify the sensible heat ratio (SHR) at rating conditions while operating in Discharge Only Mode. SHR is the sensible cooling capacity divided by the total (sensible plus latent) cooling capacity and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, cooling coil air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). Both the sensible and total cooling capacities used to define the rated SHR should be gross and not include supply fan heat. The packaged TES coil model uses SHR curves to modify the rated SHR as conditions move away from the rating conditions. This field is only used if Discharge Only Mode is available. If this input is left blank, the default is 0.7.

#### **1.41.39.1.78 Field: Discharge Only Mode Rated COP**

This field is used to specify the coefficient of performance (COP) at rating conditions while operating in Discharge Only Mode to discharge the TES. COP is the total cooling power output in watts divided by the

electric power input in watts and is dimensionless. The rating conditions are air entering the cooling coil at 26.7 °C drybulb, 19.4 °C wetbulb, cooling coil air flow rate specified in Rated Evaporator Air Flow Rate, and the state of TES at either the Fluid Storage Tank Rating Temperature (for water or fluid storage type) or an ice fraction of 0.5 (for ice storage type). The electric input power includes power for the compressor or circulation pumps and internal controls. The discharging power output is the same as the value for the Discharge Only Mode Rated Storage Discharging Capacity and is net discharging including any internal equipment. This field is only used if Discharge Only Mode is available. If this input is left blank, the default is 3.0.

#### 1.41.39.1.79 Field: Discharge Only Mode Storage Discharge Capacity Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the storage discharging capacity as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, and (2) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on two independent variables, x and y, including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The x values for the performance curve are the wetbulb temperature of air entering the evaporator section. The y values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4$  °C and  $y = 0.5$  for Ice storage type or  $y = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of the curve is multiplied by Discharge Only Mode Rated Storage Discharging Capacity to model capacity at temperatures away from the rating point. This field is required if Discharge Only Mode is available.

#### 1.41.39.1.80 Field: Discharge Only Mode Storage Discharge Capacity Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the storage discharge capacity as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable, x, including: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Quartic**, **Curve:Exponent**, **Curve:ExponentialSkewNormal**, **Curve:Sigmoid**, **Curve:RectangularHyperbola1**, **Curve:RectangularHyperbola2**, **Curve:ExponentialDecay**, **Curve:DoubleExponentialDecay**, and **Table:Lookup**. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Cooling Discharge Only Mode Rated Storage Discharging Capacity to model capacity at air flow rates away from the rating point. This field is required if Discharge Only Mode is available.

#### 1.41.39.1.81 Field: Discharge Only Mode Energy Input Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for discharging as a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, and (2) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on two independent variables, x and y, including: **Curve:Biquadratic**, **Table:Lookup**, **Curve:Bicubic**, and **Curve:QuadraticLinear**. The x values for the performance curve are the wetbulb temperature of air entering the evaporator section. The y values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types. The performance curve is normalized to have the value of 1.0 at the rating point which is defined to be  $x = 19.4$  °C and  $y = 0.5$  for Ice storage type or  $y = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of this curve is multiplied by the inverse of the

Discharge Only Mode Rated COP to model electric energy consumption at temperatures away from the rating point. This field is required if Discharge Only Mode is available.

#### 1.41.39.1.82 Field: Discharge Only Mode Energy Input Ratio Function of Flow Fraction Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) for discharging as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the inverse of the Discharge Only Mode Rated COP to model electric energy consumption at air flow rates away from the rating point. This field is required if Discharge Only Mode is available.

#### 1.41.39.1.83 Field: Discharge Only Mode Part Load Fraction Correlation Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the energy input ratio (EIR) (for storage discharging) as a function of the part load ratio (PLR). PLR is the ratio of current cooling load to the current cooling capacity. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectuangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is the part load fraction (PLF) and the runtime fraction is defined as PLR divided by PLF. The runtime fraction is then multiplied by the energy input ratio to model electric energy consumption at part load to account for inefficiencies because of compressor cycling. This field is required if Discharge Only Mode is available.

#### 1.41.39.1.84 Field: Discharge Only Mode Sensible Heat Ratio Function of Temperature Curve Name

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of temperature and optionally state of TES tank. The user can enter the name of a curve or table object that has either two or three independent variables.

For a curve or table with two independent variables the SHR is a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil and (2) the drybulb temperature of the air entering the evaporator section. The performance curve can be any curve or table based on two independent variables,  $x$  and  $y$ , including: `Curve:Biquadratic`, `Table:Lookup`, `Curve:Bicubic`, and `Curve:QuadraticLinear`. The  $x$  values for the performance curve are the wetbulb temperature of air entering the evaporator section. The  $y$  values for the performance curve are the drybulb temperature of air entering the evaporator section.

For a curve or table with three independent variables the SHR is a function of (1) the wetbulb temperature of air entering the evaporator section of the TES coil, (2) the drybulb temperature of the air entering the evaporator section and (3) the state of TES tank (in C or fraction). The performance curve can be any curve or table based on three independent variables,  $x$ ,  $y$ , and  $z$ , including: `Curve:Triquadratic` and `Table:Lookup`. The  $x$  and  $y$  values for the curve are the same as for two independent variables while the  $z$  values are the state of the TES tank which are the tank's temperature for water or fluid storage type or the storage fraction for ice storage types.

The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 19.4\text{ }^{\circ}\text{C}$ ,  $y = 26.7\text{ }^{\circ}\text{C}$ , and  $z = 0.5$  for Ice storage type or  $z = \text{Fluid Storage Tank Rating Temperature}$  when storage type is Water or UserDefinedFluidType. The result of the curve is multiplied by the Discharge Only Mode Rated Sensible Heat Ratio to model the SHR at coil entering temperatures that differ from the rating point. This field is required if Discharge Only Mode is available.

#### **1.41.39.1.85 Field: Discharge Only Mode Sensible Heat Ratio Function of Flow Fraction Curve Name**

This field is the name of a separate performance curve object that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the value of the Rated Evaporator Air Flow Rate. The performance curve can be any curve or table based on one independent variable,  $x$ , including: `Curve:Linear`, `Curve:Quadratic`, `Curve:Cubic`, `Curve:Quartic`, `Curve:Exponent`, `Curve:ExponentialSkewNormal`, `Curve:Sigmoid`, `Curve:RectangularHyperbola1`, `Curve:RectangularHyperbola2`, `Curve:ExponentialDecay`, `Curve:DoubleExponentialDecay`, and `Table:Lookup`. The performance curve is normalized to have a value of 1.0 at the rating point which is defined to be  $x = 1.0$ . The result of the curve is multiplied by the Discharge Only Mode Rated Sensible Heat Ratio to model the SHR at coil air flow rates that differ from the rating point. This field is required if Discharge Only Mode is available.

#### **1.41.39.1.86 Field: Ancillary Electricity Rate [W]**

This field is the electric power level for miscellaneous ancillary controls and standby draws, in Watts. This power is not linked to any particular operating mode and will always be on, except when the device is scheduled to not be available by the Availability Schedule. This field is optional.

#### **1.41.39.1.87 Field: Cold Weather Operation Minimum Outdoor Air Temperature [C]**

This field is the outdoor temperature at which the device operates additional electric components to protect from cold weather, in Degrees Celsius. When the outdoor temperature is below this value, the power draw specified in the next field will be turned on. The outdoor temperature is obtained from the node specified in the input field called Storage Tank Ambient Temperature Node Name.

#### **1.41.39.1.88 Field: Cold Weather Operation Ancillary Power [W]**

This field is the electric power level for cold weather protection. Cold weather protection is in effect whenever the outdoor temperature is lower than the limit set in the previous field, except when the device is scheduled to not be available by the Availability Schedule.

#### **1.41.39.1.89 Field: Condenser Air Inlet Node Name**

This field is the name of system node that serves as the inlet to the condenser section of the packaged TES coil. This node is typically specified to be an outdoor air node. The conditions exposed to the condenser are obtained from this system node. This field is required.

#### **1.41.39.1.90 Field: Condenser Air Outlet Node Name**

This field is the name of system node that serves as the outlet to the condenser section of the packaged TES coil. This node is typically not connected to anything else. The conditions leaving the condenser are applied to this system node. This field is required.

**1.41.39.1.91 Field: Condenser Design Air Flow Rate [m<sup>3</sup>/s]**

This field is the rate of air flow through the condenser section, in m<sup>3</sup>/s. The model assumes constant, single-speed condenser fans. The flow rate is not used to determine coil operation but is used to determine the conditions leaving the condenser section. This field is required, for both air-cooled and evaporatively-cooled condenser types.

This field is autocalculatable. When autocalculated, the design flow rate is determined using the sizing factor in the following input field.

**1.41.39.1.92 Field: Condenser Air Flow Sizing Factor**

This field is used if the previous input field is set to autocalculate. This sizing factor is multiplied by the Rated Evaporator Air Flow Rate to obtain a scaled value for Condenser Design Air Flow Rate, in m<sup>3</sup>/s. If this field is left blank the default value is 1.0.

**1.41.39.1.93 Field: Condenser Type**

This field is the type of condenser used by the TES coil. There are two options, **AirCooled** or **EvaporativelyCooled**. The default is AirCooled. The next six put fields are used when the condenser section is evaporatively cooled.

**1.41.39.1.94 Field: Evaporative Condenser Effectiveness**

This field is the wetbulb effectiveness for the evaporatively-cooled condenser. The effectiveness is used to model the temperature of air exposed to the condenser section as follows:

$$T_{Cond\ inlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness) (T_{db,o} - T_{wb,o}) \quad (1.193)$$

where

---

`{T_{cond};inlet}}` = the temperature of air entering the condenser section, in &deg;C. This value will be used when evaluating performance curves that depend on the drybulb entering the condenser section.

---

`{T_{wb,o}}` = the wetbulb temperature of outdoor air, in &deg;C

---

`{T_{db,o}}` = the drybulb temperature of outdoor air, in &deg;C.

---

This field is required if the condenser type is set to EvaporativelyCooled. If the field is left blank then a default of 0.7 is used.

**1.41.39.1.95 Field: Evaporative Condenser Pump Rated Power Consumption [W]**

This field is the rated power of the evaporative condenser water pump, in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default is zero, but this field is autosizable using a sizing factor of 0.004266 W of electricity per W of cooling. This field is only used when the condenser type is set to EvaporativelyCooled.

**1.41.39.1.96 Field: Basin Heater Capacity [W/K]**

This input field is the capacity of the evaporative cooler water basin heater for freeze protection in Watts per Kelvin. This field is only used when the condenser type is set to EvaporativelyCooled. This field is used with the following field to determine the electricity consumption rate for freeze protection of the water in a basin needed for evaporative cooling. The basin heater electric power is equal to this field multiplied by the difference between the Basin Heater Setpoint Temperature and the outdoor drybulb temperature. The default is zero.

**1.41.39.1.97 Field: Basin Heater Setpoint Temperature [C]**

This input field contains the setpoint temperature for basin heater operation, in °C. This field is only used when the condenser type is set to EvaporativelyCooled. The basin heater is active when the outdoor drybulb temperatures falls below this setpoint temperature. The default is 2.0 °C.

**1.41.39.1.98 Field: Basin Heater Availability Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field is only used when the condenser type is set to EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates whenever the schedule is on and the outdoor air drybulb is lower than the setpoint temperature in the previous field. If the field is left blank, the basin heater is available to operate throughout the simulation.

**1.41.39.1.99 Field: Supply Water Storage Tank Name**

This optional field is used to describe where the TES coil obtains water used for evaporative cooling of its condenser. If blank or omitted, then the unit will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the unit will attempt to obtain all its water from that tank. However, if the tank cannot provide all the water the condenser needs, then the unit will still operate and obtains the rest of the water it needs from the mains (referred to as Starved Water).

**1.41.39.1.100 Field: Condensate Collection Water Storage Tank Name**

This optional field is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of a Water Storage Tank defined elsewhere and the condensate will be collected in that tank.

**1.41.39.1.101 Field: Storage Tank Plant Connection Inlet Node Name**

This is the name of a system node that is the inlet to the TES tank. This field is optional and is only used if the TES tank is directly connected to a plant loop.

**1.41.39.1.102 Field: Storage Tank Plant Connection Outlet Node Name**

This is the name of a system node that is the inlet to the TES tank. This field is optional and is only used if the TES tank is directly connected to a plant loop.

**1.41.39.1.103 Field: Storage Tank Plant Connection Design Flow Rate**

This field is the design flow rate for the plant connection to the TES tank, in m<sup>3</sup>/s. The TES tank will make a passive request for this amount of flow. This field is required if the storage tank is connected to plant.

**1.41.39.1.104 Field: Storage Tank Plant Connection Heat Transfer Effectiveness**

This field specifies the heat transfer effectiveness between the plant connection and the TES tank. If the effectiveness is set to 1 then ideal heat transfer occurs, as if the fluids were completely mixed and the fluid leaving the tank is the same temperature as the tank. If the effectiveness is less than 1.0, then the leaving fluid temperature approaches that of the tank as would be the case with a heat exchanger. If left blank, the default is 0.7.

**1.41.39.1.105 Field: Storage Tank Minimum Operating Limit Fluid Temperature [C]**

This field is used for fluid-based TES tank (Storage Type of Water or UserDefinedFluidType) to set the a lower limit on the operating temperatures, in Degrees Celsius. This value represents the temperature of the fluid-based TES tank when fully charged. This field is optional. When left blank, the model uses the lowest temperature for which fluid properties are defined.

**1.41.39.1.106 Field:: Storage Tank Maximum Operating Limit Fluid Temperature [C]**

This field is used for fluid-based TES tank (Storage Type of Water or UserDefinedFluidType) to set the an upper limit on the operating temperatures, in Degrees Celsius. This value represents the temperature of the fluid-based TES tank when fully discharged. This field is optional. When left blank, the model uses the highest temperature for which fluid properties are defined.

#### 1.41.39.2.1 Cooling Coil Operating Mode Index []

This output variable reports the operating mode for the cooling coil. The numbers in this output are integer codes that correspond to the operating modes as described in the following table. These codes match the values used for input in schedules and EMS actuators to control operation.

Code	Operating Mode
0	Off
1	Cooling Only
2	Cooling and Charge
3	Cooling and Discharge
4	Charge Only
5	Discharge Only

#### 1.41.39.2.2 Cooling Coil Total Cooling Rate [W]

This output is the total (sensible and latent) cooling rate of the coil in Watts.

#### 1.41.39.2.3 Cooling Coil Total Cooling Energy [J]

This output is the total (sensible and latent) cooling energy transfer by the coil in Joules. This output is metered as EnergyTransfer for CoolingCoils.

#### 1.41.39.2.4 Cooling Coil Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate of the coil in Watts.

#### 1.41.39.2.5 Cooling Coil Sensible Cooling Energy [J]

This output is the moist air sensible cooling energy transfer by the coil in Joules.

#### 1.41.39.2.6 Cooling Coil Latent Cooling Rate [W]

This output is the latent cooling rate of the coil in Watts.

#### 1.41.39.2.7 Cooling Coil Latent Cooling Energy [J]

This output is the latent cooling energy transfer by the coil in Joules.

**1.41.39.2.8 Cooling Coil Electricity Rate [W]**

This output is the electricity consumption rate, in Watts, of the compressor(s), pump(s), condenser fan(s) that are inside the package to drive heat transfer for the cooling coil. This does not include ancillary electrical consumption for such things as cold weather protection, off cycle ancillary power, or supply fans.

**1.41.39.2.9 Cooling Coil Electricity Energy [J]**

This output is the electricity consumption, in Joules, of the compressor(s), pump(s), condenser fan(s) that are inside the package to drive heat transfer for the cooling coil. This does not include ancillary electrical consumption for such things as cold weather protection, off cycle ancillary power, or supply fans.

**1.41.39.2.10 Cooling Coil Runtime Fraction []**

This output is the runtime fraction of cooling coil.

**1.41.39.2.11 Cooling Coil Cold Weather Protection Electricity Rate [W]****1.41.39.2.12 Cooling Coil Cold Weather Protection Electricity Energy [J]**

These are the power and energy outputs associated with Cold Weather Operation Ancillary Power, in Watts and Joules respectively.

**1.41.39.2.13 Cooling Coil Thermal Storage Mechanical Heat Transfer Rate [W]****1.41.39.2.14 Cooling Coil Thermal Storage Mechanical Heat Transfer Energy [J]**

These are the power and energy outputs for the coil's heat exchange with the TES tank, in Watts and Joules respectively. The sign convection is that negative values are cooling the TES tank, or charging it, and positive values are heating the TES tank, or discharging. This heat transfer is driven by the mechanical systems used inside the package to charge or discharge the TES tank.

**1.41.39.2.15 Cooling Coil Thermal Storage Ambient Heat Transfer Rate [W]****1.41.39.2.16 Cooling Coil Thermal Storage Ambient Heat Transfer Energy [J]**

These are the power and energy outputs for the TES tank's heat exchange with the surrounding ambient conditions, in Watts and Joules respectively. The sign convection is that negative values are cooling the TES tank, or charging it, and positive values are heating the TES tank, or discharging. This heat transfer is driven by the temperature difference between the media in the tank and the surrounding ambient and is governed by the UA factor.

**1.41.39.2.17 Cooling Coil Ice Thermal Storage End Fraction []**

This output is the state of the TES tank as fraction of the storage capacity. Because the tank storage model is dynamic, this value corresponds to the point in time right at the end of the timestep. This output variable is only available for a storage type of Ice.

**1.41.39.2.18 Cooling Coil Fluid Thermal Storage End Temperature [C]**

This output is the state of the TES tank as the temperature of the fluid in the tank, in °C. Because the tank storage model is dynamic, this value corresponds to the point in time right at the end of the timestep. This output variable is only available for a storage type of Water or UserDefinedFluidType.

**1.41.39.2.19 Cooling Coil Condenser Inlet Temperature [C]**

This output is the inlet temperature entering the condenser section of an evaporatively cooled condenser, in °C. This temperature is for the air stream after the evaporative assist and before entering the condenser. This is the temperature used for condenser entering drybulb conditions when evaluating performance curves for evaporatively cooled condensers. This output is only available for evaporatively cooled condensers.

**1.41.39.2.20 Cooling Coil Evaporative Condenser Water Volume [m<sup>3</sup>]**

This output is the amount of water used to evaporatively cool the condenser inlet air, in cubic meters. This output is only available for evaporatively cooled condensers.

**1.41.39.2.21 Cooling Coil Evaporative Condenser Mains Supply Water Volume [m<sup>3</sup>]**

This output is the volume of water drawn from mains water service for the evaporatively cooled condenser. This output is only available for evaporatively cooled condensers.

**1.41.39.2.22 Cooling Coil Evaporative Condenser Pump Electricity Rate [W]**

This output is the average electricity consumption rate of the evaporative condenser water pump, in Watts. This output is only available for evaporatively cooled condensers.

**1.41.39.2.23 Cooling Coil Evaporative Condenser Pump Electricity Energy [J]**

This output is the electricity consumption of the evaporative condenser water pump, in Joules. This output is only available for evaporatively cooled condensers.

**1.41.39.2.24 Cooling Coil Basin Heater Electricity Rate [W]**

This output is the average electricity consumption rate of the basin heater, in Watts. This output is only available for evaporatively cooled condensers.

**1.41.39.2.25 Cooling Coil Basin Heater Electricity Energy [J]**

This output is the electricity consumption of the basin heater, in Joules. This output is only available for evaporatively cooled condensers.

**1.41.39.2.26 Cooling Coil Thermal Storage Plant Heat Transfer Rate [W]****1.41.39.2.27 Cooling Coil Thermal Storage Plant Heat Transfer Energy [J]**

These are the power and energy outputs for the TES tank's heat exchange with the plant loop, in Watts and Joules respectively. This output is only available if the plant connection to the tank is used. The sign convention is that negative values are cooling the TES tank, or charging it, and positive values are heating the TES tank, or discharging. This heat transfer is driven by the temperature difference between the media in the tank and the plant loop fluid and is governed by the effectiveness and plant fluid mass flow rate.

**1.41.40 Secondary Coils of DX System and Heat Pump**

Secondary Coils reject to or remove heat from a secondary zone as part of a DX system or an air-to-air heat pump. Secondary coil refers to a condenser of a DX system or a heat pump in cooling operating mode or an evaporator of a heat pump in heating mode. The secondary coil (e.g. condenser) of DX system or heat pumps is commonly installed outdoor but when installed inside a zone either heat is dumped to or

extracted from a secondary zone. A secondary zone is a conditioned or unconditioned zone where the secondary coil is installed. Secondary coils are not standalone DX coils but they are add-on features on existing DX coil objects. A secondary DX coil is modeled by specifying additional inputs in one of the following DX coil objects: `Coil:Cooling:DX:SingleSpeed`, `Coil:Heating:DX:SingleSpeed`, `Coil:Cooling:DX:TwoSpeed`, `Coil:Cooling:DX:MultiSpeed`, and `Coil:Heating:DX:MultiSpeed`. These additional inputs allow us to model the heat rejected or extracted by the secondary coil while the primary (active) coil is serving another controlled zone as shown in Figure. A secondary coil is not controlled directly but responds to the requirements of the primary DX coil. Heat is rejected or extracted depending on the primary DX coil operating modes. For instance, heat rejected to a secondary zone by a condenser of a DX system or a heat pump is considered as sensible only whereas the energy extracted from a secondary zone may contain sensible and latent components.

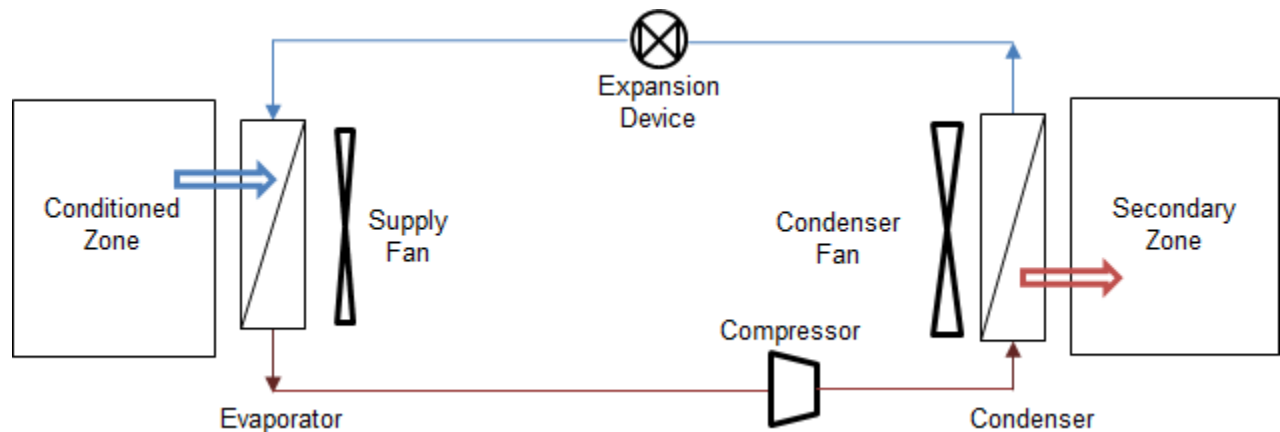

Figure 1.176:

Figure: Schematic of DX System and heat pump in cooling operating mode

Applications of this technology include: inter-zone heat pump in NTED (Dixon, 2010), and PTAC or PTHP serving Offices attached to a Warehouse, where the office partially or fully enclosed by the warehouse and the condenser is inside the Warehouse. Heat rejected or extracted by the secondary DX coil installed in a secondary zone is estimated from the DX coil models and it is considered as internal gains of the secondary zone. The capacity and electric power input of the DX system and heat pumps are determined from the operating modes of the primary cooling or heating DX coils. Calculation of a secondary coil tracks the operating modes of the primary DX coil serving the primary conditioned zone(s). Currently allowed DX coil models are single speed, two speed and multi speed DX Systems and Heat Pumps. To model secondary DX coils the condenser type should be AirCooled. There is no need to specify the condenser air inlet node. The model uses zone air node as the secondary coil air inlet node. And the fuel type in multispeed DX coils should Electricity.

**Cooling Operating Mode:** the primary DX cooling coil of a DX system serving a primary zone is active and heat is rejected by the secondary coil (condenser) into a secondary zone. The secondary zone name is specified in DX cooling coil objects. This operating mode applies to a DX cooling system and cooling operating mode of air-to-air single and multi-speed heat pumps. Heat rejected by a secondary coil (condenser) calculated at each time step becomes internal gain of the secondary zone as shown in Figure. Whenever a secondary zone name is specified in DX cooling coil objects, the secondary DX coil model calculation is invoked. The only input field required to invoke the secondary DX coil in cooling operating model is to add a zone name in the input field *Zone Name for Condenser Placement* in the DX cooling coil object.

## 1.41.40.1 Field: Zone Name for Condenser Placement

This input field is name of a conditioned or unconditioned zone where the secondary coil (condenser) of DX system or a heat pump is to be placed. This is an optional input field specified only when user desires to reject the condenser heat into this zone. The heat rejected is modeled as sensible internal gain of a secondary zone.

Figure 1.177:

Figure: Schematic of DX system and secondary coil in cooling mode

Following is an example input for a single-speed cooling DX coil with secondary DX coil run option.

**Heating Operating Mode:** When a heat pump operates in heating mode then energy is extracted from the secondary zone. Total energy extracted from a secondary zone may contain sensible and latent components. The secondary coil (evaporator) model checks for the coil inlet and outlet air condition to determine if dehumidification has occurred. The sensible and latent split of the energy extracted is done using a user specified rated sensible heat ratio (SHR) and SHR modifier curves for temperature and secondary air flow fraction. If the coil operation is dry, then the SHR is set to 1.0. In addition, the model assumes that condensed water is drained to the outside. If defrosting operation is on, then the defrosting melts the frost and the liquid water from the collecting pan is drained to the outside. Thus, defrosting energy is not included in the zone energy balance. The six optional input fields required in the DX heating coils are the following. The last five input fields are extensible depending on the speed of the heating DX coil:

#### 1.41.40.2 Field: Zone Name for Evaporator Placement

This input field is name of a conditioned or unconditioned zone where the secondary coil (evaporator) of a heat pump is installed. This is an optional input field specified only when user desires to extract heat from the zone via secondary coil. Heat extracted is modeled as internal gain. If the primary DX system is a heat pump, then the zone name should be the same as the zone name specified for placing the secondary cooling DX coil.

#### 1.41.40.3 Field: Speed Secondary Coil Air Flow Rate

This input value is the secondary coil (evaporator) air flow rate when the heat pump is working in heating mode or the secondary coil (condenser) air flow rate when the heat pump is working in cooling mode. This input field is auto-sizable.

#### 1.41.40.4 Field: Speed Secondary Coil Fan Flow Scaling Factor

This input field is scaling factor for autosizing the secondary DX coil fan flow rate. The secondary air flow rate is determined by multiplying the primary DX coil rated air flow rate by the fan flow scaling factor. Default value is 1.25. If the secondary coil fan flow rate is not autosized, then the secondary coil fan flow scaling factor is set to 1.0.

#### 1.41.40.5 Field: Speed Nominal Sensible Heat Ratio of Secondary Coil

This input value is the nominal sensible heat ratio used to split the heat extracted by a secondary DX coil (evaporator) of a heat pump into sensible and latent components. This is an optional input field. If this input field is left blank, then pure sensible internal heat gain is assumed, i.e., sensible heat ratio of 1.0.

#### 1.41.40.6 Field: Speed Sensible Heat Ratio Modifier Function of Temperature Curve Name

This input field is name of sensible heat ratio modifier biquadratic curve. The value of this curve modifies the nominal sensible heat ratio for current time step depending on the secondary zone air node wet-bulb temperature and the heating DX coil entering air dry-bulb temperature. This is an optional input field. If this input field is left blank, then the nominal sensible heat ratio modifier curve value for temperature is set to 1.0.

#### 1.41.40.7 Field: Speed Sensible Heat Ratio Modifier Function of Flow Fraction Curve Name

This input field is name of sensible heat ratio modifier curve as function of secondary air flow fraction. The value of this curve modifies the nominal sensible heat ratio for current time step depending on the secondary coil air flow fraction. This is an optional input field. If this input field is left blank, then the sensible heat ratio modifier curve value for flow fraction is set to 1.0.

Following is an example input for a single-speed heating DX coil with secondary DX coil run option.

### 1.41.41 Secondary DX Coil Output

- HVAC, Average, Secondary Coil Heat Rejection Rate [W]
- HVAC, Average, Secondary Coil Total Heat Removal Rate [W]
- HVAC, Average, Secondary Coil Sensible Heat Removal Rate [W]
- HVAC, Average, Secondary Coil Latent Heat Removal Rate [W]
- HVAC, Average, Secondary Coil Sensible Heat Ratio []
- HVAC, Average, Secondary Coil Compressor Part Load Ratio []

#### 1.41.41.1 Secondary Coil Heat Rejection Rate [W]

This is the sensible heat rejected to a zone by a secondary DX coil (condenser) in Watts. This is sum of the total cooling rate of a DX cooling coil and cooling electric power of the primary DX coil. This heat is applied as an internal gain to the secondary zone where the condenser is installed.

#### 1.41.41.2 Secondary Coil Total Heat Removal Rate [W]

This is the total energy removed from a a zone by a secondary DX coil (evaporator) in Watts. This is the total heating rate of the primary DX cooling coil minus the heating electric power of the primary DX coil. This heat is extracted from the secondary zone when the heat pump is operating in heating mode. The negative sign indicate that heat is removed from the zone.

#### 1.41.41.3 Secondary Coil Sensible Heat Removal Rate [W]

This is the sensible heat removed from a a zone by a secondary DX coil (evaporator) in Watts. This is determined by multiplying the total heat removed with sensible heat ratio of the secondary coil. This heat is extracted from the secondary zone when the heat pump is operating in heating mode. The negative sign indicate that sensible heat is removed from the zone.

#### 1.41.41.4 Secondary Coil Latent Heat Removal Rate [W]

This is the latent heat removed from a a zone by a secondary DX coil (evaporator) in Watts. This is the difference between the total heat removal rate and the sensible heat removal rate of the secondary coil. This heat is extracted from the secondary zone when the heat pump is operating in heating mode. The negative sign indicate that moisture is removed from the zone.

#### 1.41.41.5 Secondary Coil Sensible Heat Ratio []

This is the operating sensible heat ratio the secondary DX coil (condenser) when the heat pump is operating in heating mode.

#### 1.41.41.6 Secondary Coil Compressor Part Load Ratio []

This is the compressor part load ratio when the heat pump is operating in heating mode and the secondary coil is extracting heat from a zone where the coil is installed. The secondary coil DX coil compressor part load ratio can be different from the primary DX coil compressor part load ratio in that the later may include the defrosting load.

Reference: Dixon, Erin Elizabeth, “Energy Model Development and Heating Energy Investigation of the Nested Thermal Envelope Design (NTED (tm))” (2010). Theses and dissertations. Paper 974.

#### 1.41.42 Coil:Cooling:DX

This coil input structure is meant to supplant the coil objects from previous EnergyPlus versions (Coil:Cooling:DX:SingleSpeed, Coil:Cooling:DX:TwoSpeed, Coil:Cooling:DX:MultiSpeed, etc.). This coil input structure uses a combination of four objects to fully define the performance of the coil under a range of operating conditions.

1. Coil:Cooling:DX - Defines where the coil’s evaporator and condenser sections are connected to the HVAC system through node connections to air loops or zones (if condenser section rejects heat to a zone), as well as the coil’s availability.
2. Coil:Cooling:DX:CurveFit:Performance - Defines how the coil operates over a range of operating conditions.
3. Coil:Cooling:DX:CurveFit:OperatingMode - Defines the rated coil characteristics (capacity, evaporator section air flow rate, etc.) and capacity control method for a given operating mode. Operating modes are generally used to describe humidity control strategies for DX cooling coil arrangements that enable enhanced dehumidification.
4. Coil:Cooling:DX:CurveFit:Speed - Defines DX cooling coil performance for a specific speed within a single operating mode.

Note: The Coil:Cooling:DX:CurveFit:Performance object also allows users to input 3 operating modes: Base Operating Mode, Alternative Operating Mode 1, and Alternative Operating Mode 2. When the Base Operating Mode is an only mode input, the coil performs like a regular cooling DX coil and no specific dehumidification capability. The alternative operating mode 1 is used for enhanced dehumidification. When all 3 modes are inputs, the coil performs as a subcool reheat coil. When load sensible heat ratio (SHR), defined as sensible cooling load / (sensible cooling load + latent cooling load), is greater than the SHR in the Base Operating Mode at given inlet air conditions, the coil performs in Base Operating Mode only. When the load SHR is less than the SHR in the Base Operating Mode and greater than the SHR in the Alternative Operating Mode 1 at the same given inlet air conditions, the coil performs combination of both Base Operating Mode, and Alternative Operating Mode 1. Mode ratio determines a fraction of time Alternative Operating Mode 1 operates and the rest (1 - Mode ratio) of time Base Operating Mode operates in a single time step. When the load SHR is less than the SHR in the Alternative Operating Mode 1 and greater than the SHR in the Alternative Operating Mode 2 at the same given inlet air conditions, the coil performs combination of both Base Operating Mode, and Alternative Operating Mode 2. Mode ratio determines a fraction of time Alternative Operating Mode 2 operates and (1 - Mode ratio) of time Base Operating Mode operates in a single time step. When the load SHR is greater than the SHR in the Alternative Operating Mode 2, the coil performs as Alternative Operating Mode 2 alone.

Figure 1.178 below represents the hierarchy how these four input objects reference each other. Arrows pointing from one object to another represents where one object has an input field that references the name of a different object. For example, an input field of the Coil:Cooling:DX object

references the name of a Coil:Cooling:DX:CurveFit:Performance object. For this coil input structure, one Coil:Cooling:DX object can only reference one Coil:Cooling:DX:CurveFit:Performance object. However, one Coil:Cooling:DX:CurveFit:Performance object can reference multiple Coil:Cooling:DX:CurveFit:OperatingMode objects, and each Coil:Cooling:DX:CurveFit:OperatingMode object can reference multiple Coil:Cooling:DX:CurveFit:Speed objects. In the image below, the cooling coil has one single-speed operating mode and a second two-speed operating mode.

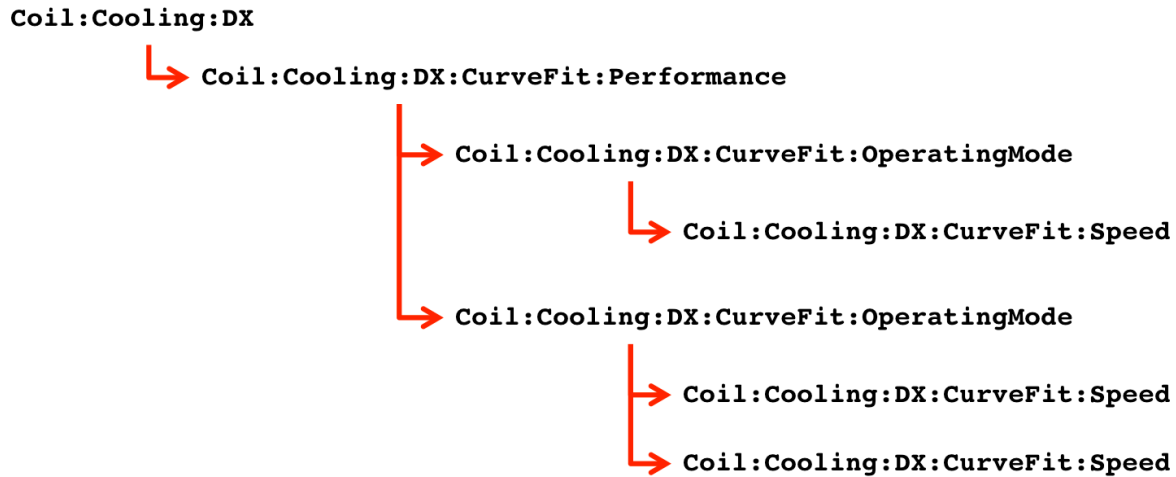

Figure 1.178: Hierarchy of references between cooling coil objects

### 1.41.42.1 Inputs

#### 1.41.42.1.1 Field: Name

A unique user-assigned name for an instance of a cooling coil. Any reference to this cooling coil by another object will use this name.

#### 1.41.42.1.2 Field: Evaporator Inlet Node Name

The name of the HVAC system node from which the evaporator of the DX cooling coil draws its inlet air.

#### 1.41.42.1.3 Field: Evaporator Outlet Node Name

The name of the HVAC system node to which the evaporator of the DX cooling coil sends its outlet air.

#### 1.41.42.1.4 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.41.42.1.5 Field: Condenser Zone Name

The name of a conditioned or unconditioned zone where the secondary coil (condenser) of DX system or a heat pump is to be placed. This is an optional input field specified only when user desires to reject the condenser heat into a zone. The heat rejected is modelled as internal sensible heat gain of the zone.

**1.41.42.1.6 Field: Condenser Inlet Node Name**

The name of the HVAC system node from which the condenser of the DX cooling coil draws its inlet air. If the condenser draws air from the outdoors, an `OutdoorAir:Node` object must be referenced.

**1.41.42.1.7 Field: Condenser Outlet Node Name**

The name of the HVAC system node to which the condenser of the DX cooling coil sends its outlet air.

**1.41.42.1.8 Field: Performance Object Name**

The name of the `Coil:Cooling:DX:CurveFit:Performance` object that defines this coil's performance specifications.

**1.41.42.1.9 Field: Condensate Collection Water Storage Tank Name**

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of a `WaterUse:Storage` object defined elsewhere and the condensate will then be collected in that tank.

**1.41.42.1.10 Field: Evaporative Condenser Supply Water Storage Tank Name**

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling of its condenser. If blank or omitted, then the unit will obtain water directly from the mains. If the name of a `WaterUse:Storage` object is used here, then the unit will obtain its water from that tank. If a tank is specified, the unit will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the condenser needs, then the unit will still operate and obtain the rest of the water it needs from the mains (referred to as `StarvedWater`).

**1.41.43 Coil:Cooling:DX:CurveFit:Performance**

This object defines basic unit control and other characteristics for one `Coil:Cooling:DX` object. For that `Coil:Cooling:DX` object, it also references one or more operating modes, which are defined using the `Coil:Cooling:DX:CurveFit:OperatingMode` object.

**1.41.43.1 Inputs****1.41.43.1.1 Field: Name**

A unique user-assigned name for an instance of a cooling coil performance specification. Any reference to this cooling coil performance specification by a cooling coil object will use this name.

**1.41.43.1.2 Field: Crankcase Heater Capacity**

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field `Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation` (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump (Ref. `Air-LoopHVAC:UnitaryHeatPump:AirToAir` or `PackageTerminal:HeatPump:AirToAir`), the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. `Coil:Heating:DX:SingleSpeed`) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

### 1.41.43.1.3 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the cooling coil compressor turns off. If this input field is left blank, the default value is -25 °C (-13 °F).

### 1.41.43.1.4 Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C (32 °F), and the default value is 10 °C (50 °F).

### 1.41.43.1.5 Field: Unit Internal Static Air Pressure

If this coil is used with a Fan:VariableVolume to model a packaged variable-air-volume unit, then ratings for standard rated net capacity, EER, and IEER will be calculated per ANSI/AHRI Standard 340/360-2007 with Addenda 1 and 2. This field is to specify the internal static air pressure, in units of Pascals, associated with the unit's supply air flow for rating purposes. This field does not affect the performance during operation. This field is optional. If this field is used, then the internal static air pressure is used with the associated fan characteristics when calculating standard rated net capacity, EER, and IEER. If this field is not used, then the standard ratings are still performed but use a default for specific fan power of 773.3 (W/(m<sup>3</sup>/s)). The air pressure drop/rise input here should be internal in the sense that it is for the entire package of unitary equipment as it would be tested in a laboratory (including other non-cooling sections inside the package for filters, dampers, and/or heating coils) but none of the external pressure drop for distributing supply air throughout the building. This is different from the input field called Pressure Rise in the fan object which includes both the external static pressure and the internal static pressure. The results of standard rating calculations are reported to the EIO file and to predefined output tables called DX Cooling Coils and VAV DX Cooling Standard Rating Details.

### 1.41.43.1.6 Field: Capacity Control Method

This choice field defined the capacity control method. Valid choices for this input field are **Discrete** and **Continuous**. The default for this field is **Discrete**. **Discrete** control mode allow the coil to operate at discrete speed levels. **Continuous** control mode allows the coil performance to be operated at continuously variable speeds.

### 1.41.43.1.7 Field: Evaporative Condenser Basin Heater Capacity

This numeric field contains the capacity of the coil's electric evaporative cooler basin heater in Watts per degree Kelvin. This field only applies for Condenser Type = **EvaporativelyCooled**. This field is used in conjunction with the Evaporative Condenser Basin Heater Setpoint Temperature and Evaporative Condenser Basin Heater Operating Schedule Name described in the following fields. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

### 1.41.43.1.8 Field: Evaporative Condenser Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = **EvaporativelyCooled**. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil

is off. This set point temperature must be greater than or equal to 2°C (35.6°F), and the default value is 2°C (35.6°F) if this field is left blank.

#### 1.41.43.1.9 Field: Evaporative Condenser Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = **EvaporativelyCooled**. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

#### 1.41.43.1.10 Field: Compressor Fuel Type

This alpha field determines the type of fuel that this cooling coil's compressor uses. This field has nine choices: **Electricity**, **NaturalGas**, **Propane**, **Diesel**, **Gasoline**, **FuelOilNo1**, **FuelOilNo2**, **OtherFuel1** and **OtherFuel2**. The default is **Electricity**.

#### 1.41.43.1.11 Field: Base Operating Mode

The name corresponding to a Coil:Cooling:DX:CurveFit:OperatingMode object. Operating Mode is always used as the base design operating mode. This field is required.

#### 1.41.43.1.12 Field: Alternate Operating Mode 1

The name corresponding to a Coil:Cooling:DX:CurveFit:OperatingMode object. Operating Mode is used as the alternate operating mode operating mode to be used for enhanced dehumidification when needed. If field is blank, the base operating mode will be used. This field is optional.

#### 1.41.43.1.13 Field: Alternate Operating Mode 1

The name corresponding to a Coil:Cooling:DX:CurveFit:OperatingMode object. Operating Mode is used as to represent a reheat mode as a subcool reheat coil. If field is blank, the base operating mode will be used. This field is optional.

If there are 3 operating modes, it represents a subcool-reheat mode coil. The Operating Mode 1 represents a base operating mode coil. The Operating Mode 2 represents a subcool mode coil with lower SHR than the Operating Mode 1. The Operating Mode 3 represents a reheat mode coil with lower SHR than the Operating Mode 2. All 3 operation modes work together to represent a subcool reheat coil model. The operation procedure is described in [1.41.42](#)

### 1.41.44 Coil:Cooling:DX:CurveFit:OperatingMode

This object defines DX cooling coil performance for a single operating mode at rated conditions. Each operating mode may have one or more speeds, which are defined using the Coil:Cooling:DX:CurveFit:Speed object. Each operation mode can reference a maximum of 10 Coil:Cooling:DX:CurveFit:Speed objects.

#### 1.41.44.1 Inputs

##### 1.41.44.1.1 Field: Name

A unique user-assigned name for an instance of a cooling coil operating mode. Any reference to this cooling coil operating mode by a cooling coil performance specification will use this name.

**1.41.44.1.2 Field: Rated Gross Total Cooling Capacity**

The total, full load gross cooling capacity (sensible plus latent) in Watts of the DX coil unit at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb (80 °F drybulb/67 °F wetbulb), air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb (95 °F drybulb/75 °F wetbulb), and a cooling coil air flow rate defined by field rated air flow rate below). Capacity should be gross (i.e., the effect of supply air fan heat is NOT accounted for). When used in a heat pump, the gross rated total cooling capacity should be within 20% of the gross rated heating capacity, otherwise a warning message is issued.

**1.41.44.1.3 Field: Rated Evaporator Air Flow Rate**

The air volume flow rate, in m<sup>3</sup> per second, across the DX cooling coil evaporator section at rated conditions. The rated air volume flow rate should be between 0.00004027 m<sup>3</sup>/s and 0.00006041 m<sup>3</sup>/s per Watt of gross rated total cooling capacity (300 to 450 cfm/ton). For DOAS applications the rated air volume flow rate should be between 0.00001677 m<sup>3</sup>/s and 0.00003355 m<sup>3</sup>/s per watt of gross rated total cooling capacity (125 to 250 cfm/ton). The gross rated total cooling capacity, gross rated SHR and gross rated COP should be performance information for the unit with air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb (80 °F drybulb/67 °F wetbulb), air entering the outdoor condenser coil at 35 °C drybulb/23.9 °C wetbulb (95 °F drybulb/75 °F wetbulb), and the rated air volume flow rate defined here.

**1.41.44.1.4 Field: Rated Condenser Air Flow Rate**

The air volume flow rate, in m<sup>3</sup> per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m<sup>3</sup>/s per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = **AirCooled**.

**1.41.44.1.5 Field: Maximum Cycling Rate**

The maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects (e.g., AirloopHVAC:UnitaryHeatCool); and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation.

**1.41.44.1.6 Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity**

Ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects (e.g., AirloopHVAC:UnitaryHeatCool); and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation.

**1.41.44.1.7 Field: Latent Capacity Time Constant**

Time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45: supply air fan operating mode must be continuous. That is, the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects (e.g., AirloopHVAC:UnitaryHeatCool).

#### 1.41.44.1.8 Field: Nominal Time for Condensate Removal to Begin

The nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other parent objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects (e.g., AirloopHVAC:UnitaryHeatCool), and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation.

#### 1.41.44.1.9 Field: Apply Latent Degradation to Speeds Greater than 1

This field determines whether latent capacity degradation is applied when the coil is operating at speeds greater than speed 1. The allowed choices are **Yes** or **No**, with the default being **No** if this field is left blank. Other input fields in this object allow the user to specify latent capacity degradation at each speed.

The latent capacity degradation model only applies when the ContinuousFanWithCyclingCompressor supply air fan operating mode is specified, to account for moisture evaporation from the wet cooling coil when the compressor cycles off but the supply air fan continues to operate. For the case of a single multi-speed compressor, latent capacity degradation may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may choose to specify **No** for this input field to neglect latent capacity degradation impacts at higher operating speeds. If latent capacity degradation is thought to be significant (e.g., intertwined or row-split cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may choose to specify **Yes** and the latent capacity degradation model will be applied for speeds 2 through 10 as appropriate. The selection for this input field does not affect latent capacity degradation between speed 1 and off.

#### 1.41.44.1.10 Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

#### 1.41.44.1.11 Field: Nominal Evaporative Condenser Pump Power

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = **AirCooled**.

#### 1.41.44.1.12 Field: Nominal Speed Number

This numeric field specifies the speed number which corresponds to the rated capacity and air flow rates specified in this object. This value must be lower than or equal to the highest speed number defined below. If blank, defaults to the highest speed number used.

**1.41.44.1.13 Field: Speed <x> Name**

For speed <x>, the name of the corresponding Coil:Cooling:DX:CurveFit:Speed object. Speed 1 is always used as the lowest speed. Speeds should be listed in ascending order from lowest capacity to highest capacity. Each coil operating mode may have up to 10 speeds defined.

**1.41.45 Coil:Cooling:DX:CurveFit:Speed**

This object defines DX cooling coil performance for a specific speed within a single operating mode. A speed can be used for a combination of air flow rates and capacities different than the rated air flow rates and capacities defined in Coil:Cooling:DX:CurveFit:OperatingMode. Each operating mode can reference a maximum of 10 speeds.

**1.41.45.1 Inputs****1.41.45.1.1 Field: Name**

A unique user-assigned name for an instance of a cooling coil operating mode's speed. Any reference to a specific speed by a cooling coil operating mode will use this name.

**1.41.45.1.2 Field: Gross Total Cooling Capacity Fraction**

This is the ratio of capacity at a specific speed to the operating mode's *Rated Gross Total Cooling Capacity*. This field should be 1.0 for the *Nominal Speed Number* specified in the Coil:Cooling:DX:CurveFit:OperatingMode object.

**1.41.45.1.3 Field: Evaporator Air Flow Rate Fraction**

This is the ratio of evaporator air flow rate at a specific speed to the operating mode's *Rated Evaporator Air Flow Rate*. This field should be 1.0 for the *Nominal Speed Number* specified in the Coil:Cooling:DX:CurveFit:OperatingMode object.

**1.41.45.1.4 Field: Condenser Air Flow Rate Fraction**

This is the ratio of condenser air flow at a specific speed to the operating mode's *Rated Condenser Air Flow Rate*. This field should be 1.0 for the *Nominal Speed Number* specified in the Coil:Cooling:DX:CurveFit:OperatingMode object.

**1.41.45.1.5 Field: Gross Sensible Heat Ratio**

This numeric field defines the gross sensible heat ratio (sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions for a specific speed. Both the sensible and total cooling capacities used should be gross (i.e., the effect of supply air fan heat is NOT accounted for).

**1.41.45.1.6 Field: Gross Cooling COP**

The coefficient of performance is the ratio of the gross total cooling capacity in Watts to electrical power input in Watts of the DX cooling coil unit at rated conditions (air entering the cooling coil at 26.7 °C drybulb/19.4 °C wetbulb (80 °F drybulb/67 °F wetbulb), air entering the outdoor condenser coil at 35 °C drybulb/ 23.9 °C wetbulb (95 °F drybulb/75 °F wetbulb), and a cooling coil air flow rate defined by field rated air flow rate below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The gross COP should NOT account for the supply air fan. If this input field is left blank, the default value is 3.0.

#### 1.41.45.1.7 Field: Active Fraction of Coil Face Area

Defines the fraction of the cooling coil face which is actively cooled at a specific speed. Value varies between 0.0 and 1.0. For non-split-face coils, this should be 1.0.

#### 1.41.45.1.8 Field: Rated Evaporator Fan Power Per Volume Flow Rate

This field is the electric power for the evaporator (cooling coil) fan per air volume flow rate through the coil at the rated conditions in  $\text{W}/(\text{m}^3/\text{s})$ . The default value is  $773.3 \text{ W}/(\text{m}^3/\text{s})$  ( $365 \text{ W}/1000 \text{ cfm}$ ) if this field is left blank. If a value is entered, it must be  $\geq 0.0$  and  $\leq 1250 \text{ W}/(\text{m}^3/\text{s})$ . This value is only used to calculate Seasonal Energy Efficiency Ratio (SEER), Energy Efficiency Ratio (EER), Integrated Energy Efficiency Ratio (IEER) and the Standard Rating (Net) Cooling Capacity which will be outputs in the EnergyPlus eio file (ref. EnergyPlus Engineering Reference, Single Speed DX Cooling Coil, Standard Ratings). This value is not used for modeling the evaporator (cooling coil) fan during simulations; instead, it is used for calculating SEER, EER, IEER and Standard Rating Cooling Capacity to assist the user in verifying their inputs for modeling this type of equipment.

#### 1.41.45.1.9 Field: Evaporative Condenser Pump Power Fraction

The ratio of evaporative condenser pump power at a specific speed to the operating mode's *Nominal Evaporative Condenser Pump Power*. This field is not used when Condenser Type = **AirCooled**.

#### 1.41.45.1.10 Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at a specific speed, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond,inlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o}) \quad (1.194)$$

where

$T_{cond,inlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Function of Temperature Curve and the Energy Input Ratio Modifier Function of Temperature Curve. The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = **AirCooled**.

If the user wants to model an air-cooled condenser, they should simply specify **AirCooled** in the field *Condenser Type*. In this case, the Total Cooling Capacity Modifier Function of Temperature Curve and the Energy Input Ratio Modifier Function of Temperature Curve input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = **EvaporativelyCooled** and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Function of Temperature Curve and the Energy Input Ratio Modifier Function of Temperature Curve input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = **Evaporatively-Cooled**. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Function of Temperature Curve and the Energy Input Ratio Modifier Function of Temperature Curve input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly

reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Function of Air Flow Fraction Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

#### **1.41.45.1.11 Field: Total Cooling Capacity Modifier Function of Temperature Curve Name**

The name of a bivariate (e.g. biquadratic) or univariate (e.g. quadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of the gross total cooling capacity for a specific speed as a function of the wet-bulb temperature of the air entering the evaporator section, and the dry-bulb temperature of the air entering the condenser section (wet-bulb temperature if modeling an evaporative-cooled condenser). If a univariate curve or table is specified, then the independent variable is the entering condenser temperature. The curve is normalized to 1 at 19.44 °C (67 °F) indoor wet-bulb temperature and 35 °C (95 °F) outdoor dry-bulb temperature. The output of this curve is multiplied by the operating mode's *Rated Gross Total Cooling Capacity* to give the gross total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

#### **1.41.45.1.12 Field: Total Cooling Capacity Modifier Function of Air Flow Fraction Curve Name**

The name of a univariate (e.g. quadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of the gross total cooling capacity for a specific speed as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate for a specific speed (i.e., fraction of full load flow). The output of this curve is multiplied by the operating mode's *Rated Gross Total Cooling Capacity* and the total cooling capacity modifier curve (function of temperature) to give the gross total cooling capacity for a specific speed at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate for Speed <x>.

#### **1.41.45.1.13 Field: Energy Input Ratio Modifier Function of Temperature Curve Name**

The name of a bivariate (e.g. biquadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of the energy input ratio (EIR) for a specific speed as a function of the wetbulb temperature of the air entering the evaporator section and the drybulb temperature of the air entering the condenser section (wetbulb temperature if modeling an evaporative-cooled condenser). The curve is normalized to 1 at 19.44 °C (67 °F) indoor wet-bulb temperature and 35 °C (95 °F) outdoor dry-bulb temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR for a specific speed (inverse of rated COP for a specific speed) to give the EIR for a specific speed at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).

#### **1.41.45.1.14 Field: Energy Input Ratio Modifier Function of Air Flow Fraction Curve Name**

The name of a univariate (e.g. quadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of the energy input ratio (EIR) for a specific speed as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate for a specific speed (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR for a specific speed at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate for a specific speed.

#### 1.41.45.1.15 Field: Part Load Fraction Correlation Curve Name

The name of a univariate (e.g. quadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity for a specific speed). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the effective EIR for a given simulation timestep for a specific speed. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 < \text{PLR} < 1$ ), the following rules apply:

---

$$\text{PLF} > = 0.7 \quad \text{and} \quad \text{PLF} > = \text{PLR}$$

---

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional DX cooling coil (a specific speed) would be:

---

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

---

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

---

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

---

#### 1.41.45.1.16 Field: Rated Waste Heat Fraction of Power Input

The fraction of energy input to the cooling coil that is available as recoverable waste heat at full load and rated conditions for a specific speed.

#### 1.41.45.1.17 Field: Waste Heat Modifier Function of Temperature Curve Name

The name of a bivariate (e.g. biquadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of the waste heat recovery as a function of outdoor dry-bulb temperature and the entering coil dry-bulb temperature at a specific speed. The output of this curve is multiplied by the rated waste heat fraction at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point. When the fuel type is electricity, this field can remain blank since it is ignored by the program in this instance. When the fuel type is not electricity and the parent object AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed does not require waste heat calculations, this field is ignored. If the field is blank, a warning will be issued and simulation continues. When the fuel type is not electricity and the parent object AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed requires waste heat calculations, if this field is left blank, the program assumes a constant value of 1 to make simulation continue and a warning will be issued.

#### 1.41.45.1.18 Field: Sensible Heat Ratio Modifier Function of Temperature Curve Name

The name of a bivariate (e.g. biquadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of the sensible heat ratio (SHR) as a function of DX cooling coil entering air wet-bulb and dry-bulb temperatures. The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of flow fraction) to give the SHR at the specific coil entering air temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 at the rated condition. This input field is optional. If this input is not blank then the *Sensible Heat Ratio Modifier Function of Flow Fraction Curve Name* must also be entered. If left blank, SHR is calculated using the apparatus dew point method based on total capacity and coil bypass factor.

**1.41.45.1.19 Field: Sensible Heat Ratio Modifier Function of Flow Fraction Curve Name**

The name of a univariate (e.g. quadratic) curve or table object (ref Curve:\* and Table:\*) that parameterizes the variation of the sensible heat ratio (SHR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated SHR and the SHR modifier curve (function of temperature) to give the SHR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This input field is optional. If this input is not blank then the *Sensible Heat Ratio Modifier Function of Temperature Curve Name* must also be entered. If left blank, SHR is calculated using the apparatus dew point method based on total capacity and coil bypass factor.

Following is an example input for a single-speed air-cooled cooling DX coil.

### 1.41.45.2 Outputs

Following are the list of possible output variables from this coil model:

- HVAC, Average, Cooling Coil Total Cooling Rate [W]
- HVAC, Sum, Cooling Coil Total Cooling Energy [J]
- HVAC, Average, Cooling Coil Sensible Cooling Rate [W]
- HVAC, Sum, Cooling Coil Sensible Cooling Energy [J]

- HVAC, Average, Cooling Coil Latent Cooling Rate [W]
- HVAC, Sum, Cooling Coil Latent Cooling Energy [J]
- HVAC, Average, Cooling Coil Electricity Rate[W]
- HVAC, Sum, Cooling Coil Electricity Energy [J]
- HVAC, Average, Cooling Coil <Fuel> Rate [W]
- HVAC, Sum, Cooling Coil <Fuel> Energy [J]
- HVAC, Average, Cooling Coil Runtime Fraction []
- HVAC, Average, Cooling Coil Crankcase Heater Electricity Rate [W]
- HVAC, Sum, Cooling Coil Crankcase Heater Electricity Energy [J]
- HVAC, Average, Cooling Coil Air Mass Flow Rate [kg/s]
- HVAC, Average, Cooling Coil Air Inlet Temperature [C]
- HVAC, Average, Cooling Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]
- HVAC, Average, Cooling Coil Air Outlet Temperature [C]
- HVAC, Average, Cooling Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]
- HVAC, Average, Cooling Coil Part Load Ratio []
- HVAC, Average, Cooling Coil Upper Speed Level []
- HVAC, Average, Cooling Coil Neighboring Speed Levels Ratio []
- HVAC, Average, Cooling Coil Condenser Inlet Temperature [C]
- HVAC, Average, Cooling Coil Dehumidification Mode []
- HVAC, Average, Cooling Coil Waste Heat Power [W]
- HVAC, Sum, Cooling Coil Waste Heat Energy [J]
- HVAC, Average, Cooling Coil Basin Heater Electricity Rate [W]
- HVAC, Sum, Cooling Coil Basin Heater Electricity Energy [J]
- HVAC, Average, Cooling Coil Condensate Volume Flow Rate [m3/s]
- HVAC, Sum, Cooling Coil Condensate Volume [m3]
- HVAC, Average, Cooling Coil Evaporative Condenser Pump Electricity Rate [W]
- HVAC, Sum, Cooling Coil Evaporative Condenser Pump Electricity Energy [J]
- HVAC, Average, Cooling Coil Evaporative Condenser Water Volume Flow Rate [m3/s]
- HVAC, Sum, Cooling Coil Evaporative Condenser Mains Supply Water Volume [m3]
- HVAC, Sum, Cooling Coil Evaporative Condenser Water Volume [m3]

- HVAC, Average, Secondary Coil Heat Rejection Rate [W]
- HVAC, Sum, Secondary Coil Heat Rejection Energy [J]
- HVAC,Average,SubcoolReheat Cooling Coil Operation Mode []
- HVAC,Average,SubcoolReheat Cooling Coil Operation Mode Ratio []
- HVAC,Average,SubcoolReheat Cooling Coil Recovered Heat Energy Rate [W]
- HVAC,Average,SubcoolReheat Cooling Coil Recovered Heat Energy [J]

#### 1.41.45.2.1 Cooling Coil Total Cooling Rate [W]

Total (sensible and latent) cooling rate output of the DX coil in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.41.45.2.2 Cooling Coil Total Cooling Energy [J]

Total (sensible and latent) cooling output of the DX coil in Joules over the timestep being reported. This output is also added to a meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (Ref. Output:Meter objects).

#### 1.41.45.2.3 Cooling Coil Sensible Cooling Rate [W]

Sensible cooling rate output of the DX coil in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.41.45.2.4 Cooling Coil Sensible Cooling Energy [J]

Sensible cooling output of the DX coil in Joules for the timestep being reported. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported.

#### 1.41.45.2.5 Cooling Coil Latent Cooling Rate [W]

Latent cooling rate output of the DX coil in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.41.45.2.6 Cooling Coil Latent Cooling Energy [J]

Latent cooling output of the DX coil in Joules for the timestep being reported. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported.

#### 1.41.45.2.7 Cooling Coil Electricity Rate [W]

Electricity consumption rate of the DX coil compressor and condenser fan(s) in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.41.45.2.8 Cooling Coil Electricity Energy [J]

Electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type = Electric, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

#### 1.41.45.2.9 Cooling Coil <Fuel> Power [W]

Fuel consumption rate of the DX coil compressor and condenser fan(s) in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.10 Cooling Coil <Fuel> Energy [J]**

Fuel consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type associated with the <Fuel> type, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

**1.41.45.2.11 Cooling Coil Runtime Fraction []**

Runtime fraction of the DX coil compressor and condenser fan(s) for the timestep being reported. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.12 Cooling Coil Crankcase Heater Electricity Rate [W]**

Electricity consumption rate of the DX coil compressor crankcase heater in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.13 Cooling Coil Crankcase Heater Electricity Energy [J]**

Electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

**1.41.45.2.14 Cooling Coil Air Mass Flow Rate [kg/s]**

Air mass flow rate through the DX coil in kg/s. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.15 Cooling Coil Air Inlet Temperature [C]**

Inlet air temperature of the DX coil in degrees Celsius. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.16 Cooling Coil Air Inlet Humidity Ratio [kgWater/kgDryAir]**

Inlet air humidity ratio of the DX coil in kgWater/kgDryAir. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.17 Cooling Coil Air Outlet Temperature [C]**

Outlet air temperature of the DX coil in degrees Celsius. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.18 Cooling Coil Air Outlet Humidity Ratio [kgWater/kgDryAir]**

Outlet air humidity ratio of the DX coil in kgWater/kgDryAir. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.19 Cooling Coil Part Load Ratio []**

Ratio of the part-load capacity to steady-state capacity of the DX coil. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.20 Cooling Coil Upper Speed Level []**

The upper speed level of the DX coil. Used for interpolating performance between two neighboring speed levels. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.21 Cooling Coil Neighboring Speed Levels Ratio []**

The average speed ratio of the DX coil. Used for interpolating performances between two neighboring speed levels. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.22 Cooling Coil Condenser Inlet Temperature [C]**

Inlet temperature of the DX coil condenser in degrees Celsius. This value can represent the outdoor air dry-bulb temperature, wet-bulb temperature, or somewhere in between from the weather data being used, depending on the value used in the input field Evaporative Condenser Effectiveness. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.23 Cooling Coil Dehumidification Mode []**

Dehumidification mode of the DX coil. A value of 0 indicates normal mode (extra dehumidification not active). A value of 1 indicates dehumidification mode 1 is active. Note that this is an averaged variable, so fractional values are likely to be reported for reporting frequencies longer than “detailed”.

**1.41.45.2.24 Cooling Coil Waste Heat Power [W]**

The fraction of power input to the DX coil that is available as recoverable waste heat at full load and rated conditions for a specific speed in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.25 Cooling Coil Waste Heat Energy [J]**

The fraction of energy input to the DX coil that is available as recoverable waste heat at full load and rated conditions for a specific speed in Joules. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported.

**1.41.45.2.26 Cooling Coil Basin Heater Electricity Rate [W]**

The electric power input to the DX coil basin electric heater in Watts. Only available for evaporatively cooled condensers. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.27 Cooling Coil Basin Heater Electricity Energy [J]**

The electric energy input to the DX coil basin electric heater in Joules. Only available for evaporatively cooled condensers. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Output: Meter objects).

**1.41.45.2.28 Cooling Coil Condensate Volume Flow Rate [m3/s]**

The flow rate of condensate water collected from the DX coil. Only available if a condensate water collection tank is specified. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.29 Cooling Coil Condensate Volume [m3]**

The volume of condensate water collected from the DX coil. Only available if a condensate water collection tank is specified. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type = OnSiteWater, End Use Key = Condensate, Group Key = System (Ref. Output:Meter objects).

**1.41.45.2.30 Cooling Coil Evaporative Condenser Pump Electricity Rate [W]**

The electricity consumption rate of the evaporative condenser water pump in Watts. Only available if an evaporative condenser supply water tank is provided. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.31 Cooling Coil Evaporative Condenser Pump Electricity Energy [J]**

The electricity consumption rate of the evaporative condenser water pump in Joules. Only available if an evaporative condenser supply water tank is provided. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type = Electric, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

**1.41.45.2.32 Cooling Coil Evaporative Condenser Water Volume Flow Rate [m3/s]**

The flow rate of water used to evaporatively cool the DX coil condenser coil inlet air in cubic meters per second. Only available if an evaporative condenser supply water tank is provided. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.33 Cooling Coil Evaporative Condenser Water Volume [m3]**

The amount of water used to evaporatively cool the DX coil condenser coil inlet air, in cubic meters. Only available if an evaporative condenser supply water tank is provided. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type = Water, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

**1.41.45.2.34 Cooling Coil Evaporative Condenser Mains Supply Water Volume [m3]**

The amount of water used to evaporatively cool the DX coil condenser coil inlet air, in cubic meters. Only available if an evaporative condenser supply water tank is provided. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This output is also added to a meter with Resource Type = MainsWater, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

**1.41.45.2.35 Secondary Coil Heat Rejection Rate [W]**

The sensible heat rejected to a zone by a secondary DX coil (condenser) in Watts. This is sum of the total cooling rate of a DX cooling coil and cooling electric power of the primary DX coil. This heat is applied as an internal gain to the secondary zone where the condenser is installed. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

**1.41.45.2.36 Secondary Coil Heat Rejection Energy [J]**

The sensible heat energy rejected to a zone by a secondary DX coil (condenser) in Joules. This is sum of the total cooling energy of a DX cooling coil and cooling electric energy of the primary DX coil. This heat is applied as an internal gain to the secondary zone where the condenser is installed. This value is

calculated for each HVAC system timestep, and the results are summed for the timestep being reported. This is the runtime fraction of the DX coil compressor and condenser fan(s) for the timestep being reported.

#### 1.41.45.2.37 SubcoolReheat Cooling Coil Operation Mode []

This output variable reports operating mode for a subcool reheat coil. When the value is 1, the coil operates at normal mode. When the value is 2, the coil operation is determined by the mode ratio through linear interpolation between normal mode and subcool mode. For example, when the mode ratio is 0.4, the coil operates at subcool mode for 40% of timestep and at normal mode for 60% of timestep. When the value is 3, the coil operation is determined by the mode ratio through linear interpolation between normal mode and reheat mode.

#### 1.41.45.2.38 SubcoolReheat Cooling Coil Operation Mode Ratio []

This output variable reports the ratio of time in a system timestep between normal mode and subcool mode when the operation mode = 2. The mode ratio represents how long the subcool mode runs as a fraction of the system timestep, and the normal mode runs in the rest of the system timestep. The output variable also reports the ratio of time in a system timestep between normal mode and reheat mode when the operation mode = 3. The value is 0.0 when the operation mode = 1.

#### 1.41.45.2.39 SubcoolReheat Cooling Coil Recovered Heat Energy Rate [W]

This output is the recovered heat energy rate output of the DX coil in Watts. This is determined by energy use difference between normal mode and subcool or reheat mode, multiplied by the mode ratio.

#### 1.41.45.2.40 SubcoolReheat Cooling Coil Recovered Heat Energy [J]

This output is the recovered heat energy rate output of the DX coil in Jouals. This is determined by energy use difference between normal mode and subcool or reheat mode, multiplied by the mode ratio.

## 1.42 Group – Fans

As of version 8.7, a new simple "Fan:SystemModel" input object was added that can be substituted for Fan:ConstantVolume, Fan:OnOff, Fan:VariableVolume, and FanPerformance:NightVentilation. Users are encouraged to migrate their models to use this new Fan in the air loop or zone equipment because the original fan objects may be deprecated and eventually removed in the future.

The following fans may be defined either in the air loop or as a zone equipment component: Fan:ConstantVolume, Fan:OnOff, Fan:VariableVolume, Fan:ZoneExhaust, and FanPerformance:NightVentilation. The data that are common to these fan types include an identifying name, an availability schedule name, a total efficiency rating, a rated pressure rise, and inlet and outlet air node names. In the case of a variable volume fan, additional input includes parameters for modeling fan performance over a range of fan speeds. See the engineering documentation for the variable speed fan for a further description of what these coefficients represent. Commonly-used values for different variable volume systems are shown in the following table.

Table 1.52: Fan Coefficient Values

Type of Fan	Fan Coeff. 1	Fan Coeff. 2	Fan Coeff. 3	Fan Coeff. 4	Fan Coeff. 5
Inlet Vane	0.35071223	0.30850535	-0.54137364	0.87198823	0.000
Dampers					

Table 1.52: Fan Coefficient Values

Type of Fan	Fan Coeff. 1	Fan Coeff. 2	Fan Coeff. 3	Fan Coeff. 4	Fan Coeff. 5
Discharge Dampers	0.37073425	0.97250253	-0.34240761	0.000	0.000
Var. Speed Motor	0.0015302446	0.0052080574	1.1086242	-0.11635563	0.000

### 1.42.1 Fan:SystemModel

This object models fans of various types using a relatively simple engineering model. This fan can be used in variable air volume, constant volume, on-off cycling, two-speed, or multi-speed applications. It was designed as a replacement for **Fan:ConstantVolume**, **Fan:OnOff**, **Fan:VariableVolume**, and **FanPerformance:NightVentilation**. The electric power consumed by the fan can be directly input or autosized using one of three optional methods. For fans that can vary the volume flow rate the performance can be described using a separate performance curve or table object. Or for fans with discrete speed control the power fraction at each speed can be input directly with no need for a performance curve.

#### 1.42.1.1 Inputs

##### 1.42.1.1.1 Field: Name

A unique name for this fan. Any reference to this fan by another object will use this name.

##### 1.42.1.1.2 Field: Availability Schedule Name

The name of an availability schedule for this fan. Schedule values greater than zero means the fan is available. If this field is blank, the fan is always available.

##### 1.42.1.1.3 Field: Air Inlet Node Name

The name of an air system node at the inlet to the fan. This field is required.

##### 1.42.1.1.4 Field: Air Outlet Node Name

The name of an air system node at the outlet of the fan. This field is required.

##### 1.42.1.1.5 Field: Design Maximum Air Flow Rate

This numeric field is the design volume flow rate of fan as installed in the HVAC system, in m<sup>3</sup>/s. This volume flow rate will be converted to a mass flow rate using an altitude-adjusted standard density of dry air at 20 °C drybulb. This the full-speed flow rate and serves as the upper limit for fans that can vary their flow rate. This field can be autosized.

##### 1.42.1.1.6 Field: Speed Control Method

This field is used to select how the fan speed can be varied. There are two choices, Continuous or Discrete. Discrete indicates that the fan can operate only at specific speed settings and cannot be continuously varied. Continuous indicates that the fan speed is variable and can change smoothly up to the Design Maximum Air Flow Rate. This input informs the program how power should be calculated with Discrete control using time-weighted averaging and Variable using flow-weighted averaging. A constant volume or on-off fan should use Discrete with Number of Speeds set to 1. A variable air volume fan should

use Continuous. Continuous requires that a fan performance curve be entered in the input field called Electric Power Function of Flow Fraction Curve Name.

#### **1.42.1.1.7 Field: Electric Power Minimum Flow Rate Fraction**

This numeric field is used to describe how low a variable speed fan can be operated. This value is used to calculate the fan power at low flow rates but does not enforce a lower end of the air flow during simulation. The value is a fraction of Design Maximum Air Flow Rate and should be between 0 and 1. This field is only used when Speed Control Method is set to Continuous.

#### **1.42.1.1.8 Field: Design Pressure Rise**

This numeric field is the total system pressure rise experienced by the fan in Pascals at full flow rate and altitude-adjusted standard density of dry air at 20 degrees Celsius drybulb. This field is required.

#### **1.42.1.1.9 Field: Motor Efficiency**

This numeric field describes the electric motor that drives the fan. Efficiency is the shaft power divided by the electric power consumed by the motor. The value must be between 0 and 1. The default is 0.9.

#### **1.42.1.1.10 Field: Motor In Air Stream Fraction**

This numeric field is the fraction of the motor heat that is added to the air stream. The value must be between 0 and 1. A value of 0 means fan motor is located completely outside of air stream and none of the motor's heat is added to the air stream. A value of 1.0 means the motor is located completely inside of air stream and all of the motor's heat is added to the air stream. Note that regardless of the value here there will be heat added to the air stream as a result of the work done to move the air, this field is only describing what happens to the heat generated as a result of the motor's inefficiency. The heat lost from the motor that is not added to the air stream can be added to the surrounding thermal zone where the motor is located by entering a zone name in the input field called Motor Loss Zone Name below.

#### **1.42.1.1.11 Field: Design Electric Power Consumption**

This numeric field is the electric power consumption at the full Design Maximum Air Flow Rate and Design Pressure Rise, in Watts. The value entered in this field is used to determine the fan efficiency. This field is autosizable and defaults to autosize. When autosized there are three different options available for the method used to size the design power and can be selected in the following field.

#### **1.42.1.1.12 Field: Design Power Sizing Method**

This field is used to select how the fan's Design Electric Power Consumption is sized when the previous field is set to autosize. There are three choices: PowerPerFlow, PowerPerFlowPerPressure, or TotalEfficiencyAndPressure. The default is PowerPerFlowPerPressure. When PowerPerFlow is selected, the value entered in the input field called Electric Power Per Unit Flow Rate is used to size the Design Electric Power Consumption. This method is useful during early-phase design modeling when little information is available for determining the Design Pressure Rise. Although the pressure rise is not used to size the Design Electric Power Consumption it is still used to determine the heat added to the air stream as a result of the work done by the fan.

When PowerPerFlowPerPressure is selected, the value entered in the input field called Electric Power Per Unit Flow Rate Per Unit Pressure is used to size the power. This method takes into account the Design Pressure Rise when sizing the Design Electric Power Consumption. When TotalEfficiencyAndPressure is selected, the values entered in the input fields called Fan Total Efficiency and Design Pressure Rise are used to size the power. This is the legacy method used by the older fan objects prior to version 8.6.

**1.42.1.1.13 Field: Electric Power Per Unit Flow Rate**

This numeric field is used when the Design Power Sizing Method is set to PowerPerFlow and the Design Electric Power Consumption is set to Autosize. This value, in  $W/(m^{<sup>3</sup>/s})$ , is used to scale the Design Electric Power Consumption directly from the Design Maximum Air Flow Rate. This scaling factor is defined such that Design Electric Power Consumption = (Electric Power Per Unit Flow Rate) \* (Design Maximum Air Flow Rate).

**1.42.1.1.14 Field: Electric Power Per Unit Flow Rate Per Unit Pressure**

This numeric field is used when the Design Power Sizing Method is set to PowerPerFlowPerPressure and the Design Electric Power Consumption is set to Autosize. This value, in  $W/((m^{<sup>3</sup>/s)-Pa)$ , is used to scale the Design Electric Power Consumption from the Design Maximum Air Flow Rate and the Design Pressure Rise. This scaling factor is defined such that Design Electric Power Consumption = (Electric Power Per Unit Flow Rate Per Unit Pressure) \* (Design Maximum Air Flow Rate) \* (Design Pressure Rise). The default is 1.66667.

**1.42.1.1.15 Field: Fan Total Efficiency**

This numeric field is used when the Design Power Sizing Method is set to TotalEfficiency and the Design Electric Power Consumption is set to Autosize. This value is used to determine the Design Electric Power Consumption from the Design Maximum Air Flow Rate and the Design Pressure Rise. The total efficiency is defined such that the Design Electric Power Consumption = (Design Maximum Air Flow Rate) \* (Design Pressure Rise) / (Fan Total Efficiency). The default is 0.7.

**1.42.1.1.16 Field: Electric Power Function of Flow Fraction Curve Name**

This field is the name of performance curve or table that describes how electric power consumption varies with air flow rate. The independent "x" variable of the performance curve or look up table is a normalized flow fraction defined as the current flow rate divided by the Design Maximum Air Flow Rate. The model actually uses the ratio of (moist) air mass flow rates with the numerator taking account of humidity and barometric pressure. The dependent variable that is the result of the performance curve or lookup table is a fraction that is multiplied by the Design Electric Power Consumption to determine the electric power use as a function of flow rate. Any of the single-independent-variable curves can be used. This field is required if the Speed Control Method is set to Continuous. This field is used when the Speed Control Method is set to Discrete and the Number of Speeds is greater than 1 and the input fields Speed "n" Electric Power Fraction are left blank. Note that the fourth order polynomial in **Curve:Quartic** can be used with the coefficients listed above to replicate the formulation used in the older **Fan:VariableVolume** input object prior to version 8.6.

**1.42.1.1.17 Field: Night Ventilation Mode Pressure Rise**

This optional numeric field is the total system pressure rise experienced by the fan when operating in night mode using **AvailabilityManager:NightVentilation**, in Pascals. This field allows modeling the fan device with a different system pressure that might occur when implementing a special strategy to precool a building at night using outdoor air with dampers fully open. This field is only used when an **AvailabilityManager:NightVentilation** object is used that specifies the fan's availability schedule. This field and the next one replace the **FanPerformance:NightVentilation** object which is not needed with this fan.

**1.42.1.1.18 Field: Night Ventilation Mode Flow Fraction**

This numeric field is the air flow fraction for the fan speed used when operating in night mode using **AvailabilityManager:NighVentilation**. This field corresponds to the input field called Maximum Flow Rate in the **FanPerformance:NightVentilation** object and, as is the case there, this field is not currently used by

the night ventilation manager (which has its own flow fraction field at present). This is a fraction between 0 and 1 and describes the speed level for the fan relative to the Design Maximum Air Flow Rate. This field and the previous one replace the **FanPerformance:NightVentilation** object which is not needed with this fan.

#### 1.42.1.1.19 Field: Motor Loss Zone Name

This optional field can be used to input the name of the Zone in which the fan motor is located. If the fan is outdoors, or the motor's thermal losses are not to be modeled then leave this field blank. If a valid Zone name is entered then the portion of the motor's thermal losses that are not added to the air stream are added to the surrounding thermal zone as internal heat gains.

#### 1.42.1.1.20 Field: Motor Loss Radiative Fraction

This optional numeric field is used when a Zone name is entered in the previous field to determine the split between thermal radiation and thermal convection for the heat losses from the fan motor. If this field is left blank then all the losses will be convective. Values should be between 0 and 1.

#### 1.42.1.1.21 Field: End-Use Subcategory

This optional field allows entering a user-defined name for the end use subcategory that will be used to meter this fan's electric energy consumption. If this field is omitted or left blank the fan will be assigned to the "General" end use subcategory. End use subcategories are helpful to organize reports in the tabular summary table and appear on special meter outputs. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table.

#### 1.42.1.1.22 Field: Number of Speeds

This numeric field is used to specify the number of different speed levels available when Speed Control Method is set to Discrete. This field and the remaining field sets are not used when the Speed Control Method is set to Continuous. For a constant volume fan enter a value of 1.0. A value of 1.0 will use the fan's maximum design and no additional field sets are needed. When set to a value greater than 1 then a pair of flow and power fraction inputs are provided for each speed in the remaining input fields.

#### 1.42.1.1.23 Field Set: (Speed Flow Fraction, Speed Electric Power Fraction)

This input object is extensible with a set of two fields for each speed that the fan can take. A field set is pair of values for the flow fraction and electric power fraction at each speed. The sets should be arranged in increasing order so that the flow fractions become larger in subsequent field sets. Typically the highest speed level will match the design maximum and have fractions of 1.0.

**1.42.1.1.24 Field: Speed <#> Flow Fraction** This is the flow fraction for the fan speed. This value is multiplied by the Design Maximum Air Flow Rate to obtain the flow rate when operating at this speed.

#### 1.42.1.1.25 Field: Speed <#> Electric Power Fraction

This field is the electric power fraction for the fan speed. This value is multiplied by the Design Electric Power Consumption to obtain the power consumption when operating at this speed. This field is optional if a performance curve is used in the input field Electric Power Function of Flow Fraction Curve Name. If omitted and the performance curve is entered, the power at this speed will be determined using the curve or table. If the power fraction is entered in this field it will be used instead of the curve or table. This

allows either overriding the curve for particular speeds or removes the necessity of creating a curve for discrete speed control.

Some examples of IDF input objects follow.

### 1.42.1.2 Outputs

- HVAC,Average,Fan Electricity Rate [W]
- HVAC,Sum,Fan Electricity Energy [J]
- HVAC,Average,Fan Rise in Air Temperature[deltaC]
- HVAC,Average,Fan Air Mass Flow Rate[kg/s]

#### 1.42.1.2.1 Fan Electricity Rate [W]

This output field contains the average electricity consumption rate for the fan in Watts for the time interval being reported.

#### 1.42.1.2.2 Fan Electricity Energy [J]

This output contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Fans, Group Key = System (ref. Output:Meter objects).

#### 1.42.1.2.3 Fan Rise in Air Temperature [deltaC]

This output contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the time interval being reported.

#### 1.42.1.2.4 Fan Air Mass Flow Rate[kg/s]

This output contains the average air mass flow rate in kg/s for the time interval being reported.

## 1.42.2 Fan:ConstantVolume

This object models a constant air volume fan that is intended to operate continuously based on a time schedule. This fan will not cycle on and off based on cooling/heating load or other control signals (Ref: [Fan:OnOff](#)).

### 1.42.2.1 Inputs

#### 1.42.2.1.1 Field: Name

A unique user-assigned name for an instance of a Fan:ConstantVolume. Any reference to this fan by another object will use this name.

#### 1.42.2.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan can run during a given time period. A schedule value of 0 indicates that the fan is off for that time period. A schedule value greater than 0 indicates that the fan can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this schedule by forcing the fan to be on or off.

#### 1.42.2.1.3 Field: Fan Total Efficiency

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

#### 1.42.2.1.4 Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20 °C and 101325 Pa).

#### 1.42.2.1.5 Field: Maximum Flow Rate

The full load air volumetric flow rate (m<sup>3</sup>/sec) at standard temperature and pressure (dry air at 20 °C drybulb). The program does use local barometric pressure to account for altitude using equation for “standard atmospheric” pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z)^{5.2559}$$

where p = pressure in Pa and Z = altitude in m

#### 1.42.2.1.6 Field: Motor Efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1. The default is 0.9.

#### 1.42.2.1.7 Field: Motor In Airstream Fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

#### 1.42.2.1.8 Field: Air Inlet Node Name

The name of the HVAC system node which supplies the inlet air conditions to the fan.

#### 1.42.2.1.9 Field: Air Outlet Node Name

The name of the HVAC system node to which the fan sends its outlet air.

### 1.42.2.1.10 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Central System”, etc. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the fan will be assigned to the “General” end-use subcategory.

## 1.42.2.2 Outputs

- HVAC,Average,Fan Electricity Rate [W]
- HVAC,Average,Fan Rise in Air Temperature [deltaC]
- HVAC,Sum,Fan Electricity Energy [J]

### 1.42.2.2.1 Fan Electricity Rate [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

### 1.42.2.2.2 Fan Rise in Air Temperature [deltaC]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the timestep being reported.

### 1.42.2.2.3 Fan Electricity Energy [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Fans, Group Key = System (ref. Output:Meter objects).

## 1.42.3 Fan:OnOff

This object models a constant air volume fan that is intended to cycle on and off in tandem with a cooling or heating system (i.e., AUTO fan control mode). The fan can also operate continuously like **Fan:ConstantVolume**. If modeling continuous operation and this object is used as part of a system that utilizes **Coil:Heating:Fuel**, **Coil:Cooling:DX:SingleSpeed** or **Coil:Heating:DX:SingleSpeed**, the user should confirm proper air flow rates (coil and fan max flows are equal) and that the coil part-load fraction correlation(s) are appropriate (e.g., part-load fraction is less than or equal to 1 for all values of coil part-load ratio). If modeling multi-speed fan operation, this object must be used as part of a compound object that allows multiple fan speeds (e.g., **AirLoopHVAC:Unitary:Furnace:HeatCool**, **Zone-HVAC:PackagedTerminalAirConditioner**, etc.). In this case, the ratio of the compound object air flow rate to the fan’s maximum air flow rate is used to determine the power at alternate fan speeds. The optional input for Fan Power Ratio Function of Speed Ratio Curve Name must be entered to model multi-speed fan operation. An optional fan total efficiency ratio curve is also available to model efficiency differences at alternate fan speeds.

### 1.42.3.1 Inputs

#### 1.42.3.1.1 Field: Name

A unique user-assigned name for an instance of a Fan:OnOff. Any reference to this fan by another object will use this name.

**1.42.3.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the fan can run during a given time period. A schedule value of 0 indicates that the fan is off for that time period. A schedule value greater than 0 indicates that the fan can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this schedule by forcing the fan to be on or off.

**1.42.3.1.3 Field: Fan Total Efficiency**

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.6.

**1.42.3.1.4 Field: Pressure Rise**

The pressure rise in Pascals at full flow and standard (sea level) conditions (20 °C and 101325 Pa).

**1.42.3.1.5 Field: Maximum Flow Rate**

The full load air volumetric flow rate (m<sup>3</sup>/sec) at standard temperature and pressure (dry air at 20 °C drybulb). The program does use local barometric pressure to account for altitude using equation for “standard atmospheric” pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z) ** 5.2559$$

where p = pressure in Pa and Z = altitude in m

**1.42.3.1.6 Field: Motor Efficiency**

The shaft power divided by the electrical power consumed. Must be between 0 and 1. The default is 0.8.

**1.42.3.1.7 Field: Motor In Airstream Fraction**

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

**1.42.3.1.8 Field: Air Inlet Node Name**

The name of the HVAC system node which supplies the inlet air conditions to the fan.

**1.42.3.1.9 Field: Air Outlet Node Name**

The name of the HVAC system node to which the fan sends its outlet air.

**1.42.3.1.10 Field: Fan Power Ratio Function of Speed Ratio Curve Name**

Enter the name of an exponent performance curve. This optional alpha field must be used to simulate multi-speed fan motors. This curve represents the ratio of actual fan power to rated fan power when a change in fan speed occurs. Leave this field blank when simulating constant-speed fan motors.

### 1.42.3.1.11 Field: Fan Efficiency Ratio Function of Speed Ratio Curve Name

Enter the name of a quadratic or cubic performance curve. This optional alpha field is used to simulate multi-speed fan motors. This curve represents the ratio of actual fan total efficiency to rated fan total efficiency when a change in fan speed occurs. Leave this field blank when simulating constant-speed fan motors.

### 1.42.3.1.12 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Main Fans”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the “General” end-use subcategory.

Following is an example input for an OnOff Fan.

```
Fan:OnOff,
  Supply Fan 1,                ! Fan Name
  FanAndCoilAvailSched,       ! Fan Schedule
  0.7,                         ! Fan Total Efficiency
  600.0,                       ! Delta Pressure [N/M^2]
  1.3,                         ! Max Flow Rate [m^3/Sec]
  0.9,                         ! Motor Efficiency
  1.0,                         ! Motor in Airstream Fraction (1.0 means motor in air stream)
  Air Loop Inlet Node, Cooling Coil Air Inlet Node; !Inlet Node, Outlet Node
```

## 1.42.3.2 Outputs

HVAC,Average,Fan Electricity Rate [W]

HVAC,Average,Fan Rise in Air Temperature [deltaC]

HVAC,Sum,Fan Electricity Energy [J]

HVAC,Average,Fan Runtime Fraction []

### 1.42.3.2.1 Fan Electricity Rate [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

### 1.42.3.2.2 Fan Rise in Air Temperature [deltaC]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the timestep being reported.

### 1.42.3.2.3 Fan Electricity Energy [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Fans, Group Key = System (ref. [Output:Meter](#) objects).

### 1.42.3.2.4 Fan Runtime Fraction []

This output field contains the fraction of time that this fan operated for the timestep being reported.

## 1.42.4 Fan:VariableVolume

### 1.42.4.1 Inputs

#### 1.42.4.1.1 Field: Name

A unique user-assigned name for an instance of a Fan:VariableVolume. Any reference to this fan by another object will use this name.

#### 1.42.4.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan can run during a given time period. A schedule value of 0 indicates that the fan is off for that time period. A schedule value greater than 0 indicates that the fan can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this schedule by forcing the fan to be on or off.

#### 1.42.4.1.3 Field: Fan Total Efficiency

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.7.

#### 1.42.4.1.4 Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20 °C and 101325 Pa).

#### 1.42.4.1.5 Field: Maximum Flow Rate

The full load air volumetric flow rate (m<sup>3</sup>/sec) at standard temperature and pressure (dry air at 20 °C drybulb). The program does use local barometric pressure to account for altitude using equation for “standard atmospheric” pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z)^{5.2559}$$

where p = pressure in Pa and Z = altitude in m

#### 1.42.4.1.6 Field: Fan Power Minimum Flow Rate Input Method

This field is a key/choice field that tells which of the next two fields is filled and is descriptive of how the minimum flow rate is specified for calculating the fan power. The key/choices are:

- Fraction

With this choice, the fan power will be calculated using the value specified in the Fan Power Minimum Flow Fraction field. (The Fan Power Minimum Flow Fraction field should be filled.)

- FixedFlowRate

With this choice, the fan power will be calculated using the value specified in the Fan Power Minimum Air Flow Rate field. (The Fan Power Minimum Air Flow Rate field should be filled.)

The default is Fraction.

#### 1.42.4.1.7 Field: Fan Power Minimum Flow Fraction

The minimum air volumetric flow rate for fan power, specified as a fraction of maximum system air flow rate. Must be between 0 and 1. Note that this field is only used to calculate the fan power. This field does not enforce the system air flow rate during simulation. The default is 0.25.

**1.42.4.1.8 Field: Fan Power Minimum Air Flow Rate**

The minimum air volumetric flow rate for fan power, specified as a constant minimum air flow rate (m3/sec). Note that this field is only used to calculate the fan power. This field does not enforce the system air flow rate during simulation.

**1.42.4.1.9 Field: Motor Efficiency**

The shaft power divided by the electrical power consumed. Must be between 0 and 1. The default is 0.9.

**1.42.4.1.10 Field: Motor In Airstream Fraction**

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

**1.42.4.1.11 Field: Fan Power Coefficient 1**

The constant coefficient ( $C_1$ ) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

**1.42.4.1.12 Field: Fan Power Coefficient 2**

The linear coefficient ( $C_2$ ) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

**1.42.4.1.13 Field: Fan Power Coefficient 3**

The quadratic coefficient ( $C_3$ ) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

**1.42.4.1.14 Field: Fan Power Coefficient 4**

The cubic coefficient ( $C_4$ ) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_{\{1\}} + C_{\{2\}} \cdot FF + C_{\{3\}} \cdot FF^2 + C_{\{4\}} \cdot FF^3 + C_{\{5\}} \cdot FF^4$$

---

**1.42.4.1.15 Field: Fan Power Coefficient 5**

The coefficient  $C_5$  in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_{\{1\}} + C_{\{2\}} \cdot FF + C_{\{3\}} \cdot FF^2 + C_{\{4\}} \cdot FF^3 + C_{\{5\}} \cdot FF^4$$

---

**1.42.4.1.16 Field: Air Inlet Node Name**

The name of the HVAC system node which supplies the inlet air conditions to the fan.

**1.42.4.1.17 Field: Air Outlet Node Name**

The name of the HVAC system node to which the fan sends its outlet air.

**1.42.4.1.18 Field: End-Use Subcategory**

Allows you to specify a user-defined end-use subcategory, e.g., “Central System”, etc. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the fan will be assigned to the “General” end-use subcategory.

**1.42.4.2 Outputs**

- HVAC,Average,Fan Electricity Rate [W]
- HVAC,Average,Fan Rise in Air Temperature [deltaC]
- HVAC,Sum,Fan Electricity Energy [J]

**1.42.4.2.1 Fan Electricity Rate [W]**

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

**1.42.4.2.2 Fan Rise in Air Temperature [deltaC]**

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the timestep being reported.

**1.42.4.2.3 Fan Electricity Energy [J]**

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Fans, Group Key = System (ref. **Output:Meter** objects).

**1.42.5 Fan:ZoneExhaust**

This fan object differs from the other fans in that it stands on its own in a zone rather than serving as one part of an HVAC air system. This object appears directly in a **ZoneHVAC:EquipmentList** object and all the controls are contained within the fan object. The zone exhaust fan model provides a way to include the electrical power used by the fan. It can also impact air flows in central air handlers by decreasing the flow of return air and sometimes increasing the outdoor air flow rate.

There are several control options available for the exhaust fan including: an on/off availability schedule, interaction with system availability managers, minimum zone air temperature control limits and a variable flow fraction schedule.

The way in which the exhaust fan impacts central air system can be controlled by declaring what portion of the flow has been balanced by simple airflow from infiltration, ventilation, or mixing. However, it is important to note that presence of an exhaust fan does not by itself drive any simple airflow such as infiltration, ventilation, or zone mixing. For balancing, the simple airflows need to have their own input objects that need to be coordinated with the exhaust fan. The **ZoneAirMassFlowConservation** object could

be a possible solution that can help with balancing unbalanced airflows by triggering the zone air mass flow conservation when desired.

### 1.42.5.1 Inputs

#### 1.42.5.1.1 Field: Name

A unique user-assigned name for an instance of a Fan:ZoneExhaust. Any reference to this fan by another object will use this name.

#### 1.42.5.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan can run during a given time period. A schedule value of 0 indicates that the fan is off for that time period. A schedule value greater than 0 indicates that the fan can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this schedule by forcing the fan to be on or off.

#### 1.42.5.1.3 Field: Fan Total Efficiency

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. The default is 0.6.

#### 1.42.5.1.4 Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20 °C and 101325 Pa).

#### 1.42.5.1.5 Field: Maximum Flow Rate

The full load air volumetric flow rate (m<sup>3</sup>/sec) at standard temperature and pressure (dry air at 20 °C drybulb). The program does use local barometric pressure to account for altitude using equation for “standard atmospheric” pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z)^{5.2559}$$

where p = pressure in Pa and Z = altitude in m

#### 1.42.5.1.6 Field: Air Inlet Node Name

The name of the HVAC system node which supplies the inlet air conditions to the fan. This node should be listed as a zone exhaust node in an associated [ZoneHVAC:EquipmentConnections](#) object.

#### 1.42.5.1.7 Field: Air Outlet Node Name

The name of the HVAC system node to which the fan sends its outlet air.

#### 1.42.5.1.8 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Kitchen Exhaust”, “Fume Hoods”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the fan will be assigned to the “General” end-use subcategory.

**1.42.5.1.9 Field: Flow Fraction Schedule Name**

This field is optional. If it is not used then the fan operates at the maximum flow rate. If a schedule is input here, then it should contain fractional values between 0.0 and 1.0, inclusive. The flow rate that the fan operates will be this fraction times the maximum flow rate. This allows a variable speed exhaust fan to be modeled according to a schedule.

**1.42.5.1.10 Field: System Availability Manager Coupling Mode**

This field is optional. If it is not used then the exhaust fan is assumed to be integrated with the central air handler's system availability manager. This field can be used to control if the exhaust fan should operate independently or not. For example, when a night cycle availability manager turns on the central air system for freeze protection, this field can be used to control if the zone exhaust fans should also run at the same time or not. The key choice Coupled indicates that the exhaust fan should be integrated with the system availability manager so that the fan runs when the air system is forced to run. The key choice Decoupled indicates that the exhaust fan should operate on its own and ignore the system availability manager's requests so that the exhaust fan can remain off when the air system runs. The default is Coupled.

**1.42.5.1.11 Field: Minimum Zone Temperature Limit Schedule Name**

This field is optional. If it is not used then there will be no temperature-related control over the operation of the exhaust fan. If the field is used, then enter the name of a schedule with values for zone temperature values (°C). The fan's control will be based on a comparison between the current zone air temperature and the schedule values. If the zone is warmer than the scheduled limit, then the fan will operate. When balancing with simple ventilation, this feature can be used to coordinate exhaust fan operation with ZoneVentilation:\* controls for minimum indoor temperature.

**1.42.5.1.12 Field: Balanced Exhaust Fraction Schedule Name**

This field is optional. If it is not used, then all the exhaust air flow is assumed to be unbalanced by any simple airflows, such as infiltration, ventilation, or zone mixing. Unbalanced exhaust is then modeled as being provided by the outdoor air system in the central air system. The modeling of unbalanced will reduce the flow rates at the zone's return air node by the flow rate that is being exhausted and will ensure that the outdoor air flow rate is sufficient to serve the exhaust. If this field is used, then enter the name of a schedule with fractional values between 0.0 and 1.0, inclusive. This fraction is applied to the exhaust fan flow rate and the model tracks the portion of the exhaust that is balanced. Balanced exhaust is then modeled as being provided by simple airflows and does not impact the central air system return air or outdoor air flow rates. For example, if a kitchen zone with an exhaust fan is designed to draw half of its make up air from a neighboring dining room and the other half from the outdoor air system, then a schedule value of 0.5 could be used here. This input field must be blank when the zone air flow balance is enforced. If user specifies a schedule and zone air flow balance is enforced, then EnergyPlus throws a warning error message, ignores the schedule and simulation continues.

**1.42.5.2 Outputs**

- HVAC,Average,Fan Electricity Rate [W]
- HVAC,Average,Fan Rise in Air Temperature[deltaC]
- HVAC,Sum,Fan Electricity Energy [J]
- HVAC,Average,Fan Unbalanced Air Mass Flow Rate [kg/s]
- HVAC,Average,Fan Balanced Air Mass Flow Rate [kg/s]

**1.42.5.2.1 Fan Electricity Rate [W]**

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

**1.42.5.2.2 Fan Rise in Air Temperature [deltaC]**

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the timestep being reported.

**1.42.5.2.3 Fan Electricity Energy [J]**

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to an output meter with Resource Type = Electricity, End Use Key = Fans, Group Key = System (ref. Output:Meter objects).

**1.42.5.2.4 Fan Unbalanced Air Mass Flow Rate [kg/s]****1.42.5.2.5 Fan Balanced Air Mass Flow Rate [kg/s]**

These two output variables are available when the exhaust fan uses the input field called Balanced Exhaust Fraction Schedule Name. The balanced air flow is the result of the current flow rate times the balance fraction. The unbalanced air flow is the difference between the current flow rate and the balanced flow rate. These outputs are the resulting flow rates in kg/s.

## 1.42.6 FanPerformance:NightVentilation

This object is used for specifying an alternate set of performance parameters for a fan. These alternate parameters are used when a system manager (such as *AvailabilityManager:NightVentilation*) sets a specified flow rate for a central forced air system. At this time, it can be used with *Fan:ConstantVolume*, *Fan:VariableVolume*, *Fan:ZoneExhaust*, *Fan:OnOff* and *Fan:SystemModel* fans, but not with *Fan:ComponentModel* fans. The fan model checks whether a fixed flow rate has been set; if it has the fan model will use these alternate performance parameters. Note that it is assumed that the fan will run at a fixed speed in the alternate mode. The inputs needed by this object are the fan name, fan total efficiency, pressure rise, flow rate, motor efficiency, and motor in airstream fraction.

### 1.42.6.1 Inputs

#### 1.42.6.1.1 Field: Fan Name

This is the name of a fan defined elsewhere in the input file. The night vent performance parameters will be applied to the named fan when a system manager has set the air system flow rate.

#### 1.42.6.1.2 Field: Fan Total Efficiency

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1. This is a required field with no default.

#### 1.42.6.1.3 Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20 °C and 101325 Pa).

#### 1.42.6.1.4 Field: Maximum Flow Rate

The design volumetric flow rate of the fan (m<sup>3</sup>/sec) at standard conditions. This input is not currently used by the night ventilation manager. The flow rate during night ventilation is specified using the *SystemAvailabilityManager:NightVentilation* “Night Venting Flow Fraction” field. This fraction is multiplied times the fan object’s design flow rate.

#### 1.42.6.1.5 Field: Motor Efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1. This is a required field with no default.

### 1.42.6.1.6 Field: Motor in Airstream Fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

An example of use in an IDF:

```
Fan:VariableVolume,
  Supply Fan 1,          !- Name
  FanAvailSched,         !- Availability Schedule Name

```

## 1.42.7 Fan:ComponentModel

The Fan:ComponentModel fan is a more detailed fan type that can be defined in the air loop for central constant-air-volume (CAV) and variable-air-volume (VAV) systems. It includes inputs that describe the air-distribution system as well as the fan, its drive belt (if used), its motor, and its variable-frequency-drive (if used). See the engineering documentation for further descriptions about the inputs for this fan type.

### 1.42.7.1 Inputs

#### 1.42.7.1.1 Field: Name

The required unique user-assigned alpha name for an instance of a Fan:ComponentModel. Any reference to this fan by another object will use this name.

#### 1.42.7.1.2 Field: Air Inlet Node Name

The required alpha name of the HVAC system node which supplies the inlet air conditions to the fan.

#### 1.42.7.1.3 Field: Air Outlet Node Name

The required alpha name of the HVAC system node to which the fan sends its outlet air.

#### 1.42.7.1.4 Field: Availability Schedule Name

The required alpha name of the schedule (ref: Schedule) that denotes whether the fan can run during a given time period. A schedule value of 0 indicates that the fan is off for that time period. A schedule value greater than 0 indicates that the fan can operate during the time period. If this field is blank, the

schedule has values of 1 for all time periods. Applicable availability managers (ref. [AvailabilityManagerAssignmentList](#)) may override this schedule by forcing the fan to be on or off.

#### 1.42.7.1.5 Field: Maximum Flow Rate

The full-load volumetric airflow ( $\text{m}^3/\text{sec}$ ) through the fan at standard temperature and pressure (dry air at 20 °C dry-bulb). To initialize the air systems being simulated, the program uses local barometric pressure adjusted for altitude, based on the equation for “standard atmospheric” pressure on p.6.1 of the 1997 ASHRAE Handbook of Fundamentals (SI edition):

$$p = 101325 * (1 - 2.25577\text{E-}05 * Z)^{5.2559}$$

where  $p$  = pressure in Pa and  $Z$  = altitude in m. Can be autosized.

Specified or autosized maximum airflow rate (including effects of scaling by Field: Fan Sizing Factor) along with corresponding fan static pressure rise and fan shaft power are reported in the .eio file as, respectively, Design Fan Airflow [ $\text{m}^3/\text{s}$ ], Design Fan Static Pressure Rise [Pa], and Design Fan Shaft Power [W].

#### 1.42.7.1.6 Field: Minimum Flow Rate

The minimum volumetric airflow ( $\text{m}^3/\text{sec}$ ) through the fan at standard temperature and pressure (see Maximum Flow Rate field above for condition details). Can be autosized.

#### 1.42.7.1.7 Field: Fan Sizing Factor

The numeric dimensionless factor ( $F_{fan}$ ) used to multiply the specified or autosized full-load volumetric airflow (see Maximum Flow Rate field above for details) for fan sizing. If specified, minimum value is 1.0. Default is 1.0 if field is blank.

#### 1.42.7.1.8 Field: Fan Wheel Diameter

The required numeric outer diameter of the fan wheel ( $D_{fan}$ , m). This value is determined from manufacturer’s data. In general, larger diameter fans have higher maximum efficiency than smaller diameter fans of the same type (Ref: AMCA Standard 205-10: Energy Efficiency Classification for Fans). Must be greater than zero.

#### 1.42.7.1.9 Field: Fan Outlet Area

The required numeric outlet area of the fan ( $A_{fan,out}$ ,  $\text{m}^2$ ). This value is determined from manufacturer’s data. It is used to convert fan total pressure rise to fan static pressure rise. Fan static pressure rise is the fan total pressure rise minus the fan outlet velocity pressure; it is not the difference between fan outlet and inlet static pressures (Ref: ANSI/AMCA Standard 210-07, ANSI/ASHRAE Standard 51-07: Laboratory Methods of Testing Fans for Certified Aerodynamic Performance Rating). Must be greater than zero.

#### 1.42.7.1.10 Field: Maximum Fan Static Efficiency

The required numeric maximum ratio ( $\eta_{fan,max}$ ) between the power delivered to the air ( $H_{air}$ , W) and the fan shaft input power ( $H_{fan}$ , W). For this parameter,  $H_{air}$  is the volumetric airflow through the fan multiplied by the fan static pressure rise. Maximum fan static efficiency is determined from analyses of manufacturers data using:

$$\eta_{fan,max} = \max \left[ \frac{(\Delta P_{fan} * Q_{fan})}{H_{fan}} \right] \quad (1.195)$$

where  $P_{fan}$  is fan static pressure rise (Pa) and  $Q_{fan}$  is airflow through the fan ( $\text{m}^3/\text{sec}$ ). Typically, do not select curves on fan performance maps of pressure rise versus flow correspond to or are near maximum efficiency. Must be greater than zero and less than or equal to 1.0.

Calculated fan static efficiency at design flow condition (including part-load effects of oversized fan) is reported in the .eio file as Design Fan Efficiency [-].

#### 1.42.7.1.11 Field: Euler Number at Maximum Fan Static Efficiency

The required numeric Euler number ( $Eu_{max}$ ), which is also called the throttling or pressure coefficient, and is the ratio of pressure forces to inertial forces. The Euler number is determined from analyses of manufacturer's data using:

$$Eu = \frac{(\Delta P_{fan} * D_{fan}^4)}{(\rho * Q_{fan}^2)} \quad (1.196)$$

where  $P_{fan}$  is fan static pressure rise (Pa; see *Fan Pressure Rise Curve Name* field),  $D_{fan}$  is wheel diameter (m),  $\rho$  is the manufacturer's reference air density ( $\text{kg}/\text{m}^3$ ), and  $Q_{fan}$  is airflow through the fan ( $\text{m}^3/\text{sec}$ ).  $Eu_{max}$  is calculated using any pair of pressure rise and airflow values that correspond with maximum fan static efficiency for the specified fan. Must be greater than zero.

#### 1.42.7.1.12 Field: Maximum Dimensionless Fan Airflow

The required numeric maximum dimensionless airflow ( $\psi_{max}$ ) through the fan, which corresponds to the maximum ratio between the airflow through the fan ( $Q_{fan}$ ,  $\text{m}^3/\text{sec}$ ) and the fan shaft rotational speed ( $\omega_{fan}$ , *rpm*) for the specified fan wheel diameter ( $D_{fan}$ , *m*).  $\psi_{max}$  is determined from manufacturers data using:

$$\psi_{max} = \frac{30}{\pi D_{fan}^3} \cdot \max \left( \frac{Q_{fan}}{\omega_{fan}} \right) \quad (1.197)$$

$\psi_{max}$  occurs at minimum  $Eu$ , which corresponds to maximum speed (high flow) with zero pressure rise. The factor  $(30/\pi)$  converts revolutions per minute (rpm) to rad/s. Must be greater than zero.

#### 1.42.7.1.13 Field: Motor Fan Pulley Ratio

The numeric dimensionless ratio of the motor pulley diameter to the fan pulley diameter ( $D_{motor,pulley} / D_{fan,pulley}$ ). If specified, must be greater than zero. This ratio can be adjusted to account for belt slip if the fractional slip is known (multiply the drive ratio with no slip by  $1+s$ , where  $s$  is the belt fractional slip). Default is 1.0 if field is blank (leave blank if no belt; i.e., direct drive). Can be autosized (assumes no slip).

Specified or autosized motor/fan pulley diameter ratio is reported in the .eio file as Drive Ratio [-]. Autosized ratio is based on fan speed in revolutions per minute (rpm), calculated at design flow condition, divided by Field: Motor Maximum Speed.

#### 1.42.7.1.14 Field: Belt Maximum Torque

The required numeric maximum output torque capacity of the fan drive belt ( $\tau_{belt,max}$  [N-m]). If specified, must be greater than zero. Can be autosized. Use autosize if no belt (i.e., direct drive).

Specified or autosized belt maximum output torque (including effects of scaling by Field: Belt Sizing Factor) is reported in the .eio file as Design Belt Output Torque [N -m]. Also, calculated maximum belt efficiency corresponding to Design Fan Shaft Power, along with belt efficiency at design flow condition (including part-load effects of oversized belt), are reported in the .eio file as, respectively, Maximum Belt Efficiency [-] and Design Belt Efficiency [-].

**1.42.7.1.15 Field: Belt Sizing Factor**

The numeric dimensionless factor ( $F_{belt}$ ) used to multiply the specified or autosized fan shaft maximum output torque ( $H_{belt,max}$ ). If specified, minimum value is 1.0. Default is 1.0 if field is blank.

**1.42.7.1.16 Field: Belt Fractional Torque Transition**

The numeric transition point ( $x_{belt,trans}$ ) between performance curves for Regions 1 and 2 for the drive belt normalized part-load efficiency. Must be between 0.0 and 1.0. Default is 0.167 (corresponds to generic V-belt) if field is blank.

**1.42.7.1.17 Field: Motor Maximum Speed**

The required numeric maximum rotational speed of the fan motor shaft ( $\omega_{motor,max}$ ) in revolutions per minute (rpm). Typical values for motors supplied by 60 Hz power are near 900, 1200, 1800, and 3600 rpm. Must be greater than zero.

**1.42.7.1.18 Field: Maximum Motor Output Power**

The required numeric maximum output power (input power to the fan drive belt) by the motor ( $H_{belt,max}$ , W). If specified, must be greater than zero. Can be autosized. In the case of direct drive,  $H_{belt,max}$  corresponds to the maximum fan shaft power ( $H_{fan,max}$ ).

Specified or autosized maximum motor output power (including effects of scaling by Field: Motor Sizing Factor) is reported in the .eio file as Design Motor Output Power [W]. Also, calculated maximum motor efficiency corresponding to Design Motor Output Power, along with motor efficiency at design flow condition (including part-load effects of oversized motor), are reported in the .eio file as, respectively, Maximum Motor Efficiency [-] and Design Motor Efficiency [-]. Note that maximum motor efficiency often occurs at less than full load.

**1.42.7.1.19 Field: Motor Sizing Factor**

The numeric dimensionless sizing factor ( $F_{motor}$ ) used to multiply the specified or autosized fan motor output power ( $H_{belt,max}$ ). If specified, minimum value is 1.0. Default is 1.0.

**1.42.7.1.20 Field: Motor In Airstream Fraction**

The numeric fraction of the combined motor and belt heat that is added to the air stream. A value of 0.0 means that the motor and belt are completely outside the air stream. A value of 1.0 means that all of the motor and belt heat loss will go into the air stream and act to cause an air enthalpy rise. Must be between 0.0 and 1.0. Default is 1.0.

**1.42.7.1.21 Field: VFD Efficiency Type**

The alpha basis for calculating fan variable-frequency-drive (VFD) efficiency: Power, which corresponds to a function of the fraction of full-load motor input power ( $H_{motor} / H_{motor,max}$ ), or Speed, which corresponds to a function of the fraction of full-load speed ( $\omega_{motor} / \omega_{max}$ ). If this field is blank, then it is assumed that the VFD efficiency is 0.97. If no VFD is used, then specify Power and also specify a VFD efficiency curve with a constant value of 1.0 (see VFD Efficiency Curve Name field for details).

**1.42.7.1.22 Field: Maximum VFD Output Power**

The required numeric maximum output power (input power to the fan motor) by the variable frequency drive ( $H_{motor,max}$ , W). If specified, must be greater than zero. Can be autosized.

Specified or autosized maximum VFD output power (including effects of scaling by Field: VFD Sizing Factor) and corresponding VFD input power are reported in the .eio file as, respectively, Design VFD Output Power [W] and Rated Power [W]. Also, calculated VFD efficiency corresponding to Design VFD

Output Power (including part-load effects of oversized VFD) along with corresponding combined system efficiency (fan, belt, motor, and VFD efficiencies multiplied together) at design flow condition are reported in the .eio file as, respectively, Design VFD Efficiency [-] and Design Combined Efficiency [-].

#### 1.42.7.1.23 Field: VFD Sizing Factor

The numeric dimensionless factor ( $F_{VFD}$ ) used to multiply the specified or autosized motor maximum input power ( $H_{motor,max}$ ). If specified, minimum value is 1.0. Default is 1.0 if field is blank.

#### 1.42.7.1.24 Field: Fan Pressure Rise Curve Name

The required alpha name of the fan total pressure rise performance curve (ref: **Curve:FanPressureRise** in Performance Curves) that parameterizes the variation of fan total pressure rise ( $P_{fan,tot}$ , Pa) as a function of volumetric flow through the fan ( $Q_{fan}$ , m<sup>3</sup>/s) and duct static pressure set point ( $P_{sm}$ , Pa). The fan outlet velocity pressure is subtracted from the output of this curve to determine fan static pressure rise, which is then used to calculate a dimensionless Euler number at each time step. The Euler number is in turn used to determine fan efficiency, speed, and torque (the Euler number is defined in the *Euler Number at Maximum Fan Static Efficiency* field). This curve should be valid for the range of volumetric flows, distribution system leakage, duct static pressures, and static pressures surrounding the ducts anticipated for the simulation period.

#### 1.42.7.1.25 Field: Duct Static Pressure Reset Curve Name

The required alpha name of the performance curve that parameterizes the variation of the duct static pressure set point ( $P_{sm}$ , Pa) as a function of volumetric flow through the fan ( $Q_{fan}$ , m<sup>3</sup>/s), which is used so that the resistance associated with VAV box damper operation is reduced.

The output of this curve is used to calculate the duct static pressure set point at each time step. This curve should be valid for the range of duct static pressure set points and volumetric flows, anticipated for the simulation period.

For an ad hoc linear duct static pressure reset scheme, the relation (ref: **Curve:Linear** in Performance Curves) between duct static pressure ( $P_{sm}$ , Pa) and flow through the fan ( $Q_{fan}$ , m<sup>3</sup>/s) for  $Q_{fan,min} \leq Q_{fan} \leq Q_{fan,max}$  is:

$$P_{sm} = P_{sm,min} + (P_{sm,max} - P_{sm,min}) * \frac{(Q_{fan} - Q_{fan,min})}{(Q_{fan,max} - Q_{fan,min})} = C_1 + C_2 * Q_{fan} \quad (1.198)$$

where  $C_1 = P_{sm,min} - C_2 * Q_{fan,min}$  and  $C_2 = \frac{(P_{sm,max} - P_{sm,min})}{(Q_{fan,max} - Q_{fan,min})}$

For  $Q_{fan} < Q_{fan,min}$ ,  $P_{sm} = P_{sm,min}$ ; for  $Q_{fan} > Q_{fan,max}$ ,  $P_{sm} = P_{sm,max}$

The minimum and maximum fan airflows ( $Q_{fan,min}$  and  $Q_{fan,max}$ ) correspond respectively to the minimum and maximum duct static pressure set points ( $P_{sm,min}$  and  $P_{sm,max}$ ).

If no duct static pressure reset scheme is used and the duct static pressure set point is constant, then parameter  $C_2$  is set to zero and  $C_1$  represents the constant duct static pressure set point.

#### 1.42.7.1.26 Field: Normalized Fan Static Efficiency Curve Name Non-Stall Region

The required alpha name of the exponential-modified skew normal performance curve (ref: **Curve:ExponentialSkewNormal** in Performance Curves) that parameterizes the normalized fan static efficiency ( $\eta_{fan}(x_{fan})/\eta_{fan,max}$ ) at each time step for the normal operating (non-stall) region of the fan performance map as a function of  $x_{fan}$ , which is defined as log-base-10 of Eu at the fan flow and pressure rise operating point divided by Eu at maximum fan static efficiency [ $\log_{10}(Eu/Eu_{max})$ ]. In this region,  $x_{fan} \leq 0$ .

The output of this curve is used to calculate the fan efficiency  $\eta_{\text{fan}}(x_{\text{fan}})$  at each time step by modifying  $\eta_{\text{fan,max}}$  (see *Maximum Fan Static Efficiency* field). This curve should have a maximum of 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

#### 1.42.7.1.27 Field: Normalized Fan Static Efficiency Curve Name Stall Region

The required alpha name of the exponential-modified skew normal performance curve (ref: **Curve:ExponentialSkewNormal** in Performance Curves) that parameterizes the normalized fan static efficiency ( $\eta_{\text{fan}}(x_{\text{fan}})/\eta_{\text{fan,max}}$ ) at each time step for the stall region of the fan performance map as a function of  $x_{\text{fan}}$  (see *Normalized Fan Static Efficiency Curve Name Non-Stall Region* field). In this region,  $x_{\text{fan}} > 0$ .

The output of this curve is used to calculate the fan efficiency  $\eta_{\text{fan}}(x_{\text{fan}})$  at each time step by modifying  $\eta_{\text{fan,max}}$  (see *Maximum Fan Static Efficiency* field). This curve should have a maximum of 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

#### 1.42.7.1.28 Field: Normalized Dimensionless Airflow Curve Name Non-Stall Region

The required alpha name of the sigmoid performance curve (ref: **Curve:Sigmoid** in Performance Curves) that parameterizes the normalized dimensionless airflow through the fan ( $\varphi(x_{\text{fan}})/\varphi_{\text{max}}$ ) at each time step for the normal operating (non-stall) region of the fan performance map as a function of  $x_{\text{fan}}$ , which is defined as log-base-10 of Eu at the fan flow and pressure rise operating point divided by Eu at maximum fan static efficiency  $[\log_{10}(Eu/Eu_{\text{max}})]$ . In this region,  $x_{\text{fan}} \leq 0$ .

The output of this curve is used to calculate the dimensionless airflow  $\varphi(x_{\text{fan}})$  at each time step by modifying  $\varphi_{\text{max}}$  (see *Maximum Dimensionless Fan Airflow* field). This curve should have a maximum of 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

#### 1.42.7.1.29 Field: Normalized Dimensionless Airflow Curve Name Stall Region

The required alpha name of the sigmoid performance curve (ref: **Curve:Sigmoid** in Performance Curves) that parameterizes the normalized dimensionless airflow through the fan ( $\varphi(x_{\text{fan}})/\varphi_{\text{max}}$ ) at each time step for the stall region of the fan performance map as a function of  $x_{\text{fan}}$  (see *Normalized Dimensionless Airflow Curve Name Non-Stall Region* field). In this region,  $x_{\text{fan}} > 0$ .

The output of this curve is used to calculate the dimensionless airflow  $\varphi(x_{\text{fan}})$  at each time step by modifying  $\varphi_{\text{max}}$  (see *Maximum Dimensionless Fan Airflow* field). This curve should have a maximum of 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

#### 1.42.7.1.30 Field: Maximum Belt Efficiency Curve Name

The alpha name of the quartic polynomial performance curve (ref: **Curve:Quartic** in Performance Curves) that determines the maximum fan drive belt efficiency in logarithmic space ( $\eta_{\text{belt,max,ln}}$ ) as a function of  $x_{\text{belt,max}}$ . The curve is:

$$\eta_{\text{belt,max,ln}} = C_1 + C_2 \cdot x_{\text{belt,max}} + C_3 \cdot x_{\text{belt,max}}^2 + C_4 \cdot x_{\text{belt,max}}^3 + C_5 \cdot x_{\text{belt,max}}^4 \quad (1.199)$$

where  $x_{\text{belt,max}} = \ln(F_{\text{belt}} \cdot H_{\text{fan,max}})$  with  $H_{\text{fan,max}}$  expressed in terms of hp.

Note that  $\eta_{\text{belt,max}} = \exp(\eta_{\text{belt,max,ln}})$ .

The output of this curve must be greater than zero and less than or equal to 1.0. If  $\eta_{\text{belt,max}}$  is known, it is represented by coefficient  $C_1 (= \ln(\eta_{\text{belt,max}}))$ . In this case, coefficients  $C_2$  through  $C_5$  are set to zero. If this field is left blank (e.g., there is no belt), the model assumes that the output of the modifier curve is 1.0 for the entire simulation (maximum belt efficiency = 1.0).

**1.42.7.1.31 Field: Normalized Belt Efficiency Curve Name Region 1**

The alpha name of the single rectangular hyperbola type 2 performance curve (ref: **Curve:RectangularHyperbola2** in Performance Curves) that determines the normalized (par-load) fan drive belt efficiency ( $\eta_{\text{belt}}(x_{\text{belt}})/\eta_{\text{belt,max}}$ ) as a function of  $x_{\text{belt}}$ . Normalized belt efficiency is represented by a segmented curve with three different regions. The curve for Region 1 ( $0 \leq x_{\text{belt}} < x_{\text{belt,trans}}$ ) is:

$$\frac{\eta_{\text{belt}}(x_{\text{belt}})}{\eta_{\text{belt,max}}} = \frac{(C_1 \cdot x_{\text{belt}})}{(C_2 + x_{\text{belt}})} + C_3 \cdot x_{\text{belt}} \quad (1.200)$$

where  $x_{\text{belt}} = \tau_{\text{belt}}/\tau_{\text{belt,max}}$ ;  $\tau_{\text{belt}}$  is the belt output torque that corresponds to the calculated power input to the fan shaft ( $H_{\text{fan}}$ , W) by the drive belt and the calculated fan shaft speed ( $\omega_{\text{fan}}$ , rpm).

The output of this curve is used to calculate the belt efficiency  $\eta_{\text{belt}}(x_{\text{belt}})$  in Region 1 at each time step by modifying  $\eta_{\text{belt,max}}$  (see *Maximum Belt Efficiency Curve Name* field). The output of this curve must be greater than zero and less than or equal to 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

If this field is left blank, the model assumes that the output of the modifier curve is 1.0 for the entire simulation (i.e., constant belt efficiency at  $\eta_{\text{belt,max}}$  in Region 1).

**1.42.7.1.32 Field: Normalized Belt Efficiency Curve Name Region 2**

The alpha name of the exponential decay performance curve (ref: **Curve:ExponentialDecay** in Performance Curves) that determines the normalized (part-load) fan drive belt efficiency ( $\eta_{\text{belt}}(x_{\text{belt}})/\eta_{\text{belt,max}}$ ) as a function of  $x_{\text{belt}}$ . Normalized belt efficiency is represented by a segmented curve with three different regions. The curve for Region 2 ( $x_{\text{belt,trans}} \leq x_{\text{belt}} \leq 1$ ) is:

$$\eta_{\text{belt}}(x_{\text{belt}})/\eta_{\text{belt,max}} = C_1 + C_2 \cdot \exp(C_3 \cdot x_{\text{belt}}) \quad (1.201)$$

where  $x_{\text{belt}} = \tau_{\text{belt}}/\tau_{\text{belt,max}}$ ;  $\tau_{\text{belt}}$  is the belt output torque that corresponds to the calculated power input to the fan shaft ( $H_{\text{fan}}$ , W) by the drive belt and the calculated fan shaft speed ( $\omega_{\text{fan}}$ , rpm).

The output of this curve is used to calculate the belt efficiency  $\eta_{\text{belt}}(x_{\text{belt}})$  in Region 2 at each time step by modifying  $\eta_{\text{belt,max}}$  (see *Maximum Belt Efficiency Curve Name* field). The output of this curve must be greater than zero and less than or equal to 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

If this field is left blank, the model assumes that the output of the modifier curve is 1.0 for the entire simulation (i.e., constant belt efficiency at  $\eta_{\text{belt,max}}$  in Region 2).

**1.42.7.1.33 Field: Normalized Belt Efficiency Curve Name Region 3**

The alpha name of the single rectangular hyperbola type 2 performance curve (ref: **Curve:RectangularHyperbola2** in Performance Curves) that determines the normalized (part-load) fan drive belt efficiency ( $\eta_{\text{belt}}(x_{\text{belt}})/\eta_{\text{belt,max}}$ ) as a function of  $x_{\text{belt}}$ . Normalized belt efficiency is represented by a segmented curve with three different regions. The curve for Region 3 ( $x_{\text{belt}} > 1$ ) is:

$$\eta_{\text{belt}}(x_{\text{belt}})/\eta_{\text{belt,max}} = (C_1 \cdot x_{\text{belt}})/(C_2 + x_{\text{belt}}) + C_3 \cdot x_{\text{belt}} \quad (1.202)$$

where  $x_{\text{belt}} = \tau_{\text{belt}}/\tau_{\text{belt,max}}$ ;  $\tau_{\text{belt}}$  is the belt output torque that corresponds to the calculated power input to the fan shaft ( $H_{\text{fan}}$ , W) by the drive belt and the calculated fan shaft speed ( $\omega_{\text{fan}}$ , rpm).

The output of this curve is used to calculate the belt efficiency  $\eta_{\text{belt}}(x_{\text{belt}})$  in Region 3 at each time step by modifying  $\eta_{\text{belt,max}}$  (see *Maximum Belt Efficiency Curve Name* field). The output of this curve must be greater than zero and less than or equal to 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

If this field is left blank, the model assumes that the output of the modifier curve is 1.0 for the entire simulation (i.e., constant belt efficiency at  $\eta_{\text{belt,max}}$  in Region 3).

#### 1.42.7.1.34 Field: Maximum Motor Efficiency Curve Name

The alpha name of the single rectangular hyperbola type 1 performance curve (ref: Curve: RectangularHyperbola1 in Performance Curves) that determines the maximum fan motor efficiency ( $\eta_{\text{motor,max}}$ ) as a function of  $x_{\text{motor,max}}$ . The curve is:

$$\eta_{\text{motor,max}} = (C_1 \cdot x_{\text{motor,max}})/(C_2 + x_{\text{motor,max}}) + C_3 \quad (1.203)$$

where  $x_{\text{motor,max}} = \ln(F_{\text{motor}} \cdot H_{\text{belt,max}})$  with  $H_{\text{belt,max}}$  expressed in terms of hp.  $H_{\text{belt,max}}$  is the maximum output power from the motor to the belt, which corresponds to the calculated maximum power input to the fan shaft ( $H_{\text{fan,max}}$ , W).

The output of this curve must be greater than zero and less than or equal to 1.0. If  $\eta_{\text{motor,max}}$  is known, it is represented by coefficient  $C_3$ . In this case, coefficients  $C_1$  and  $C_2$  are set to zero.

If this field is left blank, the model assumes that the output of the modifier curve is 1.0 for the entire simulation (maximum motor efficiency = 1.0).

#### 1.42.7.1.35 Field: Normalized Motor Efficiency Curve Name

The name of the HVAC system node to which the fan sends its outlet air.

The alpha name of the single rectangular hyperbola type 2 performance curve (ref: **Curve:RectangularHyperbola2** in Performance Curves) that determines the normalized (part-load) fan motor efficiency ( $\eta_{\text{motor}}(x_{\text{motor}})/\eta_{\text{motor,max}}$ ) as a function of the motor load fraction  $x_{\text{motor}}$ . The curve is:

$$\eta_{\text{motor}}(x_{\text{motor}})/\eta_{\text{motor,max}} = (C_1 \cdot x_{\text{motor}})/(C_2 + x_{\text{motor}}) + (C_3 \cdot x_{\text{motor}} \quad (1.204)$$

where  $x_{\text{motor}} = H_{\text{belt}}/H_{\text{belt,max}}$ .  $H_{\text{belt}}$  is the calculated output power from the motor to the belt (W), which corresponds to the calculated power input to the fan shaft ( $H_{\text{fan}}$ , W).

The output of this curve is used to calculate the motor efficiency ( $\eta_{\text{motor}}(x_{\text{motor}})$ ) at each time step by modifying  $\eta_{\text{motor,max}}$  (see *Maximum Motor Efficiency Curve Name* field). The output of this curve must be greater than zero and less than or equal to 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

If this field is left blank, the model assumes that the output of the modifier curve is 1.0 for the entire simulation (i.e., constant motor efficiency at  $\eta_{\text{motor,max}}$ ).

#### 1.42.7.1.36 Field: VFD Efficiency Curve Name

The alpha name of the single rectangular hyperbola type 2 performance curve (e.g., **Curve:RectangularHyperbola2** in Performance Curves) that determines the VFD efficiency ( $\eta_{\text{VFD}}(x_{\text{VFD}})$ ) as a function of the fractional input power of the motor or fractional motor speed ( $x_{\text{VFD}}$ ). An example of the curve is:

$$\eta_{\text{VFD}}(x_{\text{VFD}}) = (C_1 \cdot x_{\text{VFD}})/(C_2 + x_{\text{VFD}}) + C_3 \cdot x_{\text{VFD}} \quad (1.205)$$

where  $x_{\text{VFD}} = H_{\text{motor}}/H_{\text{motor,max}}$  or  $\omega_{\text{motor}}/\omega_{\text{motor,max}}$ .

The output of this curve is used to calculate the VFD efficiency  $\eta_{\text{VFD}}(x_{\text{VFD}})$  at each time step. The output of this curve must be greater than zero and less than or equal to 1.0 and should be valid for the range of volumetric flows and fan pressure rises anticipated for the simulation period.

If this field is left blank, the model assumes that the output of the modifier curve is 0.97 for the entire simulation (i.e., constant VFD efficiency of 0.97).

#### 1.42.7.1.37 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Central System”. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary

EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the fan will be assigned to the “General” end-use subcategory.

An example of use in an IDF:

```

### 1.42.7.2 Outputs

- HVAC,Average,Fan Electricity Rate [W]
- HVAC,Average,Fan Rise in Air Temperature [deltaC]
- HVAC,Sum,Fan Electricity Energy [J]

#### 1.42.7.2.1 Fan Electricity Rate [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

#### 1.42.7.2.2 Fan Rise in Air Temperature [deltaC]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the timestep being reported.

#### 1.42.7.2.3 Fan Electricity Energy [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Fans, Group Key = System (ref. Output:Meter objects).

#### 1.42.7.2.4 Other Outputs

Several parameters input by the user or calculated during component sizing for the design condition (maximum system airflow) are reported separately in the <filename>.eio file. These parameters include fan airflow and pressure rise; fan shaft input, motor output, VFD output, and VFD input (rated) power; pulley drive ratio; belt output torque; and fan, belt, motor, VFD, and combined system efficiencies. They can be identified by lines in the .eio file beginning with Component Sizing Information, Fan:ComponentModel . The same values are also reported under the ComponentSizingSummary heading in the <filename>Table.html file.

## 1.43 Group – Humidifiers and Dehumidifiers

### 1.43.1 Humidifier:Steam:Electric

The electric steam humidifier is a component that represents an electrically heated, self contained steam humidifier. The component uses electrical energy to convert ordinary tap water to steam which it then injects into the supply air stream by means of a blower fan. The actual unit might be an electrode-type humidifier or a resistance-type humidifier.

The humidifier model includes local control of the humidifier unit to meet a humidity ratio setpoint on its air outlet node. A set point manager is needed to put a setpoint on the exit node but no other local controllers are needed. The humidifier will add moisture to meet the humidity ratio setpoint.

#### 1.43.1.1 Inputs

##### 1.43.1.1.1 Field: Name

A unique user assigned name for a particular humidifier unit. Any reference to this unit by another object will use this name.

##### 1.43.1.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.43.1.1.3 Field: Rated Capacity

The nominal full output water addition rate of the unit in m<sup>3</sup>/sec of water at 5.05 °C. This field is autosizable.

##### 1.43.1.1.4 Field: Rated Power

The nominal full output power consumption of the unit in watts, exclusive of the blower fan power consumption and any standby power. This field can be autosized. When it is autosized, its calculated from the rated capacity in kg/s and the enthalpy rise in J/kg of the feed water from the a reference temperature of liquid water at 20 °C to a saturated steam at 100 °C.

**1.43.1.1.5 Field: Rated Fan Power**

The nominal full output power consumption of the blower fan in watts.

**1.43.1.1.6 Field: Standby Power**

The standby power consumption in watts. This amount of power will be consumed whenever the unit is available (as defined by the availability schedule).

**1.43.1.1.7 Field: Air Inlet Node Name**

The name of the HVAC system node from which the unit draws inlet air.

**1.43.1.1.8 Field: Air Outlet Node Name**

The name of the HVAC system node to which the unit sends its outlet air.

**1.43.1.1.9 Field: Water Storage Tank Name**

This field is optional. If left blank or omitted, then the humidifier obtains its water directly from the mains water. If the name of a Water Storage Tank is specified, then the humidifier will try to obtain its water from that tank. If the tank can't provide all the water then the rest will be drawn from the mains and the humidifier will still operate.

An IDF example:

```
Humidifier:Steam:Electric,
  Humidifier 1,                !- Name
  FanAndCoilAvailSched,        !- Availability Schedule Name
  0.00000379,                  !- Rated Capacity {m3/s}
  10200.,                      !- Rated Power {W}
  27.,                         !- Rated Fan Power {W}
  2.,                          !- Standby Power {W}
  Cooling Coil Air Outlet Node, !- Air Inlet Node Name
  Air Loop Outlet Node;        !- Air Outlet Node Name
```

**1.43.1.2 Outputs**

- HVAC,Average,Humidifier Water Volume Flow Rate [m3/s]
- HVAC,Sum,Humidifier Water Volume[m3]
- HVAC,Average,Humidifier Electricity Rate [W]
- HVAC,Sum,Humidifier Electricity Energy [J]
- Zone,Meter,Humidifier:Water [m3]
- Zone,Meter,Humidifier:Electricity [J]
- HVAC,Average,Humidifier Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Humidifier Storage Tank Water Volume [m3]
- HVAC,Average,Humidifier Starved Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Humidifier Starved Storage Tank Water Volume [m3]
- Zone,Meter,Humidifier:MainsWater [m3]
- HVAC,Sum,Humidifier Mains Water Volume [m3]

**1.43.1.2.1 Humidifier Water Volume Flow Rate [m3/s]**

This field reports the water consumption rate of the steam humidifier in cubic meters of water per second.

**1.43.1.2.2 Humidifier Water Volume[m3]**

This output is the cubic meters of water consumed by the steam humidifier over the timestep being reported.

**1.43.1.2.3 Humidifier Electricity Rate [W]**

This output is the electricity consumption rate in Watts of the steam humidifier.

**1.43.1.2.4 Humidifier Electricity Energy [J]**

This is the electricity consumption in Joules of the steam humidifier over the timestep being reported.

**1.43.1.2.5 Humidifier:Water [m3]**

This meter output contains the sum of the water consumed (in cubic meters of water during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

**1.43.1.2.6 Humidifier:Electricity [J]**

This meter output contains the sum of the electricity consumed (in Joules during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

**1.43.1.2.7 Humidifier Storage Tank Water Volume Flow Rate [m3/s]****1.43.1.2.8 Humidifier Storage Tank Water Volume [m3]**

These outputs contain the rate and volume of water obtained from water storage tank. These are only present if the humidifier is connected to a Water Storage Tank for its water supply.

**1.43.1.2.9 Humidifier Starved Storage Tank Water Volume Flow Rate [m3/s]****1.43.1.2.10 Humidifier Starved Storage Tank Water Volume [m3]**

These outputs contain the rate and volume of water that could not be obtained from the water storage tank. The component will still operate as if it did get all the water with the balance obtained directly from the mains

**1.43.1.2.11 Humidifier Mains Water Volume [m3]**

This output contains the volume of water obtained from the mains.

**1.43.2 Humidifier:Steam:Gas**

The gas fired steam humidifier is a component that represents a gas fired self-contained steam humidifier. The component uses gas fired energy to convert ordinary tap water to steam which it then blows or injects into the supply air stream. Blower fan may not be required depending on how the dry steam is delivered into the supply air stream. The humidifier model includes local control of the humidifier unit to meet a humidity ratio setpoint on its air outlet node of the unit. A humidity set point manager is needed to put a setpoint on the outlet node but no other local controllers are needed. The humidifier either blows or injects dry steam to meet the humidity ratio setpoint requirement. If the Rated Gas Use Rate input field is not autosized, the thermal efficiency input specified will be ignored and overridden by a thermal efficiency

value determined from user specified Rated Gas Use Rate, rated capacity (m<sup>3</sup>/s) and design conditions for sizing calculation.

### 1.43.2.1 Inputs

#### 1.43.2.1.1 Field: Name

A unique user assigned name for a particular humidifier unit. Any reference to this unit by another object will use this name.

#### 1.43.2.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.43.2.1.3 Field: Rated Capacity

The nominal full capacity water addition rate in m<sup>3</sup>/s of water at 5.05 °C.

#### 1.43.2.1.4 Field: Rated Gas Use Rate {W}

The nominal gas use rate in Watts. This input field can be autosized. When this input field is autosized, it is calculated from the rated capacity in kg/s, the enthalpy rise in J/kg of the feed water from a reference temperature of liquid water at 20 °C to a saturated steam at 100 °C and user specified thermal efficiency. If this input field is hardsized and the Inlet Water Temperature Option input field is selected as FixedInletWaterTemperature, then the thermal efficiency input field will not be used in the calculation or else if the Inlet Water Temperature Option input selected is VariableInletWaterTemperature, then the user specified thermal efficiency value will be overridden using internally calculated efficiency from the capacity, rated gas use rate and design condition.

#### 1.43.2.1.5 Field: Thermal Efficiency

The thermal efficiency of the gas fired humidifier. The thermal efficiency is based on the higher heating value of the fuel. The default value is 0.8. If Rated Gas Use Rate in the field above is not autosized and the Inlet Water Temperature Option input field selected is FixedInletWaterTemperature, then the thermal efficiency specified will be ignored in the calculation, or else if the Inlet Water Temperature Option input field is specified as VariableInletWaterTemperature, then the user specified thermal efficiency value will be overridden using internally calculated matching the capacity, rated gas use rate specified and design condition defined for sizing calculation.

#### 1.43.2.1.6 Field: Thermal Efficiency Modifier Curve Name

This is thermal efficiency modifier curve name of unit. This curve is normalized, i.e., the curve output value at rated condition is 1.0. If this input field is blank, then constant efficiency value specified in the input field above will be used. Allowed thermal efficiency modifier curve types are linear, quadratic, or cubic. These curves are solely a function of part load ratio.

#### 1.43.2.1.7 Field: Rated Fan Power

The nominal full capacity electric power input to the blower fan in Watts. If no blower fan is required to inject the dry steam to the supply air stream, then this input field is set to zero.

#### 1.43.2.1.8 Field: Auxiliary Electric Power

The auxiliary electric power input in watts. This amount of power will be consumed whenever the unit is available (as defined by the availability schedule). This electric power is used for control purpose only.

#### 1.43.2.1.9 Field: Air Inlet Node Name

The name of the HVAC system node from which the unit draws inlet air.

#### 1.43.2.1.10 Field: Air Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air.

#### 1.43.2.1.11 Field: Water Storage Tank Name

This field is optional. If left blank or omitted, then the humidifier obtains its water directly from the mains water. If the name of a Water Storage Tank is specified, then the humidifier will try to obtain its water from that tank. If the tank can't provide all the water then the rest will be drawn from the mains and the humidifier will still operate.

#### 1.43.2.1.12 Field: Inlet Water Temperature Option

This field is a key/choice field that tells which humidifier water inlet temperature to use: fixed inlet temperature or variable water inlet temperature that depends on the source. Currently allowed water sources are main water or water storage tank in water use objects. The key/choice are: FixedInletWaterTemperature, with this choice, the gas fired humidifier will use a fixed 20C water inlet temperature. VariableInletWaterTemperature, with this choice, the gas fired humidifier will use water inlet temperature that depends on the source temperature. If a water use storage tank name is specified, then the gas humidifier water inlet temperature will be the storage water temperature, or else it uses water main temperature. The default main water temperature is 10 °C. If left blank or omitted, then the humidifier assumes fixed inlet water temperature of 20 °C.

An IDF example:

```
Humidifier:Steam:Gas,
  Main Gas Humidifier, !- Name
  ALWAYS_ON,          !- Availability Schedule Name
  4.00E-5,             !- Rated Capacity {m3/s}
  104000,              !- Rated Gas Use Rate {W}
  1.0,                 !- Thermal Efficiency {-}
  ,                    !- Thermal Efficiency Modifier Curve Name
  0,                   !- Rated Fan Power {W}
  0,                   !- Auxiliary Electric Power {W}
  Mixed Air Node 1,    !- Air Inlet Node Name
  Main Humidifier Outlet Node, !- Air Outlet Node Name
  ;                    !- Water Storage Tank Name
```

#### Steam Gas Humidifier Outputs

- HVAC,Average,Humidifier Water Volume Flow Rate [m3/s]
- HVAC,Sum,Humidifier Water Volume[m3]
- HVAC,Average,Humidifier Gas Use Rate[W]
- HVAC,Sum,Humidifier Gas Use Energy [J]
- HVAC,Average,Humidifier Auxiliary Electricity Rate [W]
- HVAC,Sum,Humidifier Auxiliary Electricity Energy [J]
- HVAC,Meter,Humidifier:Water [m3]
- HVAC,Meter,Humidifier:Gas [J]
- HVAC,Meter,Humidifier:Electricity [J]

- HVAC,Average,Humidifier Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Humidifier Storage Tank Water Volume [m3]
- HVAC,Average,Humidifier Starved Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Humidifier Starved Storage Tank Water Volume [m3]
- Zone,Meter,Humidifier:MainsWater [m3]
- HVAC,Sum,Humidifier Mains Water Volume [m3]

#### 1.43.2.1.13 Humidifier Water Volume Flow Rate [m3/s]

This field reports the water consumption rate of the steam humidifier in cubic meters of water per second.

#### 1.43.2.1.14 Humidifier Water Volume [m3]

This output is the cubic meters of water consumed by the steam humidifier over the timestep being reported.

#### 1.43.2.1.15 Humidifier Gas Use Rate [W]

This output is the gas use rate of the gas fired steam humidifier in Watts.

#### 1.43.2.1.16 Humidifier Gas Use Energy [J]

This output is the gas consumption of the gas fired steam humidifier in Joules.

#### 1.43.2.1.17 Humidifier Auxiliary Electricity Rate [W]

This output is the auxiliary electricity consumption rate in Watts of the gas fired steam humidifier. This is the auxiliary electric power input to the blower fan and control unit.

#### 1.43.2.1.18 Humidifier Auxiliary Electricity Energy [J]

This is the auxiliary electricity consumption in Joules of the gas fired steam humidifier over the timestep being reported. This is the auxiliary electric energy consumed by the blower fan and control unit. This auxiliary electric energy is reported meter output Humidifier:Electricity.

#### 1.43.2.1.19 Humidifier:Water [m3]

This meter output contains the sum of the water consumed (in cubic meters of water during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

#### 1.43.2.1.20 Humidifier:Gas [J]

This meter output contains the sum of the gas consumed (in Joules during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

#### 1.43.2.1.21 Humidifier Storage Tank Water Volume Flow Rate [m3/s]

#### 1.43.2.1.22 Humidifier Storage Tank Water Volume [m3]

These outputs contain the rate and volume of water obtained from water storage tank. These are only present if the humidifier is connected to a Water Storage Tank for its water supply.

#### 1.43.2.1.23 Humidifier Starved Storage Tank Water Volume Flow Rate [m3/s]

#### 1.43.2.1.24 Humidifier Starved Storage Tank Water Volume [m3]

These outputs contain the rate and volume of water that could not be obtained from the water storage tank. The component will still operate as if it did get all the water with the balance obtained directly from the mains

#### 1.43.2.1.25 Humidifier Mains Water Volume [m3]

This output contains the volume of water obtained from the mains.

### 1.43.3 Dehumidifier:Desiccant:NoFans

This object models a solid desiccant dehumidifier (excluding associated fans). The process air stream is the air which is dehumidified. The regen air stream is the air which is heated to regenerate the desiccant. This object determines the process air outlet conditions, the load on the regeneration heating coil, the electric power consumption for the wheel rotor motor, and the regeneration air fan mass flow rate. All other heat exchangers are modeled as separate objects connected to the inlet and outlet nodes of the dehumidifier. The solid desiccant dehumidifier is typically used in an **AirLoopHVAC:OutdoorAirSystem** object, but can also be specified in any **AirLoopHVAC**. The regeneration heating coil can be Gas, Electric, Steam, or Hot Water coil. When hot water coil is selected as regeneration heating coil user-defined curves designed for lower temperature operation must be specified in the input field Performance Model Type along with the Nominal Regeneration Temperature input field. The default performance model type is valid for higher nominal regeneration temperature (e.g. 121C).

#### 1.43.3.1 Inputs

##### 1.43.3.1.1 Field: Name

This alpha field contains the identifying name for the desiccant dehumidifier.

##### 1.43.3.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the desiccant unit can run during a given time period. A schedule value of 0 indicates that the unit is off for that time period. A schedule value greater than 0 indicates that the unit can operate during the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.43.3.1.3 Field: Process Air Inlet Node Name

The name of the node entering the process side of the desiccant wheel.

##### 1.43.3.1.4 Field: Process Air Outlet Node Name

The name of the node leaving the process side of the desiccant wheel.

##### 1.43.3.1.5 Field: Regeneration Air inlet Node Name

The name of the node entering the regeneration side of the desiccant wheel after the regeneration coil.

##### 1.43.3.1.6 Field: Regeneration Fan Inlet Node Name

Node name for air entering the regeneration fan, mass flow is set by this desiccant dehumidifier model.

**1.43.3.1.7 Field: Control Type**

Type of setpoint control. Options are

- LeavingMaximumHumidityRatioSetpoint
- SystemNodeMaximumHumidityRatioSetpoint

**LeavingMaximumHumidityRatioSetpoint** means that the unit is controlled to deliver air at the *Leaving Maximum Humidity Ratio Setpoint*, using bypass dampers to prevent overdrying.

**SystemNodeMaximumHumidityRatioSetpoint** means that the unit is controlled to deliver air at the maximum humidity ratio setpoint (System Node Humidity Ratio Max) on the *Process Air outlet node*, using bypass dampers to prevent overdrying. This setpoint must be established using a set point manager which sets the MaximumHumidityRatio control variable:

- SetpointManager:SingleZone:Humidity:Maximum
- SetpointManager:MultiZone:MaximumHumidity:Average
- SetpointManager:MultiZone:Humidity:Maximum

This will also require the use of a **ZoneControl:Humidistat** object. If the dehumidifier is located in the outdoor air stream, it may also be necessary to use **SetpointManager:OutdoorAirPretreat**.

**1.43.3.1.8 Field: Leaving Maximum Humidity Ratio Setpoint**

Fixed setpoint for maximum process air leaving humidity ratio. Applicable only when Control Type = LeavingMaximumHumidityRatioSetpoint.

**1.43.3.1.9 Field: Nominal Process Air Flow Rate**

Process air flow rate in m<sup>3</sup>/s at nominal conditions. This field is autosizable.

**1.43.3.1.10 Field: Nominal Process Air Velocity**

Process air velocity in m/s at nominal flow. The default value is 3m/s.

**1.43.3.1.11 Field: Rotor Power**

Power input to wheel rotor motor in W. If this field is unknown, electricity consumption of the unit can be obtained from nominal power per unit air flow rate below.

**1.43.3.1.12 Field: Regeneration Coil Object Type**

Type of heating coil object for regeneration air. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the regeneration air heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Dehumidifier:Desiccant:NoFans) itself provides the “controller” function of modulating water flow. The valid choices are:

- Coil:Heating:Electric
- Coil:Heating:Fuel
- Coil:Heating:Water
- Coil:Heating:Steam

**1.43.3.1.13 Field: Regeneration Coil Name**

Name of heating coil object for regeneration air.

**1.43.3.1.14 Field: Regeneration Fan Object Type**

Type of fan object for regeneration air. For UserCurves performance (see below) **Fan:SystemModel**, **Fan:VariableVolume** and **Fan:ConstantVolume** are valid. For Default performance (see below) only **Fan:SystemModel** or **Fan:VariableVolume** are valid.

**1.43.3.1.15 Field: Regeneration Fan Name**

Name of fan object for regeneration air.

**1.43.3.1.16 Field: Performance Model Type**

Specifies whether the Default performance model or UserCurves curves should be used to model the performance. The default model is a generic solid desiccant wheel using performance curves of the form:

$$\text{curve} = C1 + C2*\text{edb} + C3*\text{edb}^2 + C4*\text{ew} + C5*\text{ew}^2 + C6*\text{vel} + C7*\text{vel}^2 + C8*\text{edb}*\text{ew} + C9*\text{edb}^2*\text{ew}^2 + C10*\text{edb}*\text{vel} + C11*\text{edb}^2*\text{vel}^2 + C12*\text{ew}*\text{vel} + C13*\text{ew}^2*\text{vel}^2 + C14*\text{ALOG}(\text{edb}) + C15*\text{ALOG}(\text{ew}) + C16*\text{ALOG}(\text{vel})$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kgWater/kgDryAir]

vel = process air velocity [m/s]

The Default curves are valid for the following range of process inlet conditions: dry-bulb temperatures of 1.67C (35F) to 48.9C (120F) and humidity ratios of 0.002857 kgWater/kgDryAir (20 gr/lb) to 0.02857 kgWater/kgDryAir (200 gr/lb). If the process inlet conditions are outside this range, the dehumidifier will not operate.

If UserCurves are specified, then performance is calculated as follows:

Leaving Dry-bulb = (Leaving Dry-Bulb Function of Entering Dry-Bulb and Humidity Ratio Curve) \* (Leaving Dry-Bulb Function of Air Velocity Curve)

Leaving Humidity Ratio = (Leaving Humidity Ratio Function of Entering Dry-Bulb and Humidity Ratio Curve) \* (Leaving Humidity Ratio Function of Air Velocity Curve)

Regeneration Energy = (Regeneration Energy Function of Entering Dry-Bulb and Humidity Ratio Curve) \* (Regeneration Energy Function of Air Velocity Curve)

Regeneration Velocity = (Regeneration Velocity Function of Entering Dry-Bulb and Humidity Ratio Curve) \* (Regeneration Velocity Function of Air Velocity Curve)

The UserCurves are limited to the following range of process inlet conditions (essentially not limited): dry-bulb temperatures of 73.3C (-100F) to 65.6C (150F) and humidity ratios of 0.0 kgWater/kgDryAir (0 gr/lb) to 0.21273 kgWater/kgDryAir (1490 gr/lb). If the process inlet conditions are outside this range, the dehumidifier will not operate.

When the Default performance model is selected, the remaining fields are ignored.

**1.43.3.1.17 Field: Leaving Dry-Bulb Function of Entering Dry-Bulb and Humidity Ratio Curve Name**

*This field is applicable only when UserCurves performance model type is specified.*

Leaving dry-bulb of process air as a function of entering dry-bulb and entering humidity ratio, bi-quadratic curve.

$$\text{curve} = C1 + C2*\text{edb} + C3*\text{edb}^2 + C4*\text{ew} + C5*\text{ew}^2 + C6*\text{edb}*\text{ew}$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kgWater/kgDryAir]

**1.43.3.1.18 Field: Leaving Dry-Bulb Function of Air Velocity Curve Name**

*This field is applicable only when UserCurves performance model type is specified.*

Leaving dry-bulb of process air as a function of air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v**2$$

v = process air velocity [m/s]

**1.43.3.1.19 Field: Leaving Humidity Ratio Function of Entering Dry-Bulb and Humidity Ratio Curve Name**

*This field is applicable only when UserCurves performance model type is specified.*

Leaving humidity ratio of process air as a function of entering dry-bulb and entering humidity ratio, biquadratic curve

$$\text{curve} = C1 + C2*edb + C3*edb**2 + C4*ew + C5*ew**2 + C6*edb*ew$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kgWater/kgDryAir]

**1.43.3.1.20 Field: Leaving Humidity Ratio Function of Air Velocity Curve Name**

*This field is applicable only when UserCurves performance model type is specified.*

Leaving humidity ratio of process air as a function of process air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v**2$$

v = process air velocity [m/s]

**1.43.3.1.21 Field: Regeneration Energy Function of Entering Dry-Bulb and Humidity Ratio Curve Name**

*This field is applicable only when UserCurves performance model type is specified.*

Regeneration energy [J/kg of water removed] as a function of entering dry-bulb and entering humidity ratio, biquadratic curve

$$\text{curve} = C1 + C2*edb + C3*edb**2 + C4*ew + C5*ew**2 + C6*edb*ew$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kgWater/kgDryAir]

**1.43.3.1.22 Field: Regeneration Energy Function of Air Velocity Curve Name**

*This field is applicable only when UserCurves performance model type is specified.*

Regeneration energy [J/kg of water removed] as a function of process air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v**2$$

v = process air velocity [m/s]

**1.43.3.1.23 Field: Regeneration Velocity Function of Entering Dry-Bulb and Humidity Ratio Curve Name**

*This field is applicable only when UserCurves performance model type is specified.*

Regeneration velocity [m/s] as a function of entering dry-bulb and entering humidity ratio, biquadratic curve

$$\text{curve} = C1 + C2*edb + C3*edb**2 + C4*ew + C5*ew**2 + C6*edb*ew$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kgWater/kgDryAir]

#### 1.43.3.1.24 Field: Regeneration Velocity Function of Air Velocity Curve Name

*This field is applicable only when UserCurves performance model type is specified.*

Regeneration velocity [m/s] as a function of process air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v**2$$

v = process air velocity [m/s]

#### 1.43.3.1.25 Field: Nominal Regeneration Temperature

*This field is applicable only when UserCurves performance model type is specified.*

Nominal regeneration temperature upon which the regeneration energy modifier curve is based. This input is ignored when Performance Model Type = Default, which assume a regeneration temperature of 121C.

#### 1.43.3.1.26 Field: Nominal Power Per Unit Air Flow Rate

This field is nominal power consumption per unit air flow rate. It is used to calculate electricity consumption of the unit when no rotor power is entered.

An example of this statement in an IDF is:

```
Dehumidifier:Desiccant:NoFans,
  Desiccant 1,                                !- Name

### 1.43.3.2 Outputs

- HVAC,Sum,Dehumidifier Removed Water Mass [kg]
- HVAC,Average,Dehumidifier Removed Water Mass Flow Rate [kg/s]
- HVAC,Average,Dehumidifier Part Load Ratio []
- HVAC,Average,Dehumidifier Electricity Rate [W]

- HVAC,Sum,Dehumidifier Electricity Energy [J]
- HVAC,Average,Dehumidifier Regeneration Specific Energy [J/kgWater]
- HVAC,Average,Dehumidifier Regeneration Rate [W]
- HVAC,Sum,Dehumidifier Regeneration Energy [J]
- HVAC,Average,Dehumidifier Regeneration Air Speed [m/s]
- HVAC,Average,Dehumidifier Regeneration Air Mass Flow Rate [kg/s]
- HVAC,Average,Dehumidifier Process Air Mass Flow Rate [kg/s]

**1.43.3.2.1 Dehumidifier Removed Water Mass [kg]**

Mass of water removed from process air stream.

**1.43.3.2.2 Dehumidifier Removed Water Mass Flow Rate [kg/s]**

Rate of water removal from process air stream.

**1.43.3.2.3 Dehumidifier Part Load Ratio []**

Dehumidifier water removal rate divided by full-load water removal rate.

**1.43.3.2.4 Dehumidifier Electricity Rate [W]**

Dehumidifier rotor electric power.

**1.43.3.2.5 Dehumidifier Electricity Energy [J]**

Dehumidifier rotor electric energy.

**1.43.3.2.6 Dehumidifier Regeneration Specific Energy [J/kgWater]**

Regeneration heating coil energy divided by water removed.

**1.43.3.2.7 Dehumidifier Regeneration Rate [W]**

Regeneration heating coil output rate.

**1.43.3.2.8 Dehumidifier Regeneration Energy [J]**

Regeneration heating coil output energy.

**1.43.3.2.9 Dehumidifier Regeneration Air Speed[m/s]**

Regeneration air velocity.

**1.43.3.2.10 Dehumidifier Regeneration Air Mass Flow Rate [kg/s]**

Regeneration air mass flow rate.

**1.43.3.2.11 Dehumidifier Process Air Mass Flow Rate [kg/s]**

Process air mass flow rate.

### 1.43.4 Dehumidifier:Desiccant:System

The Dehumidifier:Desiccant:System object models the dehumidification of an air stream, normally called the process air stream. A second heated air stream, called the regeneration air stream, is used to remove the collected moisture from the desiccant heat exchanger and this moisture-laden air is then usually exhausted from the building. This Dehumidifier:Desiccant:System object is similar to the **Dehumidifier:Desiccant:NoFans** object but has some additional modeling capabilities.

The Dehumidifier:Desiccant:System object in EnergyPlus is a compound object that can be placed anywhere in an air loop (**AirLoopHVAC**). Common locations for this object are in an **AirLoopHVAC:OutdoorAirSystem** or in the main air loop (**AirLoopHVAC**) downstream of a cooling coil (postcooling desiccant dehumidifier). This compound object coordinates the operation of several children objects: a desiccant heat exchanger, a regeneration air fan, and an optional regeneration air heater. Gas, Electric, Steam, or Hot Water heating coils can be used for regenerator air heaters. If this dehumidifier is placed in the main air loop immediately downstream of a direct expansion (DX) cooling coil, then the dehumidifier's operation can be coordinated with the operation of the companion DX coil and it is also possible to specify that the DX system's condenser waste heat can be used to help regenerate the desiccant heat exchanger. For the case of condenser waste heat regeneration, an optional exhaust fan can also be modeled by this desiccant dehumidifier compound object to help maintain a set point temperature for air entering the regeneration side of the desiccant heat exchanger.

It is important to note that the optional exhaust air fan is modeled internal to the Dehumidifier:Desiccant:System and a separate fan object should *not* be added to the input data file (idf) for this fan. On the other hand, a separate fan object *is* required in the input data file for the regeneration air fan.

Figure 1.179: Schematic of Dehumidifier:Desiccant:System with Draw Through Regeneration Fan Placement

A schematic of the compound object Dehumidifier:Desiccant:System is shown in Figure 1.179 with the draw through regeneration air fan placement. Figure 1.180 shows the Dehumidifier:Desiccant:System object

configured with the blow through regeneration air fan placement.

NOTE: As with any air loop compound object, the Dehumidifier:Desiccant:System object itself is specified on the **AirLoopHVAC** Branch or in the **AirLoopHVAC:OutdoorAirSystem:EquipmentList** for an **AirLoopHVAC:OutdoorAirSystem**. The children objects (e.g., desiccant heat exchanger, regeneration air fan, and optional regeneration air heater) must be specified separately in the input data file and their inlet/outlet connections must be as shown in Figure 1.179 or Figure 1.180.

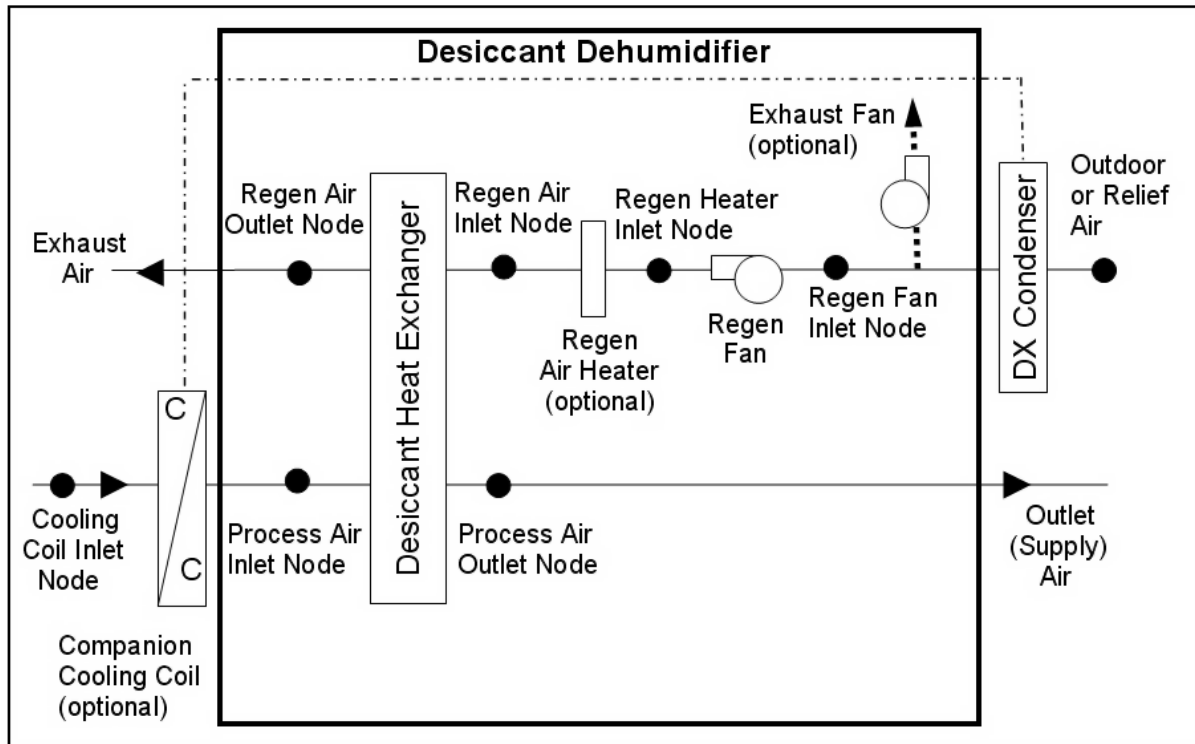

Figure 1.180: Schematic of Dehumidifier:Desiccant:System with Blow Through Regeneration Fan Placement

Currently the only heat exchanger choice for this object is HeatExchanger:Desiccant: BalancedFlow. So to model a Dehumidifier:Desiccant:System located in an air loop, the input data file should include the following objects:

- Dehumidifier:Desiccant:System (in an air loop (**AirLoopHVAC**) Branch or **AirLoopHVAC:OutdoorAirSystem:EquipmentList** for an **AirLoopHVAC:OutdoorAirSystem**)
- **HeatExchanger:Desiccant:BalancedFlow** (desiccant heat exchanger child object)
- **HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1** (desiccant heat exchanger data object)
- **ZoneControl:Humidistat**, and one of:
  - **SetpointManager:SingleZone:Humidity:Maximum**
  - **SetpointManager:MultiZone:Humidity:Maximum**
  - **SetpointManager:MultiZone:MaximumHumidity:Average**

- (when in an air loop (**AirLoopHVAC**) Branch), and **SetpointManager:OutdoorAirPretreat** (when in an **AirLoopHVAC:OutdoorAirSystem**) to place a maximum humidity ratio set point on the sensor node, typically the process air outlet node
- **Fan:SystemModel**, **Fan:OnOff**, or **Fan:ConstantVolume** (regeneration air fan)
- **Coil:Heating:Electric** or **Coil:Heating:Fuel** (optional regeneration air heater)
- **Coil:Cooling:DX:SingleSpeed**, **Coil:Cooling:DX:VariableSpeed**, or **Coil:Cooling:DX:TwoStageWithHumidityControl** (optional companion cooling coil)

If the user wants to model the **Dehumidifier:Desiccant:System** in an **AirLoopHVAC:OutdoorAirSystem**, then the process air path of the dehumidifier should be located in the outdoor air stream and the regeneration air path may be placed in the relief air stream or modeled by the desiccant dehumidifier itself where the first node for the regeneration inlet air stream must be an outdoor air node. If the user wants to model the **Dehumidifier:Desiccant:System** in an air loop (**AirLoopHVAC**) Branch, then the process air path of the dehumidifier should be located in the air loop Branch object. For this case, the regeneration air stream is modeled by the desiccant dehumidifier object itself (i.e., not part of an air loop Branch statement) and the first node for the regeneration inlet air stream must be an outdoor air node (ref. Figure 1.179 or Figure 1.180).

A description of each input field for this object is provided below:

#### 1.43.4.1 Inputs

##### 1.43.4.1.1 Field: Name

A unique, user-assigned name for a particular **Dehumidifier:Desiccant:System**. Any reference to this dehumidifier by another object will use this name.

##### 1.43.4.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the dehumidifier can operate during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the dehumidifier can operate. A value less than or equal to 0 (usually 0 is used) denotes that the dehumidifier will not operate (i.e., no heat exchange will take place and the regeneration air fan does not operate). If the field is blank, the schedule has a value of 1 for all time periods. For the case where companion cooling coil regeneration air heating has been specified, the desiccant dehumidifier's exhaust fan serves as the condenser air fan for the cooling coil system so this availability schedule will not disable exhaust fan operation.

##### 1.43.4.1.3 Field: Desiccant Heat Exchanger Object Type

This alpha field contains the type of desiccant heat exchanger used with this dehumidifier. Currently, the only valid choice is **HeatExchanger:Desiccant:BalancedFlow**.

##### 1.43.4.1.4 Field: Desiccant Heat Exchanger Name

This alpha field contains the name of the desiccant heat exchanger used with this dehumidifier.

##### 1.43.4.1.5 Field: Sensor Node Name

This alpha field specifies the name of the air loop node used to control desiccant heat exchanger operation. A set point manager must be used to place a maximum humidity ratio set point on this node (e.g., **SetpointManager:SingleZone:Humidity:Maximum** or **SetpointManager:OutdoorAirPretreat**).

**1.43.4.1.6 Field: Regeneration Air Fan Object Type**

This alpha field contains the type of regeneration air fan used. Available fan types are **Fan:SystemModel**, **Fan:OnOff** and **Fan:ConstantVolume**.

**1.43.4.1.7 Field: Regeneration Air Fan Name**

This alpha field contains the name of the regeneration air fan used with this dehumidifier.

**1.43.4.1.8 Field: Regeneration Air Fan Placement**

This alpha field specifies the fan configuration used in the desiccant dehumidifier. Valid choices are **BlowThrough** and **DrawThrough**, with a default of **DrawThrough** if this field is left blank.

**1.43.4.1.9 Field: Regeneration Air Heater Object Type**

This alpha field contains the type of heating coil used to heat the regeneration air stream. This field may be left blank when no regeneration air heater is required. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the regeneration air heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Dehumidifier:Desiccant:System) itself provides the “controller” function of modulating water flow. For autosizing regeneration air heating coil the *Design Coil Inlet Air Condition* used is the outdoor air condition if the desiccant system is on the primary air loop, or else if the desiccant system is on outdoor air system then it is the return air condition. The *Design Coil Outlet Air Temperature* is the *Regeneration Inlet Air Setpoint Temperature* specified in the input field below. Valid heating coil choices are:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

**1.43.4.1.10 Field: Regeneration Air Heater Name**

This alpha field contains the name of the heating coil used to heat the regeneration air stream. This field may be left blank when no regeneration air heater is required.

**1.43.4.1.11 Field: Regeneration Inlet Air Setpoint Temperature**

This optional numeric field specifies the regeneration air inlet temperature setpoint in Celsius. The regeneration air heater and/or the companion coil regeneration air heating will be controlled to this temperature to the extent possible. This field may be left blank when no regeneration air heater is required or when control of the exhaust fan used with the companion coil regeneration air heating option is not required. If regeneration air heating coils is autosized, then the value of this input field is used as the *Regeneration Air Heater Design Outlet Air Temperature* for the coil sizing calculation. The default value is 46.0 degrees.

**1.43.4.1.12 Field: Companion Cooling Coil Object Type**

This optional alpha field contains the type of companion cooling coil used with this desiccant dehumidifier. The only valid choices are **Coil:Cooling:DX:SingleSpeed**, **Coil:Cooling:DX:VariableSpeed**, and **Coil:Cooling:DX:TwoStageWithHumidityControlMode**.

**1.43.4.1.13 Field: Companion Cooling Coil Name**

This optional alpha field contains the name of the companion cooling coil used with this desiccant dehumidifier. This field may be left blank when no companion cooling coil is being modeled.

**1.43.4.1.14 Field: Companion Cooling Coil Upstream of Dehumidifier Process Inlet**

This choice field specifies if the companion cooling coil is located immediately upstream of the dehumidifiers process inlet. Valid choices are Yes and No. If Yes is selected, then the outlet air node for the companion cooling coil must be the same as the dehumidifier's process air inlet node (i.e., the process air inlet node name for the desiccant heat exchanger specified for this desiccant dehumidifier). For this case, the companion cooling coil and the desiccant dehumidifier are assumed to operate in tandem ; that is, if the simulation determines that the companion cooling coil is unable to meet the humidity set point specified on the sensor node based on its own operation, then the desiccant dehumidifier operates at the same time and for the same duration as the cooling coil to provide improved dehumidification. If No is selected, then the dehumidifier will control to the humidity set point specified on the sensor node to the extent possible. The default value is No if this field is left blank.

**1.43.4.1.15 Field: Companion Coil Regeneration Air Heating**

This choice field determines if the companion cooling coil's condenser waste heat is used to heat the regeneration inlet air. Valid choices are Yes and No. The default value is No if this field is left blank.

**1.43.4.1.16 Field: Exhaust Fan Maximum Flow Rate**

This optional numeric field contains the maximum fan volumetric flow rate for the exhaust fan in cubic meters per second. As noted previously, this exhaust fan is modeled internally by the Dehumidifier:Desiccant:System object and a separate fan object should NOT be specified in the input data file for this fan. This field is used only when a companion cooling coil is specified and the Companion Coil Regeneration Air Heating field is set to Yes . This field must be used in conjunction with the Exhaust Fan Maximum Power and the Exhaust Fan Power Curve Name input fields. The model assumes that the exhaust fan will operate as needed to maintain the Regeneration Inlet Air Setpoint Temperature , up to the maximum flow rate specified in this input field. If the desiccant dehumidifier is OFF for a simulation timestep but its companion cooling coil is operating and is specified to provide regeneration air heating, then the exhaust fan operates at this maximum air flow rate (i.e., this fan serves as the condenser fan for the companion cooling coil system when regeneration air heating is specified, so the inputs to the companion cooling coil object should not include the condenser fan energy since the condenser fan energy is modeled by the Dehumidifier:Desiccant:System object).

**1.43.4.1.17 Field: Exhaust Fan Maximum Power**

This optional numeric field contains the maximum power for the exhaust fan in Watts (i.e., at the Exhaust Fan Maximum Flow Rate). This field is used only when a companion cooling coil is used and the Companion Coil Regeneration Air Heating field is set to Yes . This field must be used in conjunction with the Exhaust Fan Maximum Flow Rate and the Exhaust Fan Power Curve Name input fields.

**1.43.4.1.18 Field: Exhaust Fan Power Curve Name**

This optional alpha field contains the name of the exhaust fan power modifier curve. This field is used only when a companion cooling coil is used and the Companion Coil Regeneration Air Heating field is set to Yes . This field must be used in conjunction with the Exhaust Fan Maximum Flow Rate and the Exhaust Fan Maximum Power input fields. If this field is blank, the exhaust fan operates (when required) at the maximum power specified in the field above. The curve object type for this Exhaust Fan Power Curve Name

must be **Curve:Cubic** or **Curve:Quadratic**. The curve object (**Curve:Cubic** or **Curve:Quadratic**) defines the change in exhaust fan power as a function of the ratio of the actual exhaust air flow rate divided by the maximum flow rate.

Following is an example input for this object:

```
Dehumidifier:Desiccant:System,
  Desiccant 1,                !- Name
  FanAvailSched,              !- Availability Schedule Name
  HeatExchanger:Desiccant:BalancedFlow, !- Desiccant Heat Exchanger Object Type
  Desiccant Heat Exchanger 1, !- Desiccant Heat Exchanger Name
  HX Process Outlet Node,     !- Sensor Node Name
  Fan:SystemModel,           !- Regeneration Air Fan Object Type
  Desiccant Regen Fan,        !- Regeneration Air Fan Name
  DrawThrough,               !- Regeneration Air Fan Placement
  Coil:Heating:Fuel,          !- Regeneration Air Heater Object Type
  Desiccant Regen Coil,       !- Regeneration Air Heater Name
  46.111111,                 !- Regeneration Inlet Air Setpoint Temperature {C}
  Coil:Cooling:DX:SingleSpeed, !- Companion Cooling Coil Object Type
  Desiccant DXSystem Cooling Coil, !- Companion Cooling Coil Name
  Yes,                        !- Companion Cooling Coil Upstream of Dehumidifier Process Inlet
  Yes,                        !- Companion Coil Regeneration Air Heating
  1.05,                       !- Exhaust Fan Maximum Flow Rate {m3/s}
  50,                         !- Exhaust Fan Maximum Power {W}
  EXHAUSTFANPLF;              !- Exhaust Fan Power Curve Name
```

#### 1.43.4.2 Outputs

- HVAC,Sum,Dehumidifier Removed Water Mass [kg]
- HVAC,Average,Dehumidifier Removed Water Mass Flow Rate [kg/s]
- HVAC,Average,Dehumidifier Part Load Ratio []
- HVAC,Average,Dehumidifier Exhaust Fan Electricity Rate [W]
- HVAC,Sum,Dehumidifier Exhaust Fan Electricity Energy [J]

##### 1.43.4.2.1 Dehumidifier Removed Water Mass [kg]

This output is the mass of water removed from the process air stream in kilograms for the timestep being reported.

##### 1.43.4.2.2 Dehumidifier Removed Water Mass Flow Rate [kg/s]

This output is the average rate of water removal from the process air stream in kilograms per second for the timestep being reported.

##### 1.43.4.2.3 Dehumidifier Part Load Ratio []

This output is the fraction of time that the desiccant heat exchanger (and associated regeneration air heater and fans, if appropriate) operate for the timestep being reported.

##### 1.43.4.2.4 Dehumidifier Exhaust Fan Electricity Rate [W]

This output is the average electric consumption rate for the exhaust fan in Watts for the timestep being reported.

#### 1.43.4.2.5 Dehumidifier Exhaust Fan Electricity Energy [J]

This output is the electric consumption for the exhaust fan in Joules for the timestep being reported. This output is also added to a meter with Resource Type = Electricity, EndUseKey = Cooling, GroupKey = System (ref. Output:Meter objects).

## 1.44 Group – Energy Management System (EMS)

The Energy Management System (EMS) is one of the high-level control methods available in EnergyPlus. An EMS is able to access a wide variety of sensor data and use this data to direct various types of control actions. The concept is to emulate, inside EnergyPlus, the types of controls possible with the digital energy management systems used in real buildings.

In the hierarchy of EnergyPlus controls, the EMS module is a high-level, generalized, supervisory control for building systems. The EMS replicates the functionality of many of the existing high-level control objects in EnergyPlus. Similar to the AvailabilityManager objects, the EMS can turn on and off pumps and fans. Similar to the DemandManager objects, the EMS can turn on and off lights and electric equipment, change the set points on zone thermostats, and dispatch on-site generation. Similar to the SetpointManager objects, the EMS can change the set points on system nodes. Similar to the PlantEquipmentOperation objects, the EMS can turn on and off supply-side heating, cooling, and heat rejection equipment, i.e., boilers, chillers, cooling towers, etc. Similar to the [ElectricLoadCenter:Distribution](#), the EMS can turn on and off on-site generation equipment.

A separate document called *Application Guide for EMS* contains much more information on how to use the EMS. The EMS uses the EnergyPlus Runtime Language (Erl) for custom programming of control routines.

### 1.44.1 EnergyManagementSystem:Sensor

The EnergyManagementSystem:Sensor object is used to declare an Erl variable that is linked to EnergyPlus output variables or meters. EMS sensors are used to get information from elsewhere in the model for use in control calculations. The separate output files called eplusout.rdd and eplusout.mdd provide a listing of the output variables and meters that can be used as sensors.

#### 1.44.1.1 Inputs

##### 1.44.1.1.1 Field: Name

This field contains a unique name for the sensor that becomes the name of a variable for use in Erl programs. No spaces are allowed in the object name. This name will be a global variable in Erl programs and cannot duplicate any other global scope Erl variable.

##### 1.44.1.1.2 Field: Output:Variable or Output:Meter Index Key Name

The key reference for the specified output variable. For example, if System Node Temperature is the output variable, the unique node name is the key. The *Key Name* field should be omitted for weather variables and meters because they do not have a key.

##### 1.44.1.1.3 Field: Output:Variable or Output:Meter Name

The name of the output variable or meter that is to be mapped to the Erl variable for the sensor. The names that can be used in a specific model are included in the .RDD output file.

Examples of this object follow.

```

EnergyManagementSystem:Sensor,
  T1, !Name
  Perimeter_ZN_1 , ! Output:Variable or Output:Meter Index Key Name
  Zone Mean Air Temperature ; ! Output:Variable or Output:Meter Name

EnergyManagementSystem:Sensor,
  PMV5, !Name
  Core_ZN , ! Output:Variable Index Key Name
  Zone Thermal Comfort Fanger Model PMV ; ! Output:Variable Name

EnergyManagementSystem:Sensor,
  T_VAV5FanIn, !Name
  VAV_5_HeatC-VAV_5_FanNode , ! Output:Variable Index Key Name
  System Node Temperature ; ! Output:Variable Name

EnergyManagementSystem:Sensor,
  cooling_setpoint, ! Name
  CLGSETP_SCH , ! Output:Variable Index Key Name
  Schedule Value ; ! Output:Variable Name

```

---

## 1.44.2 EnergyManagementSystem:Actuator

This object maps an Erl variable to a control actuator elsewhere in EnergyPlus. The EMS then initiates control actions by changing the value of this variable inside an Erl program. The Application Guide for EMS contains much more information on EMS actuators. The `eplusout.EDD` file can contain a listing of the actuators available for a specific model. As a debugging aid, to help catch spelling mistakes for example, the program checks to see if any actuators were never used during the simulation and issues a warning for any that it finds.

### 1.44.2.1 Inputs

#### 1.44.2.1.1 Field: Name

The field contains a unique name for the actuator that becomes the name of a variable for use in Erl programs. No spaces or other special characters including dash, plus, and minus, are allowed in the object name. This name will be a global variable in Erl programs and cannot duplicate any other global scope Erl variable.

#### 1.44.2.1.2 Field: Actuated Component Unique Name

This field defines a unique name for the specific entity that is to be controlled. The names for each individual component are listed in the EDD output file when Verbose mode is used see the input object `Output:EnergyManagementSystem` for more on the EDD file. These will often be user-defined names of input objects or system nodes, but some actuators are automatically setup by the program and will not be completely user-defined.

#### 1.44.2.1.3 Field: Actuated Component Type

The field defines the type of the entity that is to be controlled by the actuator. The component types available vary with the specifics of individual models. The types of components that can be used as actuators in a specific model are listed in the EDD output file see the input object `Output:EnergyManagementSystem` for more on the EDD file. Components can be object types defined elsewhere in the IDD but there are other types of entities such as nodes and system-level actuators that do not directly correspond to IDF objects.

#### 1.44.2.1.4 Field: Actuated Component Control Type

This field defines the type of control to be done on the specific entity being controlled. The control types available are listed in the EDD output. Specific components may have more than one type of control available, such as flow rate or temperature, and this field is used to distinguish between them.

Example input objects.

```

EnergyManagementSystem:Actuator,
  VAV_5_NightCycleStatus,      ! Name
  VAV_5,                      ! Actuated Component Unique Name
  AirLoopHVAC,                ! Actuated Component Type
  Availability Status;         ! Actuated Component Control Type

EnergyManagementSystem:Actuator,
  VAV_1_SAT_setpoint,          ! Name
  VAV_1 Supply Equipment Outlet Node , ! Actuated Component Unique Name
  System Node Setpoint,        ! Actuated Component Type
  Temperature Setpoint;        ! Actuated Component Control Type

EnergyManagementSystem:Actuator,
  myCLGSETP_SCH_Override,      ! Name
  CLGSETP_SCH,                !- Actuated Component Unique Name
  Schedule:Constant,           ! Actuated Component Type
  Schedule Value;              ! Actuated Component Control Type

```

### 1.44.3 EnergyManagementSystem:ProgramCallingManager

The **EnergyManagementSystem:ProgramCallingManager** object is used to specify when individual Erl programs are run. This object manages two temporal aspects of running Erl programs. The first is when they are run relative to the rest of EnergyPlus, and the second is when they are run relative to each other. EMS applications can use multiple **EnergyManagementSystem:ProgramCallingManager** objects. For example, one manager may execute an initialization program once at the beginning of the run period while additional managers call various sets of programs from different EMS Calling Points.

Control schemes can be organized using a multiple Erl programs and this object this specifies the order in which they are executed. *Program Name 1* is run first, *Program Name 2* is run second, etc. The run order can be important if there are interactions or dependencies between two or more programs. Within each program there may be calls to execute subroutine programs but only calling managers are used to execute main-level programs.

#### 1.44.3.1 Inputs

##### 1.44.3.1.1 Field: Name

This is a unique name for this particular program manager.

##### 1.44.3.1.2 Field: EnergyPlus Model Calling Point

This field describes when the Erl programs managed under this object are called during an EnergyPlus simulation. All of the programs listed are called at this same calling point. There are 15 possible calling points summarized below. For more information see the section on EMS Calling Points in the Application Guide for EMS.

- **BeginNewEnvironment.** This calling point occurs near the beginning of each environment period. Environment periods include sizing periods such as design days and run periods. This calling point will not be useful for control actions but is useful for initialization of Erl program variables and other one-time set up actions for EMS.

- **BeginZoneTimestepBeforeSetCurrentWeather.** This calling point occurs near the beginning of each timestep during weather data setup. It is called from “ManageWeather” before “SetCurrentWeather” which sets the environment variables for a given timestep. “SetCurrentWeather” is where the Weather Data actuators may override certain environment variables. Note that this calling point is not active during sizing.
- **AfterNewEnvironmentWarmUpIsComplete.** This calling point occurs at the beginning of each environment period but after warm up days are complete. Warm up days are used to condition the transient aspects of the model with the first day before proceeding. This calling point will not be useful for control actions but is useful for re-initializing Erl programs with fresh values after warm up is complete. Programs called from this point might be used to reset counters or summed variables that would change during warmup.
- **BeginZoneTimestepBeforeInitHeatBalance.** This calling point occurs at the beginning of each timestep before “InitHeatBalance” executes but after the weather manager and exterior energy use manager. “InitHeatBalance” refers to the step in EnergyPlus modeling when the solar shading and daylighting coefficients are calculated. This calling point is useful for controlling components that affect the building envelope including surface constructions, window shades, and shading surfaces. Programs called from this point might actuate the building envelope or internal gains based on current weather or on the results from the previous timestep. Demand management routines might use this calling point to operate window shades, change active window constructions, activate exterior shades, etc.
- **BeginZoneTimestepAfterInitHeatBalance.** This calling point occurs at the beginning of each timestep after “InitHeatBalance” executes and before “ManageSurfaceHeatBalance”. “InitHeatBalance” refers to the step in EnergyPlus modeling when the solar shading and daylighting coefficients are calculated. This calling point is useful for controlling components that affect the building envelope including surface constructions and window shades. Programs called from this point might actuate the building envelope or internal gains based on current weather or on the results from the previous timestep. Demand management routines might use this calling point to operate window shades, change active window constructions, etc.
- **BeginTimestepBeforePredictor.** This calling point happens near the beginning of each timestep but before predictor executes. Predictor refers to the step in EnergyPlus modeling where the zone’s thermal loads are calculated. This calling point is useful for controlling components that affect the thermal loads that the systems will be attempting to meet. Programs called from this point might actuate the building envelope or internal gains based on current weather and the results from the previous timestep.
- **AfterPredictorBeforeHVACManagers.** This calling point happens each timestep just after predictor executes but before the traditional supervisory control models for SetpointManager and AvailabilityManager are called. This calling point is useful for a variety of control actions. However, if there are conflicts, the EMS control actions may be overwritten by the actions of any traditional SetpointManagers or AvailabilityManagers in the model.
- **AfterPredictorAfterHVACManagers.** This calling point happens each timestep after predictor executes and after the SetpointManager and AvailabilityManager models are called. This calling point is useful for a variety of control actions. However, if there are conflicts, SetpointManager or AvailabilityManager actions may be overwritten by EMS control actions.
- **InsideHVACSystemIterationLoop.** This calling point happens each HVAC iteration. The HVAC systems solvers iterate to convergence within each timestep and this calling point is inside this

iteration loop. This calling point is useful for a variety of control actions. Being inside the iteration loop, this calling point has the advantage that input data need not necessarily be lagged from prior timestep results and can, in some cases, improve the accuracy of controls. The disadvantage is that programs may run an excessive number of times slowing down the execution of the program.

- **EndOfZoneTimestepBeforeZoneReporting.** This calling point happens each zone timestep just before the output reports are updated for zone-timestep variables and meters. This calling point is useful for custom output variables with Zone frequency because they will be in sync with the rest of the zone output variables.
- **EndOfZoneTimestepAfterZoneReporting.** This calling point happens each zone timestep just after the output reports are updated for zone-timestep variables and meters. This calling point is the last one of a timestep and is useful for making control decisions for the next zone timestep using the final meter values for the current zone timestep.
- **EndOfSystemTimestepBeforeHVACReporting.** This calling point happens each system timestep just before the output reports are updated for HVAC-timestep variables and meters. This calling point is useful for custom output variables with HVAC frequency because they will be in sync with the rest of the system output variables.
- **EndOfSystemTimestepAfterHVACReporting.** This calling point happens each system timestep just after the output reports are updated for HVAC-timestep variables and meters. This calling point is useful for making control decisions for the next system timestep using the final meter values for the current system timestep.
- **EndOfZoneSizing.** This calling point happens once during each simulation and only if the run is set to do zone sizing. The calling point occurs just after the native zone sizing calculations are completed but before the sizing results are finalized. This calling point is useful for taking the intermediate results of zone sizing calculations and modifying them based on custom calculations.
- **EndOfSystemSizing.** This calling point happens once during each simulation and only if the run is set to do system sizing. The calling point occurs just after the native air system sizing calculations are completed but before the sizing results are finalized. This calling point is useful for taking the intermediate results of zone and system sizing calculations and modifying them based on custom calculations.
- **AfterComponentInputReadIn.** This calling point occurs early in the simulation when HVAC component's input data has been processed but before any component-level calculations for automatic sizing. This calling point occurs once for each of the types of HVAC components that have EMS actuators for autosize overrides. This calling point is not directly useful for control actions but is useful for overriding the results of sizing at the component level.
- **UserDefinedComponentModel.** This calling point occurs when user-defined HVAC and plant component models are called to be simulated. This calling point is only used for the programs that model custom components. This calling point differs from the others in that when it is being used the calls to trigger include a reference to a specific **EnergyManagementSystem:ProgramCallingManager** and only the one manager is executed.
- **UnitarySystemSizing.** This calling point occurs when Unitary systems begin their calculations for determining the size values for autosized input fields. This calling point is used for overriding the autosizing outcomes for unitary systems. Each unitary system in the simulation will call this point

one time. This calling point is used to override sizing in the following input objects: `AirLoopHVAC:UnitarySystem`, `AirLoopHVAC:Unitary:Furnace:HeatOnly`, `AirLoopHVAC:Unitary:HeatOnly`, `AirLoopHVAC:Unitary:HeatCool`, `AirLoopHVAC:Unitary:Furnace:HeatCool`, `AirLoopHVAC:Unitary:HeatPump`, and `AirLoopHVAC:Unitary:HeatPump:WaterToAir`.

#### 1.44.3.1.3 Field: Program Name 1

The name of the `EnergyManagementSystem:Program` object that will be the first to run for the calling point.

#### 1.44.3.1.4 Field: Program Name 2 .. N

The name of the `EnergyManagementSystem:Program` object that will be the second to run. Additional programs can be listed. The object is automatically extensible to accommodate as many programs as needed.

IDF examples:

```
EnergyManagementSystem:ProgramCallingManager,
  Initialize EMS for Run , ! Name
  BeginNewEnvironment ,      ! EnergyPlus Model Calling Point
  InitializeMyEMS;           ! Program Name 1

EnergyManagementSystem:ProgramCallingManager,
  EMS-based Setpoint Managers , ! Name
  AfterPredictorAfterHVACManagers , ! EnergyPlus Model Calling Point
  VAV_5_SchedSetpoint , !Program Name 2
  VAV5MixedAirManagers,
  VAV_1_SchedSetpoint,
  VAV1MixedAirManagers,
  VAV_3_SchedSetpoint,
  VAV3MixedAirManagers,
  VAV_2_SchedSetpoint,
  VAV2MixedAirManagers,
  CoolSys1_SchedSetpoint,
  HeatSys1_SchedSetpoint,
  SHWSys1_SchedSetpoint,
  VAV_5_NightCycleMGR,
  VAV_1_NightCycleMGR,
  VAV_2_NightCycleMGR,
  VAV_3_NightCycleMGR;
```

### 1.44.4 EnergyManagementSystem:Program

The `EnergyManagementSystem:Program` object is the central processor of the EMS and the primary container for the *EnergyPlus Runtime Language*, or Erl. The `EnergyManagementSystem:Program` objects are run in the order and point during an EnergyPlus simulation that is specified in an `EnergyManagementSystem:ProgramCallingManager` object. Multiple `EnergyManagementSystem:Program` objects are allowed and may interact (or interfere) with each other. The *Application Guide for EMS* provides a comprehensive overview of Erl programming.

The object definition is very simple. There is a name followed by lines of Erl program code.

#### 1.44.4.1 Inputs

##### 1.44.4.1.1 Field: Name

This field is the unique name of the Erl program. The name can be used to call the program to run from another program or subroutine. No spaces or other special characters such as plus, minus, dash, are allowed in the name.

#### 1.44.4.1.2 Field Set: Program lines 1 to N

Each remaining field contains a single line of code for the *EnergyPlus Runtime Language*, or Erl. Erl is a little programming language with its own syntax. The commas separating fields can be thought of as end of line characters. The *Application Guide for EMS* provides the details on Erl program code.

Example IDF input objects follow.

```
EnergyManagementSystem:Program,
  RH_OpeningController ,      ! Name
  IF ZoneRH < 25,
  SET MyOpenFactor = 0.0 ,
  ELSEIF ZoneRH > 60,
  SET MyOpenFactor = 1.0 ,
  ELSE,
  SET MyOpenFactor = (ZoneRH - 25) / (60 - 25),
  ENDIF;

EnergyManagementSystem:Program,
  AverageZoneTemps , ! Name
  SET Zn1vol = 346.0225, ! zone air volume
  SET Zn2vol = 205.2650, ! zone air volume
  SET Zn3vol = 346.0225, ! zone air volume
  SET Zn4vol = 205.2650, ! zone air volume
  SET Zn5vol = 456.4551, ! zone air volume
  SET SumNumerator = T1*Zn1vol + T2*Zn2vol + T3*Zn3vol + T4*Zn4vol + T5*Zn5vol,
  SET SumDenominator = Zn1vol + Zn2vol + Zn3vol + Zn4vol + Zn5vol,
  SET AverageBuildingTemp = SumNumerator / SumDenominator;

EnergyManagementSystem:Program,
  VAV2MixedAirManagers , ! Name
  SET VAV_2_CoolC_Setpoint = Seasonal_Reset_SAT_Sched - ( T_VAV2FanOut - T_VAV2FanIn),
  SET VAV_2_HeatC_Setpoint = Seasonal_Reset_SAT_Sched - ( T_VAV2FanOut - T_VAV2FanIn),
  SET VAV_2_OA_Setpoint = Seasonal_Reset_SAT_Sched - ( T_VAV2FanOut - T_VAV2FanIn);
```

### 1.44.5 EnergyManagementSystem:Subroutine

The EnergyManagementSystem:Subroutine object contains a block of code written in the *EnergyPlus Runtime Language* that can be run from another Erl program. If the subroutine is never called, it will never run by itself. Subroutines are useful for encapsulating code that is called in multiple places. It is also helpful for organizing and structuring code. When the subroutine finishes running, control is returned to the object that called it. See the *Application Guide for EMS* for information on writing Erl programs.

#### 1.44.5.1 Inputs

##### 1.44.5.1.1 Field: Name

The name uniquely identifying the subroutine. The name can be used to call the subroutine to run from a program or another subroutine or even itself. No spaces or other special characters such as minus, dash, plus, are allowed in the name.

##### 1.44.5.1.2 Field set: Lines 1 to N

Each remaining field contains a single line of code for the *EnergyPlus Runtime Language*, or Erl. Erl is a little programming language with its own special syntax. The commas separating fields can be thought of as end of line characters. The *Application Guide for EMS* contains the details on the rules for Erl program code.

IDF examples:

```
EnergyManagementSystem:Subroutine,
```

```

Add4ToN,
SET N = N + 4;                                !- Name
                                              !- EnergyPlus Runtime Language

EnergyManagementSystem:Subroutine,
manage_ext_lights,
IF inc_solar > 0,                             !- Name
SET ext_lights_pwr = Off,                     !- EnergyPlus Runtime Language
ELSE,
SET ext_lights_pwr = On,
ENDIF;

EnergyManagementSystem:Subroutine,
manage_solar_collector,                      !- Name
IF Tout_F < 32,                               !- EnergyPlus Runtime Language
SET pump_pwr = On,
EXIT,
ENDIF,
SET delta_T = Tcollector      Ttank,
IF delta_T > 0,
SET pump_pwr = On,
ELSE,
SET pump_pwr = Off,
ENDIF;

```

---

## 1.44.6 EnergyManagementSystem:GlobalVariable

The EnergyManagementSystem:GlobalVariable object declares one or more global variables that can be accessed by all Erl programs in the EMS. Erl variables declared by the user as sensor and actuators objects are already global variables. Global scope variables are needed to move data in and out of subroutines because Erl does not support passing arguments within such calls. Global scope variables are also needed to pass an Erl variable result to an output variable. Each field in this object names a new global Erl variable.

### 1.44.6.1 Inputs

#### 1.44.6.1.1 Field: Erl Variable (1..N) Name

The name becomes the global Erl variable name that can be referenced in the *EnergyPlus Runtime Language*. No spaces or other special characters are allowed in the object name. The name must be unique across all global scope variables including those declared as sensor and actuators and the built-in variables.

IDF examples using this object follow:

```

EnergyManagementSystem:GlobalVariable,
global_var;                                !- Name

EnergyManagementSystem:GlobalVariable, Temp_C;

EnergyManagementSystem:GlobalVariable, Temp_F;

EnergyManagementSystem:Subroutine,
CalcFahrenheit,                             !- Name
SET Temp_F = Temp_C * (9/5) + 32;

EnergyManagementSystem:Program,
DummyProgram,                               !- Name
SET Temp_C = Tout,
RUN CalcFahrenheit,
SET Tout_F = Temp_F,
IF Tout_F > 32,
RUN FreezeProtect,
ENDIF;

```

---

### 1.44.7 EnergyManagementSystem:OutputVariable

The **EnergyManagementSystem:OutputVariable** object creates a custom output variable that is mapped to an EMS variable. These can be declared by an **EnergyManagementSystem:Sensor** object, an **EnergyManagementSystem:Actuator** object, or an **EnergyManagementSystem:GlobalVariable** object, or any local variable in an Erl program. The custom output variable can then be reported to the output file using the standard EnergyPlus output mechanisms such as with the **Output:Variable** object.

The **EnergyManagementSystem:OutputVariable** object is a primary way to obtain data from an Erl program and is likely to be essential for developing and debugging programs. This object also provides a powerful mechanism to create custom output variables. See the *Application Guide for EMS* for more information.

#### 1.44.7.1 Inputs

##### 1.44.7.1.1 Field: Name

This field contains the user-defined name for the new output variable. This is the name that will appear in the RDD output file and can be referenced in other input for output such as an **Output:Variable** object. By convention, the name is in title case for capitalization. Units are provided in the Units field.

##### 1.44.7.1.2 Field: EMS Variable Name

This field contains the EMS variable name that is to be mapped to the custom output variable. This must be used elsewhere in Erl programs and cannot have spaces.

##### 1.44.7.1.3 Field: Type of Data in Variable

This field describes the nature of the variable. There are two choices, Averaged or Summed. Averaged variables are state variables such as temperature, power, or flow rate. Summed variables are quantities such as energy that accumulate across time.

##### 1.44.7.1.4 Field: Update Frequency

This field describes which timestep the variable is associated with. There are two choices, ZoneTimestep or SystemTimestep. Variables that are related to the building or zone loads are generally associated with the zone timestep. Variables that are related to HVAC system operation are generally associated with the system timestep.

##### 1.44.7.1.5 Field: EMS Program or Subroutine Name

If the EMS variable is a local scope variable, i.e., not declared as a global scope variable, then this field identifies which program uses the variable. The field references the object name of the Erl program or subroutine object. For global variables, this field should be omitted.

##### 1.44.7.1.6 Field: Units

This field should contain the units for the output variable in standard EnergyPlus units. It does not need to be enclosed in square brackets.

Examples of this object follow.

```
EnergyManagementSystem:OutputVariable,
  Weighted Average Building Zone Air Temperature, ! Name
  AverageBuildingTemp, ! EMS Variable Name
  Averaged, ! Type of Data in Variable
  ZoneTimeStep, ! Update Frequency
  , ! EMS Program or Subroutine Name
```

```

C;

EnergyManagementSystem:OutputVariable,
Main CW Coil Total Cooling Rate,    !- Name
CWcoil1_tot_cool_Power,    !- EMS Variable Name
Averaged,                      !- Type of Data in Variable
SystemTimestep,                !- Update Frequency
MainCWCoil1_ModelOutput,    !- EMS Program or Subroutine Name
W;                             !- Units

```

---

### 1.44.8 EnergyManagementSystem:MeteredOutputVariable

The `EnergyManagementSystem:MeteredOutputVariable` object creates a custom output variable that is mapped to an EMS variable and is also included in the metering system that EnergyPlus has for aggregating results for different resources across the model. This object is very similar to `EnergyManagementSystem:OutputVariable` with the main differences being that only summed types of data in the Erl variable and the quantity is to be added to a meter. This allows for custom output variables that also impact the results for the amount of electricity or gas consumed.

#### 1.44.8.1 Field: Name

This field contains the user-defined name for the new output variable. This is the name that will appear in the RDD and MTD output files and can be referenced in other input for output such as an `Output:Variable` object. Units are provided in the Units field.

#### 1.44.8.2 Field: EMS Variable Name

This field contains the EMS variable name that is to be mapped to the custom output variable. This must be used elsewhere in Erl programs and cannot have spaces.

#### 1.44.8.3 Field: Update Frequency

This field describes which timestep the variable is associated with. There are two choices, `ZoneTimestep` or `SystemTimestep`. Variables that are related to the building or zone loads are generally associated with the zone timestep. Variables that are related to HVAC system operation are generally associated with the system timestep.

#### 1.44.8.4 Field: EMS Program or Subroutine Name

If the EMS variable is a local scope variable, i.e., not declared as a global scope variable, then this field identifies which program uses the variable. The field references the object name of the Erl program or subroutine object. For global variables, this field should be omitted.

#### 1.44.8.5 Field: Resource Type

This field is used to specify the type of resource that the output variable consumes or produces. The choice here will determine which of the meters the output should be added to when EnergyPlus aggregates results for overall consumption. The following keywords can be used to choose the type of resource that should be metered:

- **Electricity**, this selects the main meter for electricity consumption, in units of Joules [J],

- **NaturalGas**, this selects the meter for natural gas consumption, in units of Joules [J],
- **Gasoline**, this selects the meter for gasoline consumption, in units of Joules [J],
- **Diesel**, this selects the meter for diesel consumption, in units of Joules [J],
- **Coal**, this selects the meter for coal consumption, in units of Joules [J],
- **FuelOilNo1**, this selects the meter for No 1 Fuel Oil consumption, in units of Joules [J],
- **FuelOilNo2**, this selects the meter for No 2 Fuel Oil consumption, in units of Joules [J],
- **Propane**, this selects the meter for propane consumption, in units of Joules [J],
- **WaterUse**, this selects the meter for overall water consumption, in units of cubic meters [m<sup>3</sup>],
- **OnSiteWaterProduced**, this selects the meter for overall on-site water collection, in units of cubic meters [m<sup>3</sup>],
- **MainsWaterSupply**, this selects the meter for water supplied by utility mains, in units of cubic meters [m<sup>3</sup>],
- **RainWaterCollected**, this selects the meter for water collected from rain, in units of cubic meters [m<sup>3</sup>],
- **WellWaterDrawn**, this selects the meter for water drawn from a local well, in units of cubic meters [m<sup>3</sup>],
- **CondensateWaterCollected**, this selects the meter for water collected from cooling coils as condensate, in units of cubic meters [m<sup>3</sup>],
- **EnergyTransfer**, this selects the general meter for energy transfers, in units of Joules [J],
- **Steam**, this selects the meter for steam energy consumption, in units of Joules [J],
- **DistrictCooling**, this selects the meter for district chilled water energy consumption, in units of Joules [J],
- **DistrictHeating**, this selects the meter for district hot water energy consumption, in units of Joules [J],
- **ElectricityProducedOnSite**, this selects the meter for electricity produced on the site, in units of Joules [J],
- **SolarWaterHeating**, this selects the meter for hot water heating energy from solar collectors, in units of Joules [J], and,
- **SolarAirHeating**, this selects the meter for air heating energy from solar collectors in units of Joules [J],.

#### 1.44.8.6 Field: Group Type

This field is used to specify how the output variable fits into the categorization scheme used by the metering system in EnergyPlus to identify what part of the model is involved. Metered output variables are classified as being in one of the following general groups:

- **Building**, this category includes all the meters associated with parts of the building that are not related to HVAC or Plant. This includes internal and exterior services such as lights, electric equipment, exterior lights, etc.
- **HVAC**, this category includes all the meters associated with parts of the HVAC system that are related to air and zone thermal conditioning and ventilation (but not hydronic plant systems). This includes things like fans, air conditioners, furnaces etc.
- **Plant**, this category includes all the meters associated with parts of the hydronic plant system that are related to heating, cooling, service water heating, and heat rejection. This includes things like boilers, chillers, water heaters, towers, etc.

#### 1.44.8.7 Field: End-Use Category

This field is used to specify the end use category that should be assigned to the resource associated with the output variable. EnergyPlus reporting includes the breakdown of how resources are used across different end uses. Metered output variables must be classified as being in one of the following end use categories:

- Heating
- Cooling
- InteriorLights
- ExteriorLights
- InteriorEquipment
- ExteriorEquipment
- Fans
- Pumps
- HeatRejection
- Humidifier
- HeatRecovery
- WaterSystems
- Refrigeration
- OnSiteGeneration

#### 1.44.8.8 Field: End-Use Subcategory

This field is used to specify the end use subcategory that will be assigned to the output variable. EnergyPlus reporting includes the breakdown of how resources are used across different end uses with added breakdown for the different subcategories within a particular end use. This user can define his or her own subcategories and enter them in this field. Subcategories are reported in the ABUPS End Uses by Subcategory table and also appear in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If left blank, then no subcategory classification is made and the output is included in the general subcategory for the end use category determined in the previous field.

#### 1.44.8.9 Field: Units

This field should contain the units for the output variable in standard EnergyPlus units. It does not need to be enclosed in square brackets.

Examples of this object follow.

```
EnergyManagementSystem:MeteredOutputVariable,
Zone 1 WinAC Electricity Consumption,    !- Name
Zone1WinAC_ElectEnergy,    !- EMS Variable Name
SystemTimestep,            !- Update Frequency
Zone1_WinAC_ModelOutput,    !- EMS Program or Subroutine Name
Electricity,                !- Resource Type
HVAC,                        !- Group Type
Cooling,                    !- End-Use Category
Window Air Conditioners, !- End-Use Subcategory
J;                            !- Units
```

### 1.44.9 EnergyManagementSystem:TrendVariable

The EnergyManagementSystem:TrendVariable object declares a global trend EMS variable that can be accessed by all Erl programs in the EMS. Trend variables store the recent history of the Erl variable they are associated with. The trend data are useful for examining the progression of time series data. The user declares a new trend variable using this object and associates it with another global Erl variable that will be logged. Trend data are pushed into a stack so that the most recent data are always at the beginning of the stack. Once the stack is full, the oldest data are lost from the trend log. Each value in the trend log is for a zone timestep into the past. The first value in the trend is the one from the previous zone time step.

#### 1.44.9.1 Inputs

##### 1.44.9.1.1 Field: Name

The object name becomes the global EMS trend variable name that can be referenced in the *EnergyPlus Runtime Language*. No spaces or any other special characters are allowed in the name. Then name must be unique across all global scope variables including those declared as sensor and actuators and the built-in variables.

##### 1.44.9.1.2 Field: EMS Variable Name

This field contains the EMS variable name that is to be mapped to the trend variable. This must be a global EMS variable defined elsewhere and cannot have spaces.

##### 1.44.9.1.3 Field: Number of Timesteps to be Logged

This field describes how much data are to be held in the trend variable. The trended data are held in an array with one value for each data point going back in time. This field determines how many elements

are in that array. If there are six timesteps per hour and this field is set to 144, then the trend will contain data for the most recent 24 hours period.

Examples of this object follow.

```
EnergyManagementSystem:TrendVariable,
  AvgTempTrendLog1,      !- Name
  AverageBuildingTemp,    !- EMS Variable Name
  300;                    !- Number of Timesteps to be Logged

EnergyManagementSystem:TrendVariable,
  PMVtrendLog1, ,        !- Name
  PMV5,                  !- EMS Variable Name
  144;                    !- Number of Timesteps to be Logged
```

---

### 1.44.10 EnergyManagementSystem:InternalVariable

The EMS also provides a method to obtain static data from elsewhere in the model. Whereas EMS sensors are used for time-varying data, there are also data that describe certain design parameters for the building which may be useful for EMS calculations. A method for accessing internal data is provided as a time saver and means of better generalizing Erl programs for wider applicability. Information needed for this input object is output by EnergyPlus to the eplusout.edd file see the [Output:EnergyManagementSystem](#) input object. The EDD file can list the internal data index keys and types that are available for use with this object. The Application Guide for EMS discusses internal variables in more depth.

#### 1.44.10.1 Inputs

##### 1.44.10.1.1 Field: Name

This field contains a unique name for the internal variable that becomes the name of a variable for use in Erl programs. No spaces, dashes, plus symbols, minus symbols, or other special characters are allowed in the name. This name will be a global variable in Erl programs and cannot duplicate any other global scope EMS variable.

##### 1.44.10.1.2 Field: Internal Data Index Key Name

This field contains the unique identifier for the internal variable. This is usually a name defined by the user elsewhere in an IDF input object. For example, for an internal variable for the floor area of a zone, this would be the name of the zone.

##### 1.44.10.1.3 Field: Internal Data Type

This field defines the type of internal data source that is to be mapped to the EMS variable. The types of internal source data that can be used as internal variables are listed in the EIO output file when an input file has any EMS-related objects.

An example of this object follows.

```
EnergyManagementSystem:InternalVariable,
  Zn1vol,      !- Name
  Perimeter_ZN_1, !- Internal Data Index Key Name
  Zone Air Volume; !- Internal Data Type
```

---

### 1.44.11 EnergyManagementSystem:CurveOrTableIndexVariable

The EMS provides a method for reusing curve and table input objects from elsewhere in the model. Input objects, such as **Curve:Cubic**, **Curve:Biquadratic**, or **Table:Lookup**, are used by various component models to describe performance relationships in a generic way. By using an **EnergyManagementSystem:CurveOrTableIndexVariable** input object, these curves and tables can be used in your own Erl programs. This object sets up an Erl variable that contains an index that points to specific curve or table. This index variable is then used as the first argument in a call to the built-in function called **@CurveValue** so that the correct curve or table is evaluated.

#### 1.44.11.1 Inputs

##### 1.44.11.1.1 Field: Name

This field contains a unique name for the index variable that becomes the name of a variable for use in Erl programs. No special characters (including spaces) are allowed in the name. This name will be a global variable in Erl programs and cannot duplicate any other global scope EMS variable. The variable will be filled by the EMS system to have a value that points to the curve or table object named in the following field.

##### 1.44.11.1.2 Field: Curve or Table Object Name

This field contains the unique name of a **Curve:\*** or **Table:\*** object defined elsewhere in the input file. The Erl variable in the previous field will be filled with the index for the curve or table named here. The value of this index tracks the order that **Curve:** and **Table:** input objects are listed in the input file.

An example IDF object is:

```
EnergyManagementSystem:CurveOrTableIndexVariable,
  Curve_Quadratic_Ptr,           !- Name
  HPACC00LPLFFPLR_curve;       !- Curve or Table Object Name
```

### 1.44.12 EnergyManagementSystem:ConstructionIndexVariable

The EMS provides actuators for overriding the type of construction used by a surface. The **EnergyManagementSystem:ConstructionIndexVariable** input object is used to setup an Erl variable that contains an index that points to specific Construction. This index variable is then used with a special actuator called **Surface** with the control type **Construction State**. See the Application Guide for EMS for more information on how to use this index variable and the associated actuator.

#### 1.44.12.1 Inputs

##### 1.44.12.1.1 Field: Name

This field contains a unique name for the index variable that becomes the name of a variable for use in Erl programs. No spaces or characters like dashes, minuses, plus symbols, are allowed in the name. This name will be a global variable in Erl programs and cannot duplicate any other global scope EMS variable. The variable will be filled by the EMS system to have a value that points to the Construction object named in the following field.

##### 1.44.12.1.2 Field: Construction Object Name

This field contains the unique name of a Construction object defined elsewhere in the input file. The Erl variable in the previous field will be filled with the index for the Construction named here. The value of this index tracks the order that Construction input objects are listed in the input file.

An example IDF object is:

```
Construction,
  TCwindow_25,
  Clear3PPG,
  AIR 3MM,
  W018RT25,
  AIR 8MM,
  SB60Clear3PPG;

                                !- Name
                                !- Outside Layer
                                !- Layer 2
                                !- Layer 3
                                !- Layer 4
                                !- Layer 5

EnergyManagementSystem:ConstructionIndexVariable,
  TCwindow_25,
  TCwindow_25;
```

---

## 1.45 Group – Python Plugins / Python EMS

The Energy Management System in EnergyPlus was a major breakthrough in provided user-defined capabilities. By allowing the user to read simulation data, perform custom calculations, and ultimately manipulate control settings, the door was opened to any number of new applications, including evaluation of custom control strategies or custom physical component models. However, users were limited to writing scripts in the built-in, custom, EnergyPlus Runtime Language, and debugging was possible, but difficult.

Users have pushed EMS in many ways well beyond a traditional Energy “Management” System. At this point, a lot of EMS scripts are what would be called “plugins” in most software environments. As of version 9.3 of EnergyPlus, a new way to write these plugins, in the Python programming language was made available.

Note: This functionality relies on some aspects of the EnergyPlus API for making calls into EnergyPlus when these plugins are running. A majority of the API is described in section 1.4, and it is highly recommended that that section be read first, as this section will only focus on the differences, and additions. One point should be made perfectly clear. There are two Python-related ways of interacting with EnergyPlus. We can call these “modes”, with each clarified here:

**Library Mode** In library mode, an external script (C or Python) is written which leverages the EnergyPlus API to register callback functions and initiate a simulation from a function call.

**Plugin Mode** In plugin mode, a (typically) small Python script is written, then by specifying parameters in an input file, the client runs EnergyPlus(.exe) in a traditional fashion, and that EnergyPlus run will call out to the Python script as needed.

These two operation modes cannot be mixed. In plugin mode, EnergyPlus creates a new Python instance internally to allow processing the user-defined scripts. When EnergyPlus is run in an API mode, it cannot create a new Python session internally, as it may be in an existing Python session. Thus, if a plugin object is found in input during an API call, the program will abort. In the future, this limitation may be lifted, but for most use cases, if you are calling EnergyPlus as a library (API), you can simply register API callbacks to execute user-defined code at runtime, and don’t need to worry about also writing Python Plugins.

The API section has information about how to access output variable data, meters, internal variable data, simulation parameters, and actuators, so these do not need additional information here. However, plugin objects have additional ways to interact with the simulation, and the plugins themselves need description, which is here.

### 1.45.1 Python Plugin

For EnergyPlus, a Python Plugin is a user-defined Python class that overrides a premade `EnergyPlusPlugin` base class. This base class creates overrideable functions that, when overridden, determine when the user-defined code will be called by EnergyPlus. The functions are structured in this way to allow a single class to define multiple plugins. In this way, data can be shared between multiple calling points on the same class instance by using regular Python class members.

The `EnergyPlusPlugin` base class is defined in a ‘plugin.py’ file inside the ‘pyenergyplus’ folder, which is located in the root EnergyPlus install directory. When EnergyPlus starts up, if any plugins are to be run, it starts up a Python instance and adds the executable directory to the current Python search path. In this way, a user plugin should always `from pyenergyplus.plugin import EnergyPlusPlugin`. This will ensure that when EnergyPlus processes this Python file, it always finds this imported base class. The user will then create a derived class that inherits this base class, and write custom functions.

A minimal plugin does not actually have to interact with EnergyPlus. It is expected that essentially every plugin will at least read data from sensors or meters, or write data using actuators, but it is not necessary. Just like when calling EnergyPlus as a library, when operating in plugin mode, this data is accessed through the same API methods. To learn how to interact with the simulation API, see the API usage section: 1.4. Consider this minimal plugin:

```
from pyenergyplus.plugin import EnergyPlusPlugin

class DummyPlugin(EnergyPlusPlugin):
    def on_end_of_zone_timestep_before_zone_reporting(self, state):
        return 0
```

---

This skeleton captures the use of a plugin to do nothing, but still shows some important features.

1. The base class plugin is properly imported.
2. A user-defined class is created which inherits the `EnergyPlusPlugin` base class.
3. A method is overridden, which is named appropriately to describe when EnergyPlus will be calling this function, in this case, at the end of each zone time step but before zone-level data is reported.
4. The custom method returns zero to indicate success.

**NOTE!** The functional form of the plugin methods changed due to an API change between versions 9.3 and 9.4. Any plugin files created using 9.3 will need to add a second argument to the methods. This same argument will need to be passed into any EnergyPlus API methods called during the plugin. Much more information can be found in the API usage section: 1.4.

Several notes can be taken from this list. The name of the function matters, as it determines when the function will be called. The full list of possible names are:

- `on_begin_new_environment`
- `on_after_new_environment_warmup_is_complete`
- `on_begin_zone_timestep_before_init_heat_balance`
- `on_begin_zone_timestep_after_init_heat_balance`
- `on_begin_timestep_before_predictor`
- `on_after_predictor_before_hvac_managers`
- `on_after_predictor_after_hvac_managers`

- `on_inside_hvac_system_iteration_loop`
- `on_end_of_zone_timestep_before_zone_reporting`
- `on_end_of_zone_timestep_after_zone_reporting`
- `on_end_of_system_timestep_before_hvac_reporting`
- `on_end_of_system_timestep_after_hvac_reporting`
- `on_end_of_zone_sizing`
- `on_end_of_system_sizing`
- `on_end_of_component_input_read_in`
- `on_user_defined_component_model`
- `on_unitary_system_sizing`

The meaning of these names can be found in the EMSApplicationGuide which comes with the EnergyPlus install.

It is possible future versions of the program will expose additional calling points. Note: a single class can override multiple functions, so that the same class instance is called at multiple points in a simulation.

Once this plugin is created, it can be placed in a number of locations on the filesystem, as described in the PythonPlugin:SearchPaths section 1.45.2. The plugin instance, along with any other plugin related objects are declared in the input file, and then EnergyPlus is executed. More data is provided in each of the specific object sections below.

## 1.45.2 PythonPlugin:SearchPaths

Once EnergyPlus initiates a Python process, it will need to know where to search for user-defined plugin script files. A Python search path is managed that contains a list of possible folders where Python will search when encountering an import statement. The folder containing the currently running EnergyPlus process will be added no matter what, as this directory contains the plugin and API code, but additional folders can be specified to meet specific needs. These options are described in the inputs of the object.

### 1.45.2.1 Inputs

#### 1.45.2.1.1 Field: Name

An identifier given to this object. The object is required to be unique, so this field is only used for reporting purposes.

#### 1.45.2.1.2 Field: Add Current Working Directory to Search Path

Based on different workflows, EnergyPlus may be executed in directories far away from where the actual binary is stored. In these cases, it may be useful to put plugin files in the current working directory, even if the simulation input file is not located there. Turning this field to Yes will add the current working directory to the list of search paths.

#### 1.45.2.1.3 Field: Add Input File Directory to Search Path

In a lot of cases, it is expected that the plugin will be tied closely to a specific input file. In these cases, it may be useful to keep plugin files right next to the input file, regardless of the current working directory. Turning this field to Yes will add the directory where the input file is located to the list of search paths.

#### 1.45.2.1.4 Field: Search Path N

There are also some cases, where a user may keep a specific library of plugin scripts that work with a variety of input files. In this case, they may want to just point EnergyPlus to a custom directory away from any specific input file or working directory. Declaring a path in these fields will add those paths to the list of search paths. Note: This does not check the filesystem for path existence.

### 1.45.3 PythonPlugin:Instance

This object captures a single plugin instance for EnergyPlus. As previously described, a single plugin may be called at multiple calling points if there are multiple functions overridden. A single instance is analogous to a single user-defined class that inherits the EnergyPlusPlugin base class.

#### 1.45.3.1 Inputs

##### 1.45.3.1.1 Field: Name

This field represents an identifier for this plugin within EnergyPlus. In most cases, this field is just used for reporting, but for user-defined-components, this name is used as the name of the EMS program manager. Note that if this instance is used for that application, the plugin must override the `on_user_defined_component_model` function.

##### 1.45.3.1.2 Field: Run During Warmup Days

This field specifies whether EnergyPlus should execute this plugin during warmup days. In most applications, this should not be enabled, both for runtime savings, and because warmups are just used to initialize the simulation state.

##### 1.45.3.1.3 Field: Python Module Name

This is the name of the Python plugin file name – except – no file extension. For `pluginA.py`, just use `pluginA`. This file should be found in one of the folders in the plugin search path, which the user can customize using the PythonPlugin:SearchPaths object.

##### 1.45.3.1.4 Field: Plugin Class Name

This is the name of the user-defined class inside the plugin file. This class must inherit the EnergyPlusPlugin base class, or the simulation will issue an error and abort.

### 1.45.4 Global and Trend Variable API Methods

Plugins have two areas of data storage/bookkeeping that are not available on the regular EnergyPlus API: Global variables and Trend variables

**Global Variables** Global variables, in this context, reflect variables which are given space in EnergyPlus, and can be accessed in read/write fashion by all running plugin instances at any time. Global variables can then be further used as the basis for creating custom output variables and trend variables. Global variables are declared in the input file, then accessed by name in the plugin script. An example usage is provided below in the global variable section.

**Trend Variables** Trend variables are used to track the history of a previously declared plugin global variable. By first declaring a plugin global variable, and then assigning that value in plugins, this trend mechanism will keep history. The actual number of history terms is declared in the input file, and the trend variables are accessed by name in the plugin script. Example usage is provided below in the trend variable section.

### 1.45.5 PythonPlugin:Variables

This object defines the “global” variables described elsewhere in this section. The term global is carried along as it is the convention used in traditional EMS applications. There are a few reasons why users may need to use global variables:

- If a variable value is to be read/write between multiple plugins in different files.
- If a client wants to create a custom output variable, these are based on, and reference, existing global variables.
- If a client wants to create a trend variable, these are based on, and reference, existing global variables.

To use a global variable, an input object must be defined in the current input file, which specifies the variable name. Then, in a plugin, a handle can be looked up for this global variable using the `get_global_handle` function, which accepts the current state and the variable name as arguments. With the handle, the current value of the global variable can be looked up using the `get_global_value` function, which takes the current state and the handle for the variable as arguments. Finally, to update the value of the global variable, the `set_global_value` function is used, which takes the current state, the variable handle and a new value.

Assuming a global variable is defined on input called “OutdoorTemperature”, an example of this inside a plugin function follows:

```
global_var_handle = self.api.exchange.get_global_handle(state, 'OutdoorTemperature')
var_value = self.api.exchange.get_global_value(state, global_var_handle)
self.api.exchange.set_global_value(state, global_var_handle, 3.141)
```

#### 1.45.5.1 Inputs

The inputs required to declare a global variable consist of the unique PythonPlugin:GlobalVariable object, along with a series of names to identify each variable.

##### 1.45.5.1.1 Field: Name

This field is the name of this variables object, however since this is required to be a unique object, it does not do much. It is purely used for reporting of errors.

##### 1.45.5.1.2 Field Variable Name N

This field is used to declare and identify a plugin variable inside EnergyPlus. This name is used as the identifier when accessing this value to read/write in user-defined plugins.

### 1.45.6 PythonPlugin:TrendVariable

Trend variables allow a predeclared global variable to be tracked over time steps in the simulation. Once these are declared, a number of useful worker functions can be employed to process and read data from the trend. Note that trend variables are initially declared with values of zero at each history place, so the first few calls into the simulation could result in unexpected values of the trend.

To use a trend variable, an input object must be defined in the current input file, which specifies the attributes of the trend, including a name and a number of history terms to keep. Then, in a plugin, a handle can be looked up for this trend variable using the `get_trend_handle` function, which accepts the trend variable name as the only argument. With the handle, a number of aspects can be processed/looked up:

- The trend value at a specific point in history can be retrieved using the `get_trend_value` function, which accepts the current state, a trend handle and an index specifying how far back in history to evaluate the lookup.
- The average trend value over a specific range can be retrieved using the `get_trend_average` function, which accepts the current state, a trend handle and a count of how far back in history to evaluate.
- The minimum trend value over a specific range can be retrieved using the `get_trend_min` function, which accepts the current state, a trend handle and a count of how far back in history to evaluate.
- The maximum trend value over a specific range can be retrieved using the `get_trend_max` function, which accepts the current state, a trend handle and a count of how far back in history to evaluate.
- The sum of a trend value over a specific range can be retrieved using the `get_trend_sum` function, which accepts the current state, a trend handle and a count of how far back in history to evaluate.
- The trajectory of a trend (slope of a linear regression line) over a specific range can be calculated using the `get_trend_direction` function, which accepts the current state, a trend handle and a count of how far back in history to evaluate.

Assuming a global variable is defined on input called “CustomTemperature”, and a trend variable is declared called “TrendVar” with at least 5 history terms saved, an example usage of this inside a plugin function follows:

```
# update the variable throughout the simulation
global_var_handle = self.api.exchange.get_global_handle(state, 'CustomTemperature')
self.api.exchange.set_global_value(state, global_var_handle, 3.141)

# get trend values as needed
trend_var_handle = self.api.exchange.get_trend_handle(state, 'TrendVar')
trend_avg = self.api.exchange.get_trend_average(state, trend_var_handle, 5)
trend_min = self.api.exchange.get_trend_min(state, trend_var_handle, 5)
trend_max = self.api.exchange.get_trend_max(state, trend_var_handle, 5)
trend_sum = self.api.exchange.get_trend_sum(state, trend_var_handle, 5)
trend_dir = self.api.exchange.get_trend_direction(state, trend_var_handle, 5)
```

### 1.45.6.1 Inputs

#### 1.45.6.1.1 Field: Name

This field is the name of the trend object, and is used both for reporting purposes, as well as to identify this trend inside of plugin code.

#### 1.45.6.1.2 Field: Name of a Python Plugin Variable

This field should include the name of a plugin variable that is declared in the `PythonPlugin:Variables` object. A trend variable is simply a wrapper around an existing variable object, which must be read/written by plugins, so first declare the variable, then add a trend to it as needed by referencing the name here.

#### 1.45.6.1.3 Field: Number of Timesteps to be Logged

This field specifies the number of history terms to keep for this trend. Trend variables are stored for this number of zone time steps. If a plugin attempts to access a trend parameter at greater than this number, an error will occur.

### 1.45.7 Packaging Details

Implementing these plugins required structural additions to the package and to the build process. From a user perspective, the only thing that will be noticed likely is the additional size of the installer. At the very onset of this project, it was decided that we would package Python into the installer, and not require a user to install an external version. This has been successful, however, at the cost of a larger install footprint. The EnergyPlus install now includes a Python binary shared library, any dependent libraries, along with the core Python standard library of code. This allows users to create user-defined plugins that access all of the standard Python library capabilities.

The main question received about this is about installing non-standard Python packages. While we have not polished up the instructions on the process, some advice can be given. However, note that if you break your Python install, either system or EnergyPlus version, in the process, you could end up with a very, very, very broken system. So do not do this if you do not understand the consequences and have a solid understanding of Python package management. Also, once you start down this process of using anything non-standard, the development team will no longer be able to help you debug any plugin problems.

Some possibilities for using external libraries include:

- If the external package you are wanting is pure Python code, then you can download and extract it right into a local directory, add it to the SearchPaths object, and the Python process set up by EnergyPlus should be able to find it.
- For native code libraries, if you are able to install a Python version on your system with an identical version to the one that is packaged up with your install of EnergyPlus, you may be able to leverage that separate module directory. Use Pip or whatever package management tool you choose to install the package. This will install it in that version. Then you can try to point EnergyPlus to that directory, or copy those files from one package into the EnergyPlus package.

It is hoped that future versions of this will include a package management tool with EnergyPlus itself, so that installing native packages is straightforward.

## 1.46 Group ExternalInterface

The `ExternalInterface` allows coupling EnergyPlus to the Building Controls Virtual Test Bed (BCVTB). It supports the import of Functional Mock-up Units (FMUs) for co-simulation as well as the export of EnergyPlus as a FMU for co-simulation. BCVTB is a software environment that allows expert users to couple different simulation programs for distributed simulation or for a real-time simulation that is connected to a building control system. For example, the BCVTB allows simulation of the building envelope and HVAC system in EnergyPlus and the control logic in MATLAB/Simulink, while exchanging data between the two programs as they simulate. The BCVTB can be downloaded from <http://simulationresearch.lbl.gov/bcvtb>. A FMU is a component which implements the Functional Mock-up Interface (FMI) standard (<http://www.modelisar.com>).

### 1.46.1 ExternalInterface

This object activates the external interface of EnergyPlus. If the object `ExternalInterface` is present, then the external interface objects listed below will receive their values from the BCVTB interface or from FMUs at each zone time step. If this object is not present, then the values of these objects will be fixed at the value declared in the initial value field of the corresponding object, and a warning will be written to the EnergyPlus error file.

### 1.46.1.1 Inputs

#### 1.46.1.1.1 Field: Name

The name of the external interface. The only valid entries are **PtolemyServer**, **FunctionalMockupUnitImport**, and **FunctionalMockupUnitExport**.

An example IDF object is:

---

```
ExternalInterface,          !- Object to activate the external interface
  PtolemyServer;           !- Name of external interface
```

---

## 1.46.2 Building Controls Virtual Test Bed (BCVTB)

The following objects are designed to couple EnergyPlus with the BCVTB.

### 1.46.3 ExternalInterface:Schedule

This input object is similar to **Schedule:Compact**. However, during the time stepping, its value is set to the value received from the external interface. During the warm-up period and the system sizing, its value is set to the value specified by the field initial value.

#### 1.46.3.1 Inputs

##### 1.46.3.1.1 Field: Name

This field should contain a unique (within all DaySchedules) designation for this schedule. It is referenced by WeekSchedules to define the appropriate schedule values.

##### 1.46.3.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the current field values.

##### 1.46.3.1.3 Field: Initial Value

This field contains the schedule value that is used during the warm-up period and during the system sizing.

! Cooling schedule. This schedule is set directly by the external interface.

! During warm-up and system-sizing, it is fixed at 24 degC.

---

```
ExternalInterface:Schedule,
  TSetCoo,          !- Name
  Temperature,      !- ScheduleType
  24;               !- Initial value, used during warm-up
```

---

! Heating schedule. This schedule is set directly by the external interface.

! During warm-up and system-sizing, it is fixed at 20 degC.

---

```
ExternalInterface:Schedule,
  TSetHea,          !- Name
  Temperature,      !- ScheduleType
  20;               !- Initial value, used during warm-up
```

---

#### 1.46.4 ExternalInterface:Actuator

This object maps a value received from the external interface to an actuator of the Energy Management System. The object is similar to **EnergyManagementSystem:Actuator**. However, during the time stepping, its value is set to the value received from the external interface. During the warm-up period and the system sizing, its value is set to the value specified by the field initial value.

### 1.46.4.1 Inputs

#### 1.46.4.1.1 Field: Name

This field contains a unique name for the actuator. No spaces are allowed in the object name. This name will be a global read-only variable in Erl programs and cannot duplicate any other global scope Erl variable.

#### 1.46.4.1.2 Field: Actuated Component Unique Name

This field defines a unique name for the specific entity that is to be controlled. The names for each individual component are listed in the EDD output file when Verbose mode is used see the input object **Output:EnergyManagementSystem** for more on the EDD file. These will often be user-defined names of input objects or system nodes, but some actuators are automatically setup by the program and will not be completely user-defined.

#### 1.46.4.1.3 Field: Actuated Component Type

The field defines the type of the entity that is to be controlled by the actuator. The component types available vary with the specifics of individual models. The types of components that can be used as actuators in a specific model are listed in the EDD output file see the input object **Output:EnergyManagementSystem** for more on the EDD file. Components can be object types defined elsewhere in the IDD but there are other types of entities such as nodes and system-level actuators that do not directly correspond to IDF objects.

#### 1.46.4.1.4 Field: Actuated Component Control Type

This field defines the type of control to be done on the specific entity being controlled. The control types available are listed in the EDD output. Specific components may have more than one type of control available, such as flow rate or temperature, and this field is used to distinguish between them.

#### 1.46.4.1.5 Field: Initial Value

This field contains the initial value. If a value is specified, then this value is used during the warm-up period and the system sizing. If no value is specified, then the actuated component will only be updated once the time stepping starts, i.e., after the warm-up and the system-sizing. This allows, for example, to schedule a setpoint with a **Schedule:Compact** during warm-up and system-sizing, and then overwrite the value of this schedule during each zone time step based on a feedback control loop that is implemented in the BCVTB.

[illegible]

### 1.46.5 ExternalInterface:Variable

This input object is similar to **EnergyManagementSystem:GlobalVariable**. However, during the time stepping, its value is set to the value received from the external interface. During the warm-up period and the system sizing, its value is set to the value specified by the field initial value. This object can be used to move data into Erl subroutines.

#### 1.46.5.1 Inputs

##### 1.46.5.1.1 Field: Name

This field becomes the global Erl variable name that can be referenced in the EnergyPlus Runtime Language. No spaces are allowed in the object name. The name must be unique across all global scope variables including those declared as sensor and actuators and the built-in variables.

##### 1.46.5.1.2 Field: Initial Value

This field contains the initial value that is used during the warm-up period and during the system sizing.

```
ExternalInterface:Variable,
  yShade,                                !- Name of Erl variable
  1;                                     !- Initial value
```

---

### 1.46.6 Functional Mock-up Unit (FMU) Import

The following objects are designed to couple EnergyPlus with FMUs for co-simulation.

### 1.46.7 ExternalInterface:FunctionalMockupUnitImport

This object defines the FMU that will be linked to EnergyPlus.

#### 1.46.7.1 Inputs

##### 1.46.7.1.1 Field: FMU File Name

This field contains the name of the FMU file including the extension. The field should include a full path with file name, for best results. The field must be  $\leq 100$  characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

##### 1.46.7.1.2 Field: FMU Timeout

This field contains the communication timeout value in milli-seconds to allow interprocess communication to take place.

##### 1.46.7.1.3 Field: FMU LoggingOn

This field contains the loggingOn value to enable or disable debug in FMU. If loggingOn = 1, debug logging is enabled. If loggingOn = 0, debug logging is disabled.

```

ExternalInterface:FunctionalMockupUnitImport,
  MoistAir.fmu,           !- FMU File Name
  15,                    !- FMU Timeout
  0;                      !- FMU LoggingOn

```

## 1.46.8 ExternalInterface:FunctionalMockupUnitImport:From:Variable

This input object maps the names of the output variables of EnergyPlus to the input variables of the FMU.

### 1.46.8.1 Inputs

#### 1.46.8.1.1 Field: EnergyPlus Key Value

This input object maps the names of the EnergyPlus output variables (**Output:Variable** or **EnergyManagementSystem:OutputVariable**) to the input variables of the FMU.

#### 1.46.8.1.2 Field: EnergyPlus Variable Name

This field contains the output variable name as defined in the InputOutput Reference. For an **EnergyManagementSystem:OutputVariable**, the EnergyPlus Variable Name is the name of the **EnergyManagementSystem:OutputVariable**'s object.

#### 1.46.8.1.3 Field: FMU File Name

This field contains the name of the FMU file including the extension. The field should include a full path with file name, for best results. The field must be  $\leq 100$  characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

#### 1.46.8.1.4 Field: FMU Instance Name

This field contains the EnergyPlus instance name of the FMU. See External Interface Application guide for more details.

#### 1.46.8.1.5 Field: FMU Variable Name

This field contains the name of the variable in the FMU that will be mapped to the corresponding variable in EnergyPlus.

```

ExternalInterface:FunctionalMockupUnitImport:From:Variable,
  Environment,           !- EnergyPlus Key Value
  Site Outdoor Air Drybulb Temperature, !- EnergyPlus Variable Name
  MoistAir.fmu,          !- FMU File Name
  Model1,                !- FMU Instance Name
  TDryBul;               !- FMU Variable Name

```

```

ExternalInterface:FunctionalMockupUnitImport:From:Variable,
  ZONE ONE,              !- EnergyPlus Key Value
  Zone Mean Air Temperature, !- EnergyPlus Variable Name
  MoistAir.fmu,          !- FMU File Name
  Model1,                !- FMU Instance Name
  TRooMea;               !- FMU Variable Name

```

```

ExternalInterface:FunctionalMockupUnitImport:From:Variable,
  Environment,           !- EnergyPlus Key Value

```

```

Site Outdoor Air Relative Humidity,    !- EnergyPlus Variable Name
MoistAir.fmu,                          !- FMU File Name
Model1,                               !- FMU Instance Name
outRelHum;                             !- FMU Variable Name

ExternalInterface:FunctionalMockupUnitImport:From:Variable,
ZONE ONE,                             !- EnergyPlus Key Value
Zone Air Relative Humidity,    !- EnergyPlus Variable Name
MoistAir.fmu,                  !-FMU File Name
Model1,                       !- FMU Instance Name
rooRelHum;                     !- FMU Variable Name

```

---

### 1.46.9 ExternalInterface:FunctionalMockupUnitImport:To:Schedule

This input object is similar to **Schedule:Compact**. However, during the time stepping, its value is set to the value received from the external interface. During the system sizing, its value is set to the value specified by the field initial value.

#### 1.46.9.1 Inputs

##### 1.46.9.1.1 Field: EnergyPlus Variable Name

This field contains a unique (within all Schedules) designation for this schedule in EnergyPlus.

##### 1.46.9.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the current field values.

##### 1.46.9.1.3 Field: FMU File Name

This field contains the name of the FMU file including the extension. The field should include a full path with file name, for best results. The field must be  $\leq 100$  characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

##### 1.46.9.1.4 Field: FMU Instance Name

This field contains the EnergyPlus instance name of the FMU. See External Interface Application guide for more details.

##### 1.46.9.1.5 Field: FMU Variable Name

This field contains the name of the variable in the FMU that will be mapped to the schedule in EnergyPlus.

##### 1.46.9.1.6 Field: Initial Value

This field contains the schedule value that is used during the system sizing.

```

ExternalInterface:FunctionalMockupUnitImport:To:Schedule,
FMU_OthEquSen_ZoneOne,    !- EnergyPlus Variable Name
Any Number,               !- Schedule Type Limits Names
MoistAir.fmu,             !- FMU File Name
Model1,                   !- FMU Instance Name

```

```

QoSensible,                                !- FMU Variable Name
0;                                           !- Initial Value

ExternalInterface:FunctionalMockupUnitImport:To:Schedule,
FMU_OthEquLat_ZoneOne,    !- EnergyPlus Variable Name
Any Number,              !- Schedule Type Limits Names
MoistAir.fmu,            !- FMU File Name
Model1,                  !- FMU Instance Name
QLatent,                 !- FMU Variable Name
0;                       !- Initial Value

```

---

### 1.46.10 ExternalInterface:FunctionalMockupUnitImport:To:Actuator

This object maps a value received from the external interface to an actuator of the Energy Management System. The object is similar to **EnergyManagementSystem:Actuator**. However, during the warm-up and time stepping, its value is set to the value received from the external interface. During the system sizing, its value is set to the value specified by the field initial value.

#### 1.46.10.1 Inputs

##### 1.46.10.1.1 Field: EnergyPlus Variable Name

This field contains a unique name for the actuator. No spaces are allowed in the object name. This name will be a global read-only variable in Erl programs and cannot duplicate any other global scope Erl variable.

##### 1.46.10.1.2 Field: Actuated Component Unique Name

This field defines a unique name for the specific entity that is to be controlled. The names for each individual component are listed in the EDD output file when Verbose mode is used see the input object **Output:EnergyManagementSystem** for more on the EDD file. These will often be user-defined names of input objects or system nodes, but some actuators are automatically setup by the program and will not be completely user-defined.

##### 1.46.10.1.3 Field: Actuated Component Type

The field defines the type of the entity that is to be controlled by the actuator. The component types available vary with the specifics of individual models. The types of components that can be used as actuators in a specific model are listed in the EDD output file see the input object **Output:EnergyManagementSystem** for more on the EDD file. Components can be object types defined elsewhere in the IDD but there are other types of entities such as nodes and system-level actuators that do not directly correspond to IDF objects.

##### 1.46.10.1.4 Field: Actuated Component Control Type

This field defines the type of control to be done on the specific entity being controlled. The control types available are listed in the EDD output. Specific components may have more than one type of control available, such as flow rate or temperature, and this field is used to distinguish between them.

##### 1.46.10.1.5 Field: FMU File Name

This field contains the name of the FMU file including the extension. The field should include a full path with file name, for best results. The field must be  $\leq 100$  characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution

of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

#### 1.46.10.1.6 Field: FMU Instance Name

This field contains the EnergyPlus instance name of the FMU. See External Interface Application guide for more details.

#### 1.46.10.1.7 Field: FMU Variable Name

This field contains the name of the variable in the FMU that will be mapped to the actuator in EnergyPlus.

#### 1.46.10.1.8 Field: Initial Value

This field contains the value that is used during the system sizing.

```
ExternalInterface:FunctionalMockupUnitImport:To:Actuator,
  Zn001_Wall001_Win001_Shading_Deploy_Status,    !- EnergyPlus Variable Name
  Zn001:Wall001:Win001,                          !- Actuated Component Unique Name
  Window Shading Control,                        !- Actuated Component Type
  Control Status,                                !- Actuated Component Control Type
  ShadingController.fmu,                         !- FMU File Name
  Model1,                                        !- FMU Instance Name
  yShade,                                        !- FMU Variable Name
  6;                                              !- Initial Value
```

### 1.46.11 ExternalInterface:FunctionalMockupUnitImport:To:Variable

This input object is similar to [EnergyManagementSystem:GlobalVariable](#). However, during the warm-up and time stepping, its value is set to the value received from the external interface. During the system sizing its value is set to the value specified by the field initial value. This object can be used to move data into Erl subroutines.

#### 1.46.11.1 Inputs

##### 1.46.11.1.1 Field: EnergyPlus Variable Name

This field becomes the global Erl variable name that can be referenced in the EnergyPlus Runtime Language. No spaces are allowed in the object name. The name must be unique across all global scope variables including those declared as sensor and actuators and the built-in variables.

##### 1.46.11.1.2 Field: FMU File Name

This field contains the name of the FMU file including the extension. The field should include a full path with file name, for best results. The field must be  $\leq 100$  characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

##### 1.46.11.1.3 Field: FMU Instance Name

This field contains the EnergyPlus instance name of the FMU. See External Interface Application guide for more details.

#### 1.46.11.1.4 Field: FMU Variable Name

This field contains the name of the variable in the FMU that will be mapped to the corresponding variable in EnergyPlus.

#### 1.46.11.1.5 Field: Initial Value

This field contains the initial value that is used during the system sizing.

```
ExternalInterface:FunctionalMockupUnitImport:To:Variable,
  Shade_Signal,                !- EnergyPlus Variable Name
  ShadingController.fmu,       !- FMU File Name
  Model1,                      !- FMU Instance Name
  yShade,                      !- FMU Variable Name
  1;                           !- Initial Value
```

---

### 1.46.12 Functional Mock-up Unit (FMU) Export

The following objects are designed to support the export of EnergyPlus as a FMU for co-simulation.

#### 1.46.13 ExternalInterface:FunctionalMockupUnitExport:From:Variable

This object exposes the EnergyPlus output variables (**Output:Variable** or **EnergyManagementSystem:OutputVariable**) to the outside simulation program.

##### 1.46.13.1 Inputs

##### 1.46.13.1.1 Field: EnergyPlus Key Value

This field contains a Key Value for an EnergyPlus output variable (ref **Output:Variable**/.rdd file). For an **EnergyManagementSystem:OutputVariable**, the EnergyPlus Key Value needs to be set to **EMS**.

##### 1.46.13.1.2 Field: EnergyPlus Variable Name

This field contains the Variable Name as defined in the InputOutput Reference. For an **EnergyManagementSystem:OutputVariable**, the EnergyPlus Variable Name is the name of the **EnergyManagementSystem:OutputVariable**'s object.

##### 1.46.13.1.3 Field: FMU Variable Name

This field contains the name of the variable in the model description file of the FMU that will be mapped to the corresponding variable in EnergyPlus.

```
ExternalInterface:FunctionalMockupUnitExport:From:Variable,
  Environment,                !- EnergyPlus Key Value
  Site Outdoor Air Drybulb Temperature, !- EnergyPlus Variable Name
  TDryBul;                    !- FMU Variable Name

ExternalInterface:FunctionalMockupUnitExport:From:Variable,
  ZONE ONE,                   !- EnergyPlus Key Value
  Zone Mean Air Temperature, !- EnergyPlus Variable Name
  TRooMea;                    !- FMU Variable Name

ExternalInterface:FunctionalMockupUnitExport:From:Variable,
  Environment,                !- EnergyPlus Key Value
  Site Outdoor Air Relative Humidity, !- EnergyPlus Variable Name
  outRelHum;                  !- FMU Variable Name

ExternalInterface:FunctionalMockupUnitExport:From:Variable,
```

---

```

ZONE ONE,                                     !- EnergyPlus Key Value
Zone Air Relative Humidity,    !- EnergyPlus Variable Name
rooRelHum;                       !- FMU Variable Name

```

---

### 1.46.14 ExternalInterface:FunctionalMockupUnitExport:To:Schedule

This object is similar to [Schedule:Compact](#). However, during the time stepping, its value is set to the value received from the external interface. During the warm-up period and the system sizing, its value is set to the value specified by the field initial value.

#### 1.46.14.1 Inputs

##### 1.46.14.1.1 Field: EnergyPlus Variable Name

This field contains a unique (within all Schedules) designation for this schedule in EnergyPlus.

##### 1.46.14.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the current field values.

##### 1.46.14.1.3 Field: FMU Variable Name

This field contains the name of the variable in the model description file of the FMU that will be mapped to the schedule in EnergyPlus.

##### 1.46.14.1.4 Field: Initial Value

This field contains the schedule value that is used during the warm-up period and during the system sizing.

---

```

ExternalInterface:FunctionalMockupUnitExport:To:Schedule,
  FMU_OthEquSen_ZoneOne,    !- EnergyPlus Variable Name
  Any Number,               !- Schedule Type Limits Names
  QSensible,                !- FMU Variable Name
  0;                        !- Initial Value

```

---

### 1.46.15 ExternalInterface:FunctionalMockupUnitExport:To:Actuator

This object maps a value received from the external interface to an actuator of the Energy Management System. The object is similar to [EnergyManagementSystem:Actuator](#). However, during the time stepping, its value is set to the value received from the external interface. During the warm-up period and the system sizing, its value is set to the value specified by the field initial value.

#### 1.46.15.1 Inputs

##### 1.46.15.1.1 Field: EnergyPlus Variable Name

This field contains a unique name for the actuator. No spaces are allowed in the object name. This name will be a global read-only variable in Erl programs and cannot duplicate any other global scope Erl variable.

### 1.46.15.1.2 Field: Actuated Component Unique Name

This field defines a unique name for the specific entity that is to be controlled. The names for each individual component are listed in the EDD output file when Verbose mode is used see the input object **Output:EnergyManagementSystem** for more on the EDD file. These will often be user-defined names of input objects or system nodes, but some actuators are automatically setup by the program and will not be completely user-defined.

### 1.46.15.1.3 Field: Actuated Component Type

The field defines the type of the entity that is to be controlled by the actuator. The component types available vary with the specifics of individual models. The types of components that can be used as actuators in a specific model are listed in the EDD output file see the input object **Output:EnergyManagementSystem** for more on the EDD file. Components can be object types defined elsewhere in the IDD but there are other types of entities such as nodes and system-level actuators that do not directly correspond to IDF objects.

### 1.46.15.1.4 Field: Actuated Component Control Type

This field defines the type of control to be done on the specific entity being controlled. The control types available are listed in the EDD output. Specific components may have more than one type of control available, such as flow rate or temperature, and this field is used to distinguish between them.

### 1.46.15.1.5 Field: FMU Variable Name

This field contains the name of the variable in the model description file of the FMU that will be mapped to the actuator in EnergyPlus.

### 1.46.15.1.6 Field: Initial Value

This field contains the initial value. If a value is specified, then this value is used during the warm-up period and the system sizing. If no value is specified, then the actuated component will only be updated once the time stepping starts, i.e., after the warm-up and the system-sizing.

```
ExternalInterface:FunctionalMockupUnitExport:To:Actuator,
  Zn001_Wall001_Win001_Shading_Deploy_Status,    !- EnergyPlus Variable Name
  Zn001:Wall001:Win001,                          !- Actuated Component Unique Name
  Window Shading Control,                        !- Actuated Component Type
  Control Status,                               !- Actuated Component Control Type
  yShade,                                       !- FMU Variable Name
  6;                                           !- Initial Value
```

## 1.46.16 ExternalInterface:FunctionalMockupUnitExport:To:Variable

This input object is similar to **EnergyManagementSystem:GlobalVariable**. However, during the time stepping, its value is set to the value received from the external interface. During the warm-up period and the system sizing, its value is set to the value specified by the field initial value. This object can be used to move data into Erl subroutines.

### 1.46.16.1 Inputs

#### 1.46.16.1.1 Field: EnergyPlus Variable Name

This field becomes the global Erl variable name that can be referenced in the EnergyPlus Runtime Language. No spaces are allowed in the object name. The name must be unique across all global scope variables including those declared as sensor and actuators and the built-in variables.

#### 1.46.16.1.2 Field: FMU Variable Name

This field contains the name of the variable in the model description file of the FMU that will be mapped to the corresponding variable in EnergyPlus.

#### 1.46.16.1.3 Field: Initial Value

This field contains the initial value that is used during the warm-up period and during the system sizing.

```
ExternalInterface:FunctionalMockupUnitExport:To:Variable,
  Shade_Signal,          !- EnergyPlus Variable Name
  yShade,                !- FMU Variable Name
  1;                     !- Initial Value
```

---

## 1.47 Group User Defined HVAC and Plant Component Models

This group of EnergyPlus input objects provides methods for users to include their own custom models for HVAC and plant components as well as plant equipment operation. This is helpful because not every conceivable type of HVAC equipment or system configuration has already had models implemented in EnergyPlus. HVAC or plant components, or even entire system configurations, might be so new, unusual, or proprietary that no model has yet been implemented in the software. An analyst faced with project that needs to model such a device or system could do so using one or more of the user defined components described in this section.

Some building energy performance rating systems allow analysts to option of using exceptional calculation methods when a simulation program cannot perform the function required to be modeled. These user defined component models are intended to provide a means for including such exceptional calculations within the context of a full EnergyPlus model. This allows using EnergyPlus for everything it can model and extending it yourself to include a new type of HVAC or Plant component.

These objects are advanced. Making good use of them requires the user to have a detailed understanding of EnergyPlus HVAC and Plant models as well as the Energy Management System (EMS). The EnergyPlus Runtime Language (Erl) is used to program the component model. The Application Guide for EMS provides more discussion of how to use the objects in this group see the chapter called User-Defined Component Models.

### 1.47.1 ZoneHVAC:ForcedAir:UserDefined

This object is used to define a generic zone air unit for custom component models. This object has a primary air connection that connects to a zone through exhaust and inlet nodes. There is an optional secondary air connection that can be used as an air-based source or heat rejection connection. As many has three different plant connections can be made to the zone unit. Water storage tanks can be connected for supply or collection. An ambient zone can be connected for skin losses to be treated as separate internal gains.

#### 1.47.1.1 Inputs

##### 1.47.1.1.1 Field: Name

This field defines a unique user-assigned name for an instance of a custom, forced-air zone conditioning unit. Any reference to this zone unit by another object will use this name.

**1.47.1.1.2 Field: Overall Model Simulation Program Calling Manager Name**

This field specifies the Erl programs that are used to model the custom zone unit. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere. The program manager referenced here should include all the Erl programs that are to be run each time the component is simulated and use the calling point called **UserDefinedComponentModel**.

**1.47.1.1.3 Field: Model Setup and Sizing Program Calling Manager Name**

This field specifies the Erl programs that are used to initialize and size the custom zone unit. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere and uses the calling point called **UserDefinedComponentModel**. The program manager referenced here should include all the Erl programs that are needed to do any initial setup that should occur before the main modeling programs are run. These include calculating and setting values for things that do not vary over time such as component sizes, control parameters, modeling constants etc. The user defined component will trigger this calling manager at the beginning of each new environment period.

**1.47.1.1.4 Field: Primary Air Inlet Node Name**

This field defines the name of the HVAC system node from which the zone unit draws its inlet air from the zone. This node must be the name of a zone air exhaust node (ref. **ZoneHVAC:EquipmentConnection**). This field is required.

**1.47.1.1.5 Field: Primary Air Outlet Node Name**

This field defines the name of the HVAC system node to which the zone unit sends its outlet air to the zone. This node must be the name of a zone air inlet node (ref. **ZoneHVAC:EquipmentConnection**). This field is required.

**1.47.1.1.6 Field: Secondary Air Inlet Node Name**

This field defines the name of a HVAC system node from which the zone unit can draw additional air. This air inlet stream has a variety of possible uses including outdoor air supply for ventilation or a condenser inlet for heat rejection. This field is optional.

**1.47.1.1.7 Field: Secondary Air Outlet Node Name**

This field defines the name of a HVAC system node to which the zone unit can send additional air. This air outlet stream has a variety of possible uses including outdoor air relief for exhaust or a condenser outlet for heat rejection. This field is optional.

**1.47.1.1.8 Field: Number of Plant Loop Connections**

This field defines the number of different plant loop connections that the zone unit will use. Up to three separate loops can be connected if desired. This field is required. Enter a 0 if the unit does not use plant at all.

**1.47.1.1.9 Field: Plant Connection 1 Inlet Node Name**

This field defines the name of a plant system node from which the zone unit can draw fluid. This is the inlet to the component model from the first plant loop that is connected to the zone unit.

**1.47.1.1.10 Field: Plant Connection 1 Outlet Node Name**

This field defines the name of a plant system node to which the zone unit can send fluid. This is the outlet from the component model to the first plant loop that is connected to the zone unit.

**1.47.1.1.11 Field: Plant Connection 2 Inlet Node Name**

This field defines the name of a plant system node from which the zone unit can draw fluid. This is the inlet to the component model from the second plant loop that is connected to the zone unit.

**1.47.1.1.12 Field: Plant Connection 2 Outlet Node Name**

This field defines the name of a plant system node to which the zone unit can send fluid. This is the outlet from the component model to the second plant loop that is connected to the zone unit.

**1.47.1.1.13 Field: Plant Connection 3 Inlet Node Name**

This field defines the name of a plant system node from which the zone unit can draw fluid. This is the inlet to the component model from the third plant loop that is connected to the zone unit.

**1.47.1.1.14 Field: Plant Connection 3 Outlet Node Name**

This field defines the name of a plant system node to which the zone unit can send fluid. This is the outlet from the component model to the third plant loop that is connected to the zone unit.

**1.47.1.1.15 Field: Supply Inlet Water Storage Tank Name**

This field is used to describe where the zone unit obtains water if it is to be connected to a water storage tank. This water could be used for evaporative cooling. If a name of a **WaterUse:Storage** object is used here, then the unit can obtain its water from that tank. This field is optional.

**1.47.1.1.16 Field: Collection Outlet Water Storage Tank Name**

This field is used to describe where the zone unit sends water it has collected if it is to be stored in a tank. This water could be collected from coil condensate. If a name of a **WaterUse:Storage** object is used here, then the unit can send water to that tank. This field is optional.

**1.47.1.1.17 Field: Ambient Zone Name**

This field is used to connect ancillary losses from the zone unit to a thermal zone. The unit may have inefficiencies, leaks, or other non-ideal operation that results in some untended impact on the space surrounding the unit. These skin losses can be assigned to a thermal zone and appear as internal gains for the zone named here. This does not need to be the same thermal zone as the zone that unit is intended to condition.

An example of this input object follows.

```
ZoneHVAC:ForcedAir:UserDefined,
Zone1WindAC,      !- Name
Zone 1 Window AC Model Program Manager , !- Overall Model Simulation Program Calling Manager Name
Zone 1 Window AC Init Program Manager , !- Model Setup and Sizing Program Calling Manager Name
Zone1WindACAirInletNode , !- Primary Air Inlet Node Name
Zone1WindACAirOutletNode, !- Primary Air Outlet Node Name
Zone1WindACOAInNode,    !- Secondary Air Inlet Node Name
Zone1WindACExhNode,     !- Secondary Air Outlet Node Name
0 ; !- Number of Plant Loop Connections
```

**1.47.2 AirTerminal:SingleDuct:UserDefined**

This object is used to define a generic single duct air terminal unit for custom component models. This object has a primary air connection that connects a multi-zone air handler to a zone. There is an optional secondary air connection that can be used and an air-based source or heat rejection connection. As many as two different plant connections can be made to the air terminal unit. Water storage tanks can be

connected for supply or collection. An ambient zone can be connected for skin losses to be treated as separate internal gains.

#### 1.47.2.1 Field: Name

This field defines a unique user-assigned name for an instance of a custom, air terminal unit. Any reference to this air terminal by another object will use this name.

#### 1.47.2.2 Field: Overall Model Simulation Program Calling Manager Name

This field specifies the Erl programs that are used to model the custom air terminal unit. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere. The program manager referenced here should include all the Erl programs that are to be run each time the component is simulated and use the calling point called `UserDefinedComponentModel`.

#### 1.47.2.3 Field: Model Setup and Sizing Program Calling Manager Name

This field specifies the Erl programs that are used to initialize and size the custom air terminal unit. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere and uses the calling point called `UserDefinedComponentModel`. The program manager referenced here should include all the Erl programs that are needed to do any initial setup that should occur before the main modeling programs are run. These include calculating and setting values for things that do not vary over time such as component sizes, control parameters, modeling constants etc. The user defined component will trigger this calling manager at the beginning of each new environment period.

#### 1.47.2.4 Field: Primary Air Inlet Node Name

This field defines the name of the HVAC system node from which the air terminal unit draws its inlet air. This node must be the name of a HVAC system node that is listed in a zone splitter (ref. **AirLoopHVAC:ZoneSplitter**). This field is required.

#### 1.47.2.5 Field: Primary Air Outlet Node Name

This field defines the name of the HVAC system node to which the air terminal unit sends its outlet air to the zone. This node must be the name of a zone air inlet node (ref. **ZoneHVAC:EquipmentConnection**). This field is required.

#### 1.47.2.6 Field: Secondary Air Inlet Node Name

This field defines the name of a HVAC system node from which the air terminal unit can draw additional air. This air inlet stream has a variety of possible uses including outdoor air supply for ventilation or a condenser inlet for heat rejection. This field is optional.

#### 1.47.2.7 Field: Secondary Air Outlet Node Name

This field defines the name of a HVAC system node to which the air terminal unit can send additional air. This air outlet stream has a variety of possible uses including outdoor air relief for exhaust or a condenser outlet for heat rejection. This field is optional.

### 1.47.2.8 Field: Number of Plant Loop Connections

This field defines the number of different plant loop connections that the air terminal unit will use. Up to two separate loop can be connected if desired. This field is required. Enter a 0 if the unit does not use plant at all.

### 1.47.2.9 Field: Plant Connection 1 Inlet Node Name

This field defines the name of a plant system node from which the air terminal unit can draw fluid. This is the inlet to the component model from the first plant loop that is connected to the air terminal unit.

### 1.47.2.10 Field: Plant Connection 1 Outlet Node Name

This field defines the name of a plant system node to which the air terminal unit can send fluid. This is the outlet from the component model to the first plant loop that is connected to the air terminal unit.

### 1.47.2.11 Field: Plant Connection 2 Inlet Node Name

This field defines the name of a plant system node from which the air terminal unit can draw fluid. This is the inlet to the component model from the second plant loop that is connected to the air terminal unit.

### 1.47.2.12 Field: Plant Connection 2 Outlet Node Name

This field defines the name of a plant system node to which the air terminal unit can send fluid. This is the outlet from the component model to the second plant loop that is connected to the air terminal unit.

### 1.47.2.13 Field: Supply Inlet Water Storage Tank Name

This field is used to describe where the air terminal unit obtains water if it is to be connected to a water storage tank. This water could be used for evaporative cooling. If a name of a **WaterUse:Storage** object is used here, then the unit can obtain its water from that tank. This field is optional.

### 1.47.2.14 Field: Collection Outlet Water Storage Tank Name

This field is used to describe where the air terminal unit sends water it has collected if it is to be stored in a tank. This water could be collected from coil condensate. If a name of a **WaterUse:Storage** object is used here, then the unit can send water to that tank. This field is optional.

### 1.47.2.15 Field: Ambient Zone Name

This field is used to connect ancillary losses from the air terminal unit to a thermal zone. The unit may have inefficiencies, leaks, or other non-ideal operation that results in some unintended impact on the space surrounding the unit. These skin losses can be assigned to a thermal zone and appear as internal gains for the zone named here. This does not need to be the same thermal zone as the zone that terminal unit is intended to condition.

An example of this input object follows.

```
AirTerminal:SingleDuct:UserDefined,
  SPACE1-1 VAV Reheat,    !- Name
  Space1 ATU Sim Programs , !- Overall Model Simulation Program Calling Manager Name
  Space1 ATU Init Programs , !- Model Setup and Sizing Program Calling Manager Name
  SPACE1-1 ATU In Node , !- Primary Air Inlet Node Name
  SPACE1-1 In Node , !- Primary Air Outlet Node Name
```

```
,    !- Secondary Air Inlet Node Name
,    !- Secondary Air Outlet Node Name
1,    !- Number of Plant Loop Connections
SPACE1-1 Zone Coil Water In Node , !- Plant Connection 1 Inlet Node Name
SPACE1-1 Zone Coil Water Out Node; !- Plant Connection 1 Outlet Node Name
```

---

### 1.47.3 Coil:UserDefined

This object is used to define a generic coil for custom component modeling of a device that processes air as part of an air handler. The Coil:UserDefined object appears directly on a **Branch** object used to define the supply side of an air handler, or in the **AirLoopHVAC:OutdoorAirSystem:EquipmentList** object used to define outdoor air systems. This object has one or two air connections and an optional plant connection. Water storage tanks can be connected for supply or collection. An ambient zone can be connected for skin losses to be treated as separate internal gains.

#### 1.47.3.1 Field: Name

This field defines a unique user-assigned name for an instance of a custom air coil. Any reference to this coil by another object will use this name.

#### 1.47.3.2 Field: Overall Model Simulation Program Calling Manager Name

This field specifies the Erl programs that are used to model the custom coil. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere. The program manager referenced here should include all the Erl programs that are to be run each time the component is simulated and use the calling point called UserDefinedComponentModel.

#### 1.47.3.3 Field: Model Setup and Sizing Program Calling Manager Name

This field specifies the Erl programs that are used to initialize and size the custom coil. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere and uses the calling point called UserDefinedComponentModel. The program manager referenced here should include all the Erl programs that are needed to do any initial setup that should occur before the main modeling programs are run. These include calculating and setting values for things that do not vary over time such as component sizes, control parameters, modeling constants etc. The user defined component will trigger this calling manager at the beginning of each new environment period.

#### 1.47.3.4 Field: Number of Air Connections

This field defines the number of air loop connections that the coil will use. The coil must have at least one connection but a second can be used by entering a 2.

#### 1.47.3.5 Field: Air Connection 1 Inlet Node Name

This field defines the name of the HVAC system node from which the coil draws its inlet air for its first air loop connection. This node must be the outlet of the HVAC system component located upstream, if there is one. This field is required.

#### 1.47.3.6 Field: Air Connection 1 Outlet Node Name

This field defines the name of the HVAC system node to which the coil sends its outlet air for its first air loop connection. This node must be the inlet of the HVAC system component located downstream, if there is one. This field is required.

#### 1.47.3.7 Field: Air Connection 2 Inlet Node Name

This field defines the name of the HVAC system node from which the coil draws its inlet air for its second air loop connection. This node must be the outlet of the HVAC system component located upstream, if there is one. This field is optional.

#### 1.47.3.8 Field: Air Connection 2 Outlet Node Name

This field defines the name of the HVAC system node to which the coil sends its outlet air for its second air loop connection. This node must be the inlet of the HVAC system component located downstream, if there is one. This field is optional.

#### 1.47.3.9 Field: Plant Connection is Used

This field defines whether or not the plant loop connection is going to be used. Enter a Yes if the coil will use plant, enter No if not. This field is required.

#### 1.47.3.10 Field: Plant Connection Inlet Node Name

This field defines the name of a plant system node from which the coil can draw fluid. This is the inlet to the component model from the plant loop that is connected to the coil.

#### 1.47.3.11 Field: Plant Connection Outlet Node Name

This field defines the name of a plant system node to which the coil can send fluid. This is the outlet from the component model to the plant loop that is connected to the coil.

#### 1.47.3.12 Field: Supply Inlet Water Storage Tank Name

This field is used to describe where the coil obtains water if it is to be connected to a water storage tank. This water could be used for evaporative cooling. If a name of a **WaterUse:Storage** object is used here, then the unit can obtain its water from that tank. This field is optional.

#### 1.47.3.13 Field: Collection Outlet Water Storage Tank Name

This field is used to describe where the coil sends water it has collected if it is to be stored in a tank. This water could be collected from coil condensate. If a name of a **WaterUse:Storage** object is used here, then the unit can send water to that tank. This field is optional.

#### 1.47.3.14 Field: Ambient Zone Name

This field is used to connect ancillary losses from the coil to a thermal zone. The coil may have inefficiencies, leaks, or other non-ideal operation that results in some unintended impact on the space surrounding the unit. These skin losses can be assigned to a thermal zone and appear as internal gains for the zone named here. For example, this would be the mechanical room where the coil is located, not necessarily one of the zone served by the air handler.

An example of this input object follows.

```
Coil:UserDefined,
  Main Cooling Coil 1, !- Name
  Main Cooling Coil Model Program Manager , !- Overall Model Simulation Program Calling Manager Name
  Main Cooling Coil Init Program Manager , !- Model Setup and Sizing Program Calling Manager Name
  1 , !- Number of Air Connections
  Mixed Air Node 1 , !- Air Connection 1 Inlet Node Name
  Main Cooling Coil 1 Outlet Node , !- Air Connection 1 Outlet Node Name
  , !- Air Connection 2 Inlet Node Name
  , !- Air Connection 2 Outlet Node Name
  Yes , !- Plant Connection is Used
  Main Cooling Coil 1 Water Inlet Node, !- Plant Connection Inlet Node Name
  Main Cooling Coil 1 Water Outlet Node; !- Plant Connection Outlet Node Name
```

Note that the Coil:UserDefined needs to be specifically configured in **EnergyManagementSystem:MeteredOutputVariable**, in order to be included in the meters such as HeatingCoils:EnergyTransfer.

An example of this input object follows.

```
EnergyManagementSystem:Program,
  MainHWCoil1_ModelOutput, !- Name
  Set HWcoil1_Water_MdotRequest = Water_MdotRequest, !- Program Line 1
  Set HWcoil1_Air_Tout          = Air_Tout, !- Program Line 2
  Set HWcoil1_Air_Wout          = Air_Wout, !- <none>
  Set HWcoil1_tot_heat_Power    = Tot_heat_Power, !- <none>
  Set HWcoil1_tot_heat_Energy   = Tot_heat_Power * SystemTimestep * 3600, !- <none>
  Set HWcoil1_Air_MdotOut       = Air_Mdot, !- <none>
  Set HWcoil1_Water_Tout        = Water_Tout; !- <none>

EnergyManagementSystem:MeteredOutputVariable,
  HWcoil1_tot_heat_Energy, !- Name
  HWcoil1_tot_heat_Energy, !- EMS Variable Name
  SystemTimestep, !- Update Frequency
  MainHWCoil1_ModelOutput, !- EMS Program or Subroutine Name
  ENERGYTRANSFER, !- Resource Type
  System, !- Group Type
  HEATINGCOILS, !- End-Use Category
  , !- End-Use Subcategory
  J; !- Units
```

## 1.47.4 PlantComponent:UserDefined

This object is used to define a generic plant component for custom component models. This object can connect to up to four different plant loops. There is an optional air connection that can be used as an air-based source or heat rejection connection. Water storage tanks can be connected for supply or collection. An ambient zone can be connected for skin losses to be treated as separate internal gains.

The PlantComponent:UserDefined object appears directly on the **Branch** object used to describe the plant.

### 1.47.4.1 Inputs

#### 1.47.4.1.1 Field: Name

This field defines a unique user-assigned name for an instance of a custom plant component. Any reference to this component by another object will use this name.

#### 1.47.4.1.2 Field: Main Model Program Calling Manager Name

This field specifies the Erl programs that are used to model the plant component any time that the device is called to simulate. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere. The program manager referenced here should

include all the Erl programs that are to be run each time the component is simulated and use the calling point called `UserDefinedComponentModel`.

#### 1.47.4.1.3 Field: Number of Plant Loop Connections

This field defines the number of different plant loop connections that the component will use. Up to four separate loops can be connected if desired. This field is required.

#### 1.47.4.1.4 Field Set: (inlet node name, outlet node name, loading mode, flow request mode, initialization program calling manager, simulation program calling manager)

Each of the plant loop connections used is defined by a set of 6 input fields that contain an inlet node, and outlet node, a loading mode, a flow request mode, a program calling manager for setup and sizing, and a program calling manager for model calculations that should run when this loop is being simulated.

#### 1.47.4.1.5 Field: Plant Connection <#> Inlet Node Name

This field defines the name of a plant system node from which the component can draw fluid. This is the inlet to the component model from the x plant loop that is connected to the component.

#### 1.47.4.1.6 Field: Plant Connection <#> Outlet Node Name

This field defines the name of a plant system node to which the component can send fluid. This is the outlet from the component model to the first plant loop that is connected to the component.

#### 1.47.4.1.7 Field: Plant Connection <#> Loading Mode

This field defines the nature of the plant component with respect to how it affects the loads experienced by the <#> plant loop connection. One of the following choices must be selected depending on the purpose of the component model and this particular plant loop connection.

- **DemandsLoad.** This type of loading is used for plant connections that place a load on the loop.
- **MeetsLoadWithPassiveCapacity.** This type of loading is used for plant connections where the component has some capacity to meet loads but it is not really of the type that could be actively controlled.
- **MeetsLoadWithNominalCapacity.** This type of loading is used for plant connections where the component has controllable capacity to meet loads and no outlet temperature restrictions.
- **MeetsLoadWithNominalCapacityLowOutLimit.** This type of loading is used for plant connections where the component has controllable capacity to meet loads but with a lower limit on the fluid temperature at the outlet node.
- **MeetsLoadWithNominalCapacityHiOutLimit.** This type of loading is used for plant connections where the component has controllable capacity to meet loads but with an upper limit on the fluid temperature at the outlet node.

#### 1.47.4.1.8 Field: Plant Connection <#> Loop Flow Request Mode

This field defines the nature of the plant component with respect to how it affects the overall flow rate for the loop. One of the following three choices must be made depending on the nature of the plant component and this particular loop connection.

- **NeedsFlowIfLoopOn.** Devices with this flow request mode will contribute to the overall loop flow rate but will not initiate flow themselves.

- **NeedsFlowAndTurnsLoopOn.** Devices with this flow request mode will contribute to the overall loop flow rate and initiate flow.
- **ReceivesWhateverFlowAvailable.** Devices with this flow request mode will not contribute to the overall loop flow rate and do not initiate flow themselves.

#### 1.47.4.1.9 Field: Plant Connection <#> Initialization Program Calling Manager Name

This field specifies the Erl programs that are used to initialize and size the plant component with regard to this particular plant connection. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere and uses the calling point called **UserDefinedComponentModel**. The program manager referenced here should include all the Erl programs that are needed to do any initial setup that should occur before the main modeling programs are run. These include calculating and setting values for things that do not vary over time such as component sizes, control parameters, modeling constants etc. The user defined component will trigger this calling manager during the initial setup routines for plant systems.

#### 1.47.4.1.10 Field: Plant Connection <#> Simulation Program Calling Manager Name

This field specifies the Erl programs that are used to model the plant component and should execute when the component is called to simulate by this particular loop connection. This field should contain the name of an **EnergyManagementSystem:ProgramCallingManager** that is defined elsewhere. The program manager referenced here should include all the Erl programs that are to be run for this plant loop connection and use the calling point called **UserDefinedComponentModel**.

#### 1.47.4.1.11 Field: Air Connection Inlet Node Name

This field defines the name of the HVAC system node from which the plant component draws its inlet air for its air loop connection. This field is optional.

#### 1.47.4.1.12 Field: Air Connection Outlet Node Name

This field defines the name of the HVAC system node to which the plant component sends its outlet air for its air loop connection. This field is optional.

#### 1.47.4.1.13 Field: Supply Inlet Water Storage Tank Name

This field is used to describe where the plant component obtains water if it is to be connected to a water storage tank. This water could be used for evaporative cooling. If a name of a **WaterUse:Storage** object is used here, then the component can obtain its water from that tank. This field is optional.

#### 1.47.4.1.14 Field: Collection Outlet Water Storage Tank Name

This field is used to describe where the plant component sends water it has collected if it is to be stored in a tank. This water could be collected from coil condensate. If a name of a **WaterUse:Storage** object is used here, then the unit can send water to that tank. This field is optional.

#### 1.47.4.1.15 Field: Ambient Zone Name

This field is used to connect ancillary losses from the plant component to a thermal zone. The component may have inefficiencies, leaks, or other non-ideal operation that results in some untended impact on the space surrounding the device. These skin losses can be assigned to a thermal zone and appear as internal gains for the zone named here. For example, this would be the mechanical room where the plant component is located.

An example of this input object follows:

```
PlantComponent:UserDefined,
  Central Chiller,      !- Name
  , !- Main Model Program Calling Manager Name
  1 , !- Number of Plant Loop Connections
  Central Chiller Inlet Node,      !- Plant Connection 1 Inlet Node Name
  Central Chiller Outlet Node , !- Plant Connection 1 Outlet Node Name
  MeetsLoadWithNominalCapacityLowOutLimit, !- Plant Connection 1 Loading Mode
  NeedsFlowIfLoopOn , !- Plant Connection 1 Loop Flow Request Mode
  Chiller model init programs, !- Plant Connection 1 Initialization Program Calling Manager Name
  Chiller model simulation programs ,!- Plant Connection 1 Simulation Program Calling Manager Name
  , !- Plant Connection 2 Inlet Node Name
  , !- Plant Connection 2 Outlet Node Name
  , !- Plant Connection 2 Loading Mode
  , !- Plant Connection 2 Loop Flow Request Mode

  , !- Plant Connection 4 Simulation Program Calling Manager Name
  Central Chiller Condenser Inlet Node, !- Air Connection Inlet Node Name
  Central Chiller Condenser Outlet Node, !- Air Connection Outlet Node Name
  , !- Supply Inlet Water Storage Tank Name
  , !- Collection Outlet Water Storage Tank Name
  ; !- Ambient Zone Name
```

### 1.47.5 PlantEquipmentOperation:UserDefined

This object is used to define a generic plant equipment operation scheme. The PlantEquipment-Operation:UserDefined object appears directly in either a [PlantEquipmentOperationSchemes](#) or a [CondenserEquipmentOperationSchemes](#) object. The user can configure exactly how supply side equipment is dispatched to meet loads by writing EnergyPlus Runtime Language programs and using the EMS features. There are no output variables specifically associated with this object but the outcome of load distribution actuators can be examined using the output variable called Plant Component Distributed Demand Rate.

#### 1.47.5.1 Inputs

##### 1.47.5.1.1 Field: Name

This field specifies the unique user-assigned name of the custom operation scheme.

##### 1.47.5.1.2 Field: Main Model Program Calling Manager Name

This field specifies the Erl programs that are used to model the custom plant operation scheme. The field should contain the name of an [EnergyManagementSystem:ProgramCallingManager](#) that is defined elsewhere. The program manager referenced here should include all the Erl programs that are to be run each time the operation scheme is simulated and use the calling point called UserDefinedComponentModel.

### 1.47.5.1.3 Field: Initialization Program Calling Manager Name

This field specifies the Erl programs that are used to initialize and do an one-time setup needed for the custom operation scheme. This field should contain the name of an `EnergyManagementSystem:ProgramCallingManager` that is defined elsewhere and uses the calling point called `UserDefinedComponentModel`. The program manager referenced here should include all the Erl programs that are needed to do any initial setup that should occur before the main programs are run. These include calculating and setting values for things that do not vary over time such as component capacities, control range parameters, various constants etc. The user defined operation scheme will trigger this calling manager at the beginning of each new environment period.

### 1.47.5.1.4 Field Set: (Equipment Object Type, Equipment Name)

Up to ten pairs of fields can be used to define the equipment governed by this custom operation scheme.

### 1.47.5.1.5 Field: Equipment <#> Object Type

This field specifies the type of equipment, or object name, for each machine to be controlled by the scheme.

### 1.47.5.1.6 Field: Equipment <#> Name

This field specifies the user selected name of the equipment to be controlled by the scheme.

The following example shows control of a chilled water plant with two chillers that have different sizes and load dispatch is scaled so that each chiller runs at the same part load ratio.

```
PlantEquipmentOperation:UserDefined,
CoolSys1 Operation Scheme,  !- Name
Cooling_dispatch ,  !- Main Model Program Calling Manager Name

## 1.48 Group System Availability Managers

System Availability Managers are one of the high-level control constructs in EnergyPlus. A System Availability Manager is able to access data from any of the HVAC system nodes and use this data to make a decision on whether an entire **AirLoopHVAC** or **PlantLoop** should be on or off. Some of the zone component objects (e.g. unit heater, unit ventilator, packaged terminal air conditioner, packaged terminal heat pump, zone water source heat pump, window air conditioner, zone terminal unit (variable refrigerant flow), energy recovery ventilator, outdoor air unit, fan coil unit, and ventilated slab) can also individually use availability managers to make a decision regarding whether their fan should be on or off.

System Availability Managers are executed at the start of each HVAC timestep. They reside outside the HVAC system iteration loops. Thus, the System Availability Managers are executed once per HVAC timestep, and they use previous timestep information (except for zone load) to calculate their set points.

Some of the managers monitor the temperature at an air or plant node to determine whether the system should be on or off. If the system is to be controlled on the outdoor dry-bulb temperature, an **OutdoorAir:NodeList** object can be used to define a node which will have the current outdoor air conditions.

The output from each System Availability Manager is an availability status flag. This flag can have the values *NoAction*, *ForceOff*, *CycleOn*, or *CycleOnZoneFansOnly*. The availability status flags for the System Availability Managers referenced by an air or plant loop are used to set the availability status flag for each loop. For the air loops and zone components, *ForceOff* takes precedence: if any of the loop's (or zone component's) availability managers are showing status *ForceOff*, the loop (or zone component fan) status will be *ForceOff*. Next in precedence is *CycleOnZoneFansOnly* (only for air loop), followed by *CycleOn*, and *NoAction*. For the plant loops, there is no precedence among the System Availability Manager status flag values. Instead, the first availability manager giving a status flag value other than *NoAction* sets the status for the loop. The System Availability Managers are executed in **AvailabilityManagerAssignmentList** order.

The actual action of turning on or off a loop is taken by the loop prime movers: fans for **AirLoopHVACs** and zone components, and pumps for plant loops. For instance when a fan is deciding whether it is on or off, it checks its on/off schedule and whether the loop availability status flag is *CycleOn* or *ForceOff*. If the schedule is on and the status flag is *ForceOff*, the fan will be off. If the fan schedule says off and the status flag is *CycleOn*, the fan will be on. Thus the availability managers overrule the fan on/off schedule. The availability managers, air loops, and plant loops all have output variables which may be used to verify the action of the loop.

Availability managers for **AirLoopHVAC** systems also control the availability of zone exhaust fans (Ref. **Fan:ZoneExhaust**) and terminal unit fans (Ref. **AirTerminal:SingleDuct:SeriesPIU:Reheat**, **AirTerminal:SingleDuct:ParallelPIU:Reheat**, and **AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan**) in the zones served by the **AirLoopHVAC** system.

### 1.48.1 AvailabilityManager:Scheduled

The simplest System Availability Manager is when the availability is determined by an on/off schedule. The syntax for implementing such an availability manager is shown below. The identifying name refers back to the name recorded in the [AvailabilityManagerAssignmentList](#) statement described in the **Group Air Distribution** section. The schedule must be the name of a schedule defined elsewhere in the input.

#### 1.48.1.1 Inputs

##### 1.48.1.1.1 Field: Name

The unique, user-assigned name of an instance of a scheduled availability manager. Other objects that use this scheduled availability manager will reference it by this name.

##### 1.48.1.1.2 Field: Schedule Name

The name of a schedule defined elsewhere in the input. Schedule values greater than zero (usually 1 is used) indicate that the system is on. Schedule values less than or equal to zero (usually 0 is used) denote that the system is off. This schedule overrides the central fan schedule for determining whether the fan is on.

An example of this statement in an IDF is:

```
AvailabilityManager:Scheduled,
  VAV Sys 1 Avail, !- Name
  FanAvailSched;    !- Schedule Name
```

AvailabilityManager:Scheduled Outputs

The scheduled availability manager has one output variable.

- HVAC,Average,Availability Manager Scheduled Control Status

##### 1.48.1.1.3 Availability Manager Scheduled Control Status

A value of 1 indicates the manager is signaling *ForceOff*. A value of 2 means the manager is signaling *CycleOn*.

### 1.48.2 AvailabilityManager:ScheduledOn

The Schedule On Availability Manager is used when equipment must be turned on during a given time period. This availability manager will not turn the equipment off, a separate availability manager must be used to disable the equipment as necessary. The scheduled on availability is determined by an on schedule. Schedule values other than 0 set a *CycleOn* availability status. Schedule values equal to 0 set a *NoAction* availability status. The syntax for implementing such an availability manager is shown below. The identifying name refers back to the name recorded in the [AvailabilityManagerAssignmentList](#) statement described in the **Group Air Distribution** section. The schedule must be the name of a schedule defined elsewhere in the input.

#### 1.48.2.1 Inputs

##### 1.48.2.1.1 Field: Name

The unique, user-assigned name of an instance of a scheduled on availability manager. Other objects that use this scheduled on availability manager will reference it by this name.

### 1.48.2.1.2 Field: Schedule Name

The name of a schedule defined elsewhere in the input. Schedule values greater than zero (usually 1 is used) indicate that the system is on. Schedule values less than or equal to zero (usually 0 is used) denote that *NoAction* is desired. This schedule overrides the central fan schedule for determining whether the fan is on.

An example of this statement in an IDF is:

```
AvailabilityManager:ScheduledOn,
VAV Sys 1 Avail On,      !- Name
FanAvailSched;           !- Schedule Name
```

---

## 1.48.2.2 Outputs

The scheduled on availability manager has one output variable.

- HVAC,Average,Availability Manager Scheduled On Control Status

### 1.48.2.2.1 Availability Manager Scheduled On Control Status []

A value of 0 indicates the manager is signaling *NoAction*. A value of 2 means the manager is signaling *CycleOn*.

## 1.48.3 AvailabilityManager:ScheduledOff

The Schedule Off Availability Manager is used when equipment must be turned off during a given time period. This availability manager will not turn the equipment on, a separate availability manager must be used to enable the equipment as necessary. The scheduled off availability is determined by an off schedule. Schedule values equal to 0 set a *ForceOff* availability status. Schedule values other than 0 (usually a 1 is used) set a *NoAction* availability status. The syntax for implementing such an availability manager is shown below. The identifying name refers back to the name recorded in the [AvailabilityManagerAssignmentList](#) statement described in the **Group Air Distribution** section. The schedule must be the name of a schedule defined elsewhere in the input.

### 1.48.3.1 Inputs

#### 1.48.3.1.1 Field: Name

The unique, user-assigned name of an instance of a scheduled off availability manager. Other objects that use this scheduled off availability manager will reference it by this name.

#### 1.48.3.1.2 Field: Schedule Name

The name of a schedule defined elsewhere in the input. Schedule values equal to zero indicate that the system is off. Schedule values other than (usually 0 is used) denote that *NoAction* is desired.

An example of this statement in an IDF is:

```
AvailabilityManager:ScheduledOff,
VAV Sys 1 Avail Off,      !- Name
FanAvailSched;           !- Schedule Name
```

---

## 1.48.3.2 Outputs

The scheduled off availability manager has one output variable.

- HVAC,Average,Availability Manager Scheduled Off Control Status

### 1.48.3.2.1 Availability Manager Scheduled Off Control Status []

A value of 0 indicates the manager is signaling *NoAction*. A value of 1 means the manager is signaling *ForceOff*.

## 1.48.4 AvailabilityManager:NightCycle

This manager is used for cycling on an air system when one or more zones become too hot or too cold. The usual situation is that the central air handler is turned off at night. However if the building gets too cold there might be condensation on the walls and other damage. Thus the control system is usually programmed to turn the system on if 1 control thermostat or any thermostat shows a zone temperature of less than a night time set point. Similarly there might be a concern about a building getting too hot. Again the control system is programmed to turn the air handler back on if one or any zone temperature exceeds a night time cooling set point.

This object gives the user considerable flexibility in determining how the night time on/off decision will be made. The manager can look at the temperature in 1 zone or it can sample all the zones connected to the air handler. The user can specify a temperature tolerance and a run time for the system once it switches on. There is also an applicability schedule the user can schedule whether or not this availability manager itself is being applied.

### 1.48.4.1 Inputs

#### 1.48.4.1.1 Field: Name

A unique, user-assigned name for an instance of a night cycle availability manager. Other objects that use this availability manager will reference it by this name.

#### 1.48.4.1.2 Field: Applicability Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time period this availability manager is to be applied. Schedule values greater than zero (usually 1 is used) indicate the availability manager is to be applied. Schedule values less than or equal to zero (usually 0 is used) denote that the availability manager is not used for this time period.

#### 1.48.4.1.3 Field: Fan Schedule Name

The name of the central fan on/off schedule for the air system that this availability manager will affect.

#### 1.48.4.1.4 Field: Control Type

The possible inputs are *StayOff*, *CycleOnAny*, *CycleOnControlZone*, *CycleOnAnyZoneFansOnly*, *CycleOnAnyCoolingOrHeatingZone*, *CycleOnAnyCoolingZone*, *CycleOnAnyHeatingZone*, or *CycleOnAny-HeatingZoneFansOnly*. The default is *StayOff*.

- *StayOff* means the availability manager will have no effect air handler on/off will be determined by the fan schedule.
- *CycleOnAny* means that if any zone served by a system whose **AvailabilityManagerAssignmentList** references this system availability manager has an air temperature outside the cooling or heating set points the central fan will turn on even though the fan schedule indicates the fan is off.
- *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in any one or more zones specified in the Control Zone or Zone List Name field.
- *CycleOnAnyZoneFansOnly* is the same as *CycleOnAny* except that only the zone fans are cycled on and the central air handler fan is left off.

- *CycleOnAnyCoolingOrHeatingZone* means that the central fan will turn on if any zone listed in the Cooling Control Zone or Zone List Name is outside the cooling setpoint or any zone listed in the Heating Control Zone or Zone List Name is outside the heating setpoint. If the central fan is activated, then the zone fans are enabled. If the central fan is not activated, but any zone in the Heating Zone Fans Only Zone or Zone List Name is outside the heating setpoint, then the zone fans only will be enabled.
- *CycleOnAnyCoolingZone* means that the central fan will turn on if any zone listed in the Cooling Control Zone or Zone List Name is outside the cooling setpoint. If the central fan is activated, then the zone fans are enabled.
- *CycleOnAnyHeatingZone* means that the central fan will turn on if any zone listed in the Heating Control Zone or Zone List Name is outside the heating setpoint. If the central fan is activated, then the zone fans are enabled. If the central fan is not activated, but any zone in the Heating Zone Fans Only Zone or Zone List Name is outside the heating setpoint, then the zone fans only will be enabled.
- *CycleOnAnyHeatingZoneFansOnly* means that the zone fans will be enabled if any zone listed in the Heating Zone Fans Only Zone or Zone List Name is outside the heating setpoint. The central fan is never activated with this control type.

#### 1.48.4.1.5 Field: Thermostat Tolerance

The Thermostat Tolerance defines the amount by which the zone temperature must fall outside the current zone heating and cooling setpoints for the Night Cycle manager to turn the system on. The zone temperature must exceed the cooling set point or fall below the heating set point by 1/2 the Thermostat Tolerance in order for the availability manager to signal that the system should turn on. The Thermostat Tolerance is specified in degrees Celsius. The default is 1 degree C.

#### 1.48.4.1.6 Field: Cycling Run Time Control Type

The possible inputs are: *FixedRunTime*, *Thermostat*, and *ThermostatWithMinimumRunTime*. The default cycling run time control type is *FixedRunTime*.

- *FixedRunTime* cycling run time control type the AvailabilityManager:NightCycle activates an airloop or zone equipment for a fixed amount of run time when the zone air temperature is one half of the Thermostat Tolerance above the thermostat cooling setpoint or when the zone air temperature is one half of the Thermostat Tolerance below the thermostat heating setpoint.
- *Thermostat* cycling run time control type the AvailabilityManager:NightCycle activates an airloop or zone equipment until the zone air temperature is within 0.05 deg C above the thermostat cooling setpoint in cooling mode or until the zone air temperature is within 0.05 deg C below the thermostat heating setpoint in heating mode. Cycling Run Time input field below is not used for this cycling run time control type.
- *ThermostatWithMinimumRunTime* cycling run time control type the AvailabilityManager:NightCycle activates an airloop or zone equipment for the specified minimum Cycling Run Time when the zone air temperature is within 0.05 deg C above the thermostat cooling setpoint or when the zone air temperature is within 0.05 deg C below the thermostat heating setpoint and then continues running beyond the minimum Cycling Run Time until the zone air temperature reaches the thermostat setpoint within 0.05 deg C thermostat tolerance.

#### 1.48.4.1.7 Field: Cycling Run Time

The time in seconds for which the system will run after it has cycled on. The default is 3600 seconds (1 hour).

#### 1.48.4.1.8 Field: Control Zone or Zone List Name

For the option *CycleOnControlZone* this is the name of the control zone or zone list. These zones will activate the central fan for heating or cooling.

#### 1.48.4.1.9 Field: Cooling Control Zone or Zone List Name

For the options *CycleOnAnyCoolingOrHeatingZone* and *CycleOnAnyCoolingZone* this is the name of the cooling control zone or zone list. These zones will activate the central fan for cooling.

#### 1.48.4.1.10 Field: Heating Control Zone or Zone List Name

For the options *CycleOnAnyCoolingOrHeatingZone* and *CycleOnAnyHeatingZone* this is the name of the heating control zone or zone list. These zones will activate the central fan for heating.

#### 1.48.4.1.11 Field: Heating Zone Fans Only or Zone List Name

For the options *CycleOnAnyCoolingOrHeatingZone*, *CycleOnAnyHeatingZone*, and *CycleOnAnyHeatingZoneFansOnly*, this is the name of the heating zone fans control zone or zone list. These zones will activate the zone fans for heating.

An example of this statement in an IDF is:

```
AvailabilityManager:NightCycle,
  VAV Sys 1 Avail,      !- Name
  SysAvailApplicSch,    !- Applicability Schedule Name
  FanAvailSched,        !- Fan Schedule Name
  CycleOnAny,           !- Control Type
  4.0,                  !- Temperature Tolerance {delta C}
  7200.;                !- Cycle Run Time {s}
  ,                     !- Control Zone or Zone List Name
  ,                     !- Cooling Zone or Zone List Name
  ,                     !- Heating Control Zone or Zone List Name
  ;                     !- Heating Zone Fans Only Zone or Zone List Name
```

### 1.48.4.2 Outputs

The night cycle availability manager has one output variable.

- HVAC,Average,Availability Manager Night Cycle Control Status

#### 1.48.4.2.1 Availability Manager Night Cycle Control Status

A value of 0 indicates the manager is signaling *NoAction*. A value of 2 means the manager is signaling *CycleOn*. A value of 3 says that the manager is signaling *CycleOnZoneFansOnly*.

### 1.48.5 AvailabilityManager:DifferentialThermostat

The differential thermostat compares the temperatures at two different system nodes. If the temperature difference (DT) is above the *Temperature Difference On Limit*, the system is turned on. If the DT is below the *Temperature Difference Off Limit*, the system is turned off. Between the *On Limit* and *Off Limit* the system is either on or off depending on the previous state of the thermostat. Unlike other availability managers, the differential thermostat is always either “On” or “Off”; it does not use the “No Action” state. Therefore, the differential thermostat must be the last manager in the *AvailabilityManagerAssignmentList*. Any availability managers after the differential thermostat manager will never be simulated.

One application of the differential thermostat is to ensure a useful heat gain for solar heating systems, i.e. the system is only turned on when there is a significant temperature difference between the solar collector outlet node and the storage tank outlet node.

### 1.48.5.1 Inputs

#### 1.48.5.1.1 Field: Name

The name of the object. This is referenced in the [AvailabilityManagerAssignmentList](#).

#### 1.48.5.1.2 Field: Hot Node Name

The sensor node with the higher temperature.

#### 1.48.5.1.3 Field: Cold Node Name

The sensor node with the colder temperature.

#### 1.48.5.1.4 Field: Temperature Difference On Limit

Temperature difference [deltaC] between hot and cold nodes necessary to turn the system on.

#### 1.48.5.1.5 Field: Temperature Difference Off Limit

Temperature difference [deltaC] between hot and cold nodes necessary to turn the system off. This field defaults to the *Temperature Difference On Limit*.

An example of this object in an IDF is:

```
AvailabilityManager:DifferentialThermostat,
  Differential Thermostat Availability Manager,    !- Name
  Collector Outlet Node,                          !- Hot Node Name
  Water Heater Source Outlet Node,               !- Cold Node Name
  10.0,      !- Temperature Difference On Limit {delta C}
  2.0;      !- Temperature Difference Off Limit {delta C}
```

---

### 1.48.5.2 Outputs
