**1.23.6.1.7 Field: Condenser Inlet Node Name**

This alpha field contains the identifying name for the electric chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

**1.23.6.1.8 Field: Condenser Outlet Node Name**

This alpha field contains the identifying name for the electric chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

**1.23.6.1.9 Field: Minimum Part Load Ratio**

This numeric field contains the electric chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

**1.23.6.1.10 Field: Maximum Part Load Ratio**

This numeric field contains the electric chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

**1.23.6.1.11 Field: Optimum Part Load Ratio**

This numeric field contains the electric chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

**1.23.6.1.12 Field: Design Condenser Inlet Temperature**

This numeric field contains the electric chiller's condenser inlet design temperature in Celsius.

**1.23.6.1.13 Field: Temperature Rise Coefficient**

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELv_{required} - TELv_{rated}} \quad (1.52)$$

where:

$TCEnt_{required}$  = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$  = Rated entering condenser air or water temperature at rated capacity.

$TELv_{required}$  = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELv_{rated}$  = Rated leaving evaporator water outlet temperature at rated capacity.

**1.23.6.1.14 Field: Design Chilled Water Outlet Temperature**

This numeric field contains the electric chiller's evaporator outlet design temperature in Celsius.

**1.23.6.1.15 Field: Design Chilled Water Flow Rate**

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

**1.23.6.1.16 Field: Design Condenser Fluid Flow Rate**

This numeric field contains the electric chiller's design condenser water flow rate in cubic meters per second. This field is autosizable. This field is also used to enter the air flow rate if the Condenser Type = AirCooled or EvaporativelyCooled and Heat Recovery is specified.

**1.23.6.1.17 Capacity Ratio Curve**

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2\Delta_{temp} + C_3\Delta_{temp}^2 \quad (1.53)$$

Where the Delta Temperature is defined as:

$$\Delta_{Temp} = \frac{TempCondIn - TempCondInDesign}{TempRiseCoefficient} - (TempEvapOut - TempEvapOutDesign) \quad (1.54)$$

TempCondIn = Temperature entering the condenser (water or air temperature depending on condenser type).

TempCondInDesign = Design Condenser Inlet Temperature from User input above.

TempEvapOut = Temperature leaving the evaporator.

TempEvapOutDesign = Design Chilled Water Outlet Temperature from User input above.

TempRiseCoefficient = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

**1.23.6.1.18 Field: Coefficient 1 of Capacity Ratio Curve**

This numeric field contains the first coefficient for the capacity ratio curve.

**1.23.6.1.19 Field: Coefficient 2 of Capacity Ratio Curve**

This numeric field contains the second coefficient for the capacity ratio curve.

**1.23.6.1.20 Field: Coefficient 3 of Capacity Ratio Curve**

This numeric field contains the third coefficient for the capacity ratio curve.

**1.23.6.1.21 Power Ratio Curve**

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load Power at Available Capacity to Full Load Power at Nominal Capacity. The defining equation is:

$FullLoadPowerRatio = C_1 + C_2AvailToNominalCapRatio + C_3AvailToNominalCapRatio^2$  The following three fields contain the coefficients for the quadratic equation.

**1.23.6.1.22 Field: Coefficient1 of the power ratio curve**

This numeric field contains the first coefficient for the power ratio curve.

**1.23.6.1.23 Field: Coefficient 2 of Power Ratio Curve**

This numeric field contains the second coefficient for the power ratio curve.

**1.23.6.1.24 Field: Coefficient 3 of Power Ratio Curve**

This numeric field contains the third coefficient for the power ratio curve.

**1.23.6.1.25 Full Load Ratio Curve**

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$\text{FracFullLoadPower} = C_1 + C_2 \text{PartLoadRatio} + C_3 \text{PartLoadRatio}^2 \quad (1.55)$$

The following three fields contain the coefficients for the quadratic equation.

**1.23.6.1.26 Field: Coefficient 1 of Full Load Ratio Curve**

This numeric field contains the first coefficient for the full load ratio curve.

**1.23.6.1.27 Field: Coefficient 2 of Full Load Ratio Curve**

This numeric field contains the second coefficient for the full load ratio curve.

**1.23.6.1.28 Field: Coefficient 3 of Full Load Ratio Curve**

This numeric field contains the third coefficient for the full load ratio curve.

**1.23.6.1.29 Field: Chilled Water Outlet Temperature Lower Limit**

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

**1.23.6.1.30 Field: Chiller Flow Mode**

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller – for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

**1.23.6.1.31 Field: Design Heat Recovery Water Flow Rate**

This is the design flow rate used if the heat recovery option is being simulated. If this value is greater than 0.0 then a heat recovery loop must be specified and attached to the chiller using the next 2 node fields. To determine how the heat recovery algorithm works look at the Engineering Manual at the Chiller:Electric with Heat Recovery section. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the condenser heat recovery relative capacity fraction set in the field below. Note that heat recovery is only available with Condenser Type = WaterCooled.

**1.23.6.1.32 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the electric chiller heat recovery side inlet node. A heat recovery loop must be specified.

**1.23.6.1.33 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the electric chiller heat recovery side outlet node. A heat recovery loop must be specified.

**1.23.6.1.34 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

**1.23.6.1.35 Field: Basin Heater Capacity**

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

**1.23.6.1.36 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

**1.23.6.1.37 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

**1.23.6.1.38 Field: Condenser Heat Recovery Relative Capacity Fraction**

This field is optional. It can be used to describe the physical size of the heat recovery portion of a split bundle condenser section. This fraction describes the relative capacity of the heat recovery bundle of a split condenser compared to the nominal, full load heat rejection rate of the chiller. This fraction will be applied to the full heat rejection when operating at nominal capacity and nominal COP to model a capacity limit for the heat rejection. If this field is not entered then the capacity fraction is set to 1.0.

**1.23.6.1.39 Field: Heat Recovery Inlet High Temperature Limit Schedule Name**

This field is optional. It can be used to control heat recovery operation of the chiller. The schedule named here should contain temperature values, in  $^{\circ}\text{C}$ , that describe an upper limit for the return fluid temperatures entering the chiller at the heat recovery inlet node. If the fluid temperature is too high,

then the heat recovery will not operate. This is useful to restrict the chiller lift from becoming too high and to avoid overheating the hot water loop. This limit can be used with or without the alternate control using leaving setpoint that is set in the next field.

#### 1.23.6.1.40 Field: Heat Recovery Leaving Temperature Setpoint Node Name

This field is optional. It can be used to refine the model and controls for heat recovery operation of the chiller. The node named here should have a setpoint placed on it by a setpoint manager. If the plant loop’s demand calculation scheme is set to SingleSetpoint, then a single setpoint manager should be used. If the plant loop’s demand calculation is set to DualSetpointDeadband then a dual setpoint manager should be used and the upper setpoint is used for control. When this field is used, a different model is used for determining the distribution of rejected heat between the two bundles that is more appropriate for series bundle arrangements and for chiller’s that are able to produce relatively higher temperature heated fluids.

#### 1.23.6.1.41 Field: End-Use Subcategory

This optional field allows you to specify a user-defined end-use subcategory, e.g., “Process”. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the chiller will be assigned to the “General” end-use subcategory.

An example of this statement in an IDF is:

These chiller output variables are defined above under “Generic Chiller Outputs.”

### 1.23.7 Chiller:Electric:EIR

This chiller model is the empirical model used in the DOE-2.1 building energy simulation program. The model uses performance information at reference conditions along with three curve fits for cooling capacity and efficiency to determine chiller operation at off-reference conditions. Chiller performance curves can be generated by fitting manufacturer’s catalog data or measured data. Performance curves for more than 160 chillers, including the default DOE-2.1E reciprocating and centrifugal chillers, are provided in the EnergyPlus Reference DataSets (Chillers.idf and AllDataSets.idf).

Note: Chiller:Electric:EIR objects and their associated performance curve objects are developed using performance information for a specific chiller and should normally be used together for an EnergyPlus simulation. Changing the object input values, or swapping performance curves between chillers, should be done with caution.

#### 1.23.7.1 Inputs

##### 1.23.7.1.1 Field: Name

This alpha field contains the identifying name for the electric EIR chiller.

#### 1.23.7.1.2 Field: Reference Capacity

This numeric field contains the reference cooling capacity of the chiller in Watts. This should be the capacity of the chiller at the reference temperatures and water flow rates defined below. Alternately, this field can be autosized.

#### 1.23.7.1.3 Field: Reference COP

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps or cooling tower fans. This COP should be at the reference temperatures and water flow rates defined below. This value **should** include evap-cooled or air-cooled condenser fans except when the Condenser Fan Power Ratio input field defined below is used and that input value is greater than 0. For the case when condenser fan power is modeled separately, the calculated condenser fan energy is reported on the same electric meter as compressor power. Be careful to not duplicate this energy use.

#### 1.23.7.1.4 Field: Reference Leaving Chilled Water Temperature

This numeric field contains the chiller's reference leaving chilled water temperature in Celsius. The default value is 6.67°C.

#### 1.23.7.1.5 Field: Reference Entering Condenser Fluid Temperature

This numeric field contains the chiller's reference entering condenser fluid temperature in Celsius. The default value is 29.4°C. For water-cooled chillers this is the water temperature entering the condenser (e.g., leaving the cooling tower). For air- or evap-cooled condensers this is the entering outdoor air dry-bulb or wet-bulb temperature, respectively.

#### 1.23.7.1.6 Field: Reference Chilled Water Flow Rate

For a variable flow chiller this is the maximum water flow rate and for a constant flow chiller this is the operating water flow rate through the chiller's evaporator. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

#### 1.23.7.1.7 Field: Reference Condenser Fluid Flow Rate

This numeric field contains the chiller's operating condenser fluid flow rate in cubic meters per second. This field can be autosized. This field is also used to enter the air flow rate if Condenser Type = AirCooled or EvaporativelyCooled and Heat Recovery is specified. If AirCooled or EvaporativelyCooled and this field is autosized, the air flow rate is set to 0.000114 m<sup>3</sup>/s/W (850 cfm/ton) multiplied by the chiller Reference Capacity. For air- and evaporatively-cooled condensers, this flow rate is used to set condenser outlet air node conditions and used for evaporatively-cooled condensers to calculate water use rate.

#### 1.23.7.1.8 Field: Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the cooling capacity as a function of the leaving chilled water temperature and the entering condenser fluid temperature. The output of this curve is multiplied by the reference capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

Note: The curve is evaluated at the leaving chilled water (=evaporator outlet) *setpoint* temperature, not the *actual* leaving chilled water temperature.

**1.23.7.1.9 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and the entering condenser fluid temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

**1.23.7.1.10 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the part-load ratio (EIRfTPLR). The EIR is the inverse of the COP, and the part-load ratio is the actual cooling load divided by the chiller's available cooling capacity. This curve is generated by dividing the operating electric input power by the available full-load capacity (do not divide by load) at the specific operating temperatures. The curve output should decrease from 1 towards 0 as part-load ratio decreases from 1 to 0. The output of this curve is multiplied by the reference full-load EIR (inverse of the reference COP) and the Energy Input to Cooling Output Ratio Function of Temperature Curve to give the EIR at the specific temperatures and part-load ratio at which the chiller is operating. This curve should have a value of 1.0 when the part-load ratio equals 1.0. An ideal chiller with the same efficiency at all part-load ratio's would use a performance curve that has a value of 0 when the part-load ratio equals 0 (i.e., a line connecting 0,0 and 1,1 when plotted as EIRfTPLR versus PLR), however, actual systems can have part-load EIR's slightly above or below this line (i.e., part-load efficiency often differs from rated efficiency). The quadratic curve should be valid for the range of part-load ratios anticipated for the simulation.

**1.23.7.1.11 Field: Minimum Part Load Ratio**

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. Below this part-load ratio, the compressor cycles on and off to meet the cooling load. The Minimum Part Load Ratio must be less than or equal to the Maximum Part Load Ratio. The default value is 0.1.

**1.23.7.1.12 Field: Maximum Part Load Ratio**

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.0. The Maximum Part Load Ratio must be greater than or equal to the Minimum Part Load Ratio. The default value is 1.0.

**1.23.7.1.13 Field: Optimum Part Load Ratio**

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 1.0.

**1.23.7.1.14 Field: Minimum Unloading Ratio**

This numeric field contains the chiller's minimum unloading ratio. The expected range is between 0 and 1. The minimum unloading ratio is where the chiller capacity can no longer be reduced by unloading and must be false loaded to meet smaller cooling loads. A typical false loading strategy is hot-gas bypass.

The minimum unloading ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 0.2.

#### 1.23.7.1.15 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller plant side (chilled water) inlet node.

#### 1.23.7.1.16 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller plant side (chilled water) outlet node.

#### 1.23.7.1.17 Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

#### 1.23.7.1.18 Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

#### 1.23.7.1.19 Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. Valid condenser types are AirCooled, WaterCooled, and EvaporativelyCooled with the default being WaterCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, whereas the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

#### 1.23.7.1.20 Field: Condenser Fan Power Ratio

This field is used to model condenser fan power associated with air-cooled or evaporatively-cooled condensers (for cooling towers, refer to Group - Condenser Equipment). Enter the ratio of the condenser fan power to the reference chiller cooling capacity in W/W. If this input is greater than 0, the condenser fan power is modeled separately from compressor power. In addition, if condenser fan power is modeled using this input, the reference COP and “Electric Input to Cooling Output Ratio Function of” performance curves should not include condenser fan power.

#### 1.23.7.1.21 Field: Fraction of Compressor Electric Power Rejected by Condenser

This numeric input represents the fraction of compressor electrical energy consumption that must be rejected by the condenser. Enter a value of 1.0 when modeling hermetic chillers. For open chillers, enter the compressor motor efficiency. This value must be greater than 0.0 and less than or equal to 1.0, with a default value of 1.0.

**1.23.7.1.22 Field: Leaving Chilled Water Lower Temperature Limit**

This numeric field contains the lower limit for the leaving chilled water temperature in Celsius. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold. This input field is currently unused. The default value is 2°C.

**1.23.7.1.23 Field: Chiller Flow Mode**

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller – for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

**1.23.7.1.24 Field: Design Heat Recovery Water Flow Rate**

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0 (or Autosize), a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the condenser heat recovery relative capacity fraction set in the field below. Note that heat recovery is only available with Condenser Type = WaterCooled.

**1.23.7.1.25 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the chiller heat recovery side inlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified.

**1.23.7.1.26 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the chiller heat recovery side outlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified.

**1.23.7.1.27 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

**1.23.7.1.28 Field: Basin Heater Capacity**

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the

basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **1.23.7.1.29 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

#### **1.23.7.1.30 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

#### **1.23.7.1.31 Field: Condenser Heat Recovery Relative Capacity Fraction**

This field is optional. It can be used to describe the physical size of the heat recovery portion of a split bundle condenser section. This fraction describes the relative capacity of the heat recovery bundle of a split condenser compared to the nominal, full load heat rejection rate of the chiller. This fraction will be applied to the full heat rejection when operating at nominal capacity and nominal COP to model a capacity limit for the heat rejection. If this field is not entered then the capacity fraction is set to 1.0.

#### **1.23.7.1.32 Field: Heat Recovery Inlet High Temperature Limit Schedule Name**

This field is optional. It can be used to control heat recovery operation of the chiller. The schedule named here should contain temperature values, in  $^{\circ}\text{C}$ , that describe an upper limit for the return fluid temperatures entering the chiller at the heat recovery inlet node. If the fluid temperature is too high, then the heat recovery will not operate. This is useful to restrict the chiller lift from becoming too high and to avoid overheating the hot water loop. This limit can be used with or without the alternate control using leaving setpoint that is set in the next field.

#### **1.23.7.1.33 Field: Heat Recovery Leaving Temperature Setpoint Node Name**

This field is optional. It can be used to refine the model and controls for heat recovery operation of the chiller. The node named here should have a setpoint placed on it by a setpoint manager. If the plant loop's demand calculation scheme is set to SingleSetpoint, then a single setpoint manager should be used. If the plant loop's demand calculation is set to DualSetpointDeadband then a dual setpoint manager should be used and the upper setpoint is used for control. When this field is used, a different model is used for determining the distribution of rejected heat between the two bundles that is more appropriate for series bundle arrangements and for chiller's that are able to produce relatively higher temperature heated fluids.

#### **1.23.7.1.34 Field: End-Use Subcategory**

This optional field allows you to specify a user-defined end-use subcategory, e.g., "Process". A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in

the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the chiller will be assigned to the “General” end-use subcategory.

An example of this statement in an IDF is:

- HVAC,Average,Chiller Heat Recovery Outlet Temperature [C]
- HVAC,Average,Chiller Heat Recovery Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Effective Heat Rejection Temperature [C]

Most of these chiller output variables are defined above under “Generic Chiller Outputs.” Output variables not described above are discussed here.

#### 1.23.7.2.1 Chiller Condenser Fan Electricity Rate [W]

**1.23.7.2.2 Chiller Condenser Fan Electricity Energy [J]**

These outputs are for the electric power consumption of the chiller condenser fan and are applicable to air- or evaporatively-cooled chillers. These reports are available only for the Chiller:Electric:EIR and only when the Condenser Fan Power Ratio input field is greater than 0. This output is also added to a meter object with Resource Type = Electricity, End Use Key = Chillers, Group Key = Plant (Ref. Output:Meter objects).

**1.23.7.2.3 Chiller Capacity Temperature Modifier Multiplier []**

This is the output of the curve object Cooling Capacity Function of Temperature Curve.

**1.23.7.2.4 Chiller EIR Temperature Modifier Multiplier []**

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Temperature Curve.

**1.23.7.2.5 Chiller EIR Part Load Modifier Multiplier []**

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Part Load Curve.

**1.23.7.2.6 Chiller Part Load Ratio []**

This output is the ratio of the evaporator heat transfer rate plus the false load heat transfer rate (if applicable) to the available chiller capacity. This value is used to determine Chiller EIR Part Load Modifier Multiplier.

**1.23.7.2.7 Chiller Cycling Ratio []**

The cycling ratio is the amount of time the chiller operates during each simulation timestep. If the chiller part-load ratio falls below the minimum part-load ratio, the chiller cycles on and off to meet the cooling load.

**1.23.7.2.8 Chiller False Load Heat Transfer Rate [W]****1.23.7.2.9 Chiller False Load Heat Transfer Energy [J]**

These outputs are the heat transfer rate and total heat transfer due to false loading of the chiller. When the chiller part-load ratio is below the minimum unloading ratio, the chiller false loads (e.g. hot-gas bypass) to further reduce capacity. The false load heat transfer output variable is not metered.

**1.23.7.2.10 Chiller Evaporative Condenser Water Volume [m3]****1.23.7.2.11 Chiller Evaporative Condenser Mains Supply Water Volume [m3]**

These outputs are the water use for evaporatively-cooled condensers. When the chiller operates, the water consumed by the evaporatively-cooled condenser is proportional to the chiller condenser heat transfer. The evaporative condenser is assumed to be 100% effective where the condenser inlet air dry-bulb temperature is equal to the outdoor wet-bulb temperature.

### 1.23.8 Chiller:Electric:ReformulatedEIR

This chiller model, developed through the CoolTools™ project sponsored by Pacific Gas and Electric Company (PG&E), is an empirical model similar to EnergyPlus' **Chiller:Electric:EIR** model. The model uses performance information at reference conditions along with three curve fits for cooling capacity and efficiency to determine chiller operation at off-reference conditions. The model has the same capabilities as the **Chiller:Electric:EIR** model, but can potentially provide significant accuracy improvement over the **Chiller:Electric:EIR** model for variable-speed compressor drive and variable condenser water flow applications. Chiller performance curves can be generated by fitting manufacturer's catalog data or measured data. Performance curves developed from manufacturer's performance data are provided in the EnergyPlus Reference DataSets (Chillers.idf and AllDataSets.idf). This chiller model can be used to predict the performance of various chiller types (e.g., reciprocating, screw, scroll, and centrifugal) with water-cooled condensers.

The main difference between this model and the **Chiller:Electric:EIR** model is the condenser fluid temperature used in the associated performance curves: the Chiller:Electric:ReformulatedEIR model uses the LEAVING condenser water temperature while the **Chiller:Electric:EIR** model uses the ENTERING condenser water temperature.

Note: Chiller:Electric:Reformulated EIR objects and their associated performance curve objects are developed using performance information for a specific chiller and should almost always be used together for an EnergyPlus simulation. Changing the object input values, or swapping performance curves between chillers, should be done with extreme caution. For example, if the user wishes to model a chiller size that is different from the reference capacity, it is highly recommended that the reference flow rates be scaled proportionately to the change in reference capacity. Although this model can provide more accurate prediction than the **Chiller:Electric:EIR** model, it requires more performance data to develop the associated performance curves (at least 12 points from full-load performance and 7 points from part-load performance).

#### 1.23.8.1 Inputs

##### 1.23.8.1.1 Field: Chiller Name

This alpha field contains the identifying name for this chiller.

##### 1.23.8.1.2 Field: Reference Capacity

This numeric field contains the reference cooling capacity of the chiller in Watts. This should be the capacity of the chiller at the reference temperatures and water flow rates defined below. Alternately, this field can be autosized.

##### 1.23.8.1.3 Field: Reference COP

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps or cooling tower fans. This COP should be at the reference temperatures and water flow rates defined below.

##### 1.23.8.1.4 Field: Reference Leaving Chilled Water Temperature

This numeric field contains the chiller's reference leaving chilled water temperature in Celsius. The default value is 6.67°C.

##### 1.23.8.1.5 Field: Reference Leaving Condenser Water Temperature

This numeric field contains the chiller's reference leaving condenser water temperature in Celsius. The default value is 35°C.

**1.23.8.1.6 Field: Reference Chilled Water Flow Rate**

For a variable flow chiller this is the maximum water flow rate and for a constant flow chiller this is the operating water flow rate through the chiller's evaporator. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

**1.23.8.1.7 Field: Reference Condenser Water Flow Rate**

This numeric field contains the chiller's operating condenser water flow rate in cubic meters per second. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

**1.23.8.1.8 Field: Cooling Capacity Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the cooling capacity as a function of the leaving chilled water temperature and the leaving condenser water temperature. The output of this curve is multiplied by the reference capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation (otherwise the program issues warning messages).

**1.23.8.1.9 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

The name of the Electric Input to Cooling Output Ratio Function of Temperature Curve. Valid curve object types are **Curve:Quadratic** or **Table:Lookup**. The performance curve (ref: Performance Curves) parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and the leaving condenser water temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve or the **Table:Lookup** should be valid for the range of water temperatures anticipated for the simulation (otherwise the program issues warning messages).

**1.23.8.1.10 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Type**

This choice field determines which type of the Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve is used in the chiller modeling. Two curve types are available: (1) Type LeavingCondenserWaterTemperature is based on the leaving condenser water temperature. (2) Type Lift is based on the normalized lift, which is the temperature difference between the leaving condenser water temperature and the leaving evaporator water temperature.

**1.23.8.1.11 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

The name of performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the leaving condenser water temperature and the part-load ratio (EIRfTPLR). The form of this curve is based on the input for Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Type.

For the type of LeavingCondenserWaterTemperature, the curve object type should be **Curve:Bicubic** or **Table:Lookup** that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and the leaving condenser water temperature.

For the type of Lift, the curve object type should be **Curve:ChillerPartLoadWithLift** or **Table:Lookup** that parameterizes the variation of EIR as a function of the normalized fractional Lift, normalized Tdev and the PLR. Tdev is the difference between Leaving Chilled Water Temperature and Reference Chilled Water Temperature. Lift is the difference between the Leaving Condenser Water Temperature and Leaving Chilled Water Temperature. The EIR is the inverse of the COP, and the part-load ratio is the actual cooling load divided by the chiller's available cooling capacity. This curve is generated by dividing the operating electric input power by the available full-load capacity (do not divide by load) at the specific operating temperatures. The curve output should decrease from 1 towards 0 as part-load ratio decreases from 1 to 0. The output of this curve is multiplied by the reference full-load EIR (inverse of the reference COP) and the Energy Input to Cooling Output Ratio Function of Temperature Curve to give the EIR at the specific temperatures and part-load ratio at which the chiller is operating. This curve should have a value of 1.0 at the reference leaving condenser water temperature with the part-load ratio equal to 1.0. An ideal chiller with the same efficiency at all part-load ratio's would use a performance curve that has a value of 0 when the part-load ratio equals 0 (i.e., a line connecting 0,0 and 1,1 when plotted as EIRfTPLR versus PLR), however, actual systems can have part-load EIR's slightly above or below this line (i.e., part-load efficiency often differs from rated efficiency). The bicubic curve should be valid for the range of condenser water temperatures and part-load ratios anticipated for the simulation (otherwise the program issues warning messages).

Note: Although a bicubic curve requires 10 coefficients (ref. **Curve:Bicubic**), coefficients 7, 9 and 10 are typically not used in the performance curve described here and should be entered as 0 unless sufficient performance data and regression accuracy exist to justify the use of these coefficients. Additionally, coefficients 2, 3, and 6 should not be used unless sufficient temperature data is available to accurately define the performance curve (i.e., negative values may result from insufficient data).

#### 1.23.8.1.12 Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. Below this part-load ratio, the compressor cycles on and off to meet the cooling load. The Minimum Part Load Ratio must be less than or equal to the Maximum Part Load Ratio. The default value is 0.1.

#### 1.23.8.1.13 Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.0. The Maximum Part Load Ratio must be greater than or equal to the Minimum Part Load Ratio. The default value is 1.0.

#### 1.23.8.1.14 Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 1.0.

#### 1.23.8.1.15 Field: Minimum Unloading Ratio

This numeric field contains the chiller's minimum unloading ratio. The expected range is between 0 and 1. The minimum unloading ratio is where the chiller capacity can no longer be reduced by unloading and must be false loaded to meet smaller cooling loads. A typical false loading strategy is hot-gas bypass. The minimum unloading ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 0.2.

**1.23.8.1.16 Field: Chilled Water Side Inlet Node**

This required alpha field contains the identifying name for the chiller plant side (chilled water) inlet node.

**1.23.8.1.17 Field: Chilled Water Side Outlet Node**

This required alpha field contains the identifying name for the chiller plant side (chilled water) outlet node.

**1.23.8.1.18 Field: Condenser Side Inlet Node**

This required alpha field contains the identifying name for the chiller condenser side inlet node.

**1.23.8.1.19 Field: Condenser Side Outlet Node**

This required alpha field contains the identifying name for the chiller condenser side outlet node.

**1.23.8.1.20 Field: Fraction of Compressor Electric Power Rejected by Condenser**

This numeric input represents the fraction of compressor electrical energy consumption that must be rejected by the condenser. Enter a value of 1.0 when modeling hermetic chillers. For open chillers, enter the compressor motor efficiency. This value must be greater than 0.0 and less than or equal to 1.0, with a default value of 1.0.

**1.23.8.1.21 Field: Leaving Chilled Water Lower Temperature Limit**

This numeric field contains the lower limit for the leaving chilled water temperature in Celsius. This temperature acts as a cut off for heat transfer in the evaporator, so that the water doesn't get too cold. This input field is currently unused. The default value is 2°C.

**1.23.8.1.22 Field: Chiller Flow Mode Type**

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller – for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

**1.23.8.1.23 Field: Design Heat Recovery Water Flow Rate**

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0 (or autosize), a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the condenser heat recovery relative capacity fraction set in the field below.

**1.23.8.1.24 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the chiller heat recovery side inlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

**1.23.8.1.25 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the chiller heat recovery side outlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

**1.23.8.1.26 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

**1.23.8.1.27 Field: Condenser Heat Recovery Relative Capacity Fraction**

This field is optional. It can be used to describe the physical size of the heat recovery portion of a split bundle condenser section. This fraction describes the relative capacity of the heat recovery bundle of a split condenser compared to the nominal, full load heat rejection rate of the chiller. This fraction will be applied to the full heat rejection when operating at nominal capacity and nominal COP to model a capacity limit for the heat rejection. If this field is not entered then the capacity fraction is set to 1.0.

**1.23.8.1.28 Field: Heat Recovery Inlet High Temperature Limit Schedule Name**

This field is optional. It can be used to control heat recovery operation of the chiller. The schedule named here should contain temperature values, in C, that describe an upper limit for the return fluid temperatures entering the chiller at the heat recovery inlet node. If the fluid temperature is too high, then the heat recovery will not operate. This is useful to restrict the chiller lift from becoming too high and to avoid overheating the hot water loop. This limit can be used with or without the alternate control using leaving setpoint that is set in the next field.

**1.23.8.1.29 Field: Heat Recovery Leaving Temperature Setpoint Node Name**

This field is optional. It can be used to refine the model and controls for heat recovery operation of the chiller. The node named here should have a setpoint placed on it by a setpoint manager. If the plant loop's demand calculation scheme is set to SingleSetpoint, then a single setpoint manager should be used. If the plant loop's demand calculation is set to DualSetpointDeadband then a dual setpoint manager should be used and the upper setpoint is used for control. When this field is used, a different model is used for determining the distribution of rejected heat between the two bundles that is more appropriate for series bundle arrangements and for chiller's that are able to produce relatively higher temperature heated fluids.

**1.23.8.1.30 Field: End-Use Subcategory**

This optional field allows you to specify a user-defined end-use subcategory, e.g., "Process". A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in

the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the chiller will be assigned to the “General” end-use subcategory.

An example of this statement in an IDF is:

### 1.23.8.2 Outputs

The output variables for Chiller:Electric:ReformulatedEIR are the same as the output variables for Chiller:Electric:EIR (ref. Electric EIR Chiller Outputs). except for the Chiller Condenser Fan Electricity Rate and Energy reports

## 1.23.9 Chiller:EngineDriven

### 1.23.9.1 Inputs

#### 1.23.9.1.1 Field: Name

This alpha field contains the identifying name for the engine driven chiller.

#### 1.23.9.1.2 Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

#### 1.23.9.1.3 Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

#### 1.23.9.1.4 Field: Nominal COP

This numeric field contains the chiller's coefficient of performance (COP).

#### 1.23.9.1.5 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller plant side inlet node.

#### 1.23.9.1.6 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller plant side outlet node.

#### 1.23.9.1.7 Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately,

the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

#### 1.23.9.1.8 Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

#### 1.23.9.1.9 Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

#### 1.23.9.1.10 Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

#### 1.23.9.1.11 Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

#### 1.23.9.1.12 Field: Design Condenser Inlet Temperature

This numeric field contains the chiller's condenser inlet design temperature in Celsius.

#### 1.23.9.1.13 Field: Temperature Rise Coefficient

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELv_{required} - TELv_{rated}} \quad (1.56)$$

where:

$TCEnt_{required}$  = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$  = Rated entering condenser air or water temperature at rated capacity.

$TELv_{required}$  = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELv_{rated}$  = Rated leaving evaporator water outlet temperature at rated capacity.

#### 1.23.9.1.14 Field: Design Chilled Water Outlet Temperature

This numeric field contains the chiller's evaporator outlet design temperature in Celsius.

#### 1.23.9.1.15 Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

**1.23.9.1.16 Field: Design Condenser Water Flow Rate**

This numeric field contains the chiller's design condenser water flow rate in cubic meters per second. This field can be autosized. This field is not user for Condenser Type = AirCooled or EvaporativelyCooled.

**1.23.9.1.17 Capacity Ratio Curve**

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2\Delta_{temp} + C_3\Delta_{temp}^2 \quad (1.57)$$

Where the Delta Temperature is defined as:

$$FullLoadtoPowerRatio = C_1 + C_2AvailToNominalCapRatio + C_3AvailToNominalCapRatio^2 \quad (1.58)$$

TempCondIn = Temperature entering the condenser (water or air temperature depending on condenser type).

TempCondInDesign = Design Condenser Inlet Temperature from User input above.

TempEvapOut = Temperature leaving the evaporator.

TempEvapOutDesign = Design Chilled Water Outlet Temperature from User input above.

TempRiseCoefficient = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

**1.23.9.1.18 Field: Coefficient 1 of Capacity Ratio Curve**

This numeric field contains the first coefficient for the capacity ratio curve.

**1.23.9.1.19 Field: Coefficient 2 of Capacity Ratio Curve**

This numeric field contains the second coefficient for the capacity ratio curve.

**1.23.9.1.20 Field: Coefficient 3 of Capacity Ratio Curve**

This numeric field contains the third coefficient for the capacity ratio curve.

**1.23.9.1.21 Power Ratio Curve**

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load to Power. The defining equation is:

$FracFullLoadPower = C_1 + C_2PartLoadRatio + C_3PartLoadRatio^2$  The following three fields contain the coefficients for the quadratic equation.

**1.23.9.1.22 Field: Coefficient 1 of Power Ratio Curve**

This numeric field contains the first coefficient for the power ratio curve.

**1.23.9.1.23 Field: Coefficient 2 of Power Ratio Curve**

This numeric field contains the second coefficient for the power ratio curve.

**1.23.9.1.24 Field: Coefficient 3 of Power Ratio Curve**

This numeric field contains the third coefficient for the power ratio curve.

**1.23.9.1.25 Full Load Ratio Curve**

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$\text{CoolingLoadtoFuelCurve} = C_1 + C_2 * PLR + C_3 * PLR^2 \quad (1.59)$$

The following three fields contain the coefficients for the quadratic equation.

**1.23.9.1.26 Field: Coefficient 1 of Full Load Ratio Curve**

This numeric field contains the first coefficient for the full load ratio curve.

**1.23.9.1.27 Field: Coefficient 2 of Full Load Ratio Curve**

This numeric field contains the second coefficient for the full load ratio curve.

**1.23.9.1.28 Field: Coefficient 3 of Full Load Ratio Curve**

This numeric field contains the third coefficient for the full load ratio curve.

**1.23.9.1.29 Field Chilled Water Outlet Temperature Lower Limit**

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

**1.23.9.1.30 Field: Fuel Use Curve Name**

This alpha field contains the name of the Cooling Load to Fuel Use curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Fuel Use Curve is a quadratic equation that determines the ratio of Cooling Load to Fuel Energy. The defining equation is:

$$\text{RecoveryJacketHeatToFuelRatio} = C_1 + C_2 RL + C_3 RL^2 \quad (1.60)$$

where PLR is the Part Load Ratio from the Chiller. The Part Load Based Fuel Input Curve determines the ratio of fuel energy per unit time (J/s) / cooling load (W). This is illustrated by the logic block in the Engine Driven Chiller algorithm.

```
IF (PartLoadRat == 0) THEN
  EngineDrivenFuelEnergy = 0
ELSE
  ClnLoadFuelRat = CurveValue(EngineDrivenChiller(ChillerNum)%ClnLoadtoFuelCurve, PartLoadRat )
  EngineDrivenFuelEnergy = QEvaporator / ClnLoadFuelRat
END IF
```

**1.23.9.1.31 Field: Jacket Heat Recovery Curve Name**

This alpha field contains the name of the Recovery Jacket Heat curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Recovery Jacket Heat Curve is a quadratic equation that determines the ratio of recovery jacket heat to fuel energy. The defining equation is:

$$\text{RecoveryLubeHeatToFuelRatio} = C_1 + C_2 RL + C_3 RL^2 \quad (1.61)$$

where RL is the Ratio of Load to Diesel Engine Capacity

**1.23.9.1.32 Field: Lube Heat Recovery Curve Name**

This alpha field contains the name of the Recovery Lube Heat curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Recovery Lubricant Heat Curve is a quadratic equation that determines the ratio of recovery lube heat to fuel energy. The defining equation is:

$$TotalExhaustToFuelRatio = C_1 + C_2RL + C_3RL^2 \quad (1.62)$$

where RL is the Ratio of Load to Diesel Engine Capacity

**1.23.9.1.33 Field: Total Exhaust Energy Curve Name**

This alpha field contains the name of the Total Exhaust Energy curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Total Exhaust Energy Curve is a quadratic equation that determines the ratio of total exhaust energy to fuel energy. The defining equation is:

$$AbsoluteExhaustTemperature = C_1 + C_2RL + C_3RL^2 \quad (1.63)$$

where RL is the Ratio of Load to Diesel Engine Capacity

**1.23.9.1.34 Field: Exhaust Temperature Curve Name**

This alpha field contains the name of the Exhaust Temperature curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Exhaust Temperature Curve is a quadratic equation that determines the absolute exhaust temperature. The defining equation is:

$$UAToCapacityRatio = C_1 EngineCapacity^{C_2} \quad (1.64)$$

where RL is the Ratio of Load to Diesel Engine Capacity

**1.23.9.1.35 U-Factor Times Area Curve**

The U-Factor Times Area (UA) is an equation that determines the overall heat transfer coefficient for the exhaust gasses with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELv_{required} - TELv_{rated}} \quad (1.65)$$

The following two fields contain the coefficients for the equation.

**1.23.9.1.36 Field: Coefficient 1 of U-Factor Times Area Curve**

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

**1.23.9.1.37 Field: Coefficient 2 of U-Factor Times Area Curve**

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

**1.23.9.1.38 Field: Maximum Exhaust Flow per Unit of Power Output**

This numeric field contains the maximum exhaust gas mass flow rate per watt of cooling provided by the engine driven chiller

**1.23.9.1.39 Field: Design Minimum Exhaust Temperature**

This numeric field contains the steam saturation temperature in Celsius that would be used to determine the energy recovered from a water jacket heat exchanger on the engine.

**1.23.9.1.40 Field: Fuel Type**

This alpha value specifies the type of fuel used in the engine. The fuel type can be NaturalGas, Propane, Diesel, Gasoline, FuelOilNo1, FuelOilNo2, OtherFuel1 or OtherFuel2. This field is required.

**1.23.9.1.41 Field: Fuel Higher Heating Value**

This numeric field contains the higher heating value of the fuel used in kJ/kg.

**1.23.9.1.42 Field: Design Heat Recovery Water Flow Rate**

This optional numeric field is the design heat recovery plant fluid flow rate, if the heat recovery option is being simulated. If this value is greater than 0.0, or autosize, then a heat recovery loop must be specified and attached to the chiller using the next two node input fields. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the Condenser Heat Recovery Relative Capacity Fraction set in the field below.

**1.23.9.1.43 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the heat recovery side inlet node. If a loop is connected, then the jacket and lubricant heat will be recovered. There is no need for an effectiveness term, since the jacket and lubricant recovered heat energies are the actual recovered energies.

**1.23.9.1.44 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the heat recovery side outlet node.

**1.23.9.1.45 Field: Chiller Flow Mode**

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller – for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

**1.23.9.1.46 Field: Maximum Temperature for Heat Recovery at Heat Recovery Outlet Node**

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the

user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply. The temperature is specified in degrees C.

#### 1.23.9.1.47 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

#### 1.23.9.1.48 Field: Basin Heater Capacity

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### 1.23.9.1.49 Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

#### 1.23.9.1.50 Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

#### 1.23.9.1.51 Field: Condenser Heat Recovery Relative Capacity Fraction

This field is optional. It can be used to describe the physical size of the heat recovery portion of a split bundle condenser section. This fraction describes the relative capacity of the heat recovery bundle of a split condenser compared to the nominal, full load heat rejection rate of the chiller. This fraction will be applied to the full heat rejection when operating at nominal capacity and nominal COP to model a capacity limit for the heat rejection. If this field is not entered then the capacity fraction is set to 1.0.

An example of this statement in an IDF is:

- HVAC,Average,Chiller OtherFuel2 Mass Flow Rate [kg/s]

These chiller output variables are defined above under “Generic Chiller Outputs.”

### 1.23.10 Chiller:CombustionTurbine

This chiller model is the empirical model from the Building Loads and System Thermodynamics (BLAST) program. Chiller performance curves are generated by fitting catalog data to third order polynomial equations. Three sets of coefficients are required.

#### 1.23.10.1 Inputs

##### 1.23.10.1.1 Field: Name

This alpha field contains the identifying name for the combustion turbine chiller.

##### 1.23.10.1.2 Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

##### 1.23.10.1.3 Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

##### 1.23.10.1.4 Field: Nominal COP

This numeric field contains the chiller’s coefficient of performance (COP).

#### 1.23.10.1.5 Field: Chilled Water Inlet Node Name

This alpha field contains the identifying name for the combustion turbine chiller plant side inlet node.

#### 1.23.10.1.6 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the combustion turbine chiller plant side inlet node.

#### 1.23.10.1.7 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the combustion turbine chiller plant side outlet node.

#### 1.23.10.1.8 Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the combustion turbine chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

#### 1.23.10.1.9 Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the combustion turbine chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

#### 1.23.10.1.10 Field: Minimum Part Load Ratio

This numeric field contains the combustion turbine chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

#### 1.23.10.1.11 Field: Maximum Part Load Ratio

This numeric field contains the combustion turbine chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

#### 1.23.10.1.12 Field: Optimum Part Load Ratio

This numeric field contains the combustion turbine chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

#### 1.23.10.1.13 Field: Design Condenser Inlet Temperature

This numeric field contains the combustion turbine chiller's condenser inlet design temperature in Celsius.

**1.23.10.1.14 Field: Temperature Rise Coefficient**

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELv_{required} - TELv_{rated}} \quad (1.66)$$

where:

$TCEnt_{required}$  = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$  = Rated entering condenser air or water temperature at rated capacity.

$TELv_{required}$  = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELv_{rated}$  = Rated leaving evaporator water outlet temperature at rated capacity.

**1.23.10.1.15 Field: Design Chilled Water Outlet Temperature**

This numeric field contains the combustion turbine chiller's evaporator outlet design temperature in Celsius.

**1.23.10.1.16 Field: Design Chilled Water Flow Rate**

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

**1.23.10.1.17 Field: Design Condenser Water Flow Rate**

This numeric field contains the combustion turbine chiller's design condenser water flow rate in cubic meters per second. This field can be autosized. This field is not used for Condenser Type = AirCooled or EvaporativelyCooled.

**1.23.10.1.18 Capacity Ratio Curve**

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2\Delta_{temp} + C_3\Delta_{temp}^2 \quad (1.67)$$

Where the Delta Temperature is defined as:

$$FullLoadtoPowerRatio = C_1 + C_2AvailToNominalCapRatio + C_3AvailToNominalCapRatio^2 \quad (1.68)$$

$TempCondIn$  = Temperature entering the condenser (water or air temperature depending on condenser type).

$TempCondInDesign$  = Design Condenser Inlet Temperature from User input above.

$TempEvapOut$  = Temperature leaving the evaporator.

$TempEvapOutDesign$  = Design Chilled Water Outlet Temperature from User input above.

$TempRiseCoefficient$  = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

**1.23.10.1.19 Field: Coefficient 1 of Capacity Ratio Curve**

This numeric field contains the first coefficient for the capacity ratio curve.

**1.23.10.1.20 Field: Coefficient 2 of Capacity Ratio Curve**

This numeric field contains the second coefficient for the capacity ratio curve.

**1.23.10.1.21 Field: Coefficient 3 of Capacity Ratio Curve**

This numeric field contains the third coefficient for the capacity ratio curve.

**1.23.10.1.22 Power Ratio Curve**

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load to Power. The defining equation is:

$FracFullLoadPower = C_1 + C_2 PartLoadRatio + C_3 PartLoadRatio^2$  The following three fields contain the coefficients for the quadratic equation.

**1.23.10.1.23 Field: Coefficient 1 of Power Ratio Curve**

This numeric field contains the first coefficient for the power ratio curve.

**1.23.10.1.24 Field: Coefficient 2 of Power Ratio Curve**

This numeric field contains the second coefficient for the power ratio curve.

**1.23.10.1.25 Field: Coefficient 3 of Power Ratio Curve**

This numeric field contains the third coefficient for the power ratio curve.

**1.23.10.1.26 Full Load Ratio Curve**

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$FuelEnergyInput = PLoad * (FIC_1 + FIC_2 RLoad + FIC_3 RLoad^2) * (TBFIC_1 + TBFIC_2 AT_{air} + TBFIC_3 AT_{air}^2) \quad (1.69)$$

The following three fields contain the coefficients for the quadratic equation.

**1.23.10.1.27 Field: Coefficient 1 of Full Load Ratio Curve**

This numeric field contains the first coefficient for the full load ratio curve.

**1.23.10.1.28 Field: Coefficient 2 of Full Load Ratio Curve**

This numeric field contains the second coefficient for the full load ratio curve.

**1.23.10.1.29 Field: Coefficient 3 of Full Load Ratio Curve**

This numeric field contains the third coefficient for the full load ratio curve.

**1.23.10.1.30 Field: Chilled Water Outlet Temperature Lower Limit**

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

**1.23.10.1.31 Fuel Input Curve**

The Fuel Input Curve is a polynomial equation that determines the Ratio of Fuel Input to Energy Output. The equation combines both the Fuel Input Curve Coefficients and the Temperature Based Fuel Input Curve Coefficients. The defining equation is:

$$ExhaustFlowRate = GTCapacity * (C_1 + C_2 AT_{air} + C_3 AT_{air}^2) \quad (1.70)$$

where FIC represents the Fuel Input Curve Coefficients, TBFIC represents the Temperature Based Fuel Input Curve Coefficients, Rload is the Ratio of Load to Combustion Turbine Engine Capacity, and  $AT_{air}$  is the difference between the current ambient and design ambient temperatures.

The following three fields contain the coefficients for the fuel input curve.

#### 1.23.10.1.32 Field: Coefficient 1 of Fuel Input Curve

This numeric field contains the first coefficient for the Fuel Input Curve.

#### 1.23.10.1.33 Field: Coefficient 2 of Fuel Input Curve

This numeric field contains the second coefficient for the Fuel Input Curve.

#### 1.23.10.1.34 Field: Coefficient 3 of Fuel Input Curve

This numeric field contains the third coefficient for the Fuel Input Curve.

The following three fields contain the coefficients for the temperature based fuel input curve.

#### 1.23.10.1.35 Field: Coefficient 1 of Temperature Based Fuel Input Curve

This numeric field contains the first coefficient for the Temperature Based Fuel Input Curve.

#### 1.23.10.1.36 Field: Coefficient 2 of Temperature Based Fuel Input Curve

This numeric field contains the second coefficient for the Temperature Based Fuel Input Curve.

#### 1.23.10.1.37 Field: Coefficient 3 of Temperature Based Fuel Input Curve

This numeric field contains the third coefficient for the Temperature Based Fuel Input Curve.

#### 1.23.10.1.38 Exhaust Flow Curve

The Exhaust Flow Curve is a quadratic equation that determines the Ratio of Exhaust Gas Flow Rate to Engine Capacity. The defining equation is:

$$ExhaustTemperature = (C_1 + C_2 RLoad + C_3 RLoad^2) * (TBC_1 + TBC_2 AT_{air} + TBC_3 AT_{air}^2) - 273.15$$

where  $GTCapacity$  is the Combustion Turbine Engine Capacity, and  $AT_{air}$  is the difference between the current ambient and design ambient temperatures.

#### 1.23.10.1.39 Field: Coefficient 1 of Exhaust Flow Curve

This numeric field contains the first coefficient for the Exhaust Flow Curve.

#### 1.23.10.1.40 Field: Coefficient 2 of Exhaust Flow Curve

This numeric field contains the second coefficient for the Exhaust Flow Curve.

#### 1.23.10.1.41 Field: Coefficient 3 of Exhaust Flow Curve

This numeric field contains the third coefficient for the Exhaust Flow Curve.

#### 1.23.10.1.42 Exhaust Gas Temperature Curve

The Exhaust Gas Temperature Curve is a polynomial equation that determines the Exhaust Gas Temperature. The equation combines both the Exhaust Gas Temperature Curve Coefficients (Based on the Part Load Ratio) and the (Ambient) Temperature Based Exhaust Gas Temperature Curve Coefficients. The defining equation is:

$$RecoveryLubeEnergy = PLoad * (C_1 + C_2 RL + C_3 RL^2)$$

where C represents the Exhaust Gas Temperature Curve Coefficients, TBC are the Temperature Based Exhaust Gas Temperature Curve Coefficients, RLoad is the Ratio of Load to Combustion Turbine Engine Capacity, and  $AT_{air}$  is the difference between the actual ambient and design ambient temperatures.

#### **1.23.10.1.43 Field: Coefficient 1 of Exhaust Gas Temperature Curve**

This numeric field contains the first coefficient for the Exhaust Gas Temperature Curve.

#### **1.23.10.1.44 Field: Coefficient 2 of Exhaust Gas Temperature Curve**

This numeric field contains the second coefficient for the Exhaust Gas Temperature Curve.

#### **1.23.10.1.45 Field: Coefficient 3 of Exhaust Gas Temperature Curve**

This numeric field contains the third coefficient for the Exhaust Gas Temperature Curve.

#### **1.23.10.1.46 Field: Coefficient 1 of Temperature Based Exhaust Gas Temperature Curve**

This numeric field contains the first coefficient for the Temperature Based Exhaust Gas Temperature Curve.

#### **1.23.10.1.47 Field: Coefficient 2 of Temperature Based Exhaust Gas Temperature Curve**

This numeric field contains the second coefficient for the Temperature Based Exhaust Gas Temperature Curve.

#### **1.23.10.1.48 Field: Coefficient 3 of Temperature Based Exhaust Gas Temperature Curve**

This numeric field contains the third coefficient for the Temperature Based Exhaust Gas Temperature Curve.

#### **1.23.10.1.49 Recovery Lubricant Heat Curve**

The Recovery Lubricant Heat Curve is a quadratic equation that determines the recovery lube energy. The defining equation is:

$$UAToCapacityRatio = C_1 GasTurbineEngineCapacity^{C_2} \quad (1.71)$$

where Pload is the engine load and RL is the Ratio of Load to Combustion Turbine Engine Capacity. The following three fields contain the coefficients for the quadratic equation.

#### **1.23.10.1.50 Field: Coefficient 1 of Recovery Lube Heat Curve**

This numeric field contains the first coefficient for the Recovery Lube Heat curve.

#### **1.23.10.1.51 Field: Coefficient 2 of Recovery Lube Heat Curve**

This numeric field contains the second coefficient for the Recovery Lube Heat curve.

#### **1.23.10.1.52 Field: Coefficient 3 of Recovery Lube Heat Curve**

This numeric field contains the third coefficient for the Recovery Lube Heat curve.

**1.23.10.1.53 U-Factor Times Area Curve Curve**

The U-Factor Times Area Curve (UA) is an equation that determines the overall heat transfer coefficient for the exhaust gasses with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$\text{AvailableCoolingCapacity} = \text{NominalCoolingCapacity} * \text{CoolCapfT}(T_{cw,l}, T_{cond}) \quad (1.72)$$

The following two fields contain the coefficients for the equation.

**1.23.10.1.54 Field: Coefficient 1 of U-Factor Times Area Curve**

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

**1.23.10.1.55 Field: Coefficient 2 of U-Factor Times Area Curve**

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

**1.23.10.1.56 Field: Gas Turbine Engine Capacity**

This numeric field contains the capacity of the gas turbine engine in watts. This field is autosizable. When autosized the field below called Turbine Engine Efficiency can be used to scale the resulting size.

**1.23.10.1.57 Field: Maximum Exhaust Flow per Unit of Power Output**

This numeric field contains the maximum exhaust gas mass flow rate per kilowatt of power out.

**1.23.10.1.58 Field: Design Steam Saturation Temperature**

This numeric field contains the design steam saturation temperature in Celsius.

**1.23.10.1.59 Field: Fuel Higher Heating Value**

This numeric field contains the higher heating value of the fuel used in kJ/kg.

**1.23.10.1.60 Field: Design Heat Recovery Water Flow Rate**

This optional numeric field is the design heat recovery plant fluid flow rate, if the heat recovery option is being simulated. If this value is greater than 0.0, or autosize, then a heat recovery loop must be specified and attached to the chiller using the next two node input fields. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the Condenser Heat Recovery Relative Capacity Fraction set in the field below.

**1.23.10.1.61 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the heat recovery side inlet. If a loop is connected, then the jacket and lubricant heat will be recovered. There is no need for an effectiveness term, since the jacket and lubricant recovered heat energies are the actual recovered energies.

**1.23.10.1.62 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the heat recovery side outlet.

#### 1.23.10.1.63 Field: Chiller Flow Mode

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller – for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

#### 1.23.10.1.64 Field: Fuel Type

This alpha field determines the type of fuel that the chiller uses. Valid choices are: **NaturalGas**, **Propane**, **Diesel**, **Gasoline**, **FuelOilNo1**, **FuelOilNo2**, **OtherFuel1** or **OtherFuel2**. The default is **NaturalGas**.

#### 1.23.10.1.65 Field: Heat Recovery Maximum Temperature

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

The temperature is specified in degrees C.

#### 1.23.10.1.66 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

#### 1.23.10.1.67 Field: Basin Heater Capacity

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

- Zone,Meter,Cooling:Electricity [J]
- HVAC,Average,Chiller Evaporator Cooling Rate [W]
- HVAC,Sum,Chiller Evaporator Cooling Energy [J]
- Zone,Meter,EnergyTransfer:Plant [J]
- Zone,Meter,Chillers:EnergyTransfer [J]
- HVAC,Average,Chiller Evaporator Inlet Temperature [C]
- HVAC,Average,Chiller Evaporator Outlet Temperature [C]
- HVAC,Average,Chiller Evaporator Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Condenser Heat Transfer Energy Rate [W]
- HVAC,Sum,Chiller Condenser Heat Transfer Energy [J]
- Zone,Meter,HeatRejection:EnergyTransfer [J]
- HVAC,Average,Chiller COP [W/W]

Air-cooled or Evap-cooled:

- HVAC,Average,Chiller Condenser Inlet Temperature [C]

Evap-cooled:

- HVAC,Average,Chiller Basin Heater Electricity Rate [W]
- HVAC,Average,Chiller Basin Heater Electricity Energy [J]

Water-cooled:

- HVAC,Average,Chiller Condenser Inlet Temperature [C]
- HVAC,Average,Chiller Condenser Outlet Temperature [C]
- HVAC,Average,Chiller Condenser Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Drive Shaft Power [W]
- HVAC,Sum,Chiller Drive Shaft Energy [J]
- HVAC,Sum,Chiller Lube Recovered Heat Energy [J]
- Zone,Meter,HeatRecovery:EnergyTransfer [J]
- HVAC,Average,Chiller Exhaust Temperature [C]
- HVAC,Average,Chiller Heat Recovery Inlet Temperature [C]
- HVAC,Average,Chiller Heat Recovery Outlet Temperature [C]
- HVAC,Average,Chiller Heat Recovery Mass Flow Rate [kg/s]
- HVAC,Average,Chiller <Fuel Type> Rate [W]
- HVAC,Sum,Chiller <Fuel Type> Energy [J]
- HVAC,Average,Chiller <Fuel Type> Mass Flow Rate [kg/s]
- HVAC,Sum,Chiller <Fuel Type> Mass [kg]
- HVAC,Average,Chiller COP [W/W]

These chiller output variables are defined above under “Generic Chiller Outputs.” The Fuel Type input will determine which fuel type is displayed in the output. In this example with the user choice of **NaturalGas**, you will have **Gas Consumption**.

### 1.23.11 ChillerHeater:Absorption:DirectFired

This chiller is a direct fired absorption chiller-heater which is modeled using performance curves similar to the equivalent chiller in DOE-2.1E. This type of chiller is unusual for EnergyPlus, because it may be used in the same plant on both a chilled water supply branch and a hot water supply branch. The chiller has six node connections for chilled water, condenser water, and hot water, and can provide simultaneous heating and cooling. During simultaneous operation, the heating capacity is reduced as the cooling load increases (for more details see below). Some equations are provided below to help explain the function of the various performance curves. For a detailed description of the algorithm and how the curves are used in the calculations, please see the Engineering Reference.

### 1.23.11.1 Inputs

#### 1.23.11.1.1 Field: Name

This alpha field contains the identifying name for the chiller.

#### 1.23.11.1.2 Field: Nominal Cooling Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

#### 1.23.11.1.3 Field: Heating to Cooling Capacity Ratio

A positive fraction that represents the ratio of the heating capacity divided by the cooling capacity at rated conditions. The default is 0.8.

#### 1.23.11.1.4 Field: Fuel Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous cooling fuel used divided by the cooling capacity at rated conditions. The default is 0.97.

#### 1.23.11.1.5 Field: Fuel Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous heating fuel used divided by the nominal heating capacity. The default is 1.25.

#### 1.23.11.1.6 Field: Electric Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the cooling capacity at rated conditions. If the chiller is both heating and cooling only the greater of the computed cooling and heating electricity is used. The default is 0.01.

#### 1.23.11.1.7 Field: Electric Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the nominal heating capacity. If the chiller is both heating and cooling, the greater of the cooling electricity and heating electricity is used. The default is 0.0.

#### 1.23.11.1.8 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side inlet node. This node name must be the same as the inlet node name for the chilled water supply branch on which this chiller is placed.

#### 1.23.11.1.9 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side outlet node.

#### 1.23.11.1.10 Field: Condenser Inlet Node Name

This required alpha field contains the identifying name for the chiller condenser side inlet node. If the Chiller is AirCooled, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air dry-bulb temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air dry-bulb temperature is taken directly from the weather data.

#### 1.23.11.1.11 Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the chiller condenser side outlet node. It is required for WaterCooled chillers but not for AirCooled.

**1.23.11.1.12 Field: Hot Water Inlet Node Name**

This required alpha field contains the identifying name for the chiller-heater hot water side inlet node. This node name must be the same as the inlet node name for the hot water supply branch on which this chiller-heater is placed.

**1.23.11.1.13 Field: Hot Water Outlet Node Name**

This required alpha field contains the identifying name for the chiller-heater hot water side outlet node.

**1.23.11.1.14 Field: Minimum Part Load Ratio**

A positive fraction that represents the minimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If the load on the chiller is below this fraction, the chiller will cycle. If the chiller is simultaneously heating and cooling, the greater part load ratio will be used. The default is 0.1.

**1.23.11.1.15 Field: Maximum Part Load Ratio**

A positive fraction that represents the maximum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If greater than 1.0, the chiller is typically thought of as capable of being overloaded. The default is 1.0.

**1.23.11.1.16 Field: Optimum Part Load Ratio**

A positive fraction that represents the optimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. It represents the most desirable operating point for the chiller. The default is 1.0.

**1.23.11.1.17 Field: Design Entering Condenser Water Temperature**

The temperature in degrees C of the water entering the condenser of the chiller when operating at design conditions. This is usually based on the temperature delivered by the cooling tower in a water cooled application. The default is 29C.

**1.23.11.1.18 Field: Design Leaving Chilled Water Temperature**

The temperature in degrees C of the water leaving the evaporator of the chiller when operating at design conditions; also called the chilled water supply temperature or leaving chilled water temperature. The default is 7C.

**1.23.11.1.19 Field: Design Chilled Water Flow Rate**

For variable volume this is the max flow and for constant flow this is the chilled water flow rate in m<sup>3</sup>/s.

**1.23.11.1.20 Field: Design Condenser Water Flow Rate**

The water flow rate at design conditions through the condenser in m<sup>3</sup>/s. This field can be autosized. This field can be autosized. This field is not used for Condenser Type = AirCooled.

**1.23.11.1.21 Field: Design Hot Water Flow Rate**

The water flow rate at design conditions through the heater side in m<sup>3</sup>/s.

#### 1.23.11.1.22 Field: Cooling Capacity Function of Temperature Curve Name

The CoolCapfT curve represents the fraction of the cooling capacity of the chiller as it varies by temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below). If the chiller is AirCooled, the temperature of the condenser inlet node (outdoor air node) is used for the condenser temperature. The available cooling capacity is computed as follows:

$$\begin{aligned} \text{CoolFuelInput} = \\ \text{AvailCoolCap} \cdot \text{RunFrac} \cdot \text{CFIR} \cdot \text{CFIRfT}(T_{\text{cw},l}, T_{\text{cond}}) \cdot \text{CFIRfPLR}(\text{CPLR}) \end{aligned} \quad (1.73)$$

#### 1.23.11.1.23 Field: Fuel Input to Cooling Output Ratio Function of Temperature Curve Name

The CFIRfT curve represents the fraction of the fuel input to the chiller at full load as it varies by temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below). If the chiller is AirCooled, the temperature of the condenser inlet node (outdoor air node) is used for the condenser temperature.

#### 1.23.11.1.24 Field: Fuel Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The CFIRfPLR curve represents the fraction of the fuel input to the chiller as the load the chiller varies but the operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic. The cooling fuel input to the chiller is computed as follows:

$$\begin{aligned} \text{CoolElectricPower} = \\ \text{NomCoolCap} \cdot \text{RunFrac} \cdot \text{CEIR} \cdot \text{CEIRfT}(T_{\text{cw},l}, T_{\text{cond}}) \cdot \text{CEIRfPLR}(\text{CPLR}) \end{aligned} \quad (1.74)$$

#### 1.23.11.1.25 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name

The ElecCoolFT curve represents the fraction of the electricity to the chiller at full load as it varies by temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below). If the chiller is AirCooled, the temperature of the condenser inlet node (outdoor air node) is used for the condenser temperature.

#### 1.23.11.1.26 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The ElecCoolFPLR curve represents the fraction of the electricity to the chiller as the load on the chiller varies but This operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic. The cooling electric input to the chiller is computed as follows:

$$\text{AvailHeatCap} = \text{NomCoolCap} \cdot \text{HeatCoolCapRatio} \cdot \text{HeatCapfCPLR}(\text{CPLRh}) \quad (1.75)$$

**1.23.11.1.27 Field: Heating Capacity Function of Cooling Capacity Curve Name**

The HeatCapFCool curve represents how the heating capacity of the chiller varies with cooling capacity when the chiller is simultaneous heating and cooling. The curve is normalized so an input of 1.0 represents the nominal cooling capacity and an output of 1.0 represents the full heating capacity (see the Heating to Cooling Capacity Ratio input) The curve is usually linear or quadratic. The available heating capacity is computed as follows:

$$HeatFuelInput = AvailHeatCap \cdot HFIR \cdot HFIRfHPLR(HPLR) \quad (1.76)$$

**1.23.11.1.28 Field: Fuel Input to Heat Output Ratio During Heating Only Operation Curve Name**

When the chiller is operating as only a heater, the curve is used to represent the fraction of fuel used as the heating load varies. It is normalized so that a value of 1.0 is the full available heating capacity. The curve is usually linear or quadratic and will probably be similar to a boiler curve for most chillers.

$$AvailCoolCap = NomCoolCap \cdot CoolCapfT(T_{cw,l}, T_{cond}) \quad (1.77)$$

**1.23.11.1.29 Field: Temperature Curve Input Variable**

This field sets the second independent variable in the three temperature dependent performance curves to either the leaving or entering condenser water temperature. Manufacturers express the performance of their chillers using either the leaving condenser water temperature (to the tower) or the entering condenser water temperature (from the tower). Valid choices for this field are: LeavingCondenser or EnteringCondenser. It is important that the performance curves and this field are consistent with each other. The default is EnteringCondenser.

**1.23.11.1.30 Field: Condenser Type**

The condenser can either be air cooled or connected to a cooling tower. This alpha field contains the keyword for the type of condenser, either AirCooled, or WaterCooled. The default is WaterCooled.

**1.23.11.1.31 Field: Chilled Water Temperature Lower Limit**

The chilled water supply temperature in degrees C below which the chiller will shut off. The default is 2C.

**1.23.11.1.32 Field: Fuel Higher Heating Value**

The fuel higher heating value in kJ/kg. *This field is not currently used.*

**1.23.11.1.33 Field: Fuel Type**

This alpha field determines the type of fuel that the chiller uses. The default is **NaturalGas**. Valid values are **NaturalGas**, **Propane**, **Diesel**, **Gasoline**, **FuelOilNo1**, **FuelOilNo2**, **OtherFuel1**, **OtherFuel2**.

**1.23.11.1.34 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Cooling Capacity, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Hot Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

An example of this statement in an IDF is:

- HVAC,Average,Chiller Heater Cooling COP [W/W]

Outputs specific to Direct Fired Absorption Chiller during heating operation

- HVAC,Average,Chiller Heater Heating Rate [W]
- HVAC,Sum,Chiller Heater Heating Energy [J]
- HVAC,Average,Chiller Heater Heating <Fuel Type> Rate [W]
- HVAC,Sum,Chiller Heater Heating <Fuel Type> Energy [J]

- HVAC,Average,Chiller Heater Heating Electricity Rate [W]
- HVAC,Sum,Chiller Heater Heating Electricity Energy [J]
- HVAC,Average,Chiller Heater Heating Part Load Ratio []
- HVAC,Average,Chiller Heater Heating Rate [W]
- HVAC,Average,Chiller Heater Heating Inlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Outlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Mass Flow Rate [kg/s]

The “Chiller” output variables are defined above under “Generic Chiller Outputs.” The specific “Direct Fired Absorption Chiller” output variables and exceptions to the generic outputs are defined below.

#### **1.23.11.2.1 Chiller Heater Electricity Rate [W]**

#### **1.23.11.2.2 Chiller Heater Electricity Energy [J]**

These outputs are the electric power input to the chiller when operating in cooling mode, heating mode, or both. This value is not metered, but the separate cooling and heating electric consumption are metered (see below).

#### **1.23.11.2.3 Chiller Heater <Fuel Type> Rate [W]**

#### **1.23.11.2.4 Chiller Heater <Fuel Type> Energy [J]**

These outputs are the fuel input to the chiller when operating in cooling mode, heating mode, or both depending on the fuel type entered. This value is not metered, but the separate cooling and heating fuel consumption are metered (see below).

#### **1.23.11.2.5 Chiller Heater Runtime Fraction []**

This is the average fraction of the time period during which the direct fired absorption chiller-heater was operating in either cooling mode, heating mode, or both.

#### **1.23.11.2.6 Chiller Heater Cooling <Fuel Type> Rate [W]**

#### **1.23.11.2.7 Chiller Heater Cooling <Fuel Type> Energy [J]**

These outputs are the fuel input to the direct fired absorption chiller to serve cooling operation. Consumption is metered on Cooling:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

#### **1.23.11.2.8 Chiller Heater Cooling Electricity Rate [W]**

#### **1.23.11.2.9 Chiller Heater Cooling Electricity Energy [J]**

These outputs are the electricity input to the direct fired absorption chiller to serve cooling operation. Consumption is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.23.11.2.10 Chiller Heater Cooling Rate [W]**

This is the average available cooling capacity for the reported time period.

**1.23.11.2.11 Chiller Heater Cooling Part Load Ratio**

This is the average cooling load (Chiller Evaporator Cooling Rate [W]) divided by the average available cooling capacity (Chiller Heater Cooling Rate [W]) for the reported time period.

**1.23.11.2.12 Chiller Heater Cooling COP**

This is the average coefficient of performance for the chiller in cooling operation, calculated as the average cooling load (Chiller Evaporator Cooling Rate [W]) divided by the average fuel consumption during cooling (Direct Fired Absorption Chiller Cooling <Fuel Type> Consumption Rate [W]) for the reported time period. If the chiller cooling fuel consumption rate (denominator) is zero, then this output variable is set to zero.

**1.23.11.2.13 Chiller Heater Heating Rate [W]****1.23.11.2.14 Chiller Heater Heating Energy [J]**

These outputs are the heating delivered by the direct fired absorption chiller-heater to serve heating operation. Energy is metered on Boilers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

**1.23.11.2.15 Chiller Heater Heating <Fuel Type> Rate [W]****1.23.11.2.16 Chiller Heater Heating <Fuel Type> Energy [J]**

These outputs are the fuel input to the direct fired absorption chiller-heater to serve heating operation. Consumption is metered on Heating:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

**1.23.11.2.17 Chiller Heater Heating Electricity Rate [W]****1.23.11.2.18 Chiller Heating Heating Electricity Energy [J]**

These outputs are the electric power input to the direct fired absorption chiller to serve heating operation. Consumption is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

**1.23.11.2.19 Chiller Heater Heating Rate [W]**

This is the average available heating capacity for the reported time period.

**1.23.11.2.20 Chiller Heater Heating Part Load Ratio**

This is the average heating load (Chiller Heater Heating Rate [W]) divided by the average available heating capacity (Chiller Heater Heating Rate [W]) for the reported time period.

**1.23.11.2.21 Chiller Heater Heating Inlet Temperature [C]****1.23.11.2.22 Chiller Heater Heating Outlet Temperature [C]****1.23.11.2.23 Chiller Heater Heating Mass Flow Rate [kg/s]**

These outputs are the hot water inlet and outlet temperatures and flow rate for the direct fired absorption chiller-heater during heating mode operation.

### 1.23.12 ChillerHeater:Absorption:DoubleEffect

This chiller is an exhaust fired absorption chiller-heater which is modeled using performance curves similar to the direct fired absorption chiller in DOE-2.1E. The model uses the exhaust gas output from MicroTurbine. This type of chiller is unusual for EnergyPlus, because it may be used in the same plant on both a chilled water supply branch and a hot water supply branch. The chiller has six node connections for chilled water, condenser water, and hot water, and can provide simultaneous heating and cooling. During simultaneous operation, the heating capacity is reduced as the cooling load increases (for more details see below). Some equations are provided below to help explain the function of the various performance curves. For a detailed description of the algorithm and how the curves are used in the calculations, please see the Engineering Reference.

#### 1.23.12.1 Inputs

##### 1.23.12.1.1 Field: Name

This alpha field contains the identifying name for the chiller.

##### 1.23.12.1.2 Field: Nominal Cooling Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts. Autosize can be used for this field.

##### 1.23.12.1.3 Field: Heating to Cooling Capacity Ratio

A positive fraction that represents the ratio of the heating capacity divided by the cooling capacity at rated conditions. The default is 0.8.

##### 1.23.12.1.4 Field: Thermal Energy Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous cooling Thermal Energy used divided by the cooling capacity at rated conditions. The default is 0.97.

##### 1.23.12.1.5 Field: Thermal Energy Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous heating Thermal Energy used divided by the nominal heating capacity. The default is 1.25.

##### 1.23.12.1.6 Field: Electric Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the cooling capacity at rated conditions. If the chiller is both heating and cooling only the greater of the computed cooling and heating electricity is used. The default is 0.01.

##### 1.23.12.1.7 Field: Electric Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the nominal heating capacity. If the chiller is both heating and cooling, the greater of the cooling electricity and heating electricity is used. The default is 0.0.

##### 1.23.12.1.8 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side inlet node. This node name must be the same as the inlet node name for the chilled water supply branch on which this chiller is placed.

**1.23.12.1.9 Field: Chilled Water Outlet Node Name**

This required alpha field contains the identifying name for the chiller chilled water side outlet node.

**1.23.12.1.10 Field: Condenser Inlet Node Name**

This required alpha field contains the identifying name for the chiller condenser side inlet node. If the Chiller is AirCooled, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air dry-bulb temperature from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air dry-bulb temperature is taken directly from the weather data.

**1.23.12.1.11 Field: Condenser Outlet Node Name**

This alpha field contains the identifying name for the chiller condenser side outlet node. It is required for WaterCooled chillers but not for AirCooled.

**1.23.12.1.12 Field: Hot Water Inlet Node Name**

This required alpha field contains the identifying name for the chiller-heater hot water side inlet node. This node name must be the same as the inlet node name for the hot water supply branch on which this chiller-heater is placed.

**1.23.12.1.13 Field: Hot Water Outlet Node Name**

This required alpha field contains the identifying name for the chiller-heater hot water side outlet node.

**1.23.12.1.14 Field: Minimum Part Load Ratio**

A positive fraction that represents the minimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If the load on the chiller is below this fraction, the chiller will cycle. If the chiller is simultaneously heating and cooling, the greater part load ratio will be used. The default is 0.1.

**1.23.12.1.15 Field: Maximum Part Load Ratio**

A positive fraction that represents the maximum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If greater than 1.0, the chiller is typically thought of as capable of being overloaded. The default is 1.0.

**1.23.12.1.16 Field: Optimum Part Load Ratio**

A positive fraction that represents the optimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. It represents the most desirable operating point for the chiller. The default is 1.0.

**1.23.12.1.17 Field: Design Entering Condenser Water Temperature**

The temperature in degrees C of the water entering the condenser of the chiller when operating at design conditions. This is usually based on the temperature delivered by the cooling tower in a water cooled application. The default is 29°C.

**1.23.12.1.18 Field: Design Leaving Chilled Water Temperature**

The temperature in degrees C of the water leaving the evaporator of the chiller when operating at design conditions; also called the chilled water supply temperature or leaving chilled water temperature. The default is 7°C.

**1.23.12.1.19 Field: Design Chilled Water Flow Rate**

For variable volume this is the max flow and for constant flow this is the chilled water flow rate in m<sup>3</sup>/s. This field can be autosized.

**1.23.12.1.20 Field: Design Condenser Water Flow Rate**

The water flow rate at design conditions through the condenser in m<sup>3</sup>/s. This field can be autosized. This field is not used for Condenser Type = AirCooled.

**1.23.12.1.21 Field: Design Hot Water Flow Rate**

The water flow rate at design conditions through the heater side in m<sup>3</sup>/s. This field can be autosized.

**1.23.12.1.22 Field: Cooling Capacity Function of Temperature Curve Name**

The CoolCapfT curve represents the fraction of the cooling capacity of the chiller as it varies with temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and the entering condenser water temperature (see *Temperature Curve Input Variable* below). If the chiller is AirCooled, the temperature of the condenser inlet node (outdoor air node) is used for the condenser temperature. The available cooling capacity is computed as follows:

$$\text{CoolThermalEnergyInput} = \text{AvailCoolCap} \cdot \text{RunFrac} \cdot \text{TeFIR} \cdot \text{TeFIRfT}(T_{cw,l}, T_{cond}) \cdot \text{TeFIRfPLR}(CPLR) \quad (1.78)$$

**1.23.12.1.23 Field: Thermal Energy Input to Cooling Output Ratio Function of Temperature Curve Name**

The TeFIRfT curve represents the fraction of the Thermal Energy Input to the chiller at full load as it varies with temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and the entering condenser water temperature (see *Temperature Curve Input Variable* below). If the chiller is AirCooled, the temperature of the condenser inlet node (outdoor air node) is used for the condenser temperature.

**1.23.12.1.24 Field: Thermal Energy Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

The TeFIRfPLR curve represents the fraction of the Thermal Energy Input to the chiller as the load on the chiller varies but the operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic.

The cooling Thermal Energy Input to the chiller is computed as follows:

$$\text{CoolElectricPower} = \text{NomCoolCap} \cdot \text{RunFrac} \cdot \text{CEIR} \cdot \text{CEIRfT}(T_{cw,l}, T_{cond}) \cdot \text{CEIRfPLR}(CPLR) \quad (1.79)$$

**1.23.12.1.25 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

The CEIRfT curve represents the fraction of the electricity to the chiller at full load as it varies with temperature. The curve is normalized so that at design conditions the of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input*

*Variable* below). If the chiller is AirCooled, the temperature of the condenser inlet node (outdoor air node) is used for the condenser temperature.

#### 1.23.12.1.26 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The CEIRfPLR curve represents the fraction of the electricity to the chiller as the load on the chiller varies but This operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic.

The cooling electric input to the chiller is computed as follows:

$$AvailHeatCap = NomCoolCap \cdot HeatCoolCapRatio \cdot HeatCapfCPLR(CPLRh) \quad (1.80)$$

#### 1.23.12.1.27 Field: Heating Capacity Function of Cooling Capacity Curve Name

The HeatCapFCPLR curve represents how the heating capacity of the chiller varies with cooling capacity when the chiller is simultaneously heating and cooling. The curve is normalized so an input of 1.0 represents the nominal cooling capacity and an output of 1.0 represents the full heating capacity (see the Heating to Cooling Capacity Ratio input) The curve is usually linear or quadratic.

The available heating capacity is computed as follows:

$$HeatThermalEnergyInput = AvailHeatCap \cdot HFIR \cdot HFIRfHPLR(HPLR) \quad (1.81)$$

#### 1.23.12.1.28 Field: Thermal Energy Input to Heat Output Ratio During Heating Only Operation Curve Name

When the chiller is operating as only a heater, the curve is used to represent the fraction of Thermal Energy used as the heating load varies. It is normalized so that a value of 1.0 is the full available heating capacity. The curve is usually linear or quadratic and will probably be similar to a boiler curve for most chillers.

The heating Thermal Energy Input to the chiller is computed as follows:

$$TheoreticalFuelUse = \frac{BoilerLoad}{NominalThermalEfficiency} \quad (1.82)$$

#### 1.23.12.1.29 Field: Temperature Curve Input Variable

This field sets the second independent variable in the three temperature dependent performance curves to the entering condenser water temperature. Manufacturers express the performance of their chillers typically using the entering condenser water temperature (from the tower). ). This alpha field contains the keyword for the type of temperature input variable, , either **EnteringCondenserTemperature**, or **LeavingCondenserTemperature**. The default is EnteringCondenserTemperature.

#### 1.23.12.1.30 Field: Condenser Type

The condenser can either be air cooled or water cooled (connected to a cooling tower). This alpha field contains the keyword for the type of condenser, either AirCooled, or WaterCooled. The default is WaterCooled.

#### 1.23.12.1.31 Field: Chilled Water Temperature Lower Limit

The chilled water supply temperature in degrees C below which the chiller will shut off. The default is 2°C.

### 1.23.12.1.32 Field: Exhaust Source

This alpha field determines the type of exhaust source the chiller uses. The default is MicroTurbine. Key **Generator:MicroTurbine**

### 1.23.12.1.33 Field: Exhaust Source Object

This alpha field shows the name of the Exhaust source object – a **Generator:MicroTurbine** in this case

### 1.23.12.1.34 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. Min value should not be less than 0 and here is no max. The default is 1. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Cooling Capacity, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Hot Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

An example of this statement in an IDF is:

- HVAC,Average,Chiller Heater Heating Inlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Outlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Mass Flow Rate [kg/s]

The “Chiller” output variables are defined above under “Generic Chiller Outputs.” The specific “Exhaust Fired Absorption Chiller” output variables and exceptions to the generic outputs are defined below.

#### **1.23.12.2.1 Chiller Heater Electricity Rate [W]**

#### **1.23.12.2.2 Chiller Heater Electricity Energy [J]**

These outputs are the electric power input to the chiller when operating in cooling mode, heating mode, or both. This value is not metered, but the separate cooling and heating electric consumption are metered (see below).

#### **1.23.12.2.3 Chiller Heater Runtime Fraction []**

This is the average fraction of the time period during which the Exhaust Fired absorption chiller-heater was operating in either cooling mode, heating mode, or both.

These outputs are the electricity input to the Exhaust Fired absorption chiller heater to serve cooling operation. Consumption is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.23.12.2.4 Chiller Heater Maximum Cooling Rate [W]**

This is the average available cooling capacity for the reported time period.

#### **1.23.12.2.5 Chiller Heater Cooling Part Load Ratio []**

This is the average cooling load (Chiller Heater Evaporator Cooling Rate [W]) divided by the average available cooling capacity (Chiller Heater Maximum Cooling Rate [W]) for the reported time period.

#### **1.23.12.2.6 Chiller Heater Cooling Source Heat COP [W/W]**

This is the average coefficient of performance for the chiller in cooling operation, calculated as the average cooling load (Chiller Heater Evaporator Cooling Rate [W]) divided by the average thermal energy use during cooling (Chiller Heater Cooling Source Heat Transfer Rate [W]) for the reported time period. If the chiller cooling thermal energy use rate (denominator) is zero, then this output variable is set to zero.

#### **1.23.12.2.7 Chiller Heater Heating Rate [W]**

#### **1.23.12.2.8 Chiller Heater Heating Energy [J]**

#### **1.23.12.2.9 Chiller Heater Heating Electricity Rate [W]**

**1.23.12.2.10 Chiller Heater Heating Electricity Energy [J]**

These outputs are the electric power input to the Exhaust Fired absorption chiller to serve heating operation. Consumption is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

**1.23.12.2.11 Chiller Heater Maximum Heating Rate [W]**

This is the average available heating capacity for the reported time period.

**1.23.12.2.12 Chiller Heater Heating Part Load Ratio []**

This is the average heating load (Chiller Heater Heating Rate [W]) divided by the average available heating capacity (Chiller Heater Maximum Heating Rate [W]) for the reported time period.

**1.23.12.2.13 Chiller Heater Heating Inlet Temperature [C]****1.23.12.2.14 Chiller Heater Heating Outlet Temperature [C]****1.23.12.2.15 Chiller Heater Heating Mass Flow Rate [kg/s]**

These outputs are the hot water inlet and outlet temperatures and flow rate for the Exhaust Fired absorption chiller-heater during heating mode operation.

**1.23.12.2.16 Chiller Heater Heating Heat Recovery Potential Rate (W)**

The heat recovery potential calculated based on Microturbine exhaust temperature and flow rate during heating mode

**1.23.12.2.17 Chiller Heater Heating Source Heat Transfer Rate (W)**

The thermal energy consumption rate required for heating.

**1.23.12.2.18 Chiller Heater Cooling Heat Recovery Potential Rate (W)**

The heat recovery potential calculated based on Microturbine exhaust temperature and flow rate during cooling mode.

**1.23.12.2.19 Chiller Heater Cooling Source Heat Transfer Rate (W)**

The thermal energy consumption rate required for cooling.

**1.23.12.2.20 Chiller Heater Condenser Inlet Temperature [C]**

The condenser (heat rejection) inlet temperature for air-cooled or water chiller heater. For an air-cooled chiller heater, this output would be the dry-bulb temperature of the air entering the condenser coil. For a water cooled chiller heater, this output would be the wet-bulb temperature of the air entering the condenser coil.

**1.23.12.2.21 Chiller Heater Condenser Heat Transfer Energy [J]**

The condenser heat transfer energy is the heat rejected from the chiller heater to either a condenser water loop or through an air-cooled condenser. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period. Chiller Heater Condenser Heat Transfer Energy is metered on HeatRejection:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

**1.23.12.2.22 Chiller Heater Condenser Heat Transfer Rate [W]**

The condenser heat transfer is the rate of heat rejected from the chiller heater to either a condenser water loop or through an air-cooled condenser. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.23.12.2.23 Chiller Heater Condenser Mass Flow Rate [kg/s]**

This is the condenser coil outlet water mass flow rate in kilograms per second. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.23.12.2.24 Chiller Heater Condenser Outlet Temperature [C]**

This is the condenser coil outlet water temperature in degrees C. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported

**1.23.12.2.25 Chiller Heater Evaporator Cooling Energy [J]**

The evaporator heat transfer is the cooling delivered by the chiller heater. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period. Chiller Heater Evaporator Cooling Energy is metered on Chillers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

**1.23.12.2.26 Chiller Heater Evaporator Cooling Rate [W]**

The evaporator heat transfer rate of cooling delivered by the chiller heater. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.23.12.2.27 Chiller Heater Evaporator Inlet Temperature [C]**

The evaporator (chilled water) inlet temperature over the time step being reported.

**1.23.12.2.28 Chiller Heater Evaporator Mass Flow Rate [kg/s]**

The evaporator (chilled water) average mass flow rate over the time step being reported

**1.23.12.2.29 Chiller Heater Evaporator Outlet Temperature [C]**

The evaporator (chilled water) outlet temperature over the time step being reported

**1.23.12.2.30 Chiller Heater Cooling Electricity Energy [J]**

The electric power input to the exhaust fired absorption chiller to serve cooling operation. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period. Consumption is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

**1.23.12.2.31 Chiller Heater Cooling Electricity Rate [W]**

The electric power input to the Exhaust Fired absorption chiller to serve cooling operation. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.23.12.2.32 Chiller Heater Source Exhaust Inlet Mass Flow Rate [kg/s]**

The exhaust flow rate from the Micro Turbine

**1.23.12.2.33 Chiller Heater Source Exhaust Inlet Temperature [C]**

The exhaust temperature from the Micro Turbine

**1.23.13 Boiler:HotWater**

The boiler model calculates the performance of fuel oil, gas and electric boilers. Boiler performance is based on nominal thermal efficiency. A normalized efficiency performance curve may be used to more accurately represent the performance of non-electric boilers but is not considered a required input. When using the normalized efficiency performance curve, if all coefficients are not required simply set the unused coefficients to 0. For example, an electric boiler could be modeled by setting the nominal thermal efficiency to a value in the range of 0.96 to 1.0. Coefficient A0 in the normalized efficiency performance curve would equal 1 and all other coefficients would be set to 0. Coefficients for other types of non-electric boilers would set a combination of the available coefficients to non-zero values.

**1.23.13.1 Inputs****1.23.13.1.1 Field: Name**

This required alpha field contains the identifying name for the boiler.

**1.23.13.1.2 Field: Fuel Type**

This required choice field specifies the type of fuel used by the boiler. The fuel type can be **Electricity**, **NaturalGas**, **Propane**, **FuelOilNo1**, **FuelOilNo2**, **Coal**, **Diesel**, **Gasoline**, **OtherFuel1** or **OtherFuel2**.

**1.23.13.1.3 Field: Nominal capacity**

This numeric field contains the nominal operating capacity (W) of the boiler. The boiler may be autosized and would require a heating plant sizing object.

**1.23.13.1.4 Fuel Use Equation**

The model is based the following two equations:

$$FuelUsed = \frac{TheoreticalFuelUse}{NormalizedBoilerEfficiencyCurveOutput} \quad (1.83)$$

$$Linear \rightarrow Eff = A_0 + A_1 \cdot PLR \quad (1.84)$$

**1.23.13.1.5 Field: Nominal Thermal Efficiency**

This required numeric field contains the heating efficiency (as a fraction between 0 and 1) of the boiler's burner. This is the efficiency relative to the higher heating value (HHV) of fuel at a part load ratio of 1.0. Manufacturers typically specify the efficiency of a boiler using the higher heating value of the fuel. For the rare occurrences when a manufacturers (or particular data set) thermal efficiency is based on the lower heating value (LHV) of the fuel, multiply the thermal efficiency by the lower-to-higher heating value ratio. For example, assume a fuel's lower and higher heating values are approximately 45,450 and 50,000 kJ/kg, respectively. For a manufacturers thermal efficiency rating of 0.90 (based on the LHV), the nominal thermal efficiency entered here is 0.82 (i.e. 0.9 multiplied by 45,450/50,000).

### 1.23.13.1.6 Field: Efficiency Curve Temperature Evaluation Variable

This field is used to control which value for hot water temperature is used when evaluating the efficiency curve specified in the next field (if applicable). There are two options, `EnteringBoiler` or `LeavingBoiler`. `EnteringBoiler` indicates that the efficiency curves will be evaluated using the temperature at boiler inlet node. `LeavingBoiler` indicates that the efficiency curves will be evaluated using the temperature at the boiler outlet. This field is only used if type of curve is one that uses temperature as a independent variable.

### 1.23.13.1.7 Field: Normalized Boiler Efficiency Curve Name

This alpha field contains the curve name which describes the normalized heating efficiency (as a fraction of nominal thermal efficiency) of the boiler's burner. If this field is left blank, the nominal thermal efficiency is assumed to be constant (i.e., Fuel Used is equal to the Theoretical Fuel Use in the equation above). When a boiler efficiency curve is used, the curve may be any valid curve object with 1 (PLR) or 2 (PLR and boiler outlet water temperature) independent variables. A tri-quadratic curve object is not allowed since it uses 3 independent variables. The linear, quadratic, and cubic curve types may be used when the boiler efficiency is solely a function of boiler part-load ratio (PLR). When this type of curve is used, the boiler should operate at (or very near) the design boiler water outlet temperature. Other curve types may be used when the boiler efficiency is a function of both PLR and boiler water temperature. Examples of valid single and dual independent variable equations are shown below. For all curve types PLR is always the x independent variable. When using 2 independent variables, the boiler outlet water temperature (Toutlet) is always the y independent variable.

$$Quadratic \rightarrow Eff = A_0 + A_1 \cdot PLR + A_2 \cdot PLR^2 \quad (1.85)$$

$$Cubic \rightarrow Eff = A_0 + A_1 \cdot PLR + A_2 \cdot PLR^2 + A_3 \cdot PLR^3 \quad (1.86)$$

$$Cubic \rightarrow Eff = A_0 + A_1 \cdot PLR + A_2 \cdot PLR^2 + A_3 \cdot PLR^3 \quad (1.87)$$

$$BiQuadratic \rightarrow Eff = A_0 + A_1 \cdot PLR + A_2 \cdot PLR^2 + A_3 \cdot T_w + A_4 \cdot T_w^2 + A_5 \cdot PLR \cdot T_w \quad (1.88)$$

$$QuadraticLinear \rightarrow Eff = A_0 + A_1 \cdot PLR + A_2 \cdot PLR^2 + A_3 \cdot T_w + A_4 \cdot PLR \cdot T_w + A_5 \cdot PLR^2 \cdot T_w \quad (1.89)$$

$$\begin{aligned} Bicubic \rightarrow Eff = & A_0 + A_1 \cdot PLR + A_2 \cdot PLR^2 + A_3 \cdot T_w + A_4 T_w^2 + A_5 PLR \cdot T_w + A_6 PLR^3 \\ & + A_7 \cdot T_w^3 + A_8 \cdot PLR^2 \cdot T_w + A_9 \cdot PLR \cdot T_w^2 \end{aligned} \quad (1.90)$$

where

Eff = normalized boiler efficiency

PLR = boiler part-load ratio

$T_w$  = boiler water temperature [ $^{\circ}\text{C}$ ], this can be either entering or leaving temperature depending on the setting in the previous field

### 1.23.13.1.8 Field: Design Water Flow Rate

This numeric field contains the maximum design water volumetric flow rate in  $\text{m}^3/\text{sec}$ . This should be the largest flow rate than can be heated. This field is autosizable.

**1.23.13.1.9 Field: Minimum Part Load Ratio**

This numeric field contains the minimum part load ratio. If the ratio of demand to boiler nominal capacity is less than the minimum part load ratio, then the Min PLR will determine the operating PLR. The expected range is between 0 and 1. If this field is left blank, the default value is 0.0.

**1.23.13.1.10 Field: Maximum Part Load Ratio**

This numeric field contains the maximum part load ratio. If the ratio of demand to boiler nominal capacity is greater than the maximum part load ratio, then the Max PLR will determine the operating PLR. This value may exceed 1, but the normal range is between 0 and 1.1. If this field is left blank, the default value is 1.0.

**1.23.13.1.11 Field: Optimum Part Load Ratio**

This numeric field contains the optimum part load ratio. This is the part load ratio at which the boiler performs at its maximum efficiency. If this field is left blank, the default value is 1.0.

**1.23.13.1.12 Field: Boiler Water Inlet Node Name**

This required alpha field contains the water inlet node name.

**1.23.13.1.13 Field: Boiler Water Outlet Node Name**

This required alpha field contains the water outlet node name.

**1.23.13.1.14 Field: Water Outlet Upper Temperature Limit**

This numeric field contains the outlet temperature upper limit. If this field is left blank, the default value is 99.9°C.

**1.23.13.1.15 Field: Boiler Flow Mode**

This choice field determines how the boiler operates with respect to the intended fluid flow through the device. There are three different choices for specifying operating modes for the intended flow behavior: “NotModulated,” “ConstantFlow,” and “LeavingSetpointModulated.” NotModulated is useful for either variable or constant speed pumping arrangements where the boiler is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the boiler’s request for flow is more strict and can increase the overall loop flow. LeavingSetpointModulated changes the boiler model to internally vary the flow rate so that the temperature leaving the boiler matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the boiler – for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

**1.23.13.1.16 Field: Parasitic Electric Load**

This optional numeric field contains the parasitic electric power (W) consumed by a forced draft fan or other electrical device associated with the boiler. This parasitic electric load is consumed whenever the boiler is operating, and the model assumes that this parasitic power does not contribute to heating the water. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

**1.23.13.1.17 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be

altered by the sizing factor are: Nominal Capacity and Design Water Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

### 1.23.13.1.18 Field: End-Use Subcategory

This optional field allows you to specify a user-defined end-use subcategory, e.g., “Process”. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the boiler will be assigned to the “General” end-use subcategory.

An example of this statement in an IDF is:

```
Boiler:HotWater,
  Condensing Boiler,    !- Boiler Name
  NaturalGas,           !- Fuel Type

## 1.23.13.2 Outputs

Outputs available from the boiler:

- HVAC,Average,Boiler Heating Rate [W]
- HVAC,Sum,Boiler Heating Energy [J]
- Zone,Meter,Boilers:EnergyTransfer [J]
- HVAC,Average,Boiler Inlet Temperature [C]
- HVAC,Average,Boiler Outlet Temperature [C]
- HVAC,Average,Boiler Mass Flow Rate [kg/s]
- HVAC,Average,Boiler Parasitic Electricity Rate [W]

- HVAC,Sum,Boiler Ancillary Electricity Energy [J]
- HVAC,Average,Boiler Part Load Ratio
- HVAC,Average,Boiler Efficiency

One of the following blocks will be applicable based on fuel type:  
Electric:

- HVAC,Average,Boiler Electricity Rate [W]
- HVAC,Sum,Boiler Electricity Energy [J]

Gas:

- HVAC,Average,Boiler Gas Rate [W]
- HVAC,Sum,Boiler Gas Energy [J]

Propane:

- HVAC,Average,Boiler Propane Rate [W]
- HVAC,Sum,Boiler Propane Energy [J]

FuelOilNo1:

- HVAC,Average,Boiler FuelOilNo1 Rate [W]
- HVAC,Sum,Boiler FuelOilNo1 Energy [J]

FuelOilNo2:

- HVAC,Average,Boiler FuelOilNo2 Rate [W]
- HVAC,Sum,Boiler FuelOilNo2 Energy [J]

Coal:

- HVAC,Average,Boiler Coal Rate [W]
- HVAC,Sum,Boiler Coal Energy [J]

Diesel:

- HVAC,Average,Boiler Diesel Rate [W]
- HVAC,Sum,Boiler Diesel Energy [J]

Gasoline:

- HVAC,Average,Boiler Gasoline Rate [W]
- HVAC,Sum,Boiler Gasoline Energy [J]

OtherFuel1:

- HVAC,Average,Boiler OtherFuel1 Rate [W]
- HVAC,Sum,Boiler OtherFuel1 Energy [J]

OtherFuel2:

- HVAC,Average,Boiler OtherFuel2 Rate [W]
- HVAC,Sum,Boiler OtherFuel2 Energy [J]

**1.23.13.2.1 Boiler Heating Rate [W]****1.23.13.2.2 Boiler Heating Energy [J]**

These outputs are the heating output (load) of the boiler. Energy is metered on Boilers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

**1.23.13.2.3 Boiler Inlet Temperature [C]****1.23.13.2.4 Boiler Outlet Temperature [C]****1.23.13.2.5 Boiler Mass Flow Rate [kg/s]**

These outputs are the hot water inlet and outlet temperatures and flow rate for the boiler.

**1.23.13.2.6 Boiler Part Load Ratio []**

This output is the operating part-load ratio of the boiler. The part-load ratio is calculated as the boiler load divided by the boiler nominal capacity. The part-load ratio is limited by the minimum and maximum part-load ratio inputs specified by the user.

**1.23.13.2.7 Boiler Efficiency []**

This output is the thermal efficiency for the boiler during heating operation. It is calculated by multiplying the normalized output of the boiler efficiency curve and the nominal thermal efficiency.

*Note that this variable is reported as zero when the boiler is not operating. When reported for frequencies longer than “detailed” (such as timestep, hourly, daily, monthly or environment), this output will only be meaningful when the boiler is operating for the entire reporting period. To determine an efficiency for a longer time period, compute the efficiency based on boiler heating rate divided by boiler gas rate over the desired period.*

**1.23.13.2.8 Boiler <Fuel Type> Rate [W]****1.23.13.2.9 Boiler <Fuel Type> Energy [J] \****1.23.13.2.10 Boiler Electricity Rate [W]**

These outputs are the energy input to the boiler. Valid fuel types are: Electric, Gas (natural gas), Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, OtherFuel1, OtherFuel2. Consumption is metered on Heating:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

**1.23.13.2.11 Boiler Ancillary Electricity Rate [W]****1.23.13.2.12 Boiler Ancillary Electricity Energy [J]**

These outputs are the parasitic electric power and parasitic electric consumption associated with the boiler. Used when simulating a forced draft fan or other electric component. Consumption is metered on Heating:Electricity and Electricity:Plant.

### 1.23.14 Boiler:Steam

The steam boiler model provides a first order approximation of performance for fuel oil, gas and electric boilers. Boiler performance is based on a “theoretical” boiler efficiency (overall efficiency at design operating conditions) and a single quadratic fuel use/ part load ratio curve. This single curve accounts for all combustion inefficiencies and stack losses.

#### 1.23.14.1 Inputs

##### 1.23.14.1.1 Field: Name

This alpha field contains the identifying name for the Steam Boiler.

##### 1.23.14.1.2 Field: Fuel Type

This alpha value specifies the type of fuel used by the boiler. The fuel type can be **Electricity**, **NaturalGas**, **Propane**, **FuelOilNo1**, **FuelOilNo2**, **Coal**, **Diesel**, **Gasoline**, **OtherFuel1** or **OtherFuel2**.

##### 1.23.14.1.3 Field: Maximum Operating Pressure

This numeric field contains the maximum value of pressure up to which the boiler would operate, or the maximum design pressure. (Pascal)

##### 1.23.14.1.4 Field: Theoretical Efficiency

This numeric field contains the heating efficiency (as a fraction between 0 and 1) of the boiler’s burner

##### 1.23.14.1.5 Field: Design Outlet Steam Temperature

The maximum value of steam temperature the boiler can provide. (Celcius)

##### 1.23.14.1.6 Field: Nominal Capacity

This numeric field contains the nominal operating capacity (W) of the boiler.

##### 1.23.14.1.7 Field: Minimum Part Load Ratio

This numeric field contains the minimum part load ratio. If the ratio of demand to boiler nominal capacity is less than the minimum part load ratio, then the Min PLR will determine the operating PLR. The expected range is between 0 and 1.

##### 1.23.14.1.8 Field: Maximum Part Load Ratio

This numeric field contains the maximum part load ratio. If the ratio of demand to boiler nominal capacity is greater than the maximum part load ratio, then the Max PLR will determine the operating PLR. This value may exceed 1, but the normal range is between 0 and 1.1.

##### 1.23.14.1.9 Field: Optimum Part Load Ratio

This numeric field contains the optimum part load ratio. This is the part load ratio at which the boiler performs at its maximum efficiency.

##### 1.23.14.1.10 Field: Coefficient 1 of Fuel Use Function of Part Load Ratio Curve

This numeric field contains the fuel use / PLR coefficient1.

##### 1.23.14.1.11 Field: Coefficient 2 of Fuel Use Function of Part Load Ratio Curve

This numeric field contains the fuel use / PLR coefficient2.

**1.23.14.1.12 Field: Coefficient 3 of Fuel Use Function of Part Load Ratio Curve**

This numeric field contains the fuel use / PLR coefficient3.

**1.23.14.1.13 Field: Water Inlet Node Name**

This alpha field contains the water inlet node name.

**1.23.14.1.14 Field: Steam Outlet Node Name**

This alpha field contains the steam outlet node name.

**1.23.14.1.15 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

**1.23.14.1.16 Field: End-Use Subcategory**

This optional field allows you to specify a user-defined end-use subcategory, e.g., “Process”. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the boiler will be assigned to the “General” end-use subcategory.

More information on the technical aspects of steam boiler can be found in the Engineering Reference Document.

An example of a Steam Boiler input statement from an IDF is:

```
Boiler:Steam,
  Steam Boiler Plant Boiler,  !- Boiler Name
  NaturalGas,                !- Fuel Type
  160000,                    !-Maximum Boiler Pressure Pascal

**1.23.14.2 Outputs**

Outputs available from the steam boiler:

- HVAC,Average,Boiler Heating Rate [W]
- HVAC,Sum,Boiler Heating Energy [J]
- HVAC,Average,Boiler Steam Efficiency
- Zone,Meter,Boilers:EnergyTransfer [J]
- HVAC,Average,Boiler Steam Inlet Temperature [C]
- HVAC,Average,Boiler Steam Outlet Temperature [C]
- HVAC,Average,Boiler Mass Flow Rate [kg/s]

One of the following blocks will be applicable based on fuel type:  
Electric:

- HVAC,Average,Boiler Electricity Rate [W]
- HVAC,Sum,Boiler Electricity Energy [J]

Gas:

- HVAC,Average,Boiler Gas Rate [W]
- HVAC,Sum,Boiler Gas Energy [J]

Propane:

- HVAC,Average,Boiler Propane Rate [W]
- HVAC,Sum,Boiler Propane Energy [J]

FuelOilNo1:

- HVAC,Average,Boiler FuelOilNo1 Rate [W]
- HVAC,Sum,Boiler FuelOilNo1 Energy [J]

FuelOilNo2:

- HVAC,Average,Boiler FuelOilNo2 Rate [W]
- HVAC,Sum,Boiler FuelOilNo2 Energy [J]

Coal:

- HVAC,Average,Boiler Coal Rate [W]
- HVAC,Sum,Boiler Coal Energy [J]

Diesel:

- HVAC,Average,Boiler Diesel Rate [W]
- HVAC,Sum,Boiler Diesel Energy [J]

Gasoline:

- HVAC,Average,Boiler Gasoline Rate [W]
- HVAC,Sum,Boiler Gasoline Energy [J]

OtherFuel1:

- HVAC,Average,Boiler OtherFuel1 Rate [W]
- HVAC,Sum,Boiler OtherFuel1 Energy [J]

OtherFuel2:

- HVAC,Average,Boiler OtherFuel2 Rate [W]
- HVAC,Sum,Boiler OtherFuel2 Energy [J]

#### 1.23.14.2.1 Boiler Heating Rate [W]

#### 1.23.14.2.2 Boiler Heating Energy [J]

These outputs are the heating output (load) of the boiler. Energy is metered on Boilers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### 1.23.14.2.3 Boiler Steam Efficiency []

This output is the thermal efficiency for the boiler during heating operation. It is calculated as the boiler heat transfer rate (Boiler Heating Rate) divided by the “fuel” consumption rate by the boiler.

*Note that this variable is reported as zero when the boiler is not operating. When reported for frequencies longer than “detailed” (such as timestep, hourly, daily, monthly or environment), this output will only be meaningful when the boiler is operating for the entire reporting period. To determine an efficiency for a longer time period, compute the efficiency based on boiler heating rate divided by boiler <Fuel Type> rate over the desired period.*

#### 1.23.14.2.4 Boiler Steam Inlet Temperature [C]

#### 1.23.14.2.5 Boiler Steam Outlet Temperature [C]

#### 1.23.14.2.6 Boiler Steam Mass Flow Rate [kg/s]

These outputs are the steam inlet and outlet temperatures and steam flow rate for the boiler.

#### 1.23.14.2.7 Boiler <Fuel Type> Rate [W]

#### 1.23.14.2.8 Boiler <Fuel Type> Energy [J]

#### 1.23.14.2.9 Boiler Electricity Rate [W]

#### 1.23.14.2.10 Boiler Electricity Energy [J]

These outputs are the energy input to the boiler. Valid fuel types are: Electric, Gas (natural gas), Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, OtherFuel1, and OtherFuel2. Consumption is metered on Heating:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

### 1.23.15 Water to Water Heat Pumps

The EnergyPlus has three water-to-water heat pump models, parameter estimation, equation fit and an EIR-formulated version, to choose from.

#### **HeatPump:WaterToWater:EquationFit:Cooling**

#### **HeatPump:WaterToWater:EquationFit:Heating**

This model is an equation-fit model from the catalog data which resembles a black box with no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data.

#### **HeatPump:WaterToWater:ParameterEstimation:Cooling**

#### **HeatPump:WaterToWater:ParameterEstimation:Heating**

This model is a parameter estimation based model that uses physical parameters generated from the catalog data. The physical parameters are then used to predict the performance of the heat pump using thermodynamic laws and heat transfer equations. The heat pump has a reciprocating compressor that serves both the hot water and the chilled water loop. Note that this model is currently “hardwired” to fluid property R22. FluidProperties:\* objects for R-22 must be included in the idf file. These may be copied from DataSets

FluidPropertiesRefData.idf.

Descriptions and strengths of these two models are available in the following references:

Jin, Hui. 2002. Parameter Estimation Based Models of Water Source Heat Pumps. Phd. Thesis, Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Tang, C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

#### **HeatPump:PlantLoop:EIR:Cooling**

#### **HeatPump:PlantLoop:EIR:Heating**

Beginning with version 9.1, an EIR-formulated heat pump model was added. This heat pump can be operated as a water-source object with the source-side connected to another plant loop, or as an air-source object with the source-side interacting with the outdoor air. This formulation allows the user to enter curves for specifying the capacity and energy usage in a more generic way, allowing the curves to be applicable to a wide variety of components. With the original equation fit model, the curve form was locked in to a specific set of linear coefficients. With the new form, the curve can be a quadratic function of temperatures, or an even more generic lookup table.

#### **Configuration**

The Supply side of the heat pump is usually connected to a Ground Heat Exchanger for a water-source object. The figure below shows the layout and piping diagram of the water-to-water heat pump.

First, the equation fit model objects are described. This model has two sets of coefficients, one for the heating mode and other for the cooling mode.

Figure 1.91: Schematic of EnergyPlus Ground Loop Heat Exchanger

## 1.23.16 HeatPump:WaterToWater:EquationFit:Cooling

### 1.23.16.1 Inputs

#### 1.23.16.1.1 Field: Name

This alpha field contains the identifying name for the ground source heat pump.

#### 1.23.16.1.2 Field: Source Side Inlet Node Name

This alpha field contains the heat pump's source side inlet node name.

#### 1.23.16.1.3 Field: Source Side Outlet Node Name

This alpha field contains the heat pump's source side outlet node name.

#### 1.23.16.1.4 Field: Load Side Inlet Node Name

This alpha field contains the heat pump's load side inlet node name.

#### 1.23.16.1.5 Field: Load Side Outlet Node Name

This alpha field contains the heat pump's load side outlet node name.

#### 1.23.16.1.6 Field: Reference Load Side Flow Rate

This numeric field contains the design volume flow rate on the load side of the heat pump in m<sup>3</sup>/s. This corresponds to the highest load side heat transfer rate listed in the catalog data. This field is autosizable.

#### 1.23.16.1.7 Field: Reference Source Side Flow Rate

This numeric field contains the design volume flow rate on the source side of the heat pump in m<sup>3</sup>/s. This corresponds to the highest load side heat transfer rate listed in the catalog data. This field is autosizable.

**1.23.16.1.8 Field: Reference Cooling Capacity**

This numeric field contains the design cooling capacity of the heat pump in W. This corresponds to the highest load side heat transfer rate listed in the catalog data. This field is autosizable.

**1.23.16.1.9 Field: Reference Cooling Power Consumption**

This numeric field is the design electric power consumption for cooling, in W. This corresponds to the electric power use at the Reference Cooling Capacity. This field is autosizable. When autosized, the field called Reference Coefficient of Performance must be used.

**1.23.16.1.10 Fields: Cooling Capacity Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the Cooling Capacity curve. More details on how these coefficients in the curve are used are described in the Engineering Reference.

**1.23.16.1.11 Field: Cooling Compressor Power Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the Cooling Compressor Power curve. More details on how these coefficients in the curve are used are described in the Engineering Reference.

**1.23.16.1.12 Field: Reference Coefficient of Performance**

This field is required if the Reference Cooling Power Consumption is set to autosize. The nominal COP is defined by the Reference Cooling Capacity divided by the corresponding Reference Cooling Power Consumption and is non-dimensional. This field is only used for sizing; if the Reference Power Consumption is set to a fixed value then the COP of the component during simulation will be determined by the ratio of Reference Cooling Capacity divided by the corresponding Reference Cooling Power Consumption and not by the value in this field. This COP does not include power for fluid circulation pumps, it is just the heat pump itself.

**1.23.16.1.13 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Load Side Flow Rate, Reference Source Side Flow Rate, Reference Cooling Capacity, and Reference Cooling Power Consumption. The Sizing Factor allows the user to size a component to meet part of the plant loop's design load while continuing to use the autosizing feature. For example if there are two heat pumps on the supply side, each one could be sized to be half of the design load.

**1.23.16.1.14 Field: Companion Heating Heat Pump Name**

This optional name field allows the user to specify the companion heating water to water heat pump for this cooling component. This should be the name of an **HeatPump:WaterToWater:EquationFit:Heating** object defined elsewhere in the input file. Because the cooling and heating models are often intended to represent separate operating modes of one single reversible heat pump, it is useful to identify the corresponding heating heat pump input object by name. This is currently used with autosizing so that the sizing calculations can be coordinated so that the two companion heat pumps get the same design reference flow rates.

An idf example:

```

HeatPump:WaterToWater:EquationFit:Cooling,

### 1.23.16.2 Outputs

This section describes the outputs available for the water to water heat pump, equation fit model; both cooling and heating.

- HVAC,Sum,Heat Pump Electricity Energy [J]
- HVAC,Sum,Heat Pump Load Side Heat Transfer Energy [J]
- HVAC,Sum,Heat Pump Source Side Heat Transfer Energy [J]
- HVAC,Average,Heat Pump Electricity Rate [W]

- HVAC,Average,Heat Pump Load Side Heat Transfer Rate [W]
- HVAC,Average,Heat Pump Source Side Heat Transfer Rate [W]
- HVAC,Average,Heat Pump Load Side Outlet Temperature [°C]
- HVAC,Average,Heat Pump Load Side Inlet Temperature [°C]
- HVAC,Average,Heat Pump Source Side Outlet Temperature [°C]
- HVAC,Average,Heat Pump Source Side Inlet Temperature [°C]
- HVAC,Average,Heat Pump Load Side Mass Flow Rate [kg/s]
- HVAC,Average,Heat Pump Source Side Mass Flow Rate [kg/s]

#### **1.23.16.2.1 Heat Pump Electricity Energy [J]**

This output variable represents the cumulative energy used by the compressor. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

#### **1.23.16.2.2 Heat Pump Load Side Heat Transfer Energy [J]**

This output variable represents the cumulative heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

#### **1.23.16.2.3 Heat Pump Source Side Heat Transfer Energy [J]**

This output variable represents the cumulative heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

#### **1.23.16.2.4 Heat Pump Electricity Rate [W]**

This output variable represents the compressor power required to run the heat pump. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.16.2.5 Heat Pump Load Side Heat Transfer Rate [W]**

This output variable represents the heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.16.2.6 Heat Pump Source Side Heat Transfer Rate [W]**

This output variable represents the heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.16.2.7 Heat Pump Load Side Outlet Temperature [C]**

This output variable represents the average fluid temperature leaving the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.23.16.2.8 Heat Pump Load Side Inlet Temperature [C]

This output variable represents the average fluid temperature entering the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.23.16.2.9 Heat Pump Source Side Outlet Temperature [C]

This output variable represents the average fluid temperature leaving the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.23.16.2.10 Heat Pump Source Side Inlet Temperature [C]

This output variable represents the average fluid temperature entering the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.23.16.2.11 Heat Pump Load Side Mass Flow Rate [kg/s]

This output variable represents the average fluid flow rate through the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.23.16.2.12 Heat Pump Source Side Mass Flow Rate [kg/s]

This output variable represents the average fluid flow rate through the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

### 1.23.17 HeatPump:WaterToWater:EquationFit:Heating

#### 1.23.17.1 Inputs

##### 1.23.17.1.1 Field: Name

This alpha field contains the identifying name for the ground source heat pump.

##### 1.23.17.1.2 Field: Source Side Inlet Node Name

This alpha field contains the heat pump's source side inlet node name.

##### 1.23.17.1.3 Field: Source Side Outlet Node Name

This alpha field contains the heat pump's source side outlet node name.

##### 1.23.17.1.4 Field: Load Side Inlet Node Name

This alpha field contains the heat pump's load side inlet node name.

##### 1.23.17.1.5 Field: Load Side Outlet Node Name

This alpha field contains the heat pump's load side outlet node name.

##### 1.23.17.1.6 Field: Reference Load Side Flow Rate

This numeric field contains the design volume flow rate on the load side of the heat pump in m<sup>3</sup>/s. This corresponds to the highest load side heat transfer rate listed in the catalog data. This field is autosizable.

**1.23.17.1.7 Field: Reference Source Side Flow Rate**

This numeric field contains the design volume flow rate on the source side of the heat pump in m<sup>3</sup>/s. This corresponds to the highest load side heat transfer rate listed in the catalog data. This field is autosizable.

**1.23.17.1.8 Field: Reference Heating Capacity**

This numeric field contains the design heating capacity of the heat pump in W. This corresponds to the highest load side heat transfer rate listed in the catalog data. This field is autosizable.

**1.23.17.1.9 Field: Reference Heating Power Consumption**

This numeric field contains the design electric power consumption for heating, in W. This corresponds to the electric power use at the Reference Heating Capacity. This field is autosizable. When autosized, the field called Reference Coefficient of Performance must be used.

**1.23.17.1.10 Fields: Heating Capacity Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the Heating Capacity curve. More details on how these coefficients in the curve are used are described in the Engineering Reference.

**1.23.17.1.11 Field: Heating Compressor Power Curve Name**

This alpha field specifies the name of a **quadlinear** performance curve object (ref: Performance Curves) for the Heating Compressor Power curve. More details on how these coefficients in the curve are used are described in the Engineering Reference.

**1.23.17.1.12 Field: Reference Coefficient of Performance**

This field is required if the Design Heating Power Consumption is set to autosize. The nominal COP is defined by the Reference Heating Capacity divided by the corresponding Reference Heating Power Consumption and is non-dimensional. This field is only used for sizing; if the Reference Heating Power Consumption is set to a fixed value then the COP of the component during simulation will be determined by the ratio of Reference Heating Capacity divided by the corresponding Reference Heating Power Consumption and not by the value in this field.

**1.23.17.1.13 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Load Side Flow Rate, Reference Source Side Flow Rate, Reference Heating Capacity, and Reference Heating Power Consumption. The Sizing Factor allows the user to size a component to meet part of the plant loop's design load while continuing to use the autosizing feature. For example if there are two heat pumps on the supply side, each one could be sized to be half of the design load.

**1.23.17.1.14 Field: Companion Cooling Heat Pump Name**

This optional name field allows the user to specify the companion cooling water to water heat pump for this heating component. This should be the name of an **HeatPump:WaterToWater:EquationFit:Cooling** object defined elsewhere in the input file. Because the cooling and heating models are often intended to represent separate operating modes of one single reversible heat pump, it is useful to identify the corresponding cooling heat pump input object by name. This is currently used with autosizing so that the

sizing calculations can be coordinated so that the two companion heat pumps get the same design reference flow rates.

```

Next, the parameter estimation model objects are described. This model has two sets of parameters, one for the heating mode and other for the cooling mode.

## 1.23.18 HeatPump:WaterToWater:ParameterEstimation:Cooling

### 1.23.18.1 Inputs

#### 1.23.18.1.1 Field: Name

This alpha field contains the identifying name for the ground source heat pump.

**1.23.18.1.2 Field: Source Side Inlet Node Name**

This alpha field contains the heat pump's source side inlet node name.

**1.23.18.1.3 Field: Source Side Outlet Node Name**

This alpha field contains the heat pump's source side outlet node name.

**1.23.18.1.4 Field: Load Side Inlet Node Name**

This alpha field contains the heat pump's load side inlet node name.

**1.23.18.1.5 Field: Load Side Outlet Node Name**

This alpha field contains the heat pump's load side outlet node name.

**1.23.18.1.6 Field: Nominal COP**

This numeric field contains the nominal coefficient of performance of the heat pump.

**1.23.18.1.7 Field: Nominal Capacity**

This numeric field contains the nominal capacity of the heat pump in Watts.

**1.23.18.1.8 Field: Minimum Part Load Ratio**

This numeric field contains the minimum part load ratio of the heat pump usually set to 0.

**1.23.18.1.9 Field: Maximum Part Load Ratio**

This numeric field contains the maximum part load ratio of the heat pump usually set to 1.

**1.23.18.1.10 Field: Optimum Part Load Ratio**

This numeric field contains the optimal part load ratio of the heat pump usually set to 1.

**1.23.18.1.11 Field: Load Side Flow Rate**

This numeric field contains the volumetric flow rate on the load side of the heat pump in m<sup>3</sup>/s

**1.23.18.1.12 Field: Source Side Flow Rate**

This numeric field contains the volumetric flow rate on the source side of the heat pump in m<sup>3</sup>/s

**1.23.18.1.13 Field: Load Side Heat Transfer Coefficient**

This numeric field contains Estimated parameter load side heat transfer coefficient W/K.

**1.23.18.1.14 Field: Source Side Heat Transfer Coefficient**

This numeric field contains Estimated parameter source side heat transfer coefficient W/K.

**1.23.18.1.15 Field: Piston Displacement**

This numeric field contains the Estimated parameter displacement of the reciprocating compressor in m<sup>3</sup>/s.

**1.23.18.1.16 Field: Compressor Clearance Factor**

This numeric field contains the Estimated parameter clearance factor of the reciprocating compressor.

**1.23.18.1.17 Field: Compressor Suction and Discharge Pressure Drop**

This numeric field contains the estimated parameter the pressure drop at compressor suction and discharge in Pascals (N/m<sup>2</sup>).

**1.23.18.1.18 Field: Superheating**

This numeric field contains the estimated parameter superheat at the evaporator outlet in °C.

**1.23.18.1.19 Field: Constant Part of Electromechanical Power Losses**

This numeric field contains the estimated parameter power loss, which accounts for the loss of work due mechanical and electrical losses in the compressor in Watts.

**1.23.18.1.20 Field: Loss Factor**

This numeric field contains the factor of electromechanical loss that is proportional to the theoretical power percentage.

**1.23.18.1.21 Field: High Pressure Cut Off**

This numeric field contains the design pressure limit of the compressor in Pascals (N/m<sup>2</sup>).

**1.23.18.1.22 Field: Low Pressure Cut Off**

This numeric field contains the design low-pressure limit of the compressor in Pascals (N/m<sup>2</sup>).

```

**1.23.19 HeatPump:WaterToWater:ParameterEstimation:Heating****1.23.19.1 Inputs****1.23.19.1.1 Field: Name**

This alpha field contains the identifying name for the ground source heat pump.

**1.23.19.1.2 Field: Source Side Inlet Node Name**

This alpha field contains the heat pump's source side inlet node name.

**1.23.19.1.3 Field: Source Side Outlet Node Name**

This alpha field contains the heat pump's source side outlet node name.

**1.23.19.1.4 Field: Load Side Inlet Node Name**

This alpha field contains the heat pump's load side inlet node name.

**1.23.19.1.5 Field: Load Side Outlet Node Name**

This alpha field contains the heat pump's load side outlet node name.

**1.23.19.1.6 Field: Nominal COP**

This numeric field contains the nominal coefficient of performance of the heat pump.

**1.23.19.1.7 Field: Nominal Capacity**

This numeric field contains the nominal capacity of the heat pump in Watts.

**1.23.19.1.8 Field: Minimum Part Load Ratio**

This numeric field contains the minimum part load ratio of the heat pump usually set to 0.

**1.23.19.1.9 Field: Maximum Part Load Ratio**

This numeric field contains the maximum part load ratio of the heat pump usually set to 1.

**1.23.19.1.10 Field: Optimum Part Load Ratio**

This numeric field contains the optimal part load ratio of the heat pump usually set to 1.

**1.23.19.1.11 Field: Load Side Flow Rate**

This numeric field contains the volumetric flow rate on the load side of the heat pump in m<sup>3</sup>/s

**1.23.19.1.12 Field: Source Side Flow Rate**

This numeric field contains the volumetric flow rate on the source side of the heat pump in m<sup>3</sup>/s

**1.23.19.1.13 Field: Load Side Heat Transfer Coefficient**

This numeric field contains Estimated parameter load side heat transfer coefficient W/K.

**1.23.19.1.14 Field: Source Side Heat Transfer Coefficient**

This numeric field contains Estimated parameter source side heat transfer coefficient W/K.

**1.23.19.1.15 Field: Piston Displacement**

This numeric field contains the Estimated parameter displacement of the reciprocating compressor in m<sup>3</sup>/s.

**1.23.19.1.16 Field: Compressor Clearance Factor**

This numeric field contains the Estimated parameter clearance factor of the reciprocating compressor.

**1.23.19.1.17 Field: Compressor Suction and Discharge Pressure Drop**

This numeric field contains the estimated parameter the pressure drop at compressor suction and discharge in Pascals (N/m<sup>2</sup>).

**1.23.19.1.18 Field: Superheating**

This numeric field contains the estimated parameter superheat at the evaporator outlet in °C.

**1.23.19.1.19 Field: Constant Part of Electromechanical Power Losses**

This numeric field contains the estimated parameter power loss, which accounts for the loss of work due mechanical and electrical losses in the compressor in Watts.

**1.23.19.1.20 Field: Loss Factor**

This numeric field contains the factor of electromechanical loss that is proportional to the theoretical power percentage.

**1.23.19.1.21 Field: High Pressure Cut Off**

This numeric field contains the design pressure limit of the compressor in Pascals (N/m<sup>2</sup>).

**1.23.19.1.22 Field: Low Pressure Cut Off**

This numeric field contains the design low-pressure limit of the compressor in Pascals (N/m<sup>2</sup>).

**1.23.19.2 Outputs**

This section describes the outputs available for the water to water heat pump, parameter estimation model; both cooling and heating.

- HVAC,Average,Heat Pump Electricity Rate [W]
- HVAC,Sum,Heat Pump Electricity Energy [J]
- HVAC,Average,Heat Pump Load Side Heat Transfer Rate [W]
- HVAC,Sum,Heat Pump Load Side Heat Transfer Energy [J]
- HVAC,Average,Heat Pump Source Side Heat Transfer Rate [W]

- HVAC,Sum,Heat Pump Source Side Heat Transfer Energy [J]
- HVAC,Average,Heat Pump Load Side Outlet Temperature [°C]
- HVAC,Average,Heat Pump Load Side Inlet Temperature [°C]
- HVAC,Average,Heat Pump Source Side Outlet Temperature [°C]
- HVAC,Average,Heat Pump Source Side Inlet Temperature [°C]
- HVAC,Average,Heat Pump Load Side Mass Flow Rate [kg/s]
- HVAC,Average,Heat Pump Source Side Mass Flow Rate [kg/s]

#### **1.23.19.2.1 Heat Pump Electricity Rate [W]**

This output variable represents the compressor power required to run the heat pump. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.2 Heat Pump Electricity Energy [J]**

This output variable represents the cumulative energy used by the compressor. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

#### **1.23.19.2.3 Heat Pump Load Side Heat Transfer Rate [W]**

This output variable represents the heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.4 Heat Pump Load Side Heat Transfer Energy [J]**

This output variable represents the cumulative heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

#### **1.23.19.2.5 Heat Pump Source Side Heat Transfer Rate [W]**

This output variable represents the heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.6 Heat Pump Source Side Heat Transfer Energy [J]**

This output variable represents the cumulative heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

#### **1.23.19.2.7 Heat Pump Load Side Outlet Temperature [C]**

This output variable represents the average fluid temperature leaving the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.8 Heat Pump Load Side Inlet Temperature [C]**

This output variable represents the average fluid temperature entering the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.9 Heat Pump Source Side Outlet Temperature [C]**

This output variable represents the average fluid temperature leaving the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.10 Heat Pump Source Side Inlet Temperature [C]**

This output variable represents the average fluid temperature entering the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.11 Heat Pump Load Side Mass Flow Rate [kg/s]**

This output variable represents the average fluid flow rate through the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.23.19.2.12 Heat Pump Source Side Mass Flow Rate [kg/s]**

This output variable represents the average fluid flow rate through the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

### **1.23.20 HeatPump:PlantLoop:EIR:Cooling (and Heating)**

Next, the EIR-formulated model objects are described. Although the model follows the pattern of having a separate input object for cooling and heating, the inputs are essentially identical, so they are described together. Note that this component is currently a constant flow device (it will always request its full design flow from the plant), with a future addition to make it respond to outlet setpoint in order to vary the flow request.

#### **1.23.20.1 Inputs**

##### **1.23.20.1.1 Field: Name**

This alpha field contains the identifying name for the ground source heat pump.

##### **1.23.20.1.2 Field: Load Side Inlet Node Name**

This alpha field contains the heat pump's load side inlet node name.

##### **1.23.20.1.3 Field: Load Side Outlet Node Name**

This alpha field contains the heat pump's load side outlet node name.

##### **1.23.20.1.4 Field: Condenser Type**

This alpha field contains the heat pump's condenser type. Acceptable inputs are "WaterSource" or "AirSource".

**1.23.20.1.5 Field: Source Side Inlet Node Name**

This alpha field contains the heat pump's source side inlet node name.

**1.23.20.1.6 Field: Source Side Outlet Node Name**

This alpha field contains the heat pump's source side outlet node name.

**1.23.20.1.7 Field: Companion Heat Pump Name**

This optional alpha field contains the name of a companion heat pump object. If the current object is heating type then this is expected to include the paired cooling object, and vice-versa. The companion is used for sizing if plant sizing data is unavailable, and during the simulation to ensure that any unexpected simultaneous operation of the two objects provides a warning to the user.

**1.23.20.1.8 Field: Load Side Reference Flow Rate**

This autosizable field defines the reference load side flow rate for the heat pump. This field is used as the nominal flow request for this heat pump unit during the simulation. The units for this field are [m3/s].

**1.23.20.1.9 Field: Source Side Reference Flow Rate**

This autosizable field defines the reference source side flow rate for the heat pump. This field is used as the nominal flow request for this heat pump unit during the simulation. The units for this field are [m3/s].

**1.23.20.1.10 Field: Reference Capacity**

This autosizable field defines the reference load side heat capacity for the heat pump. Cooling capacity for a cooling companion heat pump and heating capacity for a heating companion heat pump. The units for this field are [W].

**1.23.20.1.11 Field: Reference Coefficient of Performance**

This field contains the reference COP for this unit, which is used when calculating the power required for the heat pump under simulation conditions. The COP is defined as the load side energy transfer divided by the power input, with dimensionless units of [W/W].

**1.23.20.1.12 Field: Sizing Factor**

This field allows the user to scale the sizing of this unit compared to the plant-determined autosized flow and heat capacity.

**1.23.20.1.13 Field: Capacity Modifier Function of Temperature Curve Name**

This field is the name of a bivariate curve or table that defines an available capacity modifier of the unit as a function of the load side outlet temperature and the source side inlet temperature. The temperatures are in degrees Celsius when used in the function and the output of the function is multiplied by the reference capacity to get a current available capacity.

**1.23.20.1.14 Field: Electric Input to Output Ratio Modifier Function of Temperature Curve Name**

This field is the name of a bivariate curve or table that defines an EIR (1/COP) modifier as a function of the load side outlet temperature and the source side inlet temperature. The temperatures are in degrees Celsius when used in the function. The output of this function and the output of the EIR Modifier Function of PLR are multiplied by the reference EIR to get a current EIR .

### 1.23.20.1.15 Field: Electric Input to Output Ratio Modifier Function of Part Load Ratio Curve Name

This field is the name of a univariate curve or table that defines an EIR modifier as a function of the current part load ratio. The output of this function and the output of the EIR Modifier Function of Temperature are multiplied by the reference EIR to get a current EIR .

An idf example for a water-source application:

### 1.23.20.2 Outputs

This section describes the outputs available for the water to water heat pump, equation fit model; both cooling and heating.

- HVAC,Average,Heat Pump Electricity Rate [W]
- HVAC,Sum,Heat Pump Electricity Energy [J]
- HVAC,Average,Heat Pump Load Side Heat Transfer Rate [W]
- HVAC,Sum,Heat Pump Load Side Heat Transfer Energy [J]
- HVAC,Average,Heat Pump Source Side Heat Transfer Rate [W]
- HVAC,Sum,Heat Pump Source Side Heat Transfer Energy [J]
- HVAC,Average,Heat Pump Load Side Inlet Temperature [°C]
- HVAC,Average,Heat Pump Load Side Outlet Temperature [°C]
- HVAC,Average,Heat Pump Source Side Inlet Temperature [°C]
- HVAC,Average,Heat Pump Source Side Outlet Temperature [°C]
- HVAC,Average,Heat Pump Load Side Mass Flow Rate [kg/s]
- HVAC,Average,Heat Pump Source Side Mass Flow Rate [kg/s]

#### 1.23.20.2.1 Heat Pump Electricity Rate [W]

This output variable represents the average power usage of this coil during the specified reporting window.

#### 1.23.20.2.2 Heat Pump Electricity Energy [J]

This output variable represents the summed energy usage of the heat pump over a specified reporting window.

#### 1.23.20.2.3 Heat Pump Load Side Heat Transfer Rate [W]

This output variable represents the average load side heat transfer during the specified output reporting window.

**1.23.20.2.4 Heat Pump Load Side Heat Transfer Energy [J]**

This output variable represents the summed load side heat transfer during the specified output reporting window.

**1.23.20.2.5 Heat Pump Source Side Heat Transfer Rate [W]**

This output variable represents the average source side heat transfer occurring for this coil during the specified output reporting window.

**1.23.20.2.6 Heat Pump Source Side Heat Transfer Energy [J]**

This output variable represents the summed source side heat transfer during the specified output reporting window.

**1.23.20.2.7 Heat Pump Load Side Inlet Temperature [°C]**

This output variable represents the inlet temperature on the load side connection of this coil.

**1.23.20.2.8 Heat Pump Load Side Outlet Temperature [°C]**

This output variable represents the outlet temperature on the load side connection of this coil.

**1.23.20.2.9 Heat Pump Source Side Inlet Temperature [°C]**

This output variable represents the inlet temperature on the source side connection of this coil.

**1.23.20.2.10 Heat Pump Source Side Outlet Temperature [°C]**

This output variable represents the outlet temperature on the source side connection of this coil.

**1.23.20.2.11 Heat Pump Load Side Mass Flow Rate [kg/s]**

This output variable represents the average load side mass flow rate during the specified reporting window.

**1.23.20.2.12 Heat Pump Source Side Mass Flow Rate [kg/s]**

This output variable represents the average source side mass flow rate during the specified reporting window.

**1.23.21 Steps to specify the Ground Source Heat Pump**

Since the heat pump is defined with two separate objects (one for heating, one for cooling), the connections to the condenser has to be done carefully. The example below shows the configuration for parameter estimation objects. The same specifications and configuration also applies to the equation fit model.

For the heating mode:

1. Specify a branch for the Heat pump in hot water loop .
2. Include the branch name in the splitter and mixer branches.
3. Add a branch in condenser loop and include its name in the respective splitter and mixer.

**! in hot water loop**

```
BRANCH,
    Heating GshpHeating Branch,
    ,
    HeatPump:WatertoWater:ParameterEstimation:Heating,
    GshpHeating,
    GshpHeating LoadSide Inlet Node,
    GshpHeating LoadSide Outlet Node;
```

---

### **!in condenser loop**

```
BRANCH,
    GshpHeating SourceSide Branch,
    ,
    HeatPump:WatertoWater:ParameterEstimation:Heating,
    GshpHeating,
    GshpHeating SourceSide Inlet Node,
    GshpHeating SourceSide Outlet Node;
```

---

### Example of Heat Pump Links

For the cooling mode:

1. Specify a branch for the Heat pump in chilled water loop .
2. Include the branch name in the splitter and mixer branches.
3. Add a branch in condenser loop and include its name in the respective splitter and mixer.

### **! in chilled water loop**

```
BRANCH,GshpCLG1 Chiller Branch,
    ,
    ,
    HeatPump:WatertoWater:ParameterEstimation:Cooling, GshpCLG1,
    GshpCLG LoadSide Inlet Node1,
    GshpCLG LoadSide Outlet Node1;
```

---

### **!in condenser loop**

```
BRANCH, GshpCLG1 Condenser Branch,
    ,
    ,
    HeatPump:WatertoWater:ParameterEstimation:Cooling, GshpCLG1,
    GshpCLG SourceSide Inlet Node1,
    GshpCLG SourceSide Outlet Node1;
```

---

## **1.23.22 DistrictCooling**

When the user is not interested in a plant simulation or there is some centralized source of chilled water, the following object can be used in the input.

### **1.23.22.1 Inputs**

#### **1.23.22.1.1 Field: Name**

This alpha field contains the identifying name for the district cooling (i.e., purchased chilled water).

#### **1.23.22.1.2 Field: Chilled Water Inlet Node Name**

This alpha field contains the identifying name for the district cooling inlet node.

### 1.23.22.1.3 Field: Chilled Water Outlet Node Name

This alpha field contains the identifying name for the district cooling outlet node.

### 1.23.22.1.4 Field: Nominal Capacity

This numeric field contains the nominal demand (W) that the district cooling will meet. This field is autosizable.

### 1.23.22.1.5 Field: Capacity Fraction Schedule Name

This alpha field contains the name of a schedule that describes how the nominal capacity varies over time. Values must non-negative. The capacity at a given point in time is determined by the product of the previous field and the value in this schedule. If the field is omitted or left blank, then the program assumes a schedule value of 1.0 all the time.

An example of this statement in an IDF is:

```
DistrictCooling, Purchased Cooling,
    NODE_35,NODE_49,
    68000;
```

## 1.23.22.2 Outputs

- HVAC,Average, District Cooling Chilled Water Rate [W]
- HVAC,Sum, District Cooling Chilled Water Energy [J]
- Zone,Meter, DistrictCooling:Plant [J]
- Zone,Meter,Cooling: DistrictCooling [J]
- HVAC,Average,District Cooling Rate [W]
- HVAC,Average,District Cooling Inlet Temperature [C]
- HVAC,Average,District Cooling Outlet Temperature [C]
- HVAC,Average,District Cooling Mass Flow Rate [kg/s]

### 1.23.22.2.1 District Cooling Chilled Water Rate [W]

### 1.23.22.2.2 District Cooling Chilled Water Energy [J]

These outputs are the energy taken from purchased chilled water. Consumption is metered on Cooling:DistrictCooling, DistrictCooling:Plant, and DistrictCooling:Facility.

### 1.23.22.2.3 District Cooling Rate [W]

This is the useful rate of cooling energy from purchased chilled water. For the current algorithm, this is the same as District Cooling Chilled Water Rate.

### 1.23.22.2.4 District Cooling Inlet Temperature [C]

### 1.23.22.2.5 District Cooling Outlet Temperature [C]

**1.23.22.2.6 District Cooling Mass Flow Rate [kg/s]**

These outputs are the supply-side plant loop chilled water inlet and outlet temperatures and mass flow rate.

**1.23.23 DistrictHeating**

When the user is not interested in a plant simulation or there is some centralized source of hot water (district heating), the following object can be used in the input.

**1.23.23.1 Inputs****1.23.23.1.1 Field: Name**

This alpha field contains the identifying name for the district heating (i.e., purchased hot water).

**1.23.23.1.2 Field: Hot Water Inlet Node Name**

This alpha field contains the identifying name for the district heating inlet node.

**1.23.23.1.3 Field: Hot Water Outlet Node Name**

This alpha field contains the identifying name for the district heating outlet node.

**1.23.23.1.4 Field: Nominal Capacity**

This numeric field contains the nominal demand (W) that the district heating will meet. This field is autosizable.

**1.23.23.1.5 Field: Capacity Fraction Schedule Name**

This alpha field contains the name of a schedule that describes how the nominal capacity varies over time. Values must non-negative. The capacity at a given point in time is determined by the product of the previous field and the value in this schedule. If the field is omitted or left blank, then the program assumes a schedule value of 1.0 all the time.

An example of this statement in an IDF is:

```
DistrictHeating,Purchased Heating,
      NODE_30,NODE_29,
      1000000;
```

**1.23.23.2 Outputs**

- HVAC,Average,District Heating Hot Water Rate [W]
- HVAC,Sum,District Heating Hot Water Energy [J]
- Zone,Meter,DistrictHeating:Plant [J]
- Zone,Meter,Heating:DistrictHeating [J]
- HVAC,Average,District Heating Rate [W]
- HVAC,Average,District Heating Inlet Temperature [C]
- HVAC,Average,District Heating Outlet Temperature [C]
- HVAC,Average,District Heating Mass Flow Rate [kg/s]

**1.23.23.2.1 District Heating Hot Water Rate [W]****1.23.23.2.2 District Heating Hot Water Energy [J]**

These outputs are the energy taken from purchased hot water. Consumption is metered on Heating:DistrictHeating, DistrictHeating:Plant, and DistrictHeating:Facility.

**1.23.23.2.3 District Heating Rate [W]**

This is the useful rate of heating energy from purchased hot water. For the current algorithm, this is the same as District Heating Hot Water Rate.

**1.23.23.2.4 District Heating Inlet Temperature [C]****1.23.23.2.5 District Heating Outlet Temperature [C]****1.23.23.2.6 District Heating Mass Flow Rate [kg/s]**

These outputs are the supply-side plant loop hot water inlet and outlet temperatures and mass flow rate.

**1.23.24 PlantComponent:TemperatureSource**

This object allows the simulation of a water (or other fluid) source at a user-specified temperature. This could include a river, well, or seawater source, or any other configuration where the fluid temperature being supplied by the component to the plant is known. The temperature may be a constant or scheduled. Of course, the scheduled value may also be overwritten via EMS in cases where the specified temperature should be calculated at run-time.

**1.23.24.1 Inputs****1.23.24.1.1 Field: Name**

This field is the string identifier for this component.

**1.23.24.1.2 Field: Inlet Node**

This is the name of this component's inlet node for the plant connection.

**1.23.24.1.3 Field: Outlet Node**

This is the name of this component's outlet node for the plant connection. The source temperature is applied to this node when the component is active.

**1.23.24.1.4 Field: Design Volume Flow Rate**

This numeric field contains the design value for component volume flow rate in  $\text{m}^3/\text{s}$ . This field may be autosized.

**1.23.24.1.5 Field: Temperature Specification Type**

This string field specifies the behavior of the source temperature. Two inputs are allowed: Constant or Scheduled. For a constant condition, a single input value (the next field) is used as the returning temperature (component outlet temperature) throughout the entire simulation. For a scheduled condition, the name of a schedule (the following field) is used to allow the temperature to vary throughout the simulation. This schedule value may be actuated via EMS to allow further flexibility on temperature specification at run-time.

**1.23.24.1.6 Field: Source Temperature**

If the Temperature Specification Type field is Constant, then the value in this field is used as the source temperature (in C) throughout the entire simulation.

**1.23.24.1.7 Field: Source Temperature Schedule Name**

If the Temperature Specification Type field is Scheduled, then this is the name of a schedule entered in the IDF which specifies the dynamic temperature of this source object. The units of this schedule should be C.

And, as shown in an IDF:

```
PlantComponent:TemperatureSource,
    FluidSource,           !- Name
    FluidSource Inlet Node, !- Inlet Node
    FluidSource Outlet Node, !- Outlet Node
    Autosize,              !- Design Volume Flow Rate {m3/s}
    Constant,              !- Temperature Specification Type
    62,                    !- Source Temperature {C}
    ;                       !- Source Temperature Schedule Name
```

---

**1.23.24.2 Outputs**

The following output variables are available for the temperature source plant components:

- HVAC,Average,Plant Temperature Source Component Mass Flow Rate [kg/s]
- HVAC,Average,Plant Temperature Source Component Inlet Temperature [C]
- HVAC,Average,Plant Temperature Source Component Outlet Temperature [C]
- HVAC,Average,Plant Temperature Source Component Source Temperature [C]
- HVAC,Average,Plant Temperature Source Component Heat Transfer Rate [W]

**1.23.24.2.1 Plant Temperature Source Component Mass Flow Rate [kg/s]**

The current mass flow rate of this component.

**1.23.24.2.2 Plant Temperature Source Component Inlet Temperature [C]**

The current entering fluid temperature of this component.

**1.23.24.2.3 Plant Temperature Source Component Outlet Temperature [C]**

The current outlet temperature of this component.

**1.23.24.2.4 Plant Temperature Source Component Source Temperature [C]**

The current source temperature of this component.

**1.23.24.2.5 Plant Temperature Source Component Heat Transfer Rate [W]**

The current heat transfer rate of this component, positive for outlet temperature > inlet temperature, or adding heat to the loop, or absorbing heat from the source.

### 1.23.24.2.6 Plant Temperature Source Component Heat Transfer Energy [J]

The current heat transfer energy over the given reporting period of this component.

## 1.23.25 CentralHeatPumpSystem

This is a central geothermal application that contains one or more chiller-heaters centrally located in the building; the available chilled and/or hot water is then piped to the individual zones. Chiller-heaters used for this particular system can be of two types: 1) standard vapor-compression, non-reversible cycle chillers designed for heat recovery or 2) reversible-cycle, water-to-water heat pump chillers. Unlike a distributed ground source heat pump configuration where individual heat pumps are located in each zone, a centralized geothermal configuration has one or more chiller-heaters. Its function is to encapsulate the extra controls needed to turn individual chiller-heater modules on/off and whether they are to operate in cooling-only, heating-only or simultaneous cooling-heating mode and whether to connect the source water to the evaporator or condenser side. A variety of control schemes can be designed by setting schedules for both zone control types and individual chiller-heaters schedules.

The fluid used in this central system is usually water, and there is no sharing of condenser or evaporator water between multiple machines. However, the control logic is such that the source water can be delivered to individual chiller-heaters depending on their operating mode, e.g., modules in simultaneous cooling-heating mode receive no source water, modules in heating-only mode can have source water directed to their evaporator, or modules in cooling-only mode can have source water directed to their condenser; the decision on which module(s) receives the source water dictated by the ‘smart’ controls. The following figures illustrate node interconnections between this central geothermal application and plant and condenser loops in various situations.

The order of the multiple chiller-heaters’ operation is assumed to be sequential. In other words, the very first chiller-heater will be called at first to see if it meets all loads that the central heat pump system should meet. If the chiller-heater meets all loads, the rest chiller-heaters are assumed to be turned off. If not, the following chiller-heater will be called to meet the remaining loads until all loads are met in the order as defined in the set of individual chiller-heater objects below. The order of individual chiller-heater modules needs to be carefully arranged in case users are intended to see the performance of various combinations of different sizes of chiller-heaters in a central heat pump system.

In the above example, the cooling load needs 3 chiller-heaters and the heating load needs 1 chiller heater. Chiller 1 is in heat recovery mode and isolated from the ground source loop while chillers 2 and 3 are in cooling-only mode, their condensers rejecting heat to the ground source loop.

In the above example, the heating load needs 3 chiller-heaters and the cooling load needs two chiller-heaters. Chillers 1 and 2 are in heat recovery mode and isolated from the ground source loop while chiller 3 is in heating-only mode, its evaporator extracting heat from the ground source loop.

Users are required to define three different nodes such as chilled water, hot water, and source water nodes. Only this central heat pump system will be metered, and individual chiller-heaters’ energy will be available for reporting only, but not metered.

### 1.23.25.1 Inputs

#### 1.23.25.1.1 Field: Name

This alpha field contains the identifying name of the central heat pump system.

#### 1.23.25.1.2 Field: Control Method

This field must contain a keyword defines how the central heat pump system controls the interaction between the chiller-heater modules and the water loops to meet the cooling and heating demands. Currently, the only available option is SmartMixing.

Diagram of chiller-heater bank in cooling-only mode, condenser heat rejected to GLHE loop.

Figure 1.92: Diagram of a central heat pump system with three chiller-heaters in cooling-only mode (Condensers reject heat to the ground source loop)

Diagram of Chiller-Heater bank with all modules in heat recovery mode, no GLHE water used.

Figure 1.93: Diagram of a central heat pump system with three chiller-heaters in heat recovery mode (No heat is exchanged with the ground source loop)

Diagram of chiller-heater bank with one module in heat recovery mode, two in cooling only mode.

Figure 1.94: Diagram of a central heat pump system with one chiller-heater in heat recovery mode and two chiller-heaters in cooling-only mode

Diagram of chiller-heater bank with 2 modules in heat recovery mode and 1 module in heating only mode.

Figure 1.95: Diagram of a central heat pump system with two chiller-heaters in heat recovery mode and one chiller-heater in heating-only mode

**1.23.25.1.3 Field: Cooling Loop Inlet Node Name**

This alpha field contains the identifying name of the chilled water inlet node.

**1.23.25.1.4 Field: Cooling Loop Outlet Node Name**

This alpha field contains the identifying name of the chilled water outlet node.

**1.23.25.1.5 Field: Source Loop Inlet Node Name**

This alpha field contains the identifying name of the source water inlet node.

**1.23.25.1.6 Field: Source Loop Outlet Node Name**

This alpha field contains the identifying name of the source water outlet node.

**1.23.25.1.7 Field: Heating Loop Inlet Node Name**

This alpha field contains the identifying name of the hot water inlet node.

**1.23.25.1.8 Field: Heating Loop Outlet Node Name**

This alpha field contains the identifying name of the hot water outlet node.

**1.23.25.1.9 Field: Ancillary Power**

This numeric field contains the ancillary power of the central heat pump system in watts.

**1.23.25.1.10 Field: Ancillary Operation Schedule Name**

This alpha field contains the identifying name of the ancillary power schedule.

**1.23.25.1.11 Field Set: Individual Chiller-Heater Module Objects**

The following four items are repeated up to a maximum of 20 individual chiller-heater modulesets. At least one module set must appear in an input file. In other words, a central heat pump system must include at least one chiller-heater module component. A set of the following four fields helps to define the specific type of a chiller-heater module, its operation control, and the number of identical chiller-heater module objects.

**1.23.25.1.12 Field: Chiller Heater Module Performance Component Object Type <x>**

This alpha field describes the type of the chiller-heater comprising this module set. Only the chiller-heater type **ChillerHeaterPerformance:Electric:EIR** is currently available. Note that up to 20 sets of chiller-heater module name, schedule, and number of identical chiller-heater may be entered for a single central heat pump system.

**1.23.25.1.13 Field: Chiller Heater Module Performance Component Name <x>**

This alpha field is paired with the preceding chiller-heater module type to define the name of the module.

**1.23.25.1.14 Field: Chiller Heater Module Control Schedule Name <x>**

This alpha field is paired with the preceding chiller-heater module type and name to define its on/off control. This schedule will be used for all identical module components as defined in the next field. Currently, this schedule only controls the module set's availability, i.e., schedule values equal to 1 indicate that the chiller-heater set is available while schedule values equal to 0 indicate that the chiller-heater set is off.

### 1.23.25.1.15 Field: Number of Chiller Heater Modules <x>

This numeric field is paired with the preceding three fields to define how many identical chiller-heaters define this module set.

- HVAC,Average,Chiller Heater System Source Mass Flow Rate [kg/s]

#### **1.23.25.2.1 Chiller Heater System Cooling Electricity Rate [W]**

#### **1.23.25.2.2 Chiller Heater System Cooling Electricity Energy [J]**

These outputs are the sums of the cooling electric power consumption of the central heat pump system containing one or more child objects. Cooling Energy is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.23.25.2.3 Chiller Heater System Heating Electricity Rate [W]**

#### **1.23.25.2.4 Chiller Heater System Heating Electricity Energy [J]**

These outputs are the sums of the heating electric power consumption of the central heat pump system. Heating Energy is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.23.25.2.5 Chiller Heater System Cooling Rate [W]**

#### **1.23.25.2.6 Chiller Heater System Cooling Energy [J]**

These outputs are the evaporator heat transfer which is the cooling delivered by the central heat pump system. These are the sums of the evaporator heat transfer of individual chiller-heater modules included in the central heat pump system. Cooling Energy is metered on Chiller:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### **1.23.25.2.7 Chiller Heater System Heating Rate [W]**

#### **1.23.25.2.8 Chiller Heater System Heating Energy [J]**

These outputs are the condenser heat transfer which is the heating delivered by the central heat pump system. These are the sums of the condenser heat transfer of individual chiller-heater modules included in the central heat pump system. Heating Energy is metered on Boiler:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### **1.23.25.2.9 Chiller Heater System Source Heat Transfer Rate [W]**

#### **1.23.25.2.10 Chiller Heater System Source Heat Transfer Energy [J]**

These outputs are heat transfer which is the heat rejected to a ground source loop or extracted from the source loop, depending on the operating modes of the chiller-heater modules. This is the sums of evaporator heat transfer of the chiller-heater modules in heating-only mode or heating dominant simultaneous cooling-heating mode while the sums of condenser heat transfer of the chiller-heater modules in cooling-only mode or cooling dominant simultaneous cooling-heating mode. Source Heat Transfer Energy is metered on HeatRejection:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### **1.23.25.2.11 Chiller Heater System Cooling Inlet Temperature [C]**

#### **1.23.25.2.12 Chiller Heater System Cooling Outlet Temperature [C]**

**1.23.25.2.13 Chiller Heater System Cooling Mass Flow Rate [kg/s]**

These outputs are the chilled water inlet and outlet temperatures and flow rate.

**1.23.25.2.14 Chiller Heater System Heating Inlet Temperature [C]****1.23.25.2.15 Chiller Heater System Heating Outlet Temperature [C]****1.23.25.2.16 Chiller Heater System Heating Mass Flow Rate [kg/s]**

These outputs are the hot water inlet and outlet temperatures and flow rate.

**1.23.25.2.17 Chiller Heater System Source Inlet Temperature [C]****1.23.25.2.18 Chiller Heater System Source Outlet Temperature [C]****1.23.25.2.19 Chiller Heater System Source Mass Flow Rate [kg/s]**

These outputs are the source water inlet and outlet temperatures and flow rate.

**1.23.26 ChillerHeaterPerformance:Electric:EIR**

The performance of the chiller-heater will be defined by two sets of curves meant to describe unloading for: 1) cooling-only mode, and 2) heating-only mode or simultaneous cooling-heating mode. Reference conditions must be defined for both because each has its own set of three unloading curves based on their associated reference conditions. The cooling-mode curves are typically (but not always) based on condenser entering water temperature while the heating-only mode curves are typically based on condenser leaving water temperature. This chiller-heater object allows the user to specify whether to use condenser leaving or condenser entering as a dependent variable to differentiate, if necessary, the condenser temperature basis used to generate the cooling- and heating-only mode curves.

**1.23.26.1 Field: Name**

This alpha field contains the identifying name of the chiller-heater to be included in a central heat pump system.

**1.23.26.2 Field: Reference Cooling Mode Evaporator Capacity**

This numeric field contains the reference cooling capacity of the evaporator in cooling mode in Watts. This value should be based on the reference temperatures and design water flow rates defined below. This field can be autosized.

**1.23.26.3 Field: Reference Cooling Mode COP**

This numeric field contains the reference coefficient of performance of the evaporator for cooling. It must be based on the values of Reference Cooling Mode Leaving Chilled Water Temperature and Reference Cooling Mode Entering Condenser Water Temperature defined in the next two fields.

**1.23.26.4 Field: Reference Cooling Mode Leaving Chilled Water Temperature**

This numeric field contains the reference leaving chilled water temperature of the evaporator for cooling in Celsius. The default value is 6.67°C.

**1.23.26.5 Field: Reference Cooling Mode Entering Condenser Water Temperature**

This numeric field contains the reference entering condenser water temperature of the condenser in the cooling mode in Celsius. The default value is 29.4°C.

**1.23.26.6 Field: Reference Cooling Mode Leaving Condenser Water Temperature**

This numeric field contains the reference leaving condenser water temperature of the condenser in the cooling mode in Celsius. The default value is 35.0°C.

**1.23.26.7 Field: Reference Heating Mode Cooling Capacity Ratio**

This numeric field contains the evaporator's capacity during the reference heating-only or simultaneous cooling-heating mode as a ratio of reference cooling capacity. For example, the ratio may be expressed as follows:

$$Ratio = \frac{EvapCapHtg@T_{chw,l}=6.67C,T_{cond,l}=51.67C}{EvapCapClg@T_{chw,l}=6.67C,T_{cond,l}=35.0C} \quad (1.91)$$

where  $T_{chw,l}$  is the leaving chilled water temperature and  $T_{cond,l}$  is the leaving condenser water temperature representing the heating-mode and cooling-mode reference temperatures defined elsewhere in this object.

The default is 0.75. This field is used to determine evaporator capacity in heating-only mode or simultaneous cooling-heating mode, multiplying it by the value entered in the field of the Reference Cooling Mode Evaporator Capacity. Note that even when there is no cooling load, i.e., the machine is in heating-only mode, the evaporator must still run and extract heat from the source water. In heating-only mode, the leaving chilled water temperature ( $T_{chw,l}$ ) may float depending on the evaporator water flow rate and the source water temperature. In simultaneous cooling and heating mode, the leaving chilled water temperature ( $T_{chw,l}$ ) does not float but is determined by the chilled water setpoint controls. For both heating-only and simultaneous cooling and heating mode, the leaving condenser temperature ( $T_{cond,l}$ ) is determined by the hot water supply setpoint controls. This value of  $T_{chw,l}$ , combined with  $T_{cond,l}$  is plugged into the CAPFT and EIRFT curves to determine the off-rated heating-mode evaporator capacity and associated compressor power.

**1.23.26.8 Field: Reference Heating Mode Cooling Power Ratio**

This numeric field contains the compressor power during simultaneous cooling-heating mode as a ratio of reference cooling compressor power. For example, the ratio may be expressed as follows:

$$Ratio = \frac{Power@T_{chw,l}=6.67C,T_{cond,l}=51.67C}{Power@T_{chw,l}=6.67C,T_{cond,l}=35.0C} \quad (1.92)$$

The default value is 1.5. This field is used to determine full load compressor power at the simultaneous cooling-heating mode's reference chilled water leaving and condenser water leaving temperatures. Note: In heating-only mode, the chilled water leaving temperature floats so the EIRFT curve is used to modify the simultaneous cooling-heating full load compressor power value.

**1.23.26.9 Field: Reference Heating Mode Leaving Chilled Water Temperature**

This numeric field contains the reference leaving chilled water temperature of the evaporator in simultaneous cooling-heating mode in Celsius. This is typically the same as the reference cooling mode value and is used to create the heating-only mode and simultaneous cooling-heating mode unloading curves. The

leaving chilled water temperature for the chiller-heater is not allowed to fall below this value during the heating-only mode and simultaneous cooling-heating mode. The default value is 6.67°C.

#### **1.23.26.10 Field: Reference Heating Mode Leaving Condenser Water Temperature**

This numeric field contains the reference leaving condenser water temperature of the condenser in heating mode in Celsius. This field is typically controlled to the design hot water supply temperature, and used to create the heating-only mode and simultaneous cooling-heating mode unloading curves. The default value is 60.0°C.

#### **1.23.26.11 Field: Reference Heating Mode Entering Condenser Water Temperature**

This numeric field contains the reference entering condenser water temperature of the condenser in heating mode in Celsius. This field typically represents the upper limit of the source water temperature. The default value is 29.44°C.

#### **1.23.26.12 Field: Heating Mode Entering Chilled Water Temperature Low Limit**

This numeric field contains the low limit of the entering chilled water temperature in heating-only mode or simultaneous cooling-heating mode in Celsius. This field typically represents the lower limit of the source water temperature. If necessary, auxiliary heat will be activated to prevent source water temperature falling below the chilled water entering minimum. The default value is 12.2°C.

#### **1.23.26.13 Field: Chilled Water Flow Mode Type**

This alpha field contains the chilled water flow control mode. Valid water flow mode includes constant flow and variable flow, and the default water flow mode is constant flow.

#### **1.23.26.14 Field: Design Chilled Water Flow Rate**

This numeric field contains the design chilled water flow rate in m<sup>3</sup>/s. The minimum value for this field must be greater than zero, and this field is autosizable.

#### **1.23.26.15 Field: Design Condenser Water Flow Rate**

This numeric field contains the design condenser water flow rate in m<sup>3</sup>/s. The minimum value for this field must be greater than zero, and this field is autosizable.

#### **1.23.26.16 Field: Design Hot Water Flow Rate**

This numeric field contains the design hot water flow rate in m<sup>3</sup>/s. The minimum value and default value for this field are zero, and this field is autosizable.

#### **1.23.26.17 Field: Compressor Motor Efficiency**

This numeric field contains the fraction of efficiency of the compressor electrical energy consumption that must be rejected by the condenser. This value must be between 0.0 and 1.0, and the default value is 1.0.

#### **1.23.26.18 Field: Condenser Type**

This alpha field contains the type of condenser. WaterCooled is the only valid type, and it requires the full specification of the condenser loop and its associated equipment.

**1.23.26.19 Field: Cooling Mode Temperature Curve Condenser Water Independent Variable**

This alpha field determines whether the entering or leaving condenser water temperature is used in the cooling mode unloading performance curves that follow. Valid variables include `EnteringCondenser` and `LeavingCondenser`, and the default variable is `EnteringCondenser`. The condenser temperature used for the cooling mode unloading performance curves will be dependent on this field input. For example, leaving condenser water temperature will be used when the `LeavingCondenser` is chosen, otherwise entering condenser water temperature.

**1.23.26.20 Field: Cooling Mode Cooling Capacity Function of Temperature Curve Name**

This alpha field contains the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the evaporator capacity as a function of the leaving chilled water temperature and either the entering condenser water temperature or the leaving condenser water temperature as defined in the previous field. It is then multiplied by the reference evaporator capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

**1.23.26.21 Field: Cooling Mode Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

This alpha field contains the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and either the entering condenser water temperature or the leaving condenser water temperature as defined by the user. The EIR is the inverse of the COP. It is then multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

**1.23.26.22 Field: Cooling Mode Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

This alpha field contains the name of a performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the part-load ratio (EIRFPLR). The EIR is the inverse of the COP, and the part-load ratio is the actual cooling load divided by the available cooling capacity of the chiller-heater. This curve is generated by dividing the operating electric input power by the available full-load capacity at the specific operating temperatures. The curve output should decrease from 1 towards 0 as part-load ratio decreases from 1 to 0. Note that the bi-cubic formulation is generally only valid when `LeavingCondenser` variable is chosen for the field of Cooling Mode Condenser Water Temperature Curve Input Variable whereas the quadratic curve can be used both choices, i.e., `LeavingCondenser` and `EnteringCondenser`. The output of this curve is then multiplied by the reference full-load EIR and the `EIRFT` to give the EIR at the specific temperatures and part-load ratio at which the chiller-heater is operating. This curve should have a value of 1.0 when the part-load ratio equals 1.0. The curve should be valid for the range of part-load ratios anticipated for the simulation.

**1.23.26.23 Field: Cooling Mode Cooling Capacity Optimum Part Load Ratio**

This numeric field contains the chiller-heater's optimum part-load ratio. This is the part-load ratio at which the chiller-heater performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the minimum part-load ratio, and less than or equal to the maximum part-load ratio. (Note: Both the minimum part-load ratio and maximum part-load ratio are taken from the Cooling Mode EIRFPLR curve definition.) The default value is 1.0.

**1.23.26.24 Field: Heating Mode Temperature Curve Condenser Water Independent Variable**

This alpha field determines whether the entering or leaving condenser water temperature is used in the heating mode unloading performance curves that follow. Valid variables include `EnteringCondenser` and `LeavingCondenser`, and the default variable is `EnteringCondenser`. The condenser temperature used for the cooling mode unloading performance curves will be dependent on this field input. For example, leaving condenser water temperature will be used when the `LeavingCondenser` is chosen, otherwise entering condenser water temperature.

**1.23.26.25 Field: Heating Mode Cooling Capacity Function of Temperature Curve Name**

This alpha field contains the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the evaporator capacity in heating mode as a function of the leaving chilled water temperature and either the entering condenser water temperature or the leaving condenser water temperature as defined in the previous field. This curve is used to evaluate the adjusted evaporator capacity during heating-only mode or simultaneous cooling-heating mode. This adjusted capacity is used as part of the cooling part-load calculation for the EIRFPLR curve. It is then multiplied by the reference evaporator capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

**1.23.26.26 Field: Heating Mode Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

This alpha field contains the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and either the entering condenser water temperature or the leaving condenser water temperature as defined by the user. The EIR is the inverse of the COP. It is then multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

**1.23.26.27 Field: Heating Mode Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

This alpha field contains the name of a performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the part-load ratio (EIRFPLR). The EIR is the inverse of the COP, and the part-load ratio is the actual evaporator load divided by the

available evaporator capacity of the chiller-heater at the reference heating and simultaneous cooling-heating mode temperatures. This curve is generated by dividing the operating electric input power by the available full-load capacity (do not divide by load) at the specific operating temperatures. The curve output should decrease from 1 towards 0 as part-load ratio decreases from 1 to 0. Note that the bicubic formulation below can only be used when the chiller-heater uses a variable speed compressor motor drive. It is also generally valid only when LeavingCondenser variable is chosen for the field of Cooling Mode Condenser Water Temperature Curve Input Variable whereas the quadratic curve can be used both choices, i.e., LeavingCondenser and EnteringCondenser. The output of this curve is then multiplied by the reference full-load EIR (inverse of the reference COP) and the EIRFT to give the EIR at the specific temperatures and part-load ratio at which the chiller-heater is operating. This curve should have a value of 1.0 when the part-load ratio equals 1.0. The curve should be valid for the range of part-load ratios anticipated for the simulation.

### 1.23.26.28 Field: Heating Mode Cooling Capacity Optimum Part Load Ratio

This numeric field contains the chiller-heater's optimum part-load ratio during heating-only mode or simultaneous cooling-heating mode. This is the part-load ratio at which the chiller-heater performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the minimum part-load ratio, and less than or equal to the maximum part-load ratio. (Note: Both the minimum part-load ratio and maximum part-load ratio are taken from the Heating Mode EIRFPLR curve definition.) The default value is 1.0.

### 1.23.26.29 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The Sizing Factor is a multiplier on the design plant chilled water loop flow rate associated with the chiller-heaters parent **CentralHeatPumpSystem** object. The chiller-heater's modified chilled water flow can then be used to autocalculate the Design Condenser Water Flow Rate and Reference Cooling Mode Evaporator Capacity values. In general, it is best to autosize all three fields or set fixed values for all three fields.

An example of this statement in an IDF is:

```
ChillerHeaterPerformance:Electric:EIR,

- HVAC,Average,Chiller Heater EIR Part Load Modifier Multiplier Unit <x> []

Note that much of these output variables are adapted from the definitions above under “Generic Chiller Outputs” and “Electric EIR Chiller Outputs.” The following outputs are repeated up to the maximum of individual chiller-heater module objects. The maximum number may be different from the number of object defined in this object when users define two or more identical chiller-heater modules for a single chiller heater object in the central heat pump system.

**1.23.27.1 Chiller Heater Operation Mode Unit <x>**

This output represents the operating mode of the chiller-heater module. Two single mode outputs and three simultaneous cooling-heating mode outputs are possible:

0. off
1. cooling-only mode
2. heating-only mode
3. heat recovery mode
4. cooling dominant simultaneous cooling-heating mode
5. heating dominant simultaneous cooling-heating mode.

The first mode 0 is reported when the chiller-heater is turned off. The next two modes 2 and 3 are reported when the chiller-heater provides only either cooling or heating, respectively. The last three modes 3 to 5 indicate when the chiller-heater is in a simultaneous cooling-heating mode. Mode 3 indicates the chiller-heaters provides simultaneous cooling and heating *without* heat exchange with the ground source. Mode 4 denotes that at least one of the chiller-heater modules in the central heat pump system provides both cooling and heating, and the chiller-heater is meeting remaining cooling demand (see Figure 1.94. Diagram of a central heat pump system with one chiller-heater in heat recovery mode and two chiller-heaters in cooling-only mode) Similarly, mode 5 indicates that at least one of the chiller-heater modules in the central heat pump system is in the heat recovery mode, and the chiller-heater is meeting remaining heating demand (see Figure 1.95).

Note that the decision to operate individual chiller-heater modules is solely dependent on the chiller-heater schedule and loads. A fraction may appear in case the chiller-heater mode varies within a zone time step. In this particular case, users may define a detailed reporting frequency for this output variable.

**1.23.27.2 Chiller Heater Part Load Ratio Unit <x>**

This output is the ratio of the evaporator heat transfer rate plus the false load heat transfer rate (if applicable) to the available chiller-heater capacity. This value is used to determine ChillerEIRFPLR.

**1.23.27.3 Chiller Heater Cycling Ratio Unit <x>**

The cycling ratio is the amount of time the chiller-heater operates during each simulation time step. If the chiller-heater part-load ratio falls below the minimum part-load ratio, the chiller-heater cycles on and off to meet the loads.

**1.23.27.4 Chiller Heater Cooling Electricity Rate Unit <x> [W]****1.23.27.5 Chiller Heater Cooling Electricity Energy Unit <x> [J]**

These outputs are the cooling electric power consumption of the chiller-heater.

**1.23.27.6 Chiller Heater Heating Electricity Rate Unit <x> [W]****1.23.27.7 Chiller Heater Heating Electricity Energy Unit <x> [J]**

These outputs are the heating electric power consumption of the chiller-heater.

**1.23.27.8 Chiller Heater Cooling Rate Unit  $\langle x \rangle$  [W]****1.23.27.9 Chiller Heater Cooling Energy Unit  $\langle x \rangle$  [J]**

These outputs are the evaporator heat transfer which is the cooling delivered by the chiller-heater module.

**1.23.27.10 Chiller Heater False Load Heat Transfer Rate Unit  $\langle x \rangle$  [W]****1.23.27.11 Chiller Heater False Load Heat Transfer Energy Unit  $\langle x \rangle$  [J]**

These outputs are the heat transfer rate and total heat transfer due to false loading of the chiller-heater. When the chiller-heater part-load ratio is below the minimum unloading ratio, the chiller-heater false loads (e.g. hot-gas bypass) to further reduce capacity.

**1.23.27.12 Chiller Heater Condenser Heat Transfer Rate Unit  $\langle x \rangle$  [C]****1.23.27.13 Chiller Heater Condenser Heat Transfer Energy Unit  $\langle x \rangle$  [C]**

These outputs are the heat transfer which is the heating delivered by the chiller-heater module in heating mode.

**1.23.27.14 Chiller Heater Evaporator Inlet Temperature Unit  $\langle x \rangle$  [C]****1.23.27.15 Chiller Heater Evaporator Outlet Temperature Unit  $\langle x \rangle$  [C]****1.23.27.16 Chiller Heater Evaporator Mass Flow Rate Unit  $\langle x \rangle$  [C]**

These outputs are the evaporator water inlet and outlet temperatures and flow rate. Note that these represent the chilled water temperatures and flow rate in cooling mode or the source water temperature and flow rate in heating mode.

**1.23.27.17 Chiller Heater Condenser Inlet Temperature Unit  $\langle x \rangle$  [C]****1.23.27.18 Chiller Heater Condenser Outlet Temperature Unit  $\langle x \rangle$  [C]****1.23.27.19 Chiller Heater Condenser Mass Flow Rate Unit  $\langle x \rangle$  [C]**

These outputs are the condenser water inlet and outlet temperatures and flow rate. Note that these represent the hot water temperatures and flow rate in heating mode or the source water temperature and flow rate in cooling mode.

**1.23.27.20 Chiller Heater COP Unit  $\langle x \rangle$  [C]**

This output is the coefficient of performance for the chiller-heater. It is calculated as the evaporator heat transfer rate divided by the chiller-heater electric power.

**1.23.27.21 Chiller Heater Capacity Temperature Modifier Multiplier Unit  $\langle x \rangle$  [C]**

This is the output of the curve object Cooling Capacity Function of Temperature Curve.

**1.23.27.22 Chiller Heater EIR Temperature Modifier Multiplier Unit  $\langle x \rangle$  [C]**

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Temperature Curve.

**1.23.27.23 Chiller Heater EIR Part Load Modifier Multiplier Unit <x> [C]**

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve.

**1.24 Group – Water Heaters and Thermal Storage**

Water heater objects are components for storing and heating water. They can be coupled to a plant loop simulation or used stand-alone. Typical water heater applications are for domestic hot water heating, low-temperature radiant space heating, and energy storage for solar hot water systems or waste heat recovery.

When coupled to the plant loop, the water heater has an inlet node and outlet node on the “source side” and an inlet node and outlet node on the “use side”. The source side typically draws cold water from the tank and returns warmer water, for instance, from solar hot water systems or waste heat recovery systems. The use side typically draws hot water from the tank and returns cooler water from the cold water supply mains or from the outlet of a heating system. The distinction between source and use sides is merely a convenience for reporting. They can actually be used interchangeably. If so desired, either source side or use side can be used by itself, without the other side being connected to the plant loop.

However, for a water heater that is indirectly heated (e.g. with a separate boiler), the source side can be used to provide remotely heated water to the tank. The source side is configured to operate as a component on the demand side of a plant loop. The design flow rate through the source side can be set by the user or autosized. If autosized, then a Plant Sizing object is needed elsewhere in the input file for the Plant Loop serving the source side. The water heater input includes an additional design parameter that describes how rapidly the tank can recover.

If the use side only consists of domestic hot water usage, a simple scheduled use flow rate can be specified in lieu of the full plant loop connections. The scheduled use flow rate can be used simultaneously with source side plant connections, but cannot be used with use side plant connections.

For stand-alone operation, there are no node connections to the plant loop on either source or use sides. The scheduled use flow rate determines all fluid exchange with the water tank.

There are currently two water heater objects in EnergyPlus:

- **WaterHeater:Mixed**
- **WaterHeater:Stratified**

There are also compound objects that uses the **WaterHeater:Mixed** and/or **WaterHeater:Stratified** as part of their strategy:

- **WaterHeater:HeatPump:PumpedCondenser** (**WaterHeater:Mixed** or **WaterHeater:Stratified**)
- **WaterHeater:HeatPump:WrappedCondenser** (**WaterHeater:Stratified** only)

The **WaterHeater:Mixed** object simulates a well-mixed, single-node water tank. The **WaterHeater:Stratified** object simulates a stratified, multi-node water tank. Both water heater objects can be appropriate for simulating many types of water heaters and storage tanks, including gas and electric residential water heaters, and a variety of large commercial water heaters. Both objects share similar features, such as stand-alone operation, on- and off-cycle parasitic loads, and thermal losses to the zone. However, each object has its advantages which may make one water heater object more appropriate than the other depending on the application.

Advantages of **WaterHeater:Mixed**:

- can simulate instantaneous/tankless water heaters

Figure 1.96: Water Heater Configuration

- requires less input than the stratified tank
- faster execution time than the stratified tank
- adequate for modeling gas water heaters with no source connections.

Advantages of **WaterHeater:Stratified**:

- better modeling of electric water heaters with two heating elements
- better modeling of thermal storage applications which rely on stratification to improve heat transfer performance.

### 1.24.1 Standard Ratings

The EIO file reports the industry standard ratings of Recovery Efficiency and Energy Factor for water heater objects. The rating method is based on the GAMA and 10CFR430 test procedures. Under certain input parameters, the rating method will not succeed and a warning message will be generated. Problems occur when inputs do not allow the tank to recover to the setpoint temperature within the test period. This can occur if the maximum heater capacity is undersized, or if the deadband temperature difference is large enough that the first draw of the test does not trigger the heater to come on. In either case, the Recovery Efficiency test will not compute properly because recovery to the setpoint was not achieved.

Standard ratings for storage-only water tanks (Heater Maximum Capacity = 0) cannot be calculated and do not report anything in the EIO file.

### 1.24.2 WaterHeater:Mixed

The WaterHeater:Mixed object analytically solves the differential equation governing the energy balance of the water tank. Within a timestep, conditions are solved separately for when the heater element or burner is “on” (on-cycle) and when it is “off” (off-cycle). This approach allows ambient losses and parasitic loads to be divided into on-cycle and off-cycle effects and accounted for in detail.

For losses to the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, a fraction of the skin losses can be added to the zone heat balance as internal heat gains.

Control options allow the heater to cycle or modulate to meet the load. When cycling, the heater element or burner is either on or off. The heater remains fully on while heating the tank up to the setpoint temperature. When the setpoint is reached, the heater turns off. The heater remains off until the tank temperature falls below the “cut-in” temperature, i.e., the setpoint temperature minus the deadband temperature difference. The heater continuously cycles on and off to maintain the tank temperature within the deadband. Most storage-tank water heaters cycle.

When modulating, the heater power varies between the maximum and minimum heater capacities. The heater stays on as long as the required total demand is above the minimum capacity. Below the minimum capacity, the heater will begin to cycle on and off based on the deadband temperature difference. Equipment is usually designed and rated to avoid this condition. Most tankless/instantaneous water heaters modulate.

#### 1.24.2.1 Inputs

##### 1.24.2.1.1 Field: Name

The name of the WaterHeater:Mixed object.

#### 1.24.2.1.2 Field: Tank Volume

The volume of the storage tank [m<sup>3</sup>]. This field is autosizable if used with a Water Heater:Sizing object. Although this field is allowed to go down to zero, even so-called “tankless” water heaters have some volume of water that is maintained around the heating elements or in the heat exchanger, typically around 0.00379 m<sup>3</sup> (1 gallon).

#### 1.24.2.1.3 Field: Setpoint Temperature Schedule Name

The reference to the schedule object specifying the hot water temperature setpoint [°C]. Also known as the “cut-out” temperature.

#### 1.24.2.1.4 Field: Deadband Temperature Difference

The delta temperature difference [ $\Delta^{\circ}\text{C}$ ] between the setpoint and the “cut-in” temperature at which the heater will turn on. In other words, the “cut-in” temperature is Setpoint – Deadband.

#### 1.24.2.1.5 Field: Maximum Temperature Limit

The temperature [°C] at which the tank water becomes dangerously hot and is vented through boiling or an automatic safety. The tank temperature will never exceed the maximum. Any extra heat added to the tank is immediately vented. Note: The maximum temperature must be greater than the setpoint temperature at all times.

#### 1.24.2.1.6 Field: Heater Control Type

The control type can be **Cycle** or **Modulate**. Cycle is appropriate for most storage tank-type water heaters. Modulate is appropriate for most instantaneous/tankless water heaters.

#### 1.24.2.1.7 Field: Heater Maximum Capacity

The maximum heat rate [W] that can be supplied to the water, probably the same as the “nominal” capacity. This field is autosizable if used with a Water Heater:Sizing object.

#### 1.24.2.1.8 Field: Heater Minimum Capacity

The minimum heat rate [W] that can be supplied to the water. This field is only used when the Heater Control Type is **Modulate**. If the total demand rate for heating is less than the minimum, even a modulating water heater will begin to cycle.

#### 1.24.2.1.9 Field: Heater Ignition Minimum Flow Rate

NOT YET IMPLEMENTED.

#### 1.24.2.1.10 Field: Heater Ignition Delay

NOT YET IMPLEMENTED.

#### 1.24.2.1.11 Field: Heater Fuel Type

The type of fuel used for heating. The fuel type can be Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, Steam, OtherFuel1, OtherFuel2 or **DistrictHeating**.

#### 1.24.2.1.12 Field: Heater Thermal Efficiency

The thermal conversion efficiency from fuel energy to heat energy for the heater element or burner. This is not the same as the overall efficiency of the water heater.

**1.24.2.1.13 Field: Part Load Factor Curve Name**

The reference to the curve object that relates the overall efficiency of the water heater to the Runtime Fraction (if Control Type **Cycle**) or Part Load Ratio (if Control Type **Modulate**). This is an additional multiplier applied to the Heater Thermal Efficiency to compute fuel energy use. The Part Load Factor Curve should not have a value less than 0.1 in the domain from 0 to 1. If the Part Load Factor Curve accounts for ambient losses and/or parasitic fuel consumption, these effects should not also be input into the related fields in this object as that would result in double-counting.

**1.24.2.1.14 Field: Off-Cycle Parasitic Fuel Consumption Rate**

Off-cycle parasitics include parts of the water heater that consume fuel when the heater is off, for example, a pilot light, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the off-cycle parasitics.

**1.24.2.1.15 Field: Off-Cycle Parasitic Fuel Type**

The type of fuel used by the off-cycle parasitics. The fuel type can be Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, Steam, OtherFuel1, OtherFuel2 or **DistrictHeating**. The fuel type can be the same or different from the Heater Fuel Type.

**1.24.2.1.16 Field: Off-Cycle Parasitic Heat Fraction to Tank**

The fraction of off-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, a pilot light would deliver most of its heat to the tank water, as long as the thermal conversion efficiency must be taken into account, so perhaps 0.80 is reasonable. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

**1.24.2.1.17 Field: On-Cycle Parasitic Fuel Consumption Rate**

On-cycle parasitics include parts of the water heater that consume fuel when the heater is on, for example, an induction fan, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the on-cycle parasitics.

**1.24.2.1.18 Field: On-Cycle Parasitic Fuel Type**

The type of fuel used by the on-cycle parasitics. The fuel type can be Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, Steam, OtherFuel1, OtherFuel2 or **DistrictHeating**. The fuel type can be the same or different from the Heater Fuel Type.

**1.24.2.1.19 Field: On-Cycle Parasitic Heat Fraction to Tank**

The fraction of on-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, an induction fan might (maybe) deliver a small fraction of its energy to the tank water for a value of 0.05. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

**1.24.2.1.20 Field: Ambient Temperature Indicator**

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be **Schedule**, **Zone**, or **Outdoors**. If **Schedule** is used, the Ambient Temperature Schedule field provides the ambient temperature. If **Zone** is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If **Outdoors** is used, the outdoor dry-bulb air temperature provides the ambient temperature.

**1.24.2.1.21 Field: Ambient Temperature Schedule Name**

The reference to the schedule object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Schedule**.

**1.24.2.1.22 Field: Ambient Temperature Zone Name**

The reference to the zone object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Zone**.

**1.24.2.1.23 Field: Ambient Temperature Outdoor Air Node Name**

This optional alpha field specifies the outdoor air node name used to define the ambient conditions surrounding the water heater tank. This field is applicable only when the Ambient Temperature Indicator is specified as **Outdoors**, otherwise this field should be left blank. The node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

**1.24.2.1.24 Field: Off-Cycle Loss Coefficient to Ambient Temperature**

The loss coefficient [W/K] to the ambient air temperature. Often this coefficient is identical to the “UA” for skin losses. However, it can also be used to model the loss effects of the flue in a combustion water heater, in addition to the skin losses.

**1.24.2.1.25 Field: Off-Cycle Loss Fraction to Zone**

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the off-cycle losses to the zone heat balance as an internal gain.

**1.24.2.1.26 Field: On-Cycle Loss Coefficient to Ambient Temperature**

The loss coefficient [W/K] to the ambient air temperature. Often this coefficient is identical to the “UA” for skin losses. If the loss effects of the flue are being modeled in the Off-Cycle Loss Coefficient, than this field would have a different value accounting only for the skin losses.

**1.24.2.1.27 Field: On-Cycle Loss Fraction to Zone**

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the on-cycle losses to the zone heat balance as an internal gain.

**1.24.2.1.28 Field: Peak Use Flow Rate**

The peak flow rate [m<sup>3</sup>/s] of domestic hot water usage for stand-alone operation, i.e., without plant loop node connections. The peak value is multiplied by the Use Flow Rate Fraction Schedule. If there are node connections, this field is not used.

**1.24.2.1.29 Field: Use Flow Rate Fraction Schedule Name**

The reference to the schedule object specifying the current fraction of Peak Volumetric Use Flow Rate of domestic hot water usage for stand-alone operation.

**1.24.2.1.30 Field: Cold Water Supply Temperature Schedule Name**

The reference to the schedule object specifying the cold water temperature [°C] from the supply mains that makes up for the hot water lost down the drain. If blank, water temperatures are calculated by the **Site:WaterMainsTemperature** object. This field is for stand-alone operation only. If there are node connections, this field is not used.

**1.24.2.1.31 Field: Use Side Inlet Node Name**

The inlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

**1.24.2.1.32 Field: Use Side Outlet Node Name**

The outlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

**1.24.2.1.33 Field: Use Side Effectiveness**

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is lower, then the use side outlet water temperature will not be as hot as the tank water, simulating a heat exchanger.

**1.24.2.1.34 Field: Source Side Inlet Node Name**

The inlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water. The source side volume flow rate is obtained from the plant loop. The magnitude of the flow rates through the source side can be controlled by setting the Maximum Branch Flow Rate field in the **Branch** object that connects the source inlet node.

**1.24.2.1.35 Field: Source Side Outlet Node Name**

The outlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water.

**1.24.2.1.36 Field: Source Side Effectiveness**

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is lower, then the source side outlet water temperature will not be as hot as the tank water, simulating a heat exchanger.

**1.24.2.1.37 Field: Use Side Design Flow Rate**

This field is optional and is used to specify the design flow rate through the Use Side of the water heater. The volumetric design flow rate is specified in  $\text{m}^3/\text{s}$ . The field is needed when the Use Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

**1.24.2.1.38 Field: Source Side Design Flow Rate**

This field is optional and is used to specify the design flow rate through the Source Side of the water heater. The volumetric design flow rate is specified in  $\text{m}^3/\text{s}$ . The field is needed when the Source Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

**1.24.2.1.39 Field: Indirect Water Heating Recovery Time**

This field is optional and is used to provide a design parameter for autosizing design flow rates when the water heater is connected to the demand side of a plant loop. The recovery time is expressed in hours. This is the time that the entire volume of the tank can be heated from 14.4°C to 57.2°C (58°F to 135°F) with an inlet temperature defined as the exit temperature in the associated Plant Sizing object. The default

is 1.5 hours. The calculation is based on log-mean temperature difference (LMTD) and includes the heat transfer effectiveness factor entered above.

#### 1.24.2.1.40 Field: Source Side Flow Control Mode

This field is optional and is used to provide control over the logic used by the source side of the water heater to request flow. There are three choices for different modes: IndirectHeatPrimarySetpoint, IndirectHeatAlternateSetpoint, or StorageTank. The mode called IndirectHeatPrimarySetpoint is the historical behavior prior to version 8.1. In this mode the water heater will request flow at the source side when the main setpoint, in the input field called Setpoint Temperature Schedule Name, and deadband call for the tank to be heated. This mode is typical for a water heater indirectly heated by a boiler. The mode called IndirectHeatAlternateSetpoint is similar but it bases its control decisions on an alternate setpoint given in the following field. This mode is useful when the indirect source of heat may not satisfy the load and an internal heater is used for backup. The mode called StorageTank is for a passive tank and it always requests flow unless the tank temperature is equal to or higher than the maximum limit given in the input field called Maximum Temperature Limit.

#### 1.24.2.1.41 Field: Indirect Alternate Setpoint Temperature Schedule Name

This field is optional and is used to provide a schedule with alternate setpoints for use with the IndirectHeatAlternateSetpoint mode in the previous field. The input field should contain a reference to a schedule object specifying the hot water temperature setpoint [°C] to use as the “cut-out” temperature for control logic at the source side.

#### 1.24.2.1.42 Field: End-Use Subcategory

This optional field allows you to specify a user-defined end-use subcategory, e.g., “Process”. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the water heater will be assigned to the “General” end-use subcategory.

### 1.24.2.2 Outputs

The following output variables are reported for the WaterHeater:Mixed object:

- HVAC,Average,Water Heater Tank Temperature [C]
- HVAC,Average,Water Heater Final Tank Temperature [C]
- HVAC,Average,Water Heater Heat Loss Rate [W]
- HVAC,Sum,Water Heater Heat Loss Energy [J]
- HVAC,Average, Water Heater Use Side Mass Flow Rate [kg/s]
- HVAC,Average,Water Heater Use Side Inlet Temperature [C]
- HVAC,Average,Water Heater Use Side Outlet Temperature [C]

- HVAC,Average,Water Heater Use Side Heat Transfer Rate [W]
- HVAC,Sum,Water Heater Use Side Heat Transfer Energy [J]
- HVAC,Average,Water Heater Source Side Mass Flow Rate [kg/s]
- HVAC,Average,Water Heater Source Side Inlet Temperature [C]
- HVAC,Average,Water Heater Source Side Outlet Temperature [C]
- HVAC,Average,Water Heater Source Side Heat Transfer Rate [W]
- HVAC,Sum,Water Heater Source Side Heat Transfer Energy [J]
- HVAC,Average,Water Heater Off Cycle Parasitic Tank Heat Transfer Rate [W]
- HVAC,Sum,Water Heater Off Cycle Parasitic Tank Heat Transfer Energy [J]
- HVAC,Average,Water Heater On Cycle Parasitic Tank Heat Transfer Rate [W]
- HVAC,Sum,Water Heater On Cycle Parasitic Tank Heat Transfer Energy [J]
- HVAC,Average,Water Heater Total Demand Heat Transfer Rate [W]
- HVAC,Sum,Water Heater Total Demand Energy [J]
- HVAC,Average,Water Heater Heating Rate [W]
- HVAC,Sum,Water Heater Heating Energy [J]
- HVAC,Average,Water Heater Unmet Demand Heat Transfer Rate [W]
- HVAC,Sum,Water Heater Unmet Demand Heat Transfer Energy [J]
- HVAC,Average,Water Heater Venting Heat Transfer Rate [W]
- HVAC,Sum,Water Heater Venting Heat Transfer Energy [J]
- HVAC,Average,Water Heater Net Heat Transfer Rate [W]
- HVAC,Sum,Water Heater Net Heat Transfer Energy [J]
- HVAC,Sum,Water Heater Cycle On Count []
- HVAC,Average,Water Heater Runtime Fraction []
- HVAC,Average,Water Heater Part Load Ratio []

- HVAC,Average,Water Heater <Fuel Type> Rate [W]
- HVAC,Sum,Water Heater <Fuel Type> Energy [J]
- HVAC,Average,Water Heater Off Cycle Parasitic <Fuel Type> Rate [W]
- HVAC,Sum,Water Heater Off Cycle Parasitic <Fuel Type> Energy [J]
- HVAC,Average,Water Heater On Cycle Parasitic <Fuel Type> Rate [W]

- HVAC,Sum,Water Heater On Cycle Parasitic <Fuel Type> Energy [J]
- HVAC,Average,Water Heater Water Volume Flow Rate [m3/s]
- HVAC,Sum,Water Heater Water Volume [m3]

#### 1.24.2.2.1 Water Heater Tank Temperature [C]

The average water tank temperature.

#### 1.24.2.2.2 Water Heater Final Tank Temperature [C]

The final water tank temperature at the end of the system timestep. If reported at the “Detailed” interval, this output variable can be used to verify an exact energy balance on the water heater. Also see the output variable: Water Heater Net Heat Transfer Energy.

#### 1.24.2.2.3 Water Heater Heat Loss Rate [W]

The average heat loss rate due to the off- and on-cycle loss coefficients to the ambient temperature.

#### 1.24.2.2.4 Water Heater Heat Loss Energy [J]

The heat loss energy due to the off- and on-cycle loss coefficients to the ambient temperature.

#### 1.24.2.2.5 Water Heater Use Side Mass Flow Rate [kg/s]

The use side mass flow rate. If stand-alone, this is the scheduled use flow rate.

#### 1.24.2.2.6 Water Heater Use Side Inlet Temperature [C]

The inlet temperature on the use side.

#### 1.24.2.2.7 Water Heater Use Side Outlet Temperature [C]

The outlet temperature on the use side.

#### 1.24.2.2.8 Water Heater Use Side Heat Transfer Rate [W]

The average heat transfer rate between the use side water and the tank water.

#### 1.24.2.2.9 Water Heater Use Side Heat Transfer Energy [J]

The heat transfer energy between the use side water and the tank water.

#### 1.24.2.2.10 Water Heater Source Side Mass Flow Rate [kg/s]

The source side mass flow rate. If in stand-alone operation, this is 0.

#### 1.24.2.2.11 Water Heater Source Side Inlet Temperature [C]

The inlet temperature on the source side.

#### 1.24.2.2.12 Water Heater Source Side Outlet Temperature [C]

The outlet temperature on the source side.

#### 1.24.2.2.13 Water Heater Source Side Heat Transfer Rate [W]

The average heat transfer rate between the source side water and the tank water.

**1.24.2.2.14 Water Heater Source Side Heat Transfer Energy [J]**

The heat transfer energy between the source side water and the tank water.

**1.24.2.2.15 Water Heater Off Cycle Parasitic Tank Heat Transfer Rate [W]**

The average heat gain rate to the tank water due to off-cycle parasitics.

**1.24.2.2.16 Water Heater Off Cycle Parasitic Tank Heat Transfer Energy [J]**

The heat gain energy to the tank water due to off-cycle parasitics.

**1.24.2.2.17 Water Heater On Cycle Parasitic Tank Heat Transfer Rate [W]**

The average heat gain rate to the tank water due to on-cycle parasitics.

**1.24.2.2.18 Water Heater On Cycle Parasitic Tank Heat Transfer Energy [J]**

The heat gain energy to the tank water due to on-cycle parasitics.

**1.24.2.2.19 Water Heater Total Demand Heat Transfer Rate [W]**

The average heating rate demanded to maintain the setpoint temperature.

**1.24.2.2.20 Water Heater Total Demand Energy [J]**

The heating energy demanded to maintain the setpoint temperature.

**1.24.2.2.21 Water Heater Heating Rate [W]**

The average heating rate supplied by the heater element or burner.

**1.24.2.2.22 Water Heater Heating Energy [J]**

The heating energy supplied by the heater element or burner.

**1.24.2.2.23 Water Heater Unmet Demand Heat Transfer Rate [W]**

The average heating rate unmet by the heater element or burner. The difference between the Total Demand Rate and the Heating Rate.

**1.24.2.2.24 Water Heater Unmet Demand Heat Transfer Energy [J]**

The heating energy unmet by the heater element or burner. The difference between the Total Demand Energy and the Heating Energy.

**1.24.2.2.25 Water Heater Venting Heat Transfer Rate [W]**

The average venting rate to keep the tank below the Maximum Temperature Limit.

**1.24.2.2.26 Water Heater Venting Heat Transfer Energy [J]**

The venting energy to keep the tank below the Maximum Temperature Limit.

**1.24.2.2.27 Water Heater Net Heat Transfer Rate [W]**

The average net heat transfer rate when considering all losses and gains.

**1.24.2.2.28 Water Heater Net Heat Transfer Energy [J]**

The net heat transfer energy when considering all losses and gains.

**1.24.2.2.29 Water Heater Cycle On Count []**

The number of times that the heater turned on in the time period.

**1.24.2.2.30 Water Heater Runtime Fraction []**

The fraction of the time period that the heater was running.

**1.24.2.2.31 Water Heater Part Load Ratio []**

The fraction of the Heater Maximum Capacity.

**1.24.2.2.32 Water Heater <Fuel Type> Rate [W]****1.24.2.2.33 Water Heater Electricity Rate [W]**

The average fuel consumption rate for the heater element or burner.

**1.24.2.2.34 Water Heater <Fuel Type> Energy [J]**

The fuel consumption energy for the heater element or burner.

**1.24.2.2.35 Water Heater Off Cycle Parasitic <Fuel Type> Rate [W]****1.24.2.2.36 Water Heater Off Cycle Parasitic Electricity Rate [W]**

The average fuel consumption rate for the off-cycle parasitics.

**1.24.2.2.37 Water Heater Off Cycle Parasitic <Fuel Type> Energy [J]**

The fuel consumption energy for the off-cycle parasitics.

**1.24.2.2.38 Water Heater On Cycle Parasitic <Fuel Type> Rate [W]****1.24.2.2.39 Water Heater On Cycle Parasitic Electricity Rate [W]**

The average fuel consumption rate for the on-cycle parasitics.

**1.24.2.2.40 Water Heater On Cycle Parasitic <Fuel Type> Energy [J]**

The fuel consumption energy for the on-cycle parasitics.

**1.24.2.2.41 Water Heater Water Volume Flow Rate [m<sup>3</sup>/s]**

The water consumption rate for the use side, if in stand-alone operation.

**1.24.2.2.42 Water Heater Water Volume [m<sup>3</sup>]**

The water consumption for the use side, if in stand-alone operation.

**1.24.2.2.43 Water Heater Mains Water Volume [m<sup>3</sup>]**

The volume of water consumption drawn from mains water service.

### 1.24.3 WaterHeater:Stratified

The WaterHeater:Stratified object divides the water tank into multiple nodes of equal volume. The nodes are coupled by vertical conduction effects, internode fluid flow, and temperature inversion mixing. The object simultaneously solves the differential equations governing the energy balances on the nodes using a numerical method. The system timestep is divided into many small substeps that allow the simulation to capture events that occur on a very short time scale. This approach allows ambient losses and parasitic loads to be divided into on-cycle and off-cycle effects and accounted for in detail.

For losses to the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, a fraction of the skin losses can be added to the zone heat balance as internal heat gains.

The WaterHeater:Stratified object allows two heating elements to be simulated. The two elements can cycle on and off to maintain the node temperature within the deadband. The Heater Priority Control field determines how the heaters work together. There are two options: MasterSlave or Simultaneous. In the MasterSlave option, Heater 1 is the master and Heater 2 is the slave. That is, both heaters are not allowed to turn on at the same time. If the thermostats ask for heat at both Heater 1 and 2, only Heater 1 will turn on. Once Heater 1 has met the set point, it turns off and Heater 2 can turn on, if necessary. In the Simultaneous option, Heater 1 and Heater 2 can turn on and off independently. Autosizing is available for only Heater 1.

#### 1.24.3.1 Inputs

##### 1.24.3.1.1 Field: Name

The name of the WaterHeater:Stratified object.

##### 1.24.3.1.2 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Laundry”, “Dish Washing”, etc. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Subcategories are also reported in the ABUPS table under the “Water Systems” end-use category and also appear in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the water use will be assigned to the “General” end-use subcategory.

##### 1.24.3.1.3 Field: Tank Volume

The actual volume [m3] of fluid in the tank. This field is autosizable if used with a Water Heater:Sizing object. The actual volume is typically not equal to the nominal volume specified by the manufacturer. Actual volume is almost always 10% lower for electric water heaters, and 5% lower for gas water heaters (Burch and Erickson 2004).

Burch, J., and P. Erickson. 2004. “Using Ratings Data to Derive Simulation-Model Inputs for Storage-Tank Water Heaters”. *Proceedings of the Solar 2004 Conference, 11-14 July 2004, Portland, Oregon*, American Solar Energy Society (ASES), pp. 393-398.

##### 1.24.3.1.4 Field: Tank Height

The height [m] of the tank. For the **HorizontalCylinder** shape (see below) the height of the tank is the measure in the axial direction, i.e., the height if you were to stand the cylinder up on its end. This field is autosizable if used with a Water Heater:Sizing object.

##### 1.24.3.1.5 Field: Tank Shape

The tank shape determines the size and skin losses of the stratified nodes. There are three options: **VerticalCylinder**, **HorizontalCylinder**, and **Other**.

**VerticalCylinder** describes most upright residential water heaters.

**HorizontalCylinder** describes a few specialty water heaters and large commercial storage tanks. **HorizontalCylinder** can also be used to model an outdoor storage tank located above a solar collector in a thermosiphon configuration. **HorizontalCylinder** implies that the tank is divided into nodes of equal mass, but not equal height.

**Other** describes water heaters or storage tanks that have a uniform horizontal cross-section, but are not cylinders, e.g., a cuboid or other shape. The length of the perimeter is then specified by the Tank Perimeter field.

If blank, the default shape is **VerticalCylinder**.

#### 1.24.3.1.6 Field: Tank Perimeter

The length of the tank perimeter [m]. This field is only used if Tank Shape is **Other**.

#### 1.24.3.1.7 Field: Maximum Temperature Limit

The temperature [°C] at which the tank water becomes dangerously hot and is vented through boiling or an automatic safety. The tank temperature will never exceed the maximum. Any extra heat added to the tank is immediately vented. Note: The maximum temperature must be greater than the setpoint temperature at all times.

#### 1.24.3.1.8 Field: Heater Priority Control

The heater priority control determines how Heater 1 and Heater 2 work together. There are two options: **MasterSlave** or **Simultaneous**. In the **MasterSlave** option, Heater 1 is the master and Heater 2 is the slave. In most residential electric water heaters, the heaters operate in a **MasterSlave** relationship. That is, both heaters are not allowed to turn on at the same time. If the thermostats ask for heat at both Heater 1 and 2, only Heater 1 will turn on. Once Heater 1 has met the set point, it turns off and Heater 2 can turn on, if necessary. In other words, only one heater can be on at any time, and Heater 1 is always has priority over Heater 2.

In the **Simultaneous** option, Heater 1 and Heater 2 can turn on and off independently.

If blank, the default is **MasterSlave**.

#### 1.24.3.1.9 Field: Heater 1 Set Point Temperature Schedule Name

The reference to the schedule object specifying the hot water temperature set point [°C] for Heater 1. Also known as the “cut-out” temperature.

#### 1.24.3.1.10 Field: Heater 1 Deadband Temperature Difference

The delta temperature difference [ $\Delta^{\circ}\text{C}$ ] between the set point and the “cut-in” temperature at which Heater 1 will turn on. In other words, the “cut-in” temperature is Set Point – Deadband.

#### 1.24.3.1.11 Field: Heater 1 Capacity

The heat rate [W] supplied to the water for Heater 1, probably the same as the “nominal” capacity. For residential electric water heaters, heating elements are usually 4500 W. This field is autosizable if used with a Water Heater:Sizing object.

#### 1.24.3.1.12 Field: Heater 1 Height

The height [m] of Heater 1 in the tank.

**1.24.3.1.13 Field: Heater 2 Set Point Temperature Schedule Name**

The reference to the schedule object specifying the hot water temperature set point [°C] for Heater 2. Also known as the “cut-out” temperature.

**1.24.3.1.14 Field: Heater 2 Deadband Temperature Difference**

The delta temperature difference [ $\Delta^{\circ}\text{C}$ ] between the set point and the “cut-in” temperature at which Heater 2 will turn on. In other words, the “cut-in” temperature is Set Point – Deadband.

**1.24.3.1.15 Field: Heater 2 Capacity**

The heat rate [W] supplied to the water for Heater 1, probably the same as the “nominal” capacity. For residential electric water heaters, heating elements are usually 4500 W.

**1.24.3.1.16 Field: Heater 2 Height**

The height [m] of Heater 2 in the tank.

**1.24.3.1.17 Field: Heater Fuel Type**

The type of fuel used for both Heaters 1 and 2. The fuel type can be Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, Steam, OtherFuel1, OtherFuel2 or **DistrictHeating**.

**1.24.3.1.18 Field: Heater Thermal Efficiency**

The thermal conversion efficiency from fuel energy to heat energy for the heater element or burner (for both Heaters 1 and 2). This is not the same as the overall efficiency of the water heater.

**1.24.3.1.19 Field: Off-Cycle Parasitic Fuel Consumption Rate**

Off-cycle parasitics include parts of the water heater that consume fuel when the heater is off, for example, a pilot light, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the off-cycle parasitics.

**1.24.3.1.20 Field: Off-Cycle Parasitic Fuel Type**

The type of fuel used by the off-cycle parasitics. The fuel type can be Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, Steam, OtherFuel1, OtherFuel2 or **DistrictHeating**. The fuel type can be the same or different from the Heater Fuel Type.

**1.24.3.1.21 Field: Off-Cycle Parasitic Heat Fraction to Tank**

The fraction of off-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, a pilot light would deliver most of its heat to the tank water, as long as the thermal conversion efficiency must be taken into account, so perhaps 0.80 is reasonable. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

**1.24.3.1.22 Field: Off-Cycle Parasitic Height**

The height [m] where any off-cycle parasitic heat gains are added to the tank.

**1.24.3.1.23 Field: On-Cycle Parasitic Fuel Consumption Rate**

On-cycle parasitics include parts of the water heater that consume fuel when the heater is on, for example, an induction fan, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the on-cycle parasitics.

#### 1.24.3.1.24 Field: On-Cycle Parasitic Fuel Type

The type of fuel used by the on-cycle parasitics. The fuel type can be Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Coal, Diesel, Gasoline, Steam, OtherFuel1, OtherFuel2 or **DistrictHeating**. The fuel type can be the same or different from the Heater Fuel Type.

#### 1.24.3.1.25 Field: On-Cycle Parasitic Heat Fraction to Tank

The fraction of on-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, an induction fan might (maybe) deliver a small fraction of its energy to the tank water for a value of 0.05. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

#### 1.24.3.1.26 Field: On-Cycle Parasitic Height

The height [m] where any on-cycle parasitic heat gains are added to the tank.

#### 1.24.3.1.27 Field: Ambient Temperature Indicator

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be **Schedule**, **Zone**, or **Outdoors**. If **Schedule** is used, the Ambient Temperature Schedule value provides the ambient temperature. If **Zone** is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If **Outdoors** is used, the outdoor dry-bulb air temperature of the outdoor air node specified in the Ambient Temperature **OutdoorAir:Node** field provides the ambient temperature.

#### 1.24.3.1.28 Field: Ambient Temperature Schedule Name

The reference to the schedule object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Schedule**.

#### 1.24.3.1.29 Field: Ambient Temperature Zone

The reference to the zone object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Zone**.

#### 1.24.3.1.30 Field: Ambient Temperature Outdoor Air Node

The reference to the outdoor air node specifying the ambient air temperature around the tank for skin losses. An outdoor air node can be defined by an **OutdoorAir:Node** object or **OutdoorAir:NodeList** object. This field is only used if Ambient Temperature Indicator is **Outdoors**.

#### 1.24.3.1.31 Field: Uniform Skin Loss Coefficient Per Unit Area to Ambient Temperature

The uniform skin loss coefficient [W/m<sup>2</sup>-K] or U-Value of the tank to the ambient air temperature. The uniform skin loss accounts for the tank insulation and applies during both off- and on-cycle operation. The overall losses at any particular node can be further modified using the Additional Loss Coefficient fields to account for thermal shorting due to pipe penetrations, water heater feet, and any other loss effects.

#### 1.24.3.1.32 Field: Skin Loss Fraction to Zone

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the skin losses to the zone heat balance as an internal gain.

**1.24.3.1.33 Field: Off-Cycle Flue Loss Coefficient to Ambient Temperature**

The off-cycle flue loss coefficient [W/K] to the ambient air temperature. This field mainly applies to gas water heaters that have a flue.

**1.24.3.1.34 Field: Off-Cycle Flue Loss Fraction to Zone**

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the off-cycle flue losses to the zone heat balance as an internal gain.

**1.24.3.1.35 Field: Peak Use Flow Rate**

The peak flow rate [m<sup>3</sup>/s] of domestic hot water usage for stand-alone operation, i.e., without plant loop node connections. The peak value is multiplied by the Use Flow Rate Fraction Schedule. If there are node connections, this field is not used.

**1.24.3.1.36 Field: Use Flow Rate Fraction Schedule Name**

The reference to the schedule object specifying the current fraction of Peak Volumetric Use Flow Rate of domestic hot water usage for stand-alone operation. If blank, the fraction defaults to 1.0 at all times.

**1.24.3.1.37 Field: Cold Water Supply Temperature Schedule Name**

The reference to the schedule object specifying the cold water temperature [°C] from the supply mains that makes up for the hot water lost down the drain. If blank, water temperatures are calculated by the [Site:WaterMainsTemperature](#) object. This field is for stand-alone operation only. If there are node connections, this field is not used.

**1.24.3.1.38 Field: Use Side Inlet Node Name**

The inlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

**1.24.3.1.39 Field: Use Side Outlet Node Name**

The outlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

**1.24.3.1.40 Field: Use Side Effectiveness**

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is less than 1.0, then the use side outlet water temperature will not be as hot as the tank water at the outlet node, simulating an external heat exchanger that is indirectly coupled to the water heater tank.

**1.24.3.1.41 Field: Use Side Inlet Height**

The height of the use side inlet to the tank. If blank, the inlet defaults to the bottom of the tank. The inlet height cannot be higher than the tank height.

**1.24.3.1.42 Field: Use Side Outlet Height**

The height of the use side outlet from the tank. If blank or **autocalculate**, the inlet defaults to the top of the tank. The outlet height cannot be higher than the tank height.

**1.24.3.1.43 Field: Source Side Inlet Node**

The inlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water.

**1.24.3.1.44 Field: Source Side Outlet Node**

The outlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water.

**1.24.3.1.45 Field: Source Side Effectiveness**

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is less than 1.0, then the source side outlet water temperature will be higher than the tank water at the outlet node, simulating an external heat exchanger that is indirectly coupled to the water heater tank.

**1.24.3.1.46 Field: Source Side Inlet Height**

The height of the source side inlet to the tank. If blank or **autocalculate**, the inlet defaults to the top of the tank. The inlet height cannot be higher than the tank height.

**1.24.3.1.47 Field: Source Side Outlet Height**

The height of the source side outlet from the tank. If blank, the inlet defaults to the bottom of the tank. The outlet height cannot be higher than the tank height.

**1.24.3.1.48 Field: Inlet Mode**

The inlet mode of entering fluid from the use and source sides. There are two options: **Fixed** or **Seeking**. In Fixed mode, the fluid enters at the fixed heights specified above. In Seeking mode, the fluid “seeks out” the stratified node that is closest to the inlet temperature and adds all flow to that node. The Seekingmode provides maximum stratification. The default is **Fixed**.

**1.24.3.1.49 Field: Use Side Design Flow Rate**

This field is optional and is used to specify the design flow rate through the Use Side of the water heater. The volumetric design flow rate is specified in  $\text{m}^3/\text{s}$ . The field is needed when the Use Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

**1.24.3.1.50 Field: Source Side Design Flow Rate**

This field is optional and is used to specify the design flow rate through the Source Side of the water heater. The volumetric design flow rate is specified in  $\text{m}^3/\text{s}$ . The field is needed when the Source Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

**1.24.3.1.51 Field: Indirect Water Heating Recovery Time**

This field is optional and is used to provide a design parameter for autosizing design flow rates when the water heater is connected to the demand side of a plant loop. The recovery time is expressed in hours. This is the time that the entire volume of the tank can be heated from 14.4°C to 57.2°C (58°F to 135°F) with an inlet temperature defined as the exit temperature in the associated Plant Sizing object. The default is 1.5 hours. The calculation is based on log-mean temperature difference (LMTD) and includes the heat transfer effectiveness factor entered above.

**1.24.3.1.52 Field: Number Of Nodes**

The number of stratified nodes in the tank. There must be at least one node. The maximum number of nodes is 12, although this limit can be increased by editing the IDD.

**1.24.3.1.53 Field: Additional Destratification Conductivity**

An additional destratification conductivity [W/m-K] is added to the fluid conductivity of water (0.6 W/m-K) to account for vertical conduction effects along the inside of the tank wall, and perhaps other vertical components such as the flue, the cold water inlet pipe (dip tube), and the anode rod.

**1.24.3.1.54 Field: Node 1-12 Additional Loss Coefficient**

An additional loss coefficient [W/K] added to the skin losses for a given node to account for thermal shorting due to pipe penetrations, water heater feet, and any other loss effects.

**1.24.3.1.55 Field: Source Side Flow Control Mode**

This field is optional and is used to provide control over the logic used by the source side of the water heater to request flow. There are three choices for different modes: IndirectHeatPrimarySetpoint, IndirectHeatAlternateSetpoint, or StorageTank. The mode called IndirectHeatPrimarySetpoint is the historical behavior prior to version 8.1. In this mode the water heater will request flow at the source side when the main setpoint, in the input field called Setpoint Temperature Schedule Name, and deadband call for the tank to be heated. This mode is typical for a water heater indirectly heated by a boiler. The mode called IndirectHeatAlternateSetpoint is similar but it bases its control decisions on an alternate setpoint given in the following field. This mode is useful when the indirect source of heat may not satisfy the load and an internal heater is used for backup. The mode called StorageTank is for a passive tank and it always requests flow unless the tank temperature is equal to or higher than the maximum limit given in the input field called Maximum Temperature Limit.

**1.24.3.1.56 Field: Indirect Alternate Setpoint Temperature Schedule Name**

This field is optional and is used to provide a schedule with alternate setpoints for use with the IndirectHeatAlternateSetpoint mode in the previous field. The input field should contain a reference to a schedule object specifying the hot water temperature setpoint [°C] to use as the “cut-out” temperature for control logic at the source side.

### 1.24.3.2 Outputs

All of the output variables reported for the WaterHeater:Mixed object also apply to the WaterHeater:Stratified object, with several qualifications noted below:

#### 1.24.3.2.1 Water Heater Tank Temperature [C]

The average water tank temperature, i.e., the average of all of the node average temperatures.

#### 1.24.3.2.2 Water Heater Final Tank Temperature [C]

The final water tank temperature at the end of the system timestep, i.e., the average of all of the final node temperatures at the end of the system timestep. If reported at the “Detailed” interval, this output variable can be used to verify an exact energy balance on the water heater.

#### 1.24.3.2.3 Water Heater Heating Rate [W]

The total average heating rate supplied by Heater 1 plus Heater 2.

#### 1.24.3.2.4 Water Heater Heating Energy [J]

The total heating energy supplied by Heater 1 plus Heater 2.

#### 1.24.3.2.5 Water Heater Cycle On Count []

The number of times that either Heater 1 or Heater 2 turned on in the time period.

**1.24.3.2.6 Water Heater Runtime Fraction []**

The fraction of the time period that either Heater 1 or Heater 2 was running.

In addition, the WaterHeater:Stratified object also reports the following output variables:

- HVAC,Average,Water Heater Heater 1 Heating Rate [W]
- HVAC,Average,Water Heater Heater 2 Heating Rate [W]
- HVAC,Sum,Water Heater Heater 1 Heating Energy [J]
- HVAC,Sum,Water Heater Heater 2 Heating Energy [J]
- HVAC,Sum,Water Heater Heater 1 Cycle On Count []
- HVAC,Sum,Water Heater Heater 2 Cycle On Count []
- HVAC,Average,Water Heater Heater 1 Runtime Fraction []
- HVAC,Average,Water Heater Heater 2 Runtime Fraction []
- HVAC,Average,Water Heater Temperature Node <x> [C]
- HVAC,Average,Water Heater Final Temperature Node <x> [C]

**1.24.3.2.7 Water Heater Heater 1 Heating Rate [W]**

The average heating rate supplied by Heater 1.

**1.24.3.2.8 Water Heater Heater 2 Heating Rate [W]**

The average heating rate supplied by Heater 2.

**1.24.3.2.9 Water Heater Heater 1 Heating Energy [J]**

The heating energy supplied by Heater 1.

**1.24.3.2.10 Water Heater Heater 2 Heating Energy [J]**

The heating energy supplied by Heater 2.

**1.24.3.2.11 Water Heater Heater 1 Cycle On Count []**

The number of times that Heater 1 turned on in the time period.

**1.24.3.2.12 Water Heater Heater 2 Cycle On Count []**

The number of times that Heater 2 turned on in the time period.

**1.24.3.2.13 Water Heater Heater 1 Runtime Fraction []**

The fraction of the time period that Heater 1 was running.

**1.24.3.2.14 Water Heater Heater 2 Runtime Fraction []**

The fraction of the time period that Heater 2 was running.

**1.24.3.2.15 Water Heater Temperature Node 1-12 [C]**

The average node temperature.

### 1.24.3.2.16 Water Heater Final Temperature Node 1-12 [C]

The final node temperature at the end of the system timestep.

## 1.24.4 WaterHeater:Sizing

The WaterHeater:Sizing object is used to provide additional input data needed for designing tank volume and/or heater capacity for either the Mixed or Stratified water heaters. This object is only needed if volume or capacity is being automatically sized. There are no output variable associated with this object – sizing results are reported to the EIO output file and some predefined summary reports.

A source of design input data for use with this object can be found in the current ASHRAE Handbook HVAC Applications chapter on Service Water Heating.

The idd entry for this object follows.

### 1.24.4.1 Inputs

#### 1.24.4.1.1 Field: WaterHeater Name

This field contains the unique name of the water heater being sized. This name should match the name of a Water Heater:Mixed or a Water Heater:Stratified input object defined elsewhere in the input file.

#### 1.24.4.1.2 Field: Design Mode

This field describes which of several methods are to be used for sizing the water heater. There are six possible choices and one of the following should be selected:

- **PeakDraw**. This design method uses the design flow rates of all the different demands placed on the water heater. The tank size is based on how long it can meet the demand and how quickly it can recover. The user enters the time in hours that the water heater can meet the demands. Only the hot water uses connected to an individual water heater, or scheduled in the water heater object for stand-alone units, are included in that water heater's peak draw.
- **ResidentialHUD-FHAMinimum** This design method is based on minimum permissible water heater sizes (established by HUD-FHA in its Minimum Property Standards for One- and Two-Family Living Units, No. 4900.1-1982). The user enters the number of bathrooms and bedrooms in this input object. The smallest allowable water heater sizes are used.
- **PerPerson** This design method scales sizes based on the total number of people in all zones in the building. Each water heater in the model will be sized using the total (peak, design) number of people for the entire model. The number of people is determined from **People** objects defined elsewhere in the input file
- **PerFloorArea** This design method scales sizes based on the total floor area in all the zones in the building. Each water heater in the model will be sized using all the floor area in the model. The floor areas are determined from the geometry input elsewhere in the input file.
- **PerUnit** This design method scales sizes based on an arbitrary number of units. This can be used, for example, to size based on the number of rooms in a lodging building. The user provides the number of units in an input field in this object.
- **PerSolarCollectorArea** This design method scales tank volume based on the collector area for a solar hot water collector. The collector area is summed for all the collectors in the model and each tank is sized for the total. The collector area is determined from input for Solar Collectors defined elsewhere in the input file.

#### 1.24.4.1.3 Field: Time Storage Can Meet Peak Draw

This field provides the time, in hours, that the tank's volume can sustain a peak draw. It is used to size the tank's volume which is the simple product of peak draw volume flow rate and the draw time. There is no assurance that the water will be at the desired temperature for the entire draw. This field is only used if the Design Mode is "**PeakDraw**." For a water heater connected to a full plant loop, it should be on the supply side and the plant loop needs a Plant Sizing object and the draw rate is the Use side design flow rate. For a stand-alone water heater, the draw rate is the maximum scheduled peak use flow rate.

#### 1.24.4.1.4 Field: Time for Tank Recovery

This field provides the the time, in hours, that tank's heater needs to recover the volume of the tank. The temperatures used to define recovery are a starting temperature of 14.4°C (58°F) and a final temperature of 57.2°C (135°F). This field is only used if the Design Mode is "**PeakDraw**."

#### 1.24.4.1.5 Field: Nominal Tank Volume for Autosizing Plant Connections

This field is used in case the water heater is indirectly heated by its source side connections and they are also autosized. Because of the complexity of such a water heater and the timing for when sizing calculation happen inside EnergyPlus, the Source side connection flow rates need to be reported before the tank's volume can be sized to meet Peak Draw. This input field is used to provide a nominal tank volume to use temporarily while the flow connections are sized. This field is only used if the Design Mode is "**PeakDraw**" and the water heater has autosized plant connections on the demand side.

#### 1.24.4.1.6 Field: Number of Bedrooms

This field is used to enter the numer of bedrooms in the model. This field is only used if the Design Mode is "**ResidentialHUD-FHAMinimum**."

#### 1.24.4.1.7 Field: Number of Bathrooms

This field is used to enter the number of bathrooms in the model. This field is only used if the Design Mode is "**ResidentialHUD-FHAMinimum**."

#### 1.24.4.1.8 Field: Storage Capacity per Person

This field is used to enter the tank's storage volume on per-person basis. The units are m<sup>3</sup>/person. This field is only used if the Design Mode is "**PerPerson**."

#### 1.24.4.1.9 Field: Recovery Capacity per Person

This field is used to enter the recovery capacity per person in units of m<sup>3</sup>/person/hr. This is the volume of water the heater can recover in one hour per person. Recovery is heating water from a starting temperature of 14.4°C (58°F) to a final temperature of 57.2°C (135°F). This field is only used if the Design Mode is "**PerPerson**."

#### 1.24.4.1.10 Field: Storage Capacity per Floor Area

This field is used to enter the tank's storage volume on a per-floor-area basis. The units are m<sup>3</sup> /m<sup>2</sup> (water/floor area). This field is only used if the Design Mode is "**PerFloorArea**."

#### 1.24.4.1.11 Field: Recovery Capacity per Floor Area

This field is used to enter the recovery capacity per floor area in units of m<sup>3</sup>/m<sup>2</sup>/hr. This is the volume water the heater can recover in an hour per floor area. Recovery is heating water from a starting temperature of 14.4°C (58°F) to a final temperature of 57.2°C (135°F). This field is only used if the Design Mode is "**PerFloorArea**."

#### 1.24.4.1.12 Field: Number of Units

This field is used to enter the number of Units for use in sizing on per-Unit basis with the next two fields. This field is only used if the Design Mode is “**PerUnit**.” This can be used to account for any arbitrary item such as lodging rooms, desks, water fixtures, restrooms, etc.

#### 1.24.4.1.13 Field: Storage Capacity per Unit

This field is used to enter the tanks’ storage volume on per-Unit basis. The units are  $\text{m}^3/\text{Unit}$ . The number of Units is entered in the previous field. This field is only used if the Design Mode is “**PerUnit**.”

#### 1.24.4.1.14 Field: Recovery Capacity per Unit

This field is used to enter the recover capacity per Unit in units of  $\text{m}^3/\text{Unit}/\text{hr}$ . This is the volume of water the heater can recover in an hour per Unit. Recovery is heating water from a starting temperature of  $14.4^\circ\text{C}$  ( $58^\circ\text{F}$ ) to a final temperature of  $57.2^\circ\text{C}$  ( $135^\circ\text{F}$ ). This field is only used if the Design Mode is “**PerUnit**.”

#### 1.24.4.1.15 Field: Storage Capacity per Collector Area

This field is used to enter the tank’s storage volume on per-solar-collector-area basis. The units are  $\text{m}^3/\text{m}^2$ . This field is only used if the Design Mode is “**PerSolarCollectorArea**.”

#### 1.24.4.1.16 Field: Height Aspect Ratio

This field is used to scale the height of a stratified tank to preserve relative geometry for different size tanks. The Height Aspect Ratio is defined at the length scale in the vertical direction (height) divided by the length scale in the horizontal direction (diameter). This field is only used if the water heater being sized is a Water Heater:Stratified, the tank height has been set to Autosize, and the tank shape is set to **VerticalCylinder**. This field can be used with any Design Mode.

### 1.24.5 WaterHeater:HeatPump:PumpedCondenser

The heat pump water heater with pumped condenser (HPWH) is a compound object consisting of a water heater tank (e.g., **WaterHeater:Mixed** or **WaterHeater:Stratified**), a direct expansion (DX) “coil” (i.e., an air-to-water DX compression system which includes a water heating coil, air coil, compressor, and water pump), and a fan to provide air flow across the air coil associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source. Numerous configurations of tank location, inlet air source, and DX coil compressor location can be modeled, with one common configuration shown below.

In this model, the heat pump water heater’s DX coil is considered the primary heat source and the water tank’s heater (element or burner) provides supplemental heat as necessary. The model also assumes that the heat pump’s fan and water pump cycle on and off with the compressor.

To model a heat pump water heater, the input data file must include some combination of the following objects depending on the configuration to be modeled:

- **WaterHeater:HeatPump:PumpedCondenser** (required)
- **WaterHeater:Mixed** OR **WaterHeater:Stratified** (required)
- **Coil:WaterHeating:AirToWaterHeatPump:Pumped** OR **Coil:WaterHeating:AirToWaterHeatPump:VariableSpeed** (required)
- **Fan:SystemModel** OR **Fan:OnOff** (required)

Figure 1.97: Schematic diagram for a heat pump water heater located in a zone

- **ZoneHVAC:EquipmentList** (when the HPWH draws some or all of its air from the zone, the heat pump water heater type and name must be in this list)
- **ZoneHVAC:EquipmentConnections** (when the HPWH draws some or all of its air from the zone, the HPWH air inlet and outlet node names must be provided in this object)
- **OutdoorAir:NodeList** (for HPWHs that use outdoor air as all or part of the heat source, the HPWH outdoor air node name must be provided in this list)

The input fields for the compound object are described in detail below:

### 1.24.5.1 Inputs

#### 1.24.5.1.1 Field: Name

This alpha field contains a unique user-assigned name for an instance of a heat pump water heater. Any reference to this heat pump water heater by another object will use this name.

#### 1.24.5.1.2 Field: Availability Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that denotes whether the heat pump compressor is available to operate during a given time period. A schedule value equal to 0 denotes that the heat pump compressor is off for that time period. A value other than 0 denotes that the heat pump compressor is available to operate during that time period. During times when the heat pump compressor is scheduled off, the heater (element or burner) in the water tank object operates based on its tank set point temperature schedule and the heat pump's parasitic electric power is also off for that time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.24.5.1.3 Field: Compressor Setpoint Temperature Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that specifies the set point (or “cut-out”) temperature for the heat pump compressor. Temperature values used in this schedule should be in degrees Celsius. The heat pump compressor cycles off when the tank water reaches this set point temperature. Once the heat pump compressor cycles off, the tank water temperature floats downward until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the “cut-in” temperature). At this point, the heat pump compressor cycles on and remains on until the heat pump compressor set point temperature is reached.

#### 1.24.5.1.4 Field: Dead Band Temperature Difference

This numeric field contains the dead band temperature difference in degrees Celsius. The heat pump compressor “cut-in” temperature is defined as the compressor set point temperature defined above minus this dead band temperature difference. The heat pump compressor cycles on when the water temperature in the tank falls below the “cut-in” temperature. The heat pump compressor remains on until the water temperature in the tank rises above the compressor set point (“cut-out”) temperature defined above. The dead band temperature difference must be greater than 0°C and less than or equal to 20°C. If this field is left blank, the default value is 5°C.

In this model, the heat pump water heater’s DX compression system is considered the primary heat source and the water tank’s heater (element or burner) provides supplemental heat as necessary. Therefore, the cut-in temperature for the heat pump compressor (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point temperature is greater than the cut-in temperature of the heat pump compressor, the heat pump compressor is disabled and the tank’s heater is used to heat the water.

#### 1.24.5.1.5 Field: Condenser Water Inlet Node Name

This alpha field contains the name of the inlet water node for the heat pump’s water heating coil (condenser). This node name must also be specified in the water heater tank object as the source outlet node name, and in the DX coil object as the condenser water inlet node name.

#### 1.24.5.1.6 Field: Condenser Water Outlet Node Name

This alpha field contains the name of the outlet water node for the heat pump’s water heating coil (condenser). This node name must also be specified in the water heater tank object as the source inlet node name, and in the DX coil object as the condenser water outlet node name.

#### 1.24.5.1.7 Field: Condenser Water Flow Rate

This numeric field contains the heat pump’s condenser water flow rate in cubic meters per second. It is the actual condenser water flow rate to be simulated, which may differ from the rated condenser water volumetric flow rate specified for the heat pump’s DX coil (Ref. Coil:WaterHeating:AirToWaterHeatPump). This water flow rate must be greater than 0 or this field is autocalculatable. If autocalculated (field value = **autocalculate**), the condenser water flow rate is set equal to the rated heating capacity of the heat pump’s DX coil multiplied by  $4.487\text{E-}8 \text{ m}^3/\text{s}/\text{W}$ . When this flow rate is different from the Rated Condenser Water Volumetric Flow Rate specified in the heat pump’s DX coil object (Ref. Coil:WaterHeating:AirToWaterHeatPump), the user should also specify a Total Heating Capacity Modifier Curve Name (function of water flow fraction) and a Heating COP Modifier Curve Name (function of water flow fraction) in the associated DX coil object to account for differences in capacity and power consumption at the off-rated water flow rate.

#### 1.24.5.1.8 Field: Evaporator Air Flow Rate

This numeric field contains the air flow rate across the heat pump's air coil (evaporator) in cubic meters per second. It is the actual air flow rate to be simulated, which may differ from the rated evaporator air volumetric flow rate specified for the heat pump's DX coil (Ref. **Coil:WaterHeating:AirToWaterHeatPump:Pumped**). Values must be greater than 0 or this field is autocalculatable. If autocalculated (field value = **autocalculate**), the evaporator air flow rate is set equal to the rated heating capacity of the heat pump's DX coil multiplied by  $5.035\text{E-}5 \text{ m}^3/\text{s}/\text{W}$ . When this flow rate is different from the Rated Evaporator Air Volumetric Flow Rate specified in the heat pump's DX coil object (Ref. **Coil:WaterHeating:AirToWaterHeatPump:Pumped**), the user should also specify a Total Heating Capacity Modifier Curve Name (function of air flow fraction) and a Heating COP Modifier Curve Name (function of air flow fraction) in the associated DX coil object to account for differences in capacity and power consumption at the off-rated air flow rate.

#### 1.24.5.1.9 Field: Inlet Air Configuration

This choice field defines the configuration of the air flow path through the heat pump air coil (evaporator) and fan section. Valid entries are **Schedule**, **ZoneAirOnly**, **OutdoorAirOnly**, or **ZoneAndOutdoorAir**. If 'Schedule' is selected, names for an inlet air temperature schedule and an inlet air humidity schedule must be defined in the fields below. If 'ZoneAirOnly' is selected, the corresponding zone name must be entered in the Inlet Air Zone Name field below. If 'ZoneAndOutdoorAir' is selected, the corresponding Inlet Air Zone Name, Inlet Air Mixer Node Name, Outlet Air Splitter Node Name, and an Inlet Air Mixer Schedule Name must be entered in the corresponding fields below.

#### 1.24.5.1.10 Field: Air Inlet Node Name

This alpha field contains the name of the node from which the heat pump water heater draws its inlet air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'ZoneAndOutdoorAir', then this node name should be the name of a zone air exhaust node (Ref. **ZoneHVAC:EquipmentConnections**). If the Inlet Air Configuration field is set to 'OutdoorAirOnly', this node name should be left blank. If the Inlet Air Configuration field is set to 'Schedule', this node name should simply be a unique name that allows the user to receive output on conditions at this node for verification purposes.

#### 1.24.5.1.11 Field: Air Outlet Node Name

This alpha field contains the name of the node to which the heat pump water heater sends its outlet air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'ZoneAndOutdoorAir', then this node name should be the name of a zone air inlet node (Ref. **ZoneHVAC:EquipmentConnections**). If the Inlet Air Configuration field is set to 'OutdoorAirOnly', this node name should be left blank. If the Inlet Air Configuration field is set to 'Schedule', this node name should simply be a unique name that allows the user to receive output on conditions at this node for verification purposes.

#### 1.24.5.1.12 Field: Outdoor Air Node Name

This alpha field contains the name of the node from which the heat pump water heater draws its outdoor air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'Schedule', this node name should be left blank. If the Inlet Air Configuration field is set to 'ZoneAndOutdoorAir' or 'OutdoorAirOnly', this node name should be the name of an outdoor air node (Ref. **OutdoorAir:NodeList**).

#### 1.24.5.1.13 Field: Exhaust Air Node Name

This alpha field contains the name of the node to which the heat pump water heater sends its exhaust air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'Schedule', this node name should be left blank. If the Inlet Air Configuration field is set to 'ZoneAndOutdoorAir' or 'OutdoorAirOnly', then

this node name should be a unique name that allows the user to receive output on conditions at this node for verification purposes.

#### 1.24.5.1.14 Field: Inlet Air Temperature Schedule Name

This alpha field contains the name of a schedule used to define the dry-bulb temperature of the inlet air to the heat pump air coil (evaporator) and fan section. Schedule values should be in degrees Celsius. This field is only used when the Inlet Air Configuration defined above is specified as ‘Schedule’, otherwise leave this field blank.

#### 1.24.5.1.15 Field: Inlet Air Humidity Schedule Name

This alpha field contains the name of a schedule used to define the humidity of the inlet air to the heat pump evaporator and fan section. Schedule values must be entered as relative humidity fraction from 0 to 1 (e.g., a schedule value of 0.5 means 50%RH). This field is only used when the Inlet Air Configuration defined above is specified as ‘Schedule’, otherwise leave this field blank.

#### 1.24.5.1.16 Field: Inlet Air Zone Name

This alpha field contains the name of the zone from which the heat pump evaporator and fan section draws some or all of its inlet air. This field is only used when the Inlet Air Configuration defined above is specified as ‘ZoneAirOnly’ or ‘ZoneAndOutdoorAir’.

#### 1.24.5.1.17 Field: Tank Object Type

This alpha (choice) field contains the type of water heater tank used by this heat pump water heater. Currently, the only valid choices are **WaterHeater:Mixed** or **WaterHeater:Stratified**.

#### 1.24.5.1.18 Field: Tank Name

This alpha field contains the name of the specific water heater tank used by this heat pump water heater. This must be a tank of type **WaterHeater:Mixed** or **WaterHeater:Stratified**.

#### 1.24.5.1.19 Field: Tank Use Side Inlet Node Name

This alpha field contains the name of the use side inlet node of the water heater tank used by this heat pump water heater. This name must match the Use Side Inlet Node Name in the water heater tank object (Ref. **WaterHeater:Mixed**). This field is required if the water heater tank use side nodes are connected to a plant loop, otherwise leave this field blank. When used, the branch object should reflect that this node is part of a **WaterHeater:HeatPump:PumpedCondenser** object (see branch object example below).

#### 1.24.5.1.20 Field: Tank Use Side Outlet Node Name

This alpha field contains the name of the use side outlet node of the water heater tank used by this heat pump water heater. This name must match the Use Side Outlet Node Name in the water heater tank object (Ref. **WaterHeater:Mixed**). This field is required if the water heater tank use side nodes are connected to a plant loop, otherwise leave this field blank. When used, the branch object should reflect that this node is part of a **WaterHeater:HeatPump:PumpedCondenser** object (see branch object example below).

#### 1.24.5.1.21 Field: DX Coil Object Type

This alpha (choice) field contains the type of DX coil used by this heat pump water heater. Currently, the only valid choice is **Coil:WaterHeating:AirToWaterHeatPump:Pumped**.

#### 1.24.5.1.22 Field: DX Coil Name

This alpha field contains the name of the specific DX coil (`Coil:WaterHeating:AirToWaterHeatPump:Pumped` or `Coil:WaterHeating:AirToWaterHeatPump:VariableSpeed` object) used by this heat pump water heater.

#### 1.24.5.1.23 Field: Minimum Inlet Air Temperature for Compressor Operation

This numeric field contains the minimum inlet air dry-bulb temperature entering the air coil (evaporator) and fan section, in degrees Celsius, below which the heat pump compressor does not operate. If this field is left blank, the default value is 10°C.

#### 1.24.5.1.24 Field: Compressor Location

This alpha (choice) field contains the location of the heat pump compressor and the air temperature for this location is used to control operation of the compressor's crankcase heater in the `Coil:WaterHeating:AirToWaterHeatPump:Pumped` object. Valid entries are **Schedule**, **Zone**, or **Outdoors**. If 'Schedule' is selected, a compressor ambient temperature schedule name must be defined in the field below; otherwise, the field below should be left blank. If 'Zone' is selected, the crankcase heater operation is controlled based on the air temperature in the zone defined in the field Inlet Air Zone Name, and the Inlet Air Configuration must be 'ZoneAirOnly' or 'ZoneAndOutdoorAir'. If 'Outdoors' is selected, crankcase heater operation is controlled based on the outdoor air temperature.

#### 1.24.5.1.25 Field: Compressor Ambient Temperature Schedule Name

This alpha field contains the name of a schedule that defines the ambient air temperature surrounding the heat pump compressor, which is used to control the compressor's crankcase heater operation. This field is only used when the compressor location field defined above is specified as 'Schedule', otherwise it should be left blank.

#### 1.24.5.1.26 Field: Fan Object Type

This alpha (choice) field contains the type of fan used by this heat pump water heater. Currently, the only valid choices are `Fan:SystemModel` and `Fan:OnOff`.

#### 1.24.5.1.27 Field: Fan Name

This alpha field contains the name of the specific fan (`Fan:SystemModel` or `Fan:OnOff` object) used by this heat pump water heater.

#### 1.24.5.1.28 Field: Fan Placement

This alpha (choice) field defines the placement of the fan in the heat pump water heater. Valid choices are **BlowThrough** (fan upstream of the air coil) and **DrawThrough** (fan downstream of the air coil). If this field is left blank, the default value is DrawThrough.

#### 1.24.5.1.29 Field: On Cycle Parasitic Electric Load

This numeric field contains the on-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump water heater. This parasitic electric load is consumed whenever the heat pump compressor is operating and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., Inlet Air Configuration field specified as 'ZoneAirOnly' or 'ZoneAndOutdoorAir') and the Parasitic Heat Rejection Location field is specified as 'Zone'. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

#### 1.24.5.1.30 Field: Off Cycle Parasitic Electric Load

This numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump compressor. This parasitic electric load is consumed whenever the heat pump water heater is available but the compressor is not operating, and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., Inlet Air Configuration field specified as 'ZoneAirOnly' or 'ZoneAndOutdoorAir') and the Parasitic Heat Rejection Location field is specified as 'Zone'. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

#### 1.24.5.1.31 Field: Parasitic Heat Rejection Location

This alpha (choice) field determines where the on-cycle and off-cycle parasitic heat is rejected. Valid choices are Zone and Exterior. If 'Zone' is selected, both the on-cycle and off-cycle parasitic heat is rejected to the zone defined in the field Inlet Air Zone Name, and the Inlet Air Configuration must be 'ZoneAirOnly' or 'ZoneAndOutdoorAir'. If 'Outdoors' is selected, this parasitic heat is rejected outdoors (does not impact the zone air heat balance) regardless of the specified Inlet Air Configuration. If this field is left blank, the default value is 'Outdoors'.

#### 1.24.5.1.32 Field: Inlet Air Mixer Node Name

This optional alpha field defines the name of the HVAC node which represents the mixture of outdoor air and zone air that enters the heat pump air coil (evaporator) and fan section. The model mixes outdoor air with zone air and places the result on this inlet air mixer node based on the Inlet Air Mixer Schedule defined below. When the schedule value is equal to 0, 100% zone air enters the evaporator coil and fan section of the heat pump water heater. When the schedule value is equal to 1, 100% outdoor air enters the evaporator coil and fan section. This node name must be provided if the Inlet Air Configuration field above is specified as 'ZoneAndOutdoor Air', otherwise this field should be left blank.

#### 1.24.5.1.33 Field: Outlet Air Splitter Node Name

This alpha field defines the name of the air node to which the heat pump air coil (evaporator) and fan sends all of its outlet air. The supply air flow downstream of this node is split between the zone and outdoors based on the Inlet Air Mixer schedule defined below. When the schedule value is equal to 0, the entire outlet air stream is diverted to the zone. When the schedule value is equal to 1, the entire outlet air stream is exhausted to outdoors. This node name must be provided if the Inlet Air Configuration field above is specified as 'Zone and Outdoor Air', otherwise this field should be left blank.

#### 1.24.5.1.34 Field: Inlet Air Mixer Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump draws its inlet air from the zone, outdoors, or a combination of zone and outdoor air. A schedule value equal to 0 indicates that the heat pump draws its inlet air from the zone. A schedule value equal to 1 denotes that the heat pump draws its inlet air from outdoors. Values between 0 and 1 denote a mixture of zone and outdoor air proportional to the schedule value. The Inlet Air Mixer schedule controls both the inlet air mixer and outlet air splitter nodes in unison to ensure that the operation of the heat pump does not contribute to zone pressurization or depressurization. For example if the Inlet Air Mixer schedule value is 0.4, then the inlet air mixer node is composed of 40% outdoor air and 60% zone air. For this same case, the outlet air splitter directs 60% of the HPWH outlet air back to the zone and 40% of the outlet air flow is exhausted outdoors. This schedule name must be provided if the Inlet Air Configuration field is specified as 'Zone and Outdoor Air', otherwise this field should be left blank.

**1.24.5.1.35 Field: Tank Element Control Logic**

This alpha field defines settings for the control logic of when to run the tank element in relation to whether the heat pump is running.

- **MutuallyExclusive** means that once the tank heating element(s) are active, the heat pump is shut down until the heating element setpoint is reached.
- **Simultaneous** (default) means that both the tank heating element and heat pump are used at the same time to recover the tank temperature.

**1.24.5.1.36 Field: Control Sensor 1 Height In Stratified Tank**

This alpha field defines where the tank temperature is sensed for heat pump control when the tank type is **WaterHeater:Stratified**. The stratified tank model produces tank temperature at different nodes in the vertical direction and various options are available for how this temperature should be sensed to control the heat pump. This is measured in height from the bottom of the tank. Internally the appropriate node is determined based on this height. If omitted, this defaults to the height of Heater1.

**1.24.5.1.37 Field: Control Sensor 1 Weight**

The model can optionally use two control sensor locations in stratified tanks. When that is the case, the temperature sensed at each location is weighted. This alpha input specifies the weight associated with Control Sensor 1. It is input as a value between 0 and 1. The weight of Control Sensor 2 is determined by subtracting this weight from 1. The default for this field is 1, indicating that only Control Sensor 1 is used.

**1.24.5.1.38 Field: Control Sensor 2 Height in Stratified Tank**

This alpha field defines the optional second location where the tank temperature is sensed for heat pump control when the tank type is **WaterHeater:Stratified**. If omitted, this defaults to the height of Heater2.

Following is an example input for the **WaterHeater:HeatPump:PumpedCondenser** compound object and the other required component objects that it references.

### 1.24.5.2 Outputs

- HVAC,Average,Water Heater Compressor Part Load Ratio
- HVAC,Average,Water Heater On Cycle Ancillary Electricity Rate [W]
- HVAC,Sum,Water Heater On Cycle Ancillary Electricity Energy [J]
- HVAC,Average,Water Heater Off Cycle Ancillary Electricity Rate [W]
- HVAC,Sum,Water Heater Off Cycle Ancillary Electricity Energy [J]

#### 1.24.5.2.1 Water Heater Compressor Part Load Ratio

This output is the average part-load ratio of the heat pump water heater’s compressor (as well as its water pump and fan) for the timestep being reported. This output is independent of the “Water Heater Part Load Ratio” (Ref. Water Heater Outputs) which represents the part-load ratio of the supplemental heater (element or burner) in the water tank. When the water tank’s (supplemental) heater set point temperature is higher than the cut-in temperature of the heat pump water heater’s compressor, the heat pump compressor is disabled and the water tank’s heater (element or burner) is used to heat the water. During these times the Water Heater Compressor Part Load Ratio is equal to 0.

#### 1.24.5.2.2 Water Heater On Cycle Ancillary Electricity Rate [W]

#### 1.24.5.2.3 Water Heater On Cycle Ancillary Electricity Energy [J]

#### 1.24.5.2.4 Water Heater Off Cycle Ancillary Electricity Rate [W]

#### 1.24.5.2.5 Water Heater Off Cycle Ancillary Electricity Energy [J]

These outputs are the parasitic electric power and consumption associated with the heat pump water heater. Specific outputs represent parasitic electrical usage during the compressor/fan on and off cycles. These outputs represent electronic controls or other electric component. The model assumes that the parasitic power does not contribute to heating the water, but it can impact the zone air heat balance depending on user inputs. The parasitic electric consumption outputs are also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

### 1.24.6 WaterHeater:HeatPump:WrappedCondenser

The heat pump water heater with wrapped condenser is a compound object very similar to the `WaterHeater:HeatPump:PumpedCondenser` object. It likewise combines a water heater tank, a direct expansion (DX) “coil”, and a fan to provide air flow across the air coil associated with the DX compression system. The primary difference is that instead of pumping water through an external condenser, the heating coils are wrapped around or submerged in the tank. This type of HPWH is most common in packaged units meant for residential applications.

To model a wrapped condenser heat pump water, the input data file must include some combination of the following objects depending on the configuration to be modeled:

- `WaterHeater:HeatPump:WrappedCondenser` (required)
- `WaterHeater:Stratified` (required)
- `Coil:WaterHeating:AirToWaterHeatPump:Wrapped` (required)
- `Fan:SystemModel!` or `Fan:OnOff` (required)
- `ZoneHVAC:EquipmentList` (when the HPWH draws some or all of its air from the zone, the heat pump water heater type and name must be in this list)
- `ZoneHVAC:EquipmentConnections` (when the HPWH draws some or all of its air from the zone, the HPWH air inlet and outlet node names must be provided in this object)
- `OutdoorAir:NodeList` (for HPWHs that use outdoor air as all or part of the heat source, the HPWH outdoor air node name must be provided in this list)

The input fields for the compound object are described in detail below:

#### 1.24.6.1 Inputs

##### 1.24.6.1.1 Field: Name

This alpha field contains a unique user-assigned name for an instance of a heat pump water heater. Any reference to this heat pump water heater by another object will use this name.

##### 1.24.6.1.2 Field: Availability Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that denotes whether the heat pump compressor is available to operate during a given time period. A schedule value equal to 0 denotes that the heat pump compressor is off for that time period. A value other than 0 denotes that the heat pump compressor is available to operate during that time period. During times when the heat pump compressor

is scheduled off, the heater (element or burner) in the water tank object operates based on its tank set point temperature schedule and the heat pump’s parasitic electric power is also off for that time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.24.6.1.3 Field: Compressor Setpoint Temperature Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that specifies the set point (or “cut-out”) temperature for the heat pump compressor. Temperature values used in this schedule should be in degrees Celsius. The heat pump compressor cycles off when the tank water reaches this set point temperature. Once the heat pump compressor cycles off, the tank water temperature floats downward until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the “cut-in” temperature). At this point, the heat pump compressor cycles on and remains on until the heat pump compressor set point temperature is reached.

#### 1.24.6.1.4 Field: Dead Band Temperature Difference

This numeric field contains the dead band temperature difference in degrees Celsius. The heat pump compressor “cut-in” temperature is defined as the compressor set point temperature defined above minus this dead band temperature difference. The heat pump compressor cycles on when the water temperature in the tank falls below the “cut-in” temperature. The heat pump compressor remains on until the water temperature in the tank rises above the compressor set point (“cut-out”) temperature defined above. The dead band temperature difference must be greater than 0°C and less than or equal to 20°C. If this field is left blank, the default value is 5°C.

In this model, the heat pump water heater’s DX compression system is considered the primary heat source and the water tank’s heater (element or burner) provides supplemental heat as necessary. Therefore, the cut-in temperature for the heat pump compressor (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point temperature is greater than the cut-in temperature of the heat pump compressor, the heat pump compressor is disabled and the tank’s heater is used to heat the water.

#### 1.24.6.1.5 Field: Condenser Bottom Location

This numeric field contains the distance from the bottom of the tank to the bottom of the wrapped condenser.

#### 1.24.6.1.6 Field: Condenser Top Location

This numeric field contains the distance from the bottom of the tank to the top of the wrapped condenser.

#### 1.24.6.1.7 Field: Evaporator Air Flow Rate

This numeric field contains the air flow rate across the heat pump’s air coil (evaporator) in cubic meters per second. It is the actual air flow rate to be simulated, which may differ from the rated evaporator air volumetric flow rate specified for the heat pump’s DX coil (Ref. [Coil:WaterHeating:AirToWaterHeatPump:Wrapped](#)). Values must be greater than 0 or this field is autocalculatable. If autocalculated (field value = **autocalculate**), the evaporator air flow rate is set equal to the rated heating capacity of the heat pump’s DX coil multiplied by 5.035E-5 m<sup>3</sup>/s/W. When this flow rate is different from the Rated Evaporator Air Volumetric Flow Rate specified in the heat pump’s DX coil object (Ref. [Coil:WaterHeating:AirToWaterHeatPump:Wrapped](#)), the user should also specify a Total Heating Capacity Modifier Curve Name (function of air flow fraction) and a Heating COP Modifier

Curve Name (function of air flow fraction) in the associated DX coil object to account for differences in capacity and power consumption at the off-rated air flow rate.

#### 1.24.6.1.8 Field: Inlet Air Configuration

This choice field defines the configuration of the air flow path through the heat pump air coil (evaporator) and fan section. Valid entries are **Schedule**, **ZoneAirOnly**, **OutdoorAirOnly**, or **ZoneAndOutdoorAir**. If ‘Schedule’ is selected, names for an inlet air temperature schedule and an inlet air humidity schedule must be defined in the fields below. If ‘ZoneAirOnly’ is selected, the corresponding zone name must be entered in the Inlet Air Zone Name field below. If ‘ZoneAndOutdoorAir’ is selected, the corresponding Inlet Air Zone Name, Inlet Air Mixer Node Name, Outlet Air Splitter Node Name, and an Inlet Air Mixer Schedule Name must be entered in the corresponding fields below.

#### 1.24.6.1.9 Field: Air Inlet Node Name

This alpha field contains the name of the node from which the heat pump water heater draws its inlet air. If the Inlet Air Configuration field defined above is set to ‘ZoneAirOnly’ or ‘ZoneAndOutdoorAir’, then this node name should be the name of a zone air exhaust node (Ref. [ZoneHVAC:EquipmentConnections](#)). If the Inlet Air Configuration field is set to ‘OutdoorAirOnly’, this node name should be left blank. If the Inlet Air Configuration field is set to ‘Schedule’, this node name should simply be a unique name that allows the user to receive output on conditions at this node for verification purposes.

#### 1.24.6.1.10 Field: Air Outlet Node Name

This alpha field contains the name of the node to which the heat pump water heater sends its outlet air. If the Inlet Air Configuration field defined above is set to ‘ZoneAirOnly’ or ‘ZoneAndOutdoorAir’, then this node name should be the name of a zone air inlet node (Ref. [ZoneHVAC:EquipmentConnections](#)). If the Inlet Air Configuration field is set to ‘OutdoorAirOnly’, this node name should be left blank. If the Inlet Air Configuration field is set to ‘Schedule’, this node name should simply be a unique name that allows the user to receive output on conditions at this node for verification purposes.

#### 1.24.6.1.11 Field: Outdoor Air Node Name

This alpha field contains the name of the node from which the heat pump water heater draws its outdoor air. If the Inlet Air Configuration field defined above is set to ‘ZoneAirOnly’ or ‘Schedule’, this node name should be left blank. If the Inlet Air Configuration field is set to ‘ZoneAndOutdoorAir’ or ‘OutdoorAirOnly’, this node name should be the name of an outdoor air node (Ref. [OutdoorAir:NodeList](#)).

#### 1.24.6.1.12 Field: Exhaust Air Node Name

This alpha field contains the name of the node to which the heat pump water heater sends its exhaust air. If the Inlet Air Configuration field defined above is set to ‘ZoneAirOnly’ or ‘Schedule’, this node name should be left blank. If the Inlet Air Configuration field is set to ‘ZoneAndOutdoorAir’ or ‘OutdoorAirOnly’, then this node name should be a unique name that allows the user to receive output on conditions at this node for verification purposes.

#### 1.24.6.1.13 Field: Inlet Air Temperature Schedule Name

This alpha field contains the name of a schedule used to define the dry-bulb temperature of the inlet air to the heat pump air coil (evaporator) and fan section. Schedule values should be in degrees Celsius. This field is only used when the Inlet Air Configuration defined above is specified as ‘Schedule’, otherwise leave this field blank.

**1.24.6.1.14 Field: Inlet Air Humidity Schedule Name**

This alpha field contains the name of a schedule used to define the humidity of the inlet air to the heat pump evaporator and fan section. Schedule values must be entered as relative humidity fraction from 0 to 1 (e.g., a schedule value of 0.5 means 50%RH). This field is only used when the Inlet Air Configuration defined above is specified as ‘Schedule’, otherwise leave this field blank.

**1.24.6.1.15 Field: Inlet Air Zone Name**

This alpha field contains the name of the zone from which the heat pump evaporator and fan section draws some or all of its inlet air. This field is only used when the Inlet Air Configuration defined above is specified as ‘ZoneAirOnly’ or ‘ZoneAndOutdoorAir’.

**1.24.6.1.16 Field: Tank Object Type**

This alpha (choice) field contains the type of water heater tank used by this heat pump water heater. Currently, the only valid choice is `WaterHeater:Stratified`.

**1.24.6.1.17 Field: Tank Name**

This alpha field contains the name of the specific water heater tank used by this heat pump water heater. This must be a tank of type `WaterHeater:Stratified`.

**1.24.6.1.18 Field: Tank Use Side Inlet Node Name**

This alpha field contains the name of the use side inlet node of the water heater tank used by this heat pump water heater. This name must match the Use Side Inlet Node Name in the water heater tank object (Ref. `WaterHeater:Stratified`). This field is required if the water heater tank use side nodes are connected to a plant loop, otherwise leave this field blank. When used, the branch object should reflect that this node is part of a `WaterHeater:HeatPump:WrappedCondenser` object (see branch object example below).

**1.24.6.1.19 Field: Tank Use Side Outlet Node Name**

This alpha field contains the name of the use side outlet node of the water heater tank used by this heat pump water heater. This name must match the Use Side Outlet Node Name in the water heater tank object (Ref. `WaterHeater:Stratified`). This field is required if the water heater tank use side nodes are connected to a plant loop, otherwise leave this field blank. When used, the branch object should reflect that this node is part of a `WaterHeater:HeatPump:WrappedCondenser` object (see branch object example below).

**1.24.6.1.20 Field: DX Coil Object Type**

This alpha (choice) field contains the type of DX coil used by this heat pump water heater. Currently, the only valid choice is `Coil:WaterHeating:AirToWaterHeatPump:Wrapped`.

**1.24.6.1.21 Field: DX Coil Name**

This alpha field contains the name of the specific DX coil (`Coil:WaterHeating:AirToWaterHeatPump:Wrapped`) used by this heat pump water heater.

**1.24.6.1.22 Field: Minimum Inlet Air Temperature for Compressor Operation**

This numeric field contains the minimum inlet air dry-bulb temperature entering the air coil (evaporator) and fan section, in degrees Celsius, below which the heat pump compressor does not operate. If this field is left blank, the default value is 10°C.

#### 1.24.6.1.23 Field: Compressor Location

This alpha (choice) field contains the location of the heat pump compressor and the air temperature for this location is used to control operation of the compressor's crankcase heater in the **Coil:WaterHeating:AirToWaterHeatPump:Wrapped** object. Valid entries are **Schedule**, **Zone**, or **Outdoors**. If 'Schedule' is selected, a compressor ambient temperature schedule name must be defined in the field below; otherwise, the field below should be left blank. If 'Zone' is selected, the crankcase heater operation is controlled based on the air temperature in the zone defined in the field Inlet Air Zone Name, and the Inlet Air Configuration must be 'ZoneAirOnly' or 'ZoneAndOutdoorAir'. If 'Outdoors' is selected, crankcase heater operation is controlled based on the outdoor air temperature.

#### 1.24.6.1.24 Field: Compressor Ambient Temperature Schedule Name

This alpha field contains the name of a schedule that defines the ambient air temperature surrounding the heat pump compressor, which is used to control the compressor's crankcase heater operation. This field is only used when the compressor location field defined above is specified as 'Schedule', otherwise it should be left blank.

#### 1.24.6.1.25 Field: Fan Object Type

This alpha (choice) field contains the type of fan used by this heat pump water heater. Currently, the only valid choices are **Fan:SystemModel** and **Fan:OnOff**.

#### 1.24.6.1.26 Field: Fan Name

This alpha field contains the name of the specific fan (**Fan:SystemModel** or **Fan:OnOff** object) used by this heat pump water heater.

#### 1.24.6.1.27 Field: Fan Placement

This alpha (choice) field defines the placement of the fan in the heat pump water heater. Valid choices are **BlowThrough** (fan upstream of the air coil) and **DrawThrough** (fan downstream of the air coil). If this field is left blank, the default value is DrawThrough.

#### 1.24.6.1.28 Field: On Cycle Parasitic Electric Load

This numeric field contains the on-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump water heater. This parasitic electric load is consumed whenever the heat pump compressor is operating and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., Inlet Air Configuration field specified as 'ZoneAirOnly' or 'ZoneAndOutdoorAir') and the Parasitic Heat Rejection Location field is specified as 'Zone'. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

#### 1.24.6.1.29 Field: Off Cycle Parasitic Electric Load

This numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump compressor. This parasitic electric load is consumed whenever the heat pump water heater is available but the compressor is not operating, and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., Inlet Air Configuration field specified as 'ZoneAirOnly' or 'ZoneAndOutdoorAir') and the Parasitic Heat Rejection Location field is specified as 'Zone'. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

**1.24.6.1.30 Field: Parasitic Heat Rejection Location**

This alpha (choice) field determines where the on-cycle and off-cycle parasitic heat is rejected. Valid choices are Zone and Exterior. If 'Zone' is selected, both the on-cycle and off-cycle parasitic heat is rejected to the zone defined in the field Inlet Air Zone Name, and the Inlet Air Configuration must be 'ZoneAirOnly' or 'ZoneAndOutdoorAir'. If 'Outdoors' is selected, this parasitic heat is rejected outdoors (does not impact the zone air heat balance) regardless of the specified Inlet Air Configuration. If this field is left blank, the default value is 'Outdoors'.

**1.24.6.1.31 Field: Inlet Air Mixer Node Name**

This optional alpha field defines the name of the HVAC node which represents the mixture of outdoor air and zone air that enters the heat pump air coil (evaporator) and fan section. The model mixes outdoor air with zone air and places the result on this inlet air mixer node based on the Inlet Air Mixer Schedule defined below. When the schedule value is equal to 0, 100% zone air enters the evaporator coil and fan section of the heat pump water heater. When the schedule value is equal to 1, 100% outdoor air enters the evaporator coil and fan section. This node name must be provided if the Inlet Air Configuration field above is specified as 'ZoneAndOutdoor Air', otherwise this field should be left blank.

**1.24.6.1.32 Field: Outlet Air Splitter Node Name**

This alpha field defines the name of the air node to which the heat pump air coil (evaporator) and fan sends all of its outlet air. The supply air flow downstream of this node is split between the zone and outdoors based on the Inlet Air Mixer schedule defined below. When the schedule value is equal to 0, the entire outlet air stream is diverted to the zone. When the schedule value is equal to 1, the entire outlet air stream is exhausted to outdoors. This node name must be provided if the Inlet Air Configuration field above is specified as 'Zone and Outdoor Air', otherwise this field should be left blank.

**1.24.6.1.33 Field: Inlet Air Mixer Schedule Name**

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump draws its inlet air from the zone, outdoors, or a combination of zone and outdoor air. A schedule value equal to 0 indicates that the heat pump draws its inlet air from the zone. A schedule value equal to 1 denotes that the heat pump draws its inlet air from outdoors. Values between 0 and 1 denote a mixture of zone and outdoor air proportional to the schedule value. The Inlet Air Mixer schedule controls both the inlet air mixer and outlet air splitter nodes in unison to ensure that the operation of the heat pump does not contribute to zone pressurization or depressurization. For example if the Inlet Air Mixer schedule value is 0.4, then the inlet air mixer node is composed of 40% outdoor air and 60% zone air. For this same case, the outlet air splitter directs 60% of the HPWH outlet air back to the zone and 40% of the outlet air flow is exhausted outdoors. This schedule name must be provided if the Inlet Air Configuration field is specified as 'Zone and Outdoor Air', otherwise this field should be left blank.

**1.24.6.1.34 Field: Tank Element Control Logic**

This alpha field defines settings for the control logic of when to run the tank element in relation to whether the heat pump is running.

- **MutuallyExclusive** means that once the tank heating element(s) are active, the heat pump is shut down until the heating element setpoint is reached.
- **Simultaneous** (default) means that both the tank heating element and heat pump are used at the same time to recover the tank temperature.

### 1.24.6.1.35 Field: Control Sensor 1 Height In Stratified Tank

This alpha field defines where the tank temperature is sensed for heat pump control when the tank type is `WaterHeater:Stratified`. The stratified tank model produces tank temperature at different nodes in the vertical direction and various options are available for how this temperature should be sensed to control the heat pump. This is measured in height from the bottom of the tank. Internally the appropriate node is determined based on this height. If omitted, this defaults to the height of Heater1.

### 1.24.6.1.36 Field: Control Sensor 1 Weight

The model can optionally use two control sensor locations in stratified tanks. When that is the case, the temperature sensed at each location is weighted. This alpha input specifies the weight associated with Control Sensor 1. It is input as a value between 0 and 1. The weight of Control Sensor 2 is determined by subtracting this weight from 1. The default for this field is 1, indicating that only Control Sensor 1 is used.

### 1.24.6.1.37 Field: Control Sensor 2 Height in Stratified Tank

This alpha field defines the optional second location where the tank temperature is sensed for heat pump control when the tank type is `WaterHeater:Stratified`. If omitted, this defaults to the height of Heater2.

Following is an example input for the `WaterHeater:HeatPump:WrappedCondenser` compound object and the other required component objects that it references.

### 1.24.6.2 Outputs

- HVAC,Average,Water Heater Compressor Part Load Ratio
- HVAC,Average,Water Heater On Cycle Ancillary Electricity Rate [W]
- HVAC,Sum,Water Heater On Cycle Ancillary Electricity Energy [J]
- HVAC,Average,Water Heater Off Cycle Ancillary Electricity Rate [W]
- HVAC,Sum,Water Heater Off Cycle Ancillary Electricity Energy [J]

#### 1.24.6.2.1 Water Heater Compressor Part Load Ratio

This output is the average part-load ratio of the heat pump water heater’s compressor (as well as its water pump and fan) for the timestep being reported. This output is independent of the “Water Heater Part Load Ratio” (Ref. Water Heater Outputs) which represents the part-load ratio of the supplemental heater (element or burner) in the water tank. When the water tank’s (supplemental) heater set point temperature is higher than the cut-in temperature of the heat pump water heater’s compressor, the heat pump compressor is disabled and the water tank’s heater (element or burner) is used to heat the water. During these times the Water Heater Compressor Part Load Ratio is equal to 0.

#### 1.24.6.2.2 Water Heater On Cycle Ancillary Electricity Rate [W]

#### 1.24.6.2.3 Water Heater On Cycle Ancillary Electricity Energy [J]

#### 1.24.6.2.4 Water Heater Off Cycle Ancillary Electricity Rate [W]

### 1.24.6.2.5 Water Heater Off Cycle Ancillary Electricity Energy [J]

These outputs are the parasitic electric power and consumption associated with the heat pump water heater. Specific outputs represent parasitic electrical usage during the compressor/fan on and off cycles. These outputs represent electronic controls or other electric component. The model assumes that the parasitic power does not contribute to heating the water, but it can impact the zone air heat balance depending on user inputs. The parasitic electric consumption outputs are also added to a meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Output:Meter objects).

## 1.24.7 Cold Thermal Storage Objects

There are four types of cold thermal storage objects that can be added to plant loops. (To model cold thermal storage integrated with packaged air-conditioning units, see the thermal storage cooling coil in section 1.41.39. The four cold thermal storage objects for plant loops are:

- **ThermalStorage:Ice:Simple**
- **ThermalStorage:Ice:Detailed**
- **ThermalStorage:ChilledWater:Mixed**
- **ThermalStorage:ChilledWater:Stratified**

These objects are typically placed on the supply side of a primary chilled water loop in series or in parallel with one or more chillers. Using the the component set point (**PlantEquipmentOperation:ComponentSetpoint**) plant operation scheme type, the chiller and storage tank setpoints are used to control operation. Using a **SetpointManager:Scheduled** object (or other appropriate type of set point manager), the setpoints on the chiller outlet node and the ice storage outlet node can be used to control how the cooling load is shared and when charging of storage occurs. Example setpoints to use for various modes of operation are shown in the table below:

Mode	Chiller Setpoint	Storage Setpoint
Charging ice storage tank	-5C	7C
Cooling with chiller only	7C	99C
Cooling with chiller and storage (fully load chiller before using storage))	7C	7C
Cooling with chiller and storage (chiller carries portion of load, valid if chiller is upstream of storage)	10C	7C

Example files have been developed for three common storage configurations:

1. Series – Chiller Upstream: In this configuration, a chiller is placed first on the same branch as the storage unit.
2. Series – Chiller Downstream: In this configuration, a chiller is placed second on the same branch as the storage unit.
3. Parallel: In this configuration, the chiller is on a branch parallel to the storage unit branch when it is not charging. During charging mode, valves will be changed so that the chiller is in series upstream of the storage. To accomplish this in EnergyPlus, the chiller must be modeled using two different chiller objects to represent the same chiller. One chiller object on a parallel branch operates only

when storage is not being charged. The other chiller object, in series upstream of the storage unit operates only during charging mode.

Other considerations for applying cold thermal storage objects include:

- In the **PlantLoop** object, the “Minimum Loop Temperature” must be set equal to or less than the lowest setpoint to be used anywhere in the loop.
- To end the storage charging cycle, use a **AvailabilityManager:LowTemperatureTurnOff** to shut off the primary chilled water loop when the temperature leaving the storage tank nears the charging mode chiller setpoint indicating that the tank is fully charged. For example, if the chiller is set to provide  $-5^{\circ}\text{C}$  chilled water during charging, then charging can be shut down when the water temperature leaving the storage unit reaches  $-4^{\circ}\text{C}$ . When using a primary-secondary loop arrangement, it may be necessary to schedule this availability manager to be active only when the HVAC systems are off to avoid fighting between the demand controls and the availability manager.

### 1.24.8 ThermalStorage:Ice:Simple

This thermal storage model is based on a simple simulation of an ice storage tank with a fixed capacity. The tank is charged, or frozen, in an ice-on-coil configuration where ice builds up on the outside of the tubes carrying the brine or glycol solution from the chiller. There are two discharge (melt) options, internal or external. Internal melt uses the same fluid tubes for charging and discharging. External melt uses a separate fluid path for discharge such that the outer layers of ice melt first. The ice storage model includes an implied 3-way valve to control the amount of charge/discharge based on the incoming water temperature and the outlet node setpoint temperature. The storage tank is assumed to be fully charged (full of ice) at the beginning of each environment. The tank is then allowed to charge and discharge during the warmup days of the environment. The tank is best controlled using the **PlantEquipmentOperation:ComponentSetpoint** plant operation scheme, and requires that a setpoint be placed by a set point manager on the ice storage Plant Outlet Node.

The input fields for the object are described in detail below:

#### 1.24.8.1 Inputs

##### 1.24.8.1.1 Field: Name

This alpha field contains the identifying name for the ice storage tank.

##### 1.24.8.1.2 Field: Ice Storage Type

This alpha field specifies the type of ice storage tank to be modeled. There are two options: “**IceOnCoilInternal**” models ice-on-coil, internal melt. “**IceOnCoilExternal**” models ice-on-coil, external melt.

##### 1.24.8.1.3 Field: Capacity

This numeric field contains the nominal capacity of the ice storage in GJ (Giga is  $10^9$ ).

##### 1.24.8.1.4 Field: Inlet Node Name

This alpha field specifies the name of the chilled water inlet node.

### 1.24.8.1.5 Field: Outlet Node Name

This alpha field specifies the name of the chilled water outlet node.

Following is an example input for the THERMAL STORAGE:ICE:SIMPLE object.

```
ThermalStorage:Ice:Simple,
    ITS,                !- Ice Storage Name
    IceOnCoilInternal,   !- Ice Storage Type
    1.5,                !- Ice Storage Capacity {GJ}
    ITS Inlet Node,      !- Plant Loop Inlet Node
    ITS Outlet Node;     !- Plant Loop Outlet Node
```

---

## 1.24.8.2 Outputs

The following outputs are available for simple Ice Storage model:

- HVAC,Average,Ice Thermal Storage Requested Load [W]
- Zone,Average,Ice Thermal Storage End Fraction[]
- HVAC,Average,Ice Thermal Storage Mass Flow Rate [kg/s]
- HVAC,Average,Ice Thermal Storage Inlet Temperature [C]
- HVAC,Average,Ice Thermal Storage Outlet Temperature [C]
- HVAC,Average,Ice Thermal Storage Cooling Discharge Rate [W]
- HVAC,Sum,Ice Thermal Storage Cooling Discharge Energy [J]
- HVAC,Average,Ice Thermal Storage Cooling Charge Rate [W]
- HVAC,Sum,Ice Thermal Storage Cooling Charge Energy [J]

### 1.24.8.2.1 Ice Thermal Storage Requested Load [W]

The load requested by the plant control scheme. A positive value indicates a cooling load or a request to discharge (melt) the tank. A negative value indicates a request to charge (freeze) the tank.

### 1.24.8.2.2 Ice Thermal Storage End Fraction []

The fraction of full ice storage which is present at the end of the current HVAC timestep. When reported at a frequency less than detailed, this value is averaged over the reporting period.

### 1.24.8.2.3 Ice Thermal Storage Mass Flow Rate [kg/s]

The total water mass flow rate through the ice storage component. Because the component includes an implied 3-way valve, this flow may be all through the tank, all bypassed through the valve, or a mixture of both.

### 1.24.8.2.4 Ice Thermal Storage Inlet Temperature [C]

The water temperature entering the ice storage component.

### 1.24.8.2.5 Ice Thermal Storage Outlet Temperature [C]

The water temperature leaving the ice storage component.

#### 1.24.8.2.6 Ice Thermal Storage Cooling Discharge Rate [W]

The rate of cooling delivered by the ice storage component. A positive value indicates the ice tank is discharging (melting). A zero value indicates the tank is charging or dormant.

#### 1.24.8.2.7 Ice Thermal Storage Cooling Discharge Energy [J]

The cooling energy delivered by the ice storage component. A positive value indicates the ice tank is discharging (melting). A zero value indicates the tank is charging or dormant.

#### 1.24.8.2.8 Ice Thermal Storage Cooling Charge Rate [W]

The rate of charging delivered to the ice storage component. A positive value indicates the ice tank is charging (freezing). A zero value indicates the tank is discharging or dormant.

#### 1.24.8.2.9 Ice Thermal Storage Cooling Charge Energy [J]

The charging energy delivered to the ice storage component. A positive value indicates the ice tank is charging (freezing). A zero value indicates the tank is discharging or dormant.

### 1.24.9 ThermalStorage:Ice:Detailed

The detailed ice storage model allows the users of EnergyPlus to model more closely specific manufacturers' ice storage units. This is possible due to the use of curve fits to simulate the performance of the ice storage unit during charging and discharging. In this implementation, both charging and discharging are a function of the fraction charged/discharged as well as the log mean temperature difference across the storage unit. More information on the model is provided in the Engineering Reference for EnergyPlus. The remainder of this section describes the input required for the detailed ice storage model and the output that it can produce.

#### 1.24.9.1 Inputs

##### 1.24.9.1.1 Field: Name

This field is the name of the detailed ice storage system given to it by the user.

##### 1.24.9.1.2 Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that determines whether or not the ice storage system is available during a particular time period. This allows the system to be turned off during a particular season. A value of less than or equal to zero indicates that the ice storage system is not available. Any value greater than zero indicates that the system is available. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.24.9.1.3 Field: Capacity

This number is the maximum amount of latent thermal storage available in the ice storage system. This model does not allow the removal or addition of sensible energy from the tank. Thus, it is always assumed to be at the freezing temperature of the storage material. The capacity is expressed in units of GJ.

##### 1.24.9.1.4 Field: Inlet Node Name

This is the name of the node that connects the ice storage system to the plant loop. It is the inlet node to the ice storage component. The next field defines the outlet node. Due to presence of an internal bypass in this model, there are other "nodes" that are handled internally within the program. Users do not need to define any nodes other than the inlet and outlet nodes.

#### 1.24.9.1.5 Field: Outlet Node Name

This is the name of the other node that connects the ice storage system to the plant loop. It is the outlet node to the ice storage component.

#### 1.24.9.1.6 Field: Discharging Curve Variable Specifications

The detailed ice storage model in EnergyPlus takes advantage of the Curve feature of the program. The discharging curve can use any curve that has two independent variables. This field controls which two parameters are the independent variables in modeling the performance of the detailed ice storage model during discharging. There are four different independent variable specifications:

- FractionChargedLMTD (where Fraction Charged is the first independent variable and LMTD is the second independent variable)
- FractionDischargedLMTD (where Fraction Discharged is the first independent variable and LMTD is the second independent variable)
- LMTDMassFlow (where LMTD is the first independent variable and Mass Flow rate is the second independent variable)
- LMTDFractionCharged (where LMTD is the first independent variable and Fraction Charged is the second independent variable)

More information on curve types can be found in the section on Curves. For additional information on how these curves are used in the Detailed Ice Storage model, please consult the Engineering Reference.

#### 1.24.9.1.7 Field: Discharging Curve Name

This field specifies the name of the actual curve fit to be used to model the discharging process of the detailed ice storage system. Note that this must be a curve that has two independent variables.

#### 1.24.9.1.8 Field: Charging Curve Variable Specifications

The detailed ice storage model in EnergyPlus takes advantage of the Curve feature of the program. The charging curve can use any curve that has two independent variables. This field controls which two parameters are the independent variables in modeling the performance of the detailed ice storage model during charging. There are four different independent variable specifications:

- FractionChargedLMTD (where Fraction Charged is the first independent variable and LMTD is the second independent variable)
- FractionDischargedLMTD (where Fraction Discharged is the first independent variable and LMTD is the second independent variable)
- LMTDMassFlow (where LMTD is the first independent variable and Mass Flow rate is the second independent variable)
- LMTDFractionCharged (where LMTD is the first independent variable and Fraction Charged is the second independent variable)

More information on curve types can be found in the section on Curves. For additional information on how these curves are used in the Detailed Ice Storage model, please consult the Engineering Reference.

#### 1.24.9.1.9 Field: Charging Curve Name

This field specifies the name of the actual curve fit to be used to model the charging process of the detailed ice storage system. Note that this must be a curve that has two independent variables.

#### 1.24.9.1.10 Field: Timestep of the Curve Data

This field defines what timestep was used to produce the curve fits named in the previous inputs. This parameter is important because the curve fit is non-dimensional. Thus, the data used to develop the curve fits were based on a specific length of time. In many cases, this is probably one hour or 1.0. The units for this parameter are hours.

#### 1.24.9.1.11 Field: Parasitic Electric Load During Discharging

This field defines the amount of parasitic electric consumption (for controls or other miscellaneous electric consumption associate with the ice storage unit itself) during the discharge phase. This parameter is dimensionless and gets multiplied by the current load on the tank.

#### 1.24.9.1.12 Field: Parasitic Electric Load During Charging

This field defines the amount of parasitic electric consumption (for controls or other miscellaneous electric consumption associate with the ice storage unit itself) during the charge phase. This parameter is dimensionless and gets multiplied by the current load on the tank.

#### 1.24.9.1.13 Field: Tank Loss Coefficient

This field defines the loss of ice stored during a particular hour. This field is dimensionless (per hour). It is not multiplied by any temperature difference between the tank and the environment in which it might be located.

#### 1.24.9.1.14 Field: Freezing Temperature of Storage Medium

This parameter defines the freezing/melting temperature of the ice storage medium in degrees Celsius. For most tanks, this is simply 0.0°C (the default value). However, some tanks may use other materials or salts which would change the freezing temperature. This can be changed using this parameter.

#### 1.24.9.1.15 Field: Thaw Process Indicator

This input field assists in more accurate modeling of the charging process by defining how the thawing of ice takes place. There are two options for this input: **InsideMelt** and **OutsideMelt**. Some ice storage systems, by their nature, start the charging process with a bare coil or no ice left on the charging surface even though there is still ice stored in the tank. An example of such a system is sometimes referred to as an ice-on-coil inside melt system, and these systems would define this parameter using the “InsideMelt” option for this field. Other systems melt the ice from the outside, leaving ice still on the charging surface when charging begins. These systems are modeled using the “OutsideMelt” option. For systems that have a charging process that does not vary significantly with fraction charged can ignore this input by accepting the default value. The default value for this field is “OutsideMelt”.

An IDF example:

```
ThermalStorage:Ice:Detailed,
  Ice Tank,                !- Ice Storage Name
  ON,                      !- Ice Storage availability schedule
  0.5,                    !- Ice Storage Capacity {GJ}
  Ice Tank Inlet Node,     !- Plant Loop Inlet Node
  Ice Tank Outlet Node,    !- Plant Loop Outlet Node
  FractionDischargedLMTD,  !- Discharging Curve Fit Type
  DischargeCurve,         !- Discharging Curve Name
  FractionChargedLMTD,     !- Charging Curve Fit Type
```

---

```

ChargeCurve,          !- Charging Curve Name
1.0,                  !- Timestep of Curve Fit Data
0.0001,               !- Parasitic electric load during discharging
0.0002,               !- Parasitic electric load during charging
0.0003,               !- Tank loss coefficient
0.0;                  !- Freezing temperature [C]

```

### 1.24.9.2 Outputs

Current detailed ice storage output variables are:

- System, Average, Ice Thermal Storage Cooling Rate [W]
- System, Average, Ice Thermal Storage Change Fraction []
- System, Average, Ice Thermal Storage End Fraction []
- System, Average, Ice Thermal Storage Mass Flow Rate [kg/s]
- System, Average, Ice Thermal Storage Bypass Mass Flow Rate [kg/s]
- System, Average, Ice Thermal Storage Tank Mass Flow Rate [kg/s]
- System, Average, Ice Thermal Storage Fluid Inlet Temperature [C]
- System, Average, Ice Thermal Storage Blended Outlet Temperature [C]
- System, Average, Ice Thermal Storage Tank Outlet Temperature [C]
- System, Average, Ice Thermal Storage Cooling Discharge Rate [W]
- System, Sum, Ice Thermal Storage Cooling Discharge Energy [J]
- System, Average, Ice Thermal Storage Cooling Charge Rate [W]
- System, Sum, Ice Thermal Storage Cooling Charge Energy [J]
- System, Average, Ice Thermal Storage Ancillary Electricity Rate [W]
- System, Sum, Ice Thermal Storage Ancillary Electricity Energy [J]
- System, Average, Ice Thermal Storage On Coil Fraction []

#### 1.24.9.2.1 Ice Thermal Storage Cooling Rate [W]

The actual load (absolute value) provided by the ice storage system during the current timestep

#### 1.24.9.2.2 Ice Thermal Storage Change Fraction []

The change in the ice tank's charge fraction charged during the current timestep (positive for charging, negative for discharging).

#### 1.24.9.2.3 Ice Thermal Storage End Fraction []

The fraction charge of the ice storage system at the end of the timestep

#### 1.24.9.2.4 Ice Thermal Storage On Coil Fraction []

The fraction of ice that is actually on the freezing surface at the end of the timestep. This can be different for an “inside melt” system than the end fraction (see previous output parameter).

**1.24.9.2.5 Ice Thermal Storage Mass Flow Rate [kg/s]**

The mass flow through the ice storage component

**1.24.9.2.6 Ice Thermal Storage Bypass Mass Flow Rate [kg/s]**

The mass flow through the ice storage component bypass (bypasses the actual unit)

**1.24.9.2.7 Ice Thermal Storage Tank Mass Flow Rate [kg/s]**

The mass flow through the ice storage unit itself

**1.24.9.2.8 Ice Thermal Storage Fluid Inlet Temperature [C]**

The inlet temperature to the ice storage component

**1.24.9.2.9 Ice Thermal Storage Blended Outlet Temperature [C]**

The outlet temperature of the component after mixing any bypass flow with flow through the ice storage unit

**1.24.9.2.10 Ice Thermal Storage Tank Outlet Temperature [C]**

The outlet temperature of the ice storage unit itself below mixing with any bypass flow

**1.24.9.2.11 Ice Thermal Storage Cooling Discharge Rate [W]**

The cooling done (as a rate) by the ice storage unit or its discharge rate

**1.24.9.2.12 Ice Thermal Storage Cooling Discharge Energy [J]**

The total cooling done by the ice storage unit or its discharge rate

**1.24.9.2.13 Ice Thermal Storage Cooling Charge Rate [W]**

The charging done (as a rate) to the ice storage unit

**1.24.9.2.14 Ice Thermal Storage Cooling Charge Energy [J]**

The total charging done to the ice storage unit

**1.24.9.2.15 Ice Thermal Storage Ancillary Electricity Rate [W]**

The electric power as a result of parasitic loads on the ice storage unit for things like controls or other miscellaneous parts of the ice storage unit itself

**1.24.9.2.16 Ice Thermal Storage Ancillary Electricity Energy [J]**

The electric consumption as a result of parasitic loads on the ice storage unit for things like controls or other miscellaneous parts of the ice storage unit itself

**1.24.10 ThermalStorage:ChilledWater:Mixed**

The ThermalStorage:ChilledWater:Mixed object analytically solves the differential equation governing the energy balance of the water tank. The chilled water is “used” by drawing from the “Use Side” of the water tank. The tank is indirectly charged by circulating cold water through the “Source Side” of the water tank.

Control is based on cycling flow through the source side. When the tank temperature rises above a “cut-in” temperature, source side flow is requested. Source side flow will continue until the tank is cooled to below the tank set point or “cut-out” temperature.

For heat gains from the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, the skin gains are removed from the zone heat balance as negative internal heat gains.

### 1.24.10.1 Inputs

#### 1.24.10.1.1 Field: Name

The unique name of the ThermalStorage:ChilledWater:Mixed object.

#### 1.24.10.1.2 Field: Tank Volume

The volume of the thermal storage tank [m<sup>3</sup>].

#### 1.24.10.1.3 Field: Setpoint Temperature Schedule Name

The reference to the schedule object specifying the chilled water temperature setpoint [°C]. Also known as the “cut-out” temperature.

#### 1.24.10.1.4 Field: Deadband Temperature Difference

The delta temperature difference [ $\Delta^{\circ}\text{C}$ ] between the setpoint and the “cut-in” temperature at which the storage tank will request cooling. In other words, the “cut-in” temperature is Setpoint + Deadband.

#### 1.24.10.1.5 Field: Minimum Temperature Limit

The temperature [°C] at which the tank water becomes too cold. No source side flow is allowed when the tank temperature is below this limit. The minimum temperature must be lower than the setpoint temperature at all times.

#### 1.24.10.1.6 Field: Nominal Cooling Capacity

This field describes the typical cooling capacity that the chilled water tank will provide. Since this is a passive device, the actual cooling capacity depends on water temperatures and flow rates. However, this field is used to describe the chilled water tank’s nominal cooling capacity for supervisory control where plant operation schemes require a cooling capacity to model how equipment is dispatched.

#### 1.24.10.1.7 Field: Ambient Temperature Indicator

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be “Schedule”, “Zone”, or “Exterior.” If *Schedule* is used, the Ambient Temperature Schedule Name field provides the values for ambient temperature. If *Zone* is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If *Exterior* is used, the outdoor dry-bulb air temperature provides the ambient temperature.

#### 1.24.10.1.8 Field: Ambient Temperature Schedule Name

The field contains the name of a schedule object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Schedule*.

#### 1.24.10.1.9 Field: Ambient Temperature Zone Name

The reference to the zone object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Zone*.

**1.24.10.1.10 Field: Ambient Temperature Outdoor Air Node Name**

This optional alpha field specifies the outdoor air node (**OutdoorAir:Node**) name used to define the ambient conditions surrounding the chilled water tank. This field is applicable only when the Ambient Temperature Indicator is specified as *Exterior*, otherwise this field should be left blank. The node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

**1.24.10.1.11 Field: Heat Gain Coefficient from Ambient Temperature**

The gain coefficient [W/K] from the ambient air temperature. This coefficient is often referred to as the “UA” for the overall tank thermal performance with respect to heat gains from the tank’s skin..

**1.24.10.1.12 Field: Use Side Inlet Node Name**

The inlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side draws chilled water from the tank and returns warmer water.

**1.24.10.1.13 Field: Use Side Outlet Node Name**

The outlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side chilled water from the tank and returns warmer water.

**1.24.10.1.14 Field: Use Side Heat Transfer Effectiveness**

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is lower, then the use side outlet water temperature will not be as cold as the tank water, simulating a heat exchanger.

**1.24.10.1.15 Field: Use Side Availability Schedule Name**

This field contains the name of an availability schedule for the use side of the water tank. If the schedule’s value is 0.0, then the use side is not available and flow will not be requested. If the schedule’s value is not equal to 0.0 (usually 1 is used), the use side is available. If this field is blank, the schedule has values of 1 for all time periods.

**1.24.10.1.16 Field: Use Side Design Flow Rate**

This field is used to specify the design flow rate through the Use Side of the chilled water tank. The volumetric design flow rate is specified in m<sup>3</sup>/s. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop connected to the Use side. Sizing results are reported in the EIO file.

**1.24.10.1.17 Field: Source Side Inlet Node Name**

The inlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water. The source side volume flow rate is obtained from the plant loop. The magnitude of the flow rates through the source side can be controlled by setting the Maximum Branch Flow Rate field in the **BRANCH** object that connects the source inlet node.

**1.24.10.1.18 Field: Source Side Outlet Node Name**

The outlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water.

**1.24.10.1.19 Field: Source Side Heat Transfer Effectiveness**

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is lower, then the source side outlet water temperature will not be as cold as the tank water, simulating a heat exchanger.

**1.24.10.1.20 Field: Source Side Availability Schedule Name**

This field contains the name of an availability schedule for the source side of the water tank. If the schedule's value is 0.0, then the source side is not available and flow will not be requested. If the schedule's value is not equal to 0.0 (usually 1 is used), the source side is available. If this field is blank, the schedule has values of 1 for all time periods.

**1.24.10.1.21 Field: Source Side Design Flow Rate**

This field is used to specify the design flow rate through the Source Side of the chilled water tank. The volumetric design flow rate is specified in m<sup>3</sup>/s. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

**1.24.10.1.22 Field: Tank Recovery Time**

This field is used to autosize the Source Side Design Flow Rate. The field is used if the previous field is set to autosize and the water tank's source side is on the demand side of a plant loop. This the the time, in hours, that the chilled water tank is to be indirectly cooled from 14.4°C to 9.0°C using the exit temperature of in the associated Plant Sizing object.

An example input object follows.

```
ThermalStorage:ChilledWater:Mixed,

**1.24.10.2 Outputs**

The following output variables are reported for chilled water thermal storage tanks.

- Chilled Water Thermal Storage Tank Temperature                      !- HVAC Average [C]
- Chilled Water Thermal Storage Final Tank Temperature            !- HVAC Average [C]
- Chilled Water Thermal Storage Tank Heat Gain Rate                !- HVAC Average [W]
- Chilled Water Thermal Storage Tank Heat Gain Energy             !- HVAC Sum [J]
- Chilled Water Thermal Storage Use Side Mass Flow Rate           !- HVAC Average [kg/s]
- Chilled Water Thermal Storage Use Side Inlet Temperature       !- HVAC Average [C]
- Chilled Water Thermal Storage Use Side Outlet Temperature       !- HVAC Average [C]
- Chilled Water Thermal Storage Use Side Heat Transfer Rate       !- HVAC Average [W]
- Chilled Water Thermal Storage Use Side Heat Transfer Energy     !- HVAC Sum [J]
- Chilled Water Thermal Storage Source Side Mass Flow Rate       !- HVAC Average [kg/s]
- Chilled Water Thermal Storage Source Side Inlet Temperature   !- HVAC Average [C]
- Chilled Water Thermal Storage Source Side Outlet Temperature   !- HVAC Average [C]
- Chilled Water Thermal Storage Source Side Heat Transfer Rate     !- HVAC Average [W]
- Chilled Water Thermal Storage Source Side Heat Transfer Energy   !- HVAC Sum [J]

#### 1.24.10.2.1 Chilled Water Thermal Storage Tank Temperature [C]

The average water tank temperature.

#### 1.24.10.2.2 Chilled Water Thermal Storage Final Tank Temperature [C]

The final water tank temperature at the end of the system timestep. If reported at the “Detailed” interval, this output variable can be used to verify an exact energy balance on the water storage tank.

#### 1.24.10.2.3 Chilled Water Thermal Storage Tank Heat Gain Rate [W]

The average heat exchange rate to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

#### 1.24.10.2.4 Chilled Water Thermal Storage Tank Heat Gain Energy [J]

The energy exchange to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

#### 1.24.10.2.5 Chilled Water Thermal Storage Use Side Mass Flow Rate [kg/s]

The use side mass flow rate.

#### 1.24.10.2.6 Chilled Water Thermal Storage Use Side Inlet Temperature [C]

The inlet temperature on the use side.

#### 1.24.10.2.7 Chilled Water Thermal Storage Use Side Outlet Temperature [C]

The outlet temperature on the use side.

**1.24.10.2.8 Chilled Water Thermal Storage Use Side Heat Transfer Rate [W]**

The average heat transfer rate between the use side water and the tank water.

**1.24.10.2.9 Chilled Water Thermal Storage Use Side Heat Transfer Energy [J]**

The heat transfer energy between the use side water and the tank water.

**1.24.10.2.10 Chilled Water Thermal Storage Source Side Mass Flow Rate [kg/s]**

The source side mass flow rate.

**1.24.10.2.11 Chilled Water Thermal Storage Source Side Inlet Temperature [C]**

The inlet temperature on the source side.

**1.24.10.2.12 Chilled Water Thermal Storage Source Side Outlet Temperature [C]**

The outlet temperature on the source side.

**1.24.10.2.13 Chilled Water Thermal Storage Source Side Heat Transfer Rate [W]**

The average heat transfer rate between the source side water and the tank water.

**1.24.10.2.14 Chilled Water Thermal Storage Source Side Heat Transfer Energy [J]**

The heat transfer energy between the source side water and the tank water.

**1.24.11 ThermalStorage:ChilledWater:Stratified**

The ThermalStorage:ChilledWater:Stratified object divides the water tank into multiple nodes of equal volume. The nodes are coupled by vertical conduction effects, internode fluid flow, and temperature inversion mixing. The object simultaneously solves the differential equations governing the energy balances on the nodes using a numerical method. The system timestep is divided into many small substeps that allow the simulation to capture events that occur on a very short time scale. The chilled water is “used” by drawing from the “Use Side” of the water tank. The tank is indirectly charged by circulating cold water through the “Source Side” of the water tank.

Control is based on cycling flow through the source side. When the tank temperature rises above a “cut-in” temperature, source side flow is requested. Source side flow will continue until the tank is cooled to below the tank set point or “cut-out” temperature.

For heat gains from the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, the skin gains are removed from the zone heat balance as negative internal heat gains.

**1.24.11.1 Inputs****1.24.11.1.1 Field: Name**

The unique name of the ThermalStorage:ChilledWater:Stratified object.

**1.24.11.1.2 Field: Tank Volume**

The volume of the thermal storage tank [m<sup>3</sup>].

**1.24.11.1.3 Field: Tank Height**

The height [m] of the tank. For the HorizontalCylinder shape (see below) the height of the tank is the measure in the axial direction, i.e., the height if you were to stand the cylinder up on its end.

**1.24.11.1.4 Field: Tank Shape**

The tank shape determines the size and skin losses of the stratified nodes. There are three options: “VerticalCylinder,” “HorizontalCylinder,” and “Other.”

*VerticalCylinder* describes most upright cylindrical water tanks.

*HorizontalCylinder* describes a few specialty water tanks and some large commercial storage tanks. *HorizontalCylinder* implies that the tank is divided into nodes of equal mass, but not equal height.

*Other* describes water storage tanks that have a uniform horizontal cross-section, but are not cylinders, e.g., a cuboid or other shape. The length of the perimeter is then specified by the Tank Perimeter field.

If blank, the default shape is *VerticalCylinder*.

**1.24.11.1.5 Field: Tank Perimeter**

The length of the tank perimeter [m]. This field is only used if Tank Shape is *Other*.

**1.24.11.1.6 Field: Setpoint Temperature Schedule Name**

The reference to the schedule object specifying the chilled water temperature setpoint [°C]. Also known as the “cut-out” temperature.

**1.24.11.1.7 Field: Deadband Temperature Difference**

The delta temperature difference [ $\Delta^{\circ}\text{C}$ ] between the setpoint and the “cut-in” temperature at which the storage tank will request cooling. In other words, the “cut-in” temperature is Setpoint + Deadband.

**1.24.11.1.8 Field: Temperature Sensor Height**

This field is used to describe the location in the tank where the temperature is sensed for control decisions. The program will associate one of the nodes with this height and use that node’s temperature for control decisions. The location is described in meters from the bottom of the tank.

**1.24.11.1.9 Field: Minimum Temperature Limit**

The temperature [°C] at which the tank water becomes too cold. No source side flow is allowed when the tank temperature is below this limit. The minimum temperature must be lower than the setpoint temperature at all times.

**1.24.11.1.10 Field: Nominal Cooling Capacity**

This field describes the typical cooling capacity that the chilled water tank will provide. Since this is a passive device, the actual cooling capacity depends on water temperatures and flow rates. However, this field is used to describe the chilled water tank’s nominal cooling capacity for supervisory control where plant operation schemes require a cooling capacity to model how equipment is dispatched.

**1.24.11.1.11 Field: Ambient Temperature Indicator**

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be “Schedule”, “Zone”, or “Exterior.” If *Schedule* is used, the Ambient Temperature Schedule Name field provides the values for ambient temperature. If *Zone* is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If *Exterior* is used, the outdoor dry-bulb air temperature provides the ambient temperature.

**1.24.11.1.12 Field: Ambient Temperature Schedule Name**

The field contains the name of a schedule object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Schedule*.

**1.24.11.1.13 Field: Ambient Temperature Zone Name**

The reference to the zone object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Zone*.

**1.24.11.1.14 Field: Ambient Temperature Outside Air Node Name**

This optional alpha field specifies the outdoor air node name used to define the ambient conditions surrounding the chilled water tank. This field is applicable only when the Ambient Temperature Indicator is specified as *Exterior*, otherwise this field should be left blank. The node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

**1.24.11.1.15 Field: Uniform Skin Loss Coefficient per Unit Area to Ambient Temperature**

The uniform skin loss coefficient [ $\text{W}/\text{m}^2\text{-K}$ ] or U-Value of the tank to the ambient air temperature. The uniform skin loss accounts for the tank insulation. The overall losses at any particular tank node can be further modified using the Additional Loss Coefficient fields to account for thermal shorting due to pipe penetrations, tank feet, and any other loss effects.

**1.24.11.1.16 Field: Use Side Inlet Node Name**

The inlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side draws chilled water from the tank and returns warmer water.

**1.24.11.1.17 Field: Use Side Outlet Node Name**

The outlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side chilled water from the tank and returns warmer water.

**1.24.11.1.18 Field: Use Side Heat Transfer Effectiveness**

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is lower, then the use side outlet water temperature will not be as cold as the tank water, simulating a heat exchanger.

**1.24.11.1.19 Field: Use Side Availability Schedule Name**

This field contains the name of an availability schedule for the use side of the water tank. If the schedule's value is 0.0, then the use side is not available and flow will not be requested. If the schedule's value is not equal to 0.0 (usually 1 is used), then the use side is available. If this field is blank, the schedule has values of 1 for all time periods.

**1.24.11.1.20 Field: Use Side Inlet Height**

The height of the use side inlet to the tank. If blank, the inlet defaults to the top of the tank. The inlet height cannot be higher than the tank height.

**1.24.11.1.21 Field: Use Side Outlet Height**

The height of the use side outlet from the tank. If blank or **autocalculate**, the inlet defaults to the bottom of the tank. The outlet height cannot be higher than the tank height.

**1.24.11.1.22 Field: Use Side Design Flow Rate**

This field is used to specify the design flow rate through the Use Side of the water tank. The volumetric design flow rate is specified in  $\text{m}^3/\text{s}$ . The field is needed when the Use Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

**1.24.11.1.23 Field: Source Side Inlet Node Name**

The inlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water. The source side volume flow rate is obtained from the plant loop. The magnitude of the flow rates through the source side can be controlled by setting the Maximum Branch Flow Rate field in the BRANCH object that connects the source inlet node.

**1.24.11.1.24 Field: Source Side Outlet Node Name**

The outlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water.

**1.24.11.1.25 Field: Source Side Heat Transfer Effectiveness**

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is less than 1.0, then the source side outlet water temperature will be less than the tank water at the outlet node, simulating a heat exchanger.

**1.24.11.1.26 Field: Source Side Availability Schedule Name**

This field contains the name of an availability schedule for the source side of the water tank. If the schedule's value is 0.0, then the source side is not available and flow will not be requested. If the schedule's value is not equal to 0.0 (usually 1 is used), then the source side is available. If this field is blank, the schedule has values of 1 for all time periods.

**1.24.11.1.27 Field: Source Side Inlet Height**

The height of the source side inlet to the tank. If blank or **autocalculate**, the inlet defaults to the bottom of the tank. The inlet height cannot be higher than the tank height.

**1.24.11.1.28 Field: Source Side Outlet Height**

The height of the source side outlet from the tank. If blank, the inlet defaults to the top of the tank. The outlet height cannot be higher than the tank height.

**1.24.11.1.29 Field: Source Side Design Flow Rate**

This field is optional and is used to specify the design flow rate through the Source Side of the water heater. The volumetric design flow rate is specified in  $\text{m}^3/\text{s}$ . The field is needed when the Source Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

**1.24.11.1.30 Field: Tank Recovery Time**

This field is used to autosize the Source Side Design Flow Rate. The field is used if the previous field is set to autosize and the water tank's source side is on the demand side of a plant loop. This the the time, in hours, that the chilled water tank is to be indirectly cooled from 14.4C to 9.0C using the exit temperature of in the associated Plant Sizing object.

**1.24.11.1.31 Field: Inlet Mode**

The inlet mode of entering fluid from the use and source sides. There are two options: “Fixed” or “Seeking.” In *Fixed* mode, the fluid enters at the fixed heights specified above. In *Seeking* mode, the fluid “seeks out” the stratified node that is closest to the inlet temperature and adds all flow to that node. The *Seeking* mode provides maximum stratification.

**1.24.11.1.32 Field: Number of Nodes**

The number of stratified nodes in the tank. There must be at least one node. The maximum number of nodes is 10, although this limit can be increased by editing the IDD.

**1.24.11.1.33 Field: Additional Destratification Conductivity**

An additional destratification conductivity [W/m-K] is added to the fluid conductivity of water (0.6 W/m-K) to account for vertical conduction effects along the inside of the tank wall, and perhaps other vertical components such as a dip tube pipe or anode rod.

**1.24.11.1.34 Field: Node 1-10 Additional Loss Coefficient**

An additional heat gain coefficient [W/K] added to the skin gains for a given node to account for thermal shorting due to pipe penetrations, tank feet, and any other loss effects.

An example input object follows.

**1.24.11.2 Outputs**

The following output variables are reported for stratified chilled water thermal storage tanks.

- Chilled Water Thermal Storage Tank Temperature                      !- HVAC Average [C]
- Chilled Water Thermal Storage Final Tank Temperature                !- HVAC Average [C]
- Chilled Water Thermal Storage Tank Heat Gain Rate                    !- HVAC Average [W]
- Chilled Water Thermal Storage Tank Heat Gain Energy                 !- HVAC Sum [J]
- Chilled Water Thermal Storage Use Side Mass Flow Rate                !- HVAC Average [kg/s]
- Chilled Water Thermal Storage Use Side Inlet Temperature            !- HVAC Average [C]
- Chilled Water Thermal Storage Use Side Outlet Temperature          !- HVAC Average [C]
- Chilled Water Thermal Storage Use Side Heat Transfer Rate             !- HVAC Average [W]
- Chilled Water Thermal Storage Use Side Heat Transfer Energy         !- HVAC Sum [J]
- Chilled Water Thermal Storage Source Side Mass Flow Rate            !- HVAC Average [kg/s]
- Chilled Water Thermal Storage Source Side Inlet Temperature        !- HVAC Average [C]
- Chilled Water Thermal Storage Source Side Outlet Temperature       !- HVAC Average [C]
- Chilled Water Thermal Storage Source Side Heat Transfer Rate         !- HVAC Average [W]
- Chilled Water Thermal Storage Source Side Heat Transfer Energy       !- HVAC Sum [J]
- Chilled Water Thermal Storage Temperature Node <1 - 10>            !- HVAC Average [C]
- Chilled Water Thermal Storage Final Temperature Node <1 - 10>      !- HVAC Average [C]

#### 1.24.11.2.1 Chilled Water Thermal Storage Tank Temperature [C]

The average water tank temperature, i.e., the average of all of the node average temperatures.

#### 1.24.11.2.2 Chilled Water Thermal Storage Tank Final Temperature [C]

The final water tank temperature at the end of the system timestep, i.e., the average of all of the final node temperatures at the end of the system timestep. If reported at the “Detailed” interval, this output variable can be used to verify an exact energy balance on the water storage tank.

#### 1.24.11.2.3 Chilled Water Thermal Storage Tank Heat Gain Rate [W]

The average heat exchange rate to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

#### 1.24.11.2.4 Chilled Water Thermal Storage Tank Heat Gain Energy [J]

The energy exchange to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

#### 1.24.11.2.5 Chilled Water Thermal Storage Use Side Mass Flow Rate [kg/s]

The use side mass flow rate.

#### 1.24.11.2.6 Chilled Water Thermal Storage Use Side Inlet Temperature [C]

The inlet temperature on the use side.

**1.24.11.2.7 Chilled Water Thermal Storage Use Side Outlet Temperature [C]**

The outlet temperature on the use side.

**1.24.11.2.8 Chilled Water Thermal Storage Use Side Heat Transfer Rate [W]**

The average heat transfer rate between the use side water and the tank water.

**1.24.11.2.9 Chilled Water Thermal Storage Use Side Heat Transfer Energy [J]**

The heat transfer energy between the use side water and the tank water.

**1.24.11.2.10 Chilled Water Thermal Storage Source Side Mass Flow Rate [kg/s]**

The source side mass flow rate.

**1.24.11.2.11 Chilled Water Thermal Storage Source Side Inlet Temperature [C]**

The inlet temperature on the source side.

**1.24.11.2.12 Chilled Water Thermal Storage Source Side Outlet Temperature [C]**

The outlet temperature on the source side.

**1.24.11.2.13 Chilled Water Thermal Storage Source Side Heat Transfer Rate [W]**

The average heat transfer rate between the source side water and the tank water.

**1.24.11.2.14 Chilled Water Thermal Storage Source Side Heat Transfer Energy [J]**

The heat transfer energy between the source side water and the tank water.

**1.24.11.2.15 Chilled Water Thermal Storage Temperature Node 1-10 [C]**

The average node temperature.

**1.24.11.2.16 Chilled Water Thermal Storage Final Temperature Node 1-10 [C]**

The final node temperature at the end of the system timestep.

## 1.25 Group – Condenser Equipment

### 1.25.1 Equipment Types

In each `CondenserEquipmentList`, various equipment types and names must be given. Each type-name pair must then have a corresponding equipment definition. This subsection lists the various equipment types that are available and examples from an IDF. Where appropriate, notes and comments on the input structure are provided.

### 1.25.2 CoolingTower:SingleSpeed

Cooling towers are components that may be assigned to condenser loops. The cooling tower is modeled as a counterflow heat exchanger with a single-speed fan (induced draft configuration) based on Merkel’s theory. The user must define tower performance via one of two methods: design heat transfer coefficient-area product (UA) and design water flow rate, or nominal tower capacity at a specific rating point. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified. The model will also account for tower performance in the “free convection” regime, when the tower fan is off

but the water pump remains on and heat transfer still occurs (albeit at a low level). If the user wants the model to account for “free convection”, they must specify the corresponding airflow rate and heat transfer coefficient-area product (UA), or the nominal tower capacity during this mode of operation.

The cooling tower seeks to maintain the temperature of the water exiting the cooling tower at (or below) a set point. The set point schedule value is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the **CondenserLoop** object. The model first checks to determine the impact of “free convection”, if specified by the user, on the tower exiting water temperature. If the exiting water temperature based on “free convection” is at or below the set point, then the tower fan is not turned on. If the exiting water temperature based on “free convection” is below the set point, the tower will operate in FluidBypass mode – portion of the water goes through the tower media and gets cooled while the remaining water flow gets bypassed, two water flows then mix together trying to meet the water setpoint temperature. If the exiting water temperature remains above the set point after “free convection” is modeled, then the tower fan is turned on to reduce the exiting water temperature to the set point. If the capacity control is FanCycling, the model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., tower fan on for the entire simulation timestep and tower fan off for the entire simulation timestep). Cyclic losses are not taken into account. If the capacity control is FluidBypass, the model determines the fraction of water flow to be bypassed while the remaining water goes through the tower cooling media and gets cooled, then the two water flows mix to meet the setpoint temperature. In this case, the fan runs at full speed for the entire timestep.

Cooling towers here are “wet” and consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the towers. The last six input fields are optional and provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a water storage tanks (i.e. **WaterUse:Storage** objects).

For the operation of multi-cell towers, the first step is to determine the number of cells to operate based on the cell control method – between the minimum number of cells subject to the maximum water flow rate fraction per cell, and maximum number of cells subject to the minimum water flow rate fraction per cell. If the calculated cells do not meet the loads, additional cells will be operating to help meet the loads. Inside each cell, the existing capacity controls still apply.

For multi-cell towers, the following inputs are assumed to be for the entire tower including all cells:

- Design Water Flow Rate; Design Air Flow Rate; Fan Power at Design Air Flow Rate;
- Air Flow Rate in Free Convection Regime; Nominal Capacity; Free Convection Capacity
- BASIN HEATER (we assume that there is a common basin)

### 1.25.2.1 Inputs

#### 1.25.2.1.1 Field: Name

This alpha field contains the identifying name for the cooling tower.

#### 1.25.2.1.2 Field: Water Inlet Node Name

This alpha field contains the identifying name for the cooling tower’s water inlet node.

#### 1.25.2.1.3 Field: Water Outlet Node Name

This alpha field contains the identifying name for the cooling tower’s water outlet node.

**1.25.2.1.4 Field: Design Water Flow Rate**

This numeric field contains the design water flow rate through the tower in m<sup>3</sup>/s. This value is the flow rate of the condenser loop water being cooled by the tower (not the flow rate of water being sprayed on the outside of the heat exchange coil). If the input field “Performance Input Method” is specified as “*UFactorTimesAreaAndDesignWaterFlowRate*”, then a water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections). If “Performance Input Method” is specified as “*NominalCapacity*”, then this field must be left blank since the model automatically assumes a water flow rate of 5.382E-8 m<sup>3</sup>/s per watt (3 gpm/ton) of tower capacity specified in the field “Nominal Capacity”.

**1.25.2.1.5 Field: Design Air Flow Rate**

This numeric field contains the design air flow rate induced by the tower fan in m<sup>3</sup>/s. A value greater than zero must be defined regardless of the tower performance input method. Alternately, this field can be autosized. If autosized, the design air flow rate is calculated as follows:

$$\text{Design Air Flow Rate} = \frac{0.5\rho_{air}(\text{Fan power at Design Air Flow Rate})}{190.} \quad (1.93)$$

where a fan pressure rise of 190 Pascals and total fan efficiency of 0.5 are assumed.

**1.25.2.1.6 Field: Design Fan Power**

This numeric field contains the fan power (in watts) at the design air flow rate specified in the previous field. A value greater than zero must be specified regardless of the tower performance input method, or this field can be autosized. If autosized, the fan power is calculated as follows:

If “Performance Input Method” is specified as “*UFactorTimesAreaAndDesignWaterFlowRate*”, then

$$\text{Fan power} = 0.0105 \cdot \rho_{water} \cdot C_{p,water} \cdot \text{Design Water Flow Rate} \cdot \text{Design Loop}\Delta T \quad (1.94)$$

is used.

If “Performance Input Method” is specified as “*NominalCapacity*”, then

$$\text{Fan power} = 0.0105 \cdot \text{Tower Nominal Capacity} \quad (1.95)$$

is used.

**1.25.2.1.7 Field: Design U-Factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (UA) in watts per Kelvin corresponding to the design air and water flow rates specified above. If the input field “Performance Input Method” is specified as “*UFactorTimesAreaAndDesignWaterFlowRate*”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design tower UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections), assuming a tower water inlet temperature of 35C and tower inlet air at 35C drybulb/25.6C wetbulb. If “Performance Input Method” is specified as “*NominalCapacity*”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Nominal Capacity”.

#### 1.25.2.1.8 Field: Free Convection Regime Air Flow Rate

This numeric field contains the air flow rate ( $\text{m}^3/\text{s}$ ) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “Design Air Flow Rate”. This field may be autocalculated, in which case it is set to a fraction of the “Design Air Flow Rate” determined in the following input field. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If the user specifies the U-Factor Times Area Value at Free Convection Air Flow Rate or Free Convection Capacity as a value greater than zero, then the free convection air flow rate must be specified greater than 0.0.

#### 1.25.2.1.9 Field: Free Convection Regime Air Flow Rate Sizing Factor

This numeric field contains the sizing factor to use when calculating the free convection regime air flow rate. The default is 0.1.

#### 1.25.2.1.10 Field: Free Convection Regime U-Factor Times Area Value

This numeric field contains the heat transfer coefficient-area product ( $\text{W/K}$ ) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “U-Factor Times Area Value at Design Air Flow Rate”. This field may be autosized, in which case it is set to a fraction of the “U-Factor Times Area Value at Design Air Flow Rate” determined in the following input field. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Free Convection Capacity”.

#### 1.25.2.1.11 Field: Free Convection U-Factor Times Area Value Sizing Factor

This numeric field contains the sizing factor to use when calculating the free convection regime U-Factor times area value. The default is 0.1.

#### 1.25.2.1.12 Field: Performance Input Method

This alpha field contains the method by which the user will specify tower performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”. If this field is left blank in the input data file, the default input method is assumed to be “UFactorTimesAreaAndDesignWaterFlowRate”. If the method “UFactorTimesAreaAndDesignWaterFlowRate” is selected, then the user must enter design UA values, design water flow rates and air flow rates as described for the previous input fields. If the method “NominalCapacity” is selected then the fields “Design Water Flow Rate”, “U-Factor Times Area Value at Design Air Flow Rate” and “U-Factor Times Area Value at Free Convection Air Flow Rate” must be left blank, but the fields “Nominal Capacity” and “Free Convection Capacity” must be entered as described below.

#### 1.25.2.1.13 Field: Heat Rejection Capacity and Nominal Capacity Sizing Ratio

This numeric field contains the value for the ratio of actual tower heat rejection to nominal capacity. This ratio is defined at entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. Historically this ratio has been set at 1.25 based on the assumption that the tower must dissipate 0.25 W of compressor power for every what of heat removed at the chiller evaporator. The default is 1.25.

**1.25.2.1.14 Field: Nominal Capacity**

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be 5.382E-8 m<sup>3</sup>/s per watt of nominal capacity (3 gpm/ton). The value in the previous field times this nominal tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate additional heat from the compressor heat for heat removed at the evaporator).

**1.25.2.1.15 Field: Free Convection Capacity**

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts when the tower is in the “free convection” regime (water flow exists but tower fan is turned off), with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be 5.382E-8 m<sup>3</sup>/s per watt of nominal tower capacity (input field above). The heat rejection capacity and nominal capacity sizing ratio is applied to this free convection tower capacity to give the actual tower heat rejection at these operating conditions (typical value is 1.25 based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). The value specified for this field must be less than the value specified for the field “Tower Nominal Capacity”. If the user does not wish to model “free convection”, then this field should be set to 0.0. If the user specifies a value greater than zero, then the “Air Flow Rate in Free Convection Regime” field must contain a value greater than zero. This field can be automatically calculated using the sizing factor in the following field.

**1.25.2.1.16 Field: Free Convection Nominal Capacity Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Free Convection Capacity. The default is 0.1.

**1.25.2.1.17 Field: Design Inlet Air Dry-Bulb Temperature**

This numeric field specifies the design inlet air dry-bulb temperature of the tower. The default is 35.0 °C.

**1.25.2.1.18 Field: Design Inlet Air Wet-Bulb Temperature**

This numeric field specifies the design inlet air wet-bulb temperature of the tower. The default is 25.6 °C.

**1.25.2.1.19 Field: Design Approach Temperature**

This numeric field specifies the design approach temperature of the tower corresponding to the design inlet air wet-bulb temperature and the design temperature range. The approach temperature should be the outlet water temperature minus the inlet air wet-bulb temperature at design conditions. This parameter is autosizable and when autosized it is set to 3.9 °C.

**1.25.2.1.20 Field: Design Temperature Range**

This numeric field specifies the design temperature range of the tower corresponding to the design inlet air wet-bulb temperature and the design approach temperature. The design range should be the inlet water temperature minus the outlet water temperature at design conditions. This parameter is autosizable and when autosized it is set to 5.5 °C.

#### 1.25.2.1.21 Field: Basin Heater Capacity

This numeric field contains the capacity of the tower's electric basin heater in watts per degree Kelvin. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the tower fan is off and water is not flowing through the tower, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### 1.25.2.1.22 Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the tower fan is off and water is not flowing through the tower. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

#### 1.25.2.1.23 Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the cooling tower fan is off and water is not flowing through the tower.

#### 1.25.2.1.24 Field: Evaporation Loss Mode

This field is used to choose which method is used to model the amount of water evaporated by the cooling tower. There are two options: **LossFactor** or **SaturatedExit**. The default is **SaturatedExit**. The user-defined loss factor is entered in the following field. By assuming that the air leaving the tower is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the cooling tower model (and does not require additional user input).

#### 1.25.2.1.25 Field: Evaporation Loss Factor

This field is used to specify the rate of water evaporated from the cooling tower and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to **LossFactor**. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-degree Kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Typical values are from 0.15 to 0.27 [percent/K]. The default is 0.2.

#### 1.25.2.1.26 Field: Drift Loss Percent

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Typical values for towers with efficient drift eliminators are between 0.002 and 0.2% of the condenser water flow rate. The default value is 0.008%.

#### 1.25.2.1.27 Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options **ConcentrationRatio** or **ScheduledRate**. The choice will determine which of the two models below is used. The default is **ConcentrationRatio**.

**1.25.2.1.28 Field: Blowdown Concentration Ratio**

This field is used to dynamically adjust the rate of blowdown in the cooling tower as a function of the rate of evaporation. Blowdown is water intentionally drained from the tower in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values for tower operation are 3 to 5. The default value is 3.

**1.25.2.1.29 Field: Blowdown Makeup Water Usage Schedule Name**

This alpha field contains the name of the schedule used to define the amount of water ( $\text{m}^3/\text{s}$ ) flushed from the basin on a periodic basis to purge the tower of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation Mode is set to ScheduledRate. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Typical values range from 0.0002 to 0.0013  $\text{m}^3/\text{s}$  (17.3 to 112.3  $\text{m}^3/\text{day}$ ). This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the cooling tower is active and water is flowing through the tower (regardless of the water usage defined by this schedule).

**1.25.2.1.30 Field: Supply Water Storage Tank Name**

This field is optional. It is used to describe where the tower obtains water used for evaporative cooling. If blank or omitted, then the tower will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the tower will obtain its water from that tank. If a tank is specified, the tower will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the tower needs, then the tower will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

**1.25.2.1.31 Field: Outdoor Air Inlet Node Name**

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the cooling tower. If this field is left blank, the outdoor air conditions entering the cooling tower are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

**1.25.2.1.32 Field:Capacity Control**

This alpha field contains the cooling capacity control for the cooling tower. Two choices are available: **FanCycling** and **FluidBypass**. During part-load conditions, there are two ways to maintain the exiting water temperature at the setpoint: either cycling the tower fan, or bypassing portion of the tower water with a three-way valve. For FluidBypass, the tower fan still runs at full speed for the entire timestep, but only portion of the water flow goes through the cooling tower media to get cooled while the remaining portion of the water flow gets bypassed. Two water flows then mix at the common water sump to meet the setpoint temperature.

**1.25.2.1.33 Field: Number of Cells**

This integer field contains the number of cells in the multi-cell cooling tower. If not entered, the program will assume it is a single-cell cooling tower

- HVAC,Average,Cooling Tower Water Evaporation Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Evaporation Volume [m3]
- HVAC,Average,Cooling Tower Water Drift Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Drift Volume [m3]
- HVAC,Average,Cooling Tower Water Blowdown Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Blowdown Volume [m3]

IF specified:

- HVAC,Average,Cooling Tower Basin Heater Electricity Rate [W]
- HVAC,Sum,Cooling Tower Basin Heater Electricity Energy [J]

#### **1.25.2.2.1 Cooling Tower Fan Electricity Rate [W]**

#### **1.25.2.2.2 Cooling Tower Fan Electricity Energy [J]**

These outputs are the electric power input to the tower fans. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.25.2.2.3 Cooling Tower Heat Transfer Rate [W]**

This is the rate at which heat is removed from the condenser water loop by the tower.

#### **1.25.2.2.4 Cooling Tower Inlet Temperature [C]**

#### **1.25.2.2.5 Cooling Tower Outlet Temperature [C]**

#### **1.25.2.2.6 Cooling Tower Mass Flow Rate [kg/s]**

These outputs are the tower water inlet and outlet temperatures, and mass flow rate of the circulating condenser water loop.

#### **1.25.2.2.7 Cooling Tower Basin Heater Electricity Rate [W]**

#### **1.25.2.2.8 Cooling Tower Basin Heater Electricity Energy [J]**

These outputs are the electric power input to the tower basin heater. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility

#### **1.25.2.2.9 Cooling Tower Make Up Water Volume Flow Rate [m3/s]**

**1.25.2.2.10 Cooling Tower Make Up Water Volume [m3]**

These outputs are the water consumed by the wet cooling tower for external water sprays used to augment heat transfer. This is the total of evaporation, drift, and blowdown.

**1.25.2.2.11 Cooling Tower Water Evaporation Volume Flow Rate [m3/s]****1.25.2.2.12 Cooling Tower Water Evaporation Volume [m3]****1.25.2.2.13 Cooling Tower Water Drift Volume Flow Rate [m3/s]****1.25.2.2.14 Cooling Tower Water Drift Volume [m3]****1.25.2.2.15 Cooling Tower Water Blowdown Volume Flow Rate [m3/s]****1.25.2.2.16 Cooling Tower Water Blowdown Volume [m3]**

These outputs provide the breakdown of the different components of water use during cooling tower operation.

**1.25.2.2.17 Cooling Tower Make Up Mains Water Volume [m3]**

This is the volume of water drawn from mains service to feed the cooling tower.

If a water storage tank is used to provide water to the tower, then the following output variables will also be available.

**1.25.2.2.18 Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]****1.25.2.2.19 Cooling Tower Storage Tank Water Volume [m3]**

These are the rate and volume of water provided by the Water Storage Tank.

**1.25.2.2.20 Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]****1.25.2.2.21 Cooling Tower Starved Storage Tank Water Volume [m3]**

These are the rate and volume of water the Storage Tank connections was not able to provide. The starved water is assumed to come from the mains. The tower's operation is not affected by a lack of storage tank water.

**1.25.2.2.22 Cooling Tower Fan Cycling Ratio []**

This represents the fraction of a time-step when tower fan is on.

**1.25.2.2.23 Cooling Tower Bypass Fraction []**

This represents the fraction of a fluid bypassing the tower when a mixture of the tower fluid and tower return water is able to meet the set point temperature.

**1.25.2.2.24 Cooling Tower Operating Cells Count []**

This represents the number of cells operating at each time step.

### 1.25.3 CoolingTower:TwoSpeed

The two-speed cooling tower is modeled in a similar fashion to the single-speed tower. The cooling tower is modeled as a counterflow heat exchanger with a two-speed fan (induced draft configuration) based on Merkel’s theory. The user must define tower performance via one of two methods: heat transfer coefficient-area product (UA) and design water flow rate, or nominal tower capacity at a specific rating point. Regardless of which method is chosen, the airflow rate and corresponding fan power at both high and low fan speed must be specified. The model will also account for tower performance in the “free convection” regime, when the tower fan is off but the water pump remains on and heat transfer still occurs (albeit at a low level). If the user wants the model to account for “free convection”, they must specify the corresponding air flow rate and heat transfer coefficient-area product (UA), or the nominal tower capacity during this mode of operation.

The cooling tower seeks to maintain the temperature of the water exiting the cooling tower at (or below) a set point. The set point schedule value is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the **CondenserLoop** object. The model first checks to determine the impact of “free convection”, if specified by the user, on the tower exiting water temperature. If the exiting water temperature based on “free convection” is at or below the set point, then the tower fan is not turned on. If the exiting water temperature remains above the set point after “free convection” is modeled, then the tower fan is turned on at low speed to reduce the exiting water temperature. If operating the tower fan at low speed does not reduce the exiting water temperature to the set point, then the tower fan is increased to its high speed.

The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., tower fan at high speed for the entire simulation timestep and tower fan at low speed for the entire simulation timestep, or tower fan at low speed for the entire simulation timestep and tower fan off for the entire simulation timestep). Cyclic losses are not taken into account.

Cooling towers here are “wet” and consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the towers. The last six input fields are optional and provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a **WaterUse:Storage** object.

For the operation of multi-cell towers, the first step is to determine the number of cells to operate based on the cell control method – between the minimum number of cells subject to the maximum water flow rate fraction per cell, and maximum number of cells subject to the minimum water flow rate fraction per cell. If the calculated cells do not meet the loads, additional cells will be operating to help meet the loads. Inside each cell, the existing capacity controls still apply.

For multi-cell towers, the following inputs are assumed to be for the entire tower including all cells:

- Design Water Flow Rate; Design Air Flow Rate; Fan Power at Design Air Flow Rate;
- Air Flow Rate in Free Convection Regime; Nominal Capacity; Free Convection Capacity
- BASIN HEATER (we assume that there is a common basin)

#### 1.25.3.1 Inputs

##### 1.25.3.1.1 Field: Name

This alpha field contains the identifying name for the cooling tower.

##### 1.25.3.1.2 Field: Water Inlet Node Name

This alpha field contains the identifying name for the cooling tower’s water inlet node.

### 1.25.3.1.3 Field: Water Outlet Node Name

This alpha field contains the identifying name for the cooling tower's water outlet node.

### 1.25.3.1.4 Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the tower in m<sup>3</sup>/s. This value is the flow rate of the condenser loop water being cooled by the tower (not the flow rate of water being sprayed on the outside of the heat exchange coil). If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections). If "Performance Input Method" is specified as "NominalCapacity", then this field must be left blank since the model automatically assumes a design water flow rate of 5.382E-8 m<sup>3</sup>/s per watt (3 gpm/ton) of tower capacity specified in the field "Tower High-Speed Nominal Capacity".

### 1.25.3.1.5 Field: High Fan Speed Air Flow Rate

This numeric field contains the tower air flow rate at high fan speed in m<sup>3</sup>/s. A value greater than zero must be defined regardless of the tower performance input method. Alternately, this field can be autosized. If autosized, the design air flow rate is calculated as follows:

$$\text{Air Flow Rate at High Fan Speed} = \frac{0.5\rho_{air}(\text{Fan Power at High Fan Speed})}{190.} \quad (1.96)$$

where a fan pressure rise of 190 Pascals and total fan efficiency of 0.5 are assumed.

#### **Field: High Fan Speed Fan Power**

This numeric field contains the fan power (in Watts) at the high-speed air flow rate specified in the previous field. A value greater than zero must be specified regardless of the tower performance input method, or this field can be autosized. If autosized, the fan power is calculated as follows:

If "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then

$$\text{Fan power}_{\text{High Fan Speed}} = 0.0105 \cdot \rho_{\text{water}} \cdot C_{p,\text{water}} \cdot \text{Design Water Flow Rate} \cdot \text{Design Loop } \Delta T \quad (1.97)$$

is used.

If "Performance Input Method" is specified as "NominalCapacity", then

$$\text{Fan power}_{\text{High Fan Speed}} = 0.0105 \cdot \text{Tower High - Speed Nominal Capacity} \quad (1.98)$$

is used.

### 1.25.3.1.6 Field: High Fan Speed U-Factor Times Area Value

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the high-speed air flow rate and design water flow rate specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the tower UA value at high fan speed is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections), assuming a tower water inlet temperature of 35C and tower inlet air at 35C drybulb/25.6C wetbulb. If "Performance Input Method" is specified as "NominalCapacity", then this field must be left blank since the model automatically calculates the tower UA based on the capacity specified in the field "High-Speed Nominal Capacity".

**1.25.3.1.7 Field: Low Fan Speed Air Flow Rate**

This numeric field contains the tower air flow rate at low fan speed in  $\text{m}^3/\text{s}$ . This value must be greater than zero, less than the value specified for the field “Air Flow Rate at High Fan Speed”, and greater than the value specified for the field “Air Flow Rate in Free Convection Regime”. This field may be autocalculated, in which case it is set to a fraction of the “Air Flow Rate at High Fan Speed” determined in the next field.

**1.25.3.1.8 Field: Low Fan Speed Air Flow Rate Sizing Factor**

This numeric field contains the sizing factor to use when calculating the low fan speed air flow rate. The default is 0.5.

**1.25.3.1.9 Field: Low Fan Speed Fan Power**

This numeric field contains the fan power (in Watts) at the low-speed air flow rate specified in the previous field. This value must be specified greater than zero or the field may be autocalculated, in which case it is set to a fraction of the “Fan Power at High Fan Speed” determined in the next field.

**1.25.3.1.10 Field: Low Fan Speed Fan Power Sizing Factor**

This numeric field contains the sizing factor to use when calculating the low speed fan power. The default is 0.16.

**1.25.3.1.11 Field: Low Fan Speed U-Factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the design water flow rate and low-speed air flow rate specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, this value must be greater than zero but less than or equal to 300,000, less than the value specified for the field “U-Factor Times Area Value at High Fan Speed”, and greater than the value specified for the field “U-Factor Times Area Value at Free Convection Air Flow Rate”. This field may be autocalculated, in which case it is set to a fraction of the “U-Factor Times Area Value at High Fan Speed” determined in the following field. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Low Speed Nominal Capacity”.

**1.25.3.1.12 Field: Low Fan Speed U-Factor Times Area Sizing Factor**

This numeric field contains the sizing factor to use when calculating the low speed heat transfer coefficient-area product (UA). The default is 0.6.

**1.25.3.1.13 Field: Free Convection Regime Air Flow Rate**

This numeric field contains the air flow rate ( $\text{m}^3/\text{s}$ ) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “Air Flow Rate at Low Fan Speed”. This field may be autocalculated, in which case it is set to a fraction of the “Air Flow Rate at High Fan Speed” determined in the following field. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If the user specifies the U-Factor Times Area Value at Free Convection Air Flow Rate or Free Convection Capacity as a value greater than zero, then the free convection air flow rate must be specified greater than 0.0.

**1.25.3.1.14 Field: Free Convection Air Flow Rate Sizing Factor**

This numeric field contains the sizing factor to use when calculating the free convection regime air flow rate. The default is 0.1.

**1.25.3.1.15 Field: Free Convection U-Factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product ( $W/^\circ C$ ) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “U-Factor Times Area Value at Low Fan Speed”. This field may be autocalculated, in which case it is set to a fraction of the “U-Factor Times Area Value at High Fan Speed” determined in the following field. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Free Convection Capacity”.

**1.25.3.1.16 Field: Free Convection U-Factor Times Area Value Sizing Factor**

This numeric field contains the sizing factor to use when calculating the free convection regime U-Factor times area value. The default is 0.1.

**1.25.3.1.17 Field: Performance Input Method**

This alpha field contains the method by which the user will specify tower performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”. If this field is left blank in the input data file, the default input method is assumed to be “UFactorTimesAreaAndDesignWaterFlowRate”. If the method “UFactorTimesAreaAndDesignWaterFlowRate” is selected, then the user must enter UA values, design water flow rate and air flow rates as described for the previous input fields. If the method “NominalCapacity” is selected then the fields “Design Water Flow Rate”, “U-Factor Times Area Value at High Fan Speed”, “U-Factor Times Area Value at Low Fan Speed” and “U-Factor Times Area Value at Free Convection Air Flow Rate” must be left blank, but the fields “High Speed Nominal Capacity”, “Low Speed Nominal Capacity” and “Free Convection Capacity” must be entered as described below.

**1.25.3.1.18 Field: Heat Rejection Capacity and Nominal Capacity Sizing Ratio**

This numeric field contains the value for the ratio of actual tower heat rejection to nominal capacity. This ratio is defined at entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. Historically this ratio has been set at 1.25 based on the assumption that the tower must dissipate 0.25 W of compressor power for every what of heat removed at the chiller evaporator. The default is 1.25.

**1.25.3.1.19 Field: High Speed Nominal Capacity**

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under high-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be  $5.382E-8 \text{ m}^3/\text{s}$  per watt of high-speed nominal capacity (3 gpm/ton). The Heat Rejection Capacity and Nominal Capacity Sizing Ratio set in the previous field is applied to this nominal tower capacity to give the actual tower heat rejection at these operating.

**1.25.3.1.20 Field: Low Speed Nominal Capacity**

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under low-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering

air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be  $5.382\text{E-}8 \text{ m}^3/\text{s}$  per watt of high-speed nominal tower capacity (input field above). The Heat Rejection Capacity and Nominal Capacity Sizing Ratio is applied to this nominal tower capacity to give the actual tower heat rejection at these operating conditions. The value specified for this field must be greater than zero but less than the value specified for the field “High-Speed Nominal Capacity”. This field may be autocalculated, in which case it is set to a fraction of the High Speed Nominal Capacity determined in the following field.

#### **1.25.3.1.21 Field: Low Speed Nominal Capacity Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Low Speed Nominal Capacity. The default is 0.5.

#### **1.25.3.1.22 Field: Free Convection Capacity**

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts when the tower is in the “free convection” regime (water flow exists but tower fan is turned off), with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be  $5.382\text{E-}8 \text{ m}^3/\text{s}$  per watt of high-speed nominal tower capacity (input field above). The Heat Rejection Capacity and Nominal Capacity Sizing Ratio is applied to this free convection tower capacity to give the actual tower heat rejection at these operating conditions. The value specified for this field must be less than the value specified for the field “Tower Low-Speed Nominal Capacity”. If the user does not wish to model “free convection”, then this field should be set to 0.0. If the user specifies a value greater than zero, then the “Air Flow Rate in Free Convection Regime” field must contain a value greater than zero. This field may be autocalculated, in which case it is set to a fraction of the High Speed Nominal Capacity determined in the following field.

#### **1.25.3.1.23 Field: Free Convection Nominal Capacity Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Free Convection Capacity. The default is 0.1.

#### **1.25.3.1.24 Field: Design Inlet Air Dry-Bulb Temperature**

This numeric field specifies the design inlet air dry-bulb temperature of the tower. The default is 35.0°C.

#### **1.25.3.1.25 Field: Design Inlet Air Wet-Bulb Temperature**

This numeric field specifies the design inlet air wet-bulb temperature of the tower. The default is 25.6°C.

#### **1.25.3.1.26 Field: Design Approach Temperature**

This numeric field specifies the design approach temperature of the tower corresponding to the design inlet air wet-bulb temperature and the design temperature range. The approach temperature should be the outlet water temperature minus the inlet air wet-bulb temperature at design conditions. This parameter is autosizable and when autosized it is set to 3.9°C.

#### **1.25.3.1.27 Field: Design Temperature Range**

This numeric field specifies the design temperature range of the tower corresponding to the design inlet air wet-bulb temperature and the design approach temperature. The design range should be the inlet water temperature minus the outlet water temperature at design conditions. This parameter is autosizable and when autosized it is set to 5.5°C.

**1.25.3.1.28 Field: Basin Heater Capacity**

This numeric field contains the capacity of the tower's electric basin heater in watts per degree Kelvin. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the tower fan is off and water is not flowing through the tower, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

**1.25.3.1.29 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the tower fan is off and water is not flowing through the tower. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

**1.25.3.1.30 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the cooling tower fan is off and water is not flowing through the tower.

**1.25.3.1.31 Field: Evaporation Loss Mode**

This field is used to choose which method is used to model the amount of water evaporated by the cooling tower. There are two options: 'LossFactor' or 'SaturatedExit'. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the tower is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the cooling tower model (and does not require additional user input).

**1.25.3.1.32 Field: Evaporation Loss Factor**

This field is used to specify the rate of water evaporated from the cooling tower and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to LossFactor. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-degree Kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Typical values are from 0.15 to 0.27 [percent/K]. The default is 0.2.

**1.25.3.1.33 Field: Drift Loss Percent**

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Typical values for towers with efficient drift eliminators are between 0.002 and 0.2% of the condenser water flow rate. The default value is 0.008%.

**1.25.3.1.34 Field: Blowdown Calculation Mode**

This field specifies which method is used to determine blowdown rates. There two options ConcentrationRatio or ScheduledRate. The choice will determine which of the two models below is used. The default is ConcentrationRatio

**1.25.3.1.35 Field: Blowdown Concentration Ratio**

This field is used to dynamically adjust the rate of blowdown in the cooling tower as a function of the rate of evaporation. Blowdown is water intentionally drained from the tower in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values for tower operation are 3 to 5. The default value is 3.

**1.25.3.1.36 Field: Blowdown Makeup Water Usage Schedule Name**

This alpha field contains the name of the schedule used to define the amount of water ( $\text{m}^3/\text{s}$ ) flushed from the basin on a periodic basis to purge the tower of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation mode is set to ScheduledRate. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Typical values range from 0.0002 to 0.0013  $\text{m}^3/\text{s}$  (17.3 to 112.3  $\text{m}^3/\text{day}$ ). This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the cooling tower is active and water is flowing through the tower (regardless of the water usage defined by this schedule).

**1.25.3.1.37 Field: Supply Water Storage Tank Name**

This field is optional. It is used to describe where the tower obtains water used for evaporative cooling. If blank or omitted, then the tower will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the tower will obtain its water from that tank. If a tank is specified, the tower will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the tower needs, then the tower will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

**1.25.3.1.38 Field: Outdoor Air Inlet Node Name**

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the cooling tower. If this field is left blank, the outdoor air conditions entering the cooling tower are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

**1.25.3.1.39 Field: Number of Cells**

This integer field contains the number of cells in the multi-cell cooling tower. If not entered, the program will assume it is a single-cell cooling tower

**1.25.3.1.40 Field: Cell Control**

This alpha field specifies the method used to control the number of cells used to meet the load, the two choices are:

**MinimalCell:** the program will use minimal number of cells needed, all other cells will be shut down with no water flow. It will attempt to use as few cells as possible to cool the fluid. In no case, however, will the flow per cell be allowed to exceed its maximum value defined by the *Maximum Water Flow Rate Fraction*.

**MaximalCell:** As many cells as possible will be turned on. In no case, however, will the flow per cell be allowed to drop below its minimum value specified by the *Minimum Water Flow Rate Fraction*.

#### 1.25.3.1.41 Field: Cell Minimum Water Flow Rate Fraction

This numeric field specifies the allowable smallest fraction of the design water flow rate. Flows less than this value will commonly result in fluid distribution problems; the pressure at each nozzle will be too weak for the fluid to be sprayed out in the correct pattern, not all the fill would be wet. If this field is left blank, the default value is 0.33.

#### 1.25.3.1.42 Field: Cell Maximum Water Flow Rate Fraction

This numeric field specifies the allowable largest fraction of the design water flow rate. If this field is left blank, the default value is 2.5.

#### 1.25.3.1.43 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Air Flow Rate at High Fan Speed;
3. Fan Power at High Fan Speed;
4. U-Factor Times Area Value at High Fan Speed;
5. Air Flow Rate at Low Fan Speed;
6. Fan Power at Low Fan Speed;
7. U-Factor Times Area Value at Low Fan Speed;
8. Air Flow Rate in Free Convection Regime;
9. U-Factor Times Area Value at Free Convection Air Flow Rate.

Note that the U-Factor Times Area Value at High Fan Speed is not *multiplied* by the Sizing Factor. Instead the design tower load is multiplied by the sizing factor and the design UA then calculated as usual. The U-Factor Times Area Value at Low Fan Speed is set to a fraction of the full load design UA determined by the field Low Fan Speed U-Factor Times Area Sizing Factor. The U-Factor Times Area Value at Free Convection Air Flow Rate is set to a fraction of the design Tower UA determined by the field Free Convection Air U-Factor Times Area Value Sizing Factor.

#### 1.25.3.1.44 Field: End-Use Subcategory

This optional field allows you to specify a user-defined end-use subcategory, e.g., “Process”. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the cooling tower will be assigned to the “General” end-use subcategory.

Four examples of an IDF specification for this object are shown below:

### 1.25.3.2 Outputs

- HVAC,Average,Cooling Tower Fan Electricity Rate [W]
- HVAC,Sum,Cooling Tower Fan Electricity Energy [J]
- HVAC,Average,Cooling Tower Heat Transfer Rate [W]
- HVAC,Average,Cooling Tower Inlet Temperature [C]
- HVAC,Average,Cooling Tower Outlet Temperature [C]
- HVAC,Average,Cooling Tower Mass Flow Rate [kg/s]

- HVAC,Average,Cooling Tower Fan Cycling Ratio []
- HVAC,Average,Cooling Tower Operating Cells Count []
- HVAC,Average,Cooling Tower Fan Speed Level []
- HVAC,Average,Cooling Tower Bypass Fraction []

A tower uses either mains water or storage tank for make-up water.

*When mains water is used:*

- HVAC,Average,Cooling Tower Make Up Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Make Up Water Volume [m3]
- HVAC,Sum,Cooling Tower Make Up Mains Water Volume [m3]

*When storage tank water is used:*

- HVAC,Average,Cooling Tower Make Up Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Make Up Water Volume [m3]
- HVAC,Sum,Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Storage Tank Water Volume [m3]
- HVAC,Sum,Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Starved Storage Tank Water Volume [m3]
- HVAC,Sum,Cooling Tower Make Up Mains Water Volume [m3]
- HVAC,Average,Cooling Tower Water Evaporation Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Evaporation Volume [m3]
- HVAC,Average,Cooling Tower Water Drift Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Drift Volume [m3]
- HVAC,Average,Cooling Tower Water Blowdown Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Blowdown Volume [m3]

IF specified:

- HVAC,Average,Cooling Tower Basin Heater Electricity Rate [W]
- HVAC,Sum,Cooling Tower Basin Heater Electricity Energy [J]

#### 1.25.3.2.1 Cooling Tower Fan Electricity Rate [W]

#### 1.25.3.2.2 Cooling Tower Fan Electricity Energy [J]

These outputs are the electric power input to the tower fans. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

**1.25.3.2.3 Cooling Tower Heat Transfer Rate [W]**

This is the rate at which heat is removed from the condenser water loop by the tower.

**1.25.3.2.4 Cooling Tower Inlet Temperature [C]****1.25.3.2.5 Cooling Tower Outlet Temperature [C]****1.25.3.2.6 Cooling Tower Mass Flow Rate [kg/s]**

These outputs are the tower water inlet and outlet temperatures, and mass flow rate.

**1.25.3.2.7 Cooling Tower Basin Heater Electricity Rate [W]****1.25.3.2.8 Cooling Tower Basin Heater Electricity Energy [J]**

These outputs are the electric power input to the tower basin heater. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility

**1.25.3.2.9 Cooling Tower Make Up Water Volume Flow Rate [m3/s]****1.25.3.2.10 Cooling Tower Make Up Water Volume [m3]**

These outputs are the water consumed by the wet cooling tower for external water sprays used to augment heat transfer. This is the total of evaporation, drift, and blowdown.

**1.25.3.2.11 Cooling Tower Water Evaporation Volume Flow Rate [m3/s]****1.25.3.2.12 Cooling Tower Water Evaporation Volume [m3]****1.25.3.2.13 Cooling Tower Water Drift Volume Flow Rate [m3/s]****1.25.3.2.14 Cooling Tower Water Drift Volume [m3]****1.25.3.2.15 Cooling Tower Water Blowdown Volume Flow Rate [m3/s]****1.25.3.2.16 Cooling Tower Water Blowdown Volume [m3]**

These outputs provide the breakdown of the different components of water use during cooling tower operation.

**1.25.3.2.17 Cooling Tower Make Up Mains Water Volume [m3]**

This is the volume of water drawn from mains service to feed the cooling tower. If a water storage tank is used to provide water to the tower, then the following output variables will also be available.

**1.25.3.2.18 Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]****1.25.3.2.19 Cooling Tower Storage Tank Water Volume [m3]**

These are the rate and volume of water provided by the Water Storage Tank.

**1.25.3.2.20 Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]**

**1.25.3.2.21 Cooling Tower Starved Storage Tank Water Volume [m3]**

These are the rate and volume of water the Storage Tank connections was not able to provide. The starved water is assumed to come from the mains. The tower's operation is not affected by a lack of storage tank water.

**1.25.3.2.22 Cooling Tower Fan Cycling Ratio []**

This represents the fraction of a time-step when tower fan is on. The fan can cycle at both speeds.

**1.25.3.2.23 Cooling Tower Operating Cells Count []**

This represents the number of cells operating at each time step.

**1.25.3.2.24 Cooling Tower Fan Speed Level []**

This represents the fan speed operating at each time step: 2 for High Speed, 1 for Low Speed, and 0 when the fan is OFF.

**1.25.4 CoolingTower:VariableSpeed:Merkel**

This variable speed tower model is based on Merkel's theory and is similar to the single-speed and two-speed tower models. The open wet cooling tower is modeled as a counter flow heat exchanger with a variable-speed fan drawing air through the tower (induced-draft configuration). The model also includes a "free convection" regime where cooling tower performance modeled with the fan off.

For this model, Merkel's theory is modified to include adjustments developed by Scheier to alter the heat transfer effectiveness based on current wetbulb, air flow rates, and water flow rates. The input requires performance curves or lookup tables to describe these three adjustment factors.

For a multi-cell tower, the capacity and air/water flow rate inputs are for the entire tower.

**1.25.4.1 Inputs****1.25.4.1.1 Field: Name**

This alpha field contains the identifying name for the cooling tower.

**1.25.4.1.2 Field: Water Inlet Node Name**

This alpha field contains the identifying name for the cooling tower's water inlet node.

**1.25.4.1.3 Field: Water Outlet Node Name**

This alpha field contains the identifying name for the cooling tower's water outlet node.

**1.25.4.1.4 Field: Performance Input Method**

This alpha field contains the method by which the user will specify tower performance: "UFactorTimesAreaAndDesignWaterFlowRate" or "NominalCapacity". If this field is left blank in the input data file, the default input method is assumed to be "NominalCapacity". If the method "UFactorTimesAreaAndDesignWaterFlowRate" is selected, then the user must enter design UA values, design water flow rates and air flow rates as described for the previous input fields. If the method "NominalCapacity" is selected then the fields "Design Water Flow Rate", "U-Factor Times Area Value at Design Air Flow Rate" and "U-Factor Times Area Value at Free Convection Air Flow Rate" must be left blank, but the fields "Nominal Capacity" and "Free Convection Capacity" must be entered as described below.

#### 1.25.4.1.5 Field: Heat Rejection Capacity and Nominal Capacity Sizing Ratio

This numeric field contains the value for the ratio of actual tower heat rejection to nominal capacity. This ratio is defined at entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. Historically this ratio has been set at 1.25 based on the assumption that the tower must dissipate 0.25 W of compressor power for every what of heat removed at the chiller evaporator. The default is 1.25.

#### 1.25.4.1.6 Field: Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under full-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The Heat Rejection Capacity and Nominal Capacity Sizing Ratio set in the previous field is applied to this nominal tower capacity to give the actual tower heat rejection at these operating conditions. This field can be autosized, in which case a **Sizing:Plant** object is needed for the condenser loop.

#### 1.25.4.1.7 Field: Free Convection Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts when the tower is in the “free convection” regime (water flow exists but tower fan is turned off), with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The Heat Rejection Capacity and Nominal Capacity Sizing Ratio is applied to this free convection tower capacity to give the actual tower heat rejection at these operating conditions. The value specified for this field must be less than the value specified for the field “Tower Low-Speed Nominal Capacity”. If the user does not wish to model “free convection”, then this field should be set to 0.0. If the user specifies a value greater than zero, then the “Air Flow Rate in Free Convection Regime” field must contain a value greater than zero. This field may be autocalculated, in which case it is set to a fraction of the High Speed Nominal Capacity determined in the following field.

#### 1.25.4.1.8 Field: Free Convection Nominal Capacity Sizing Factor

This numeric field contains the sizing factor to use when calculating the Free Convection Capacity. The default is 0.1.

#### 1.25.4.1.9 Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the tower in  $\text{m}^3/\text{s}$ . This value is the flow rate of the condenser loop water being cooled by the tower. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a water flow rate greater than zero must be defined or the field can be autosized. If autosized, a **Sizing:Plant** object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections). If “Performance Input Method” is specified as “NominalCapacity”, then this field can be autocalculated using the sizing factor in the following field.

#### 1.25.4.1.10 Field: Design Water Flow Rate per Unit of Nominal Capacity

This numeric field contains a scalable sizing factor for design water flow rate that scales with nominal capacity, in units of  $\text{m}^3/\text{s}/\text{W}$ . The default value is  $5.382 \times 10^{-8}$ . This field is only used if the previous field is set to autocalculate and performance input method is NominalCapacity. (If the performance input method is set to UFactorTimesAreaAndDesignWaterFlowRate then the design water flow rate is obtained from the plant sizing result.)

**1.25.4.1.11 Field: Design Air Flow Rate**

This numeric field contains the tower air flow rate at full fan speed, in  $\text{m}^3/\text{s}$ . The value can be autocalculated, in which case the air flow rate is based off of the scalable sizing factor in the following input field.

**1.25.4.1.12 Field: Design Air Flow Rate Per Unit of Nominal Capacity**

This numeric field contains the sizing factor to use when calculating the design air flow rate from the nominal capacity, in units of  $\text{m}^3/\text{s}/\text{W}$ . The default is  $2.76316 \times 10^{-5}$ . When this field is left blank, then the default value is used but the flow rate is also scaled to account for elevation (with larger volume flow rates at higher altitudes). When a hard value is entered, even if it is the same as the default, then the design air flow rate is not also adjusted for elevation and the scaling factor is used directly.

**1.25.4.1.13 Field: Minimum Air Flow Rate Ratio**

This numeric field contains the minimum air flow rate ratio. The tower fan is allowed to operate between the ratio defined here and a maximum air flow rate ratio of 1.0 (which corresponds to the design [maximum] tower air flow rate). Below this value the tower is assumed to operate in the “free convection” regime with the tower fan off. The minimum air flow rate ratio must be greater than or equal to 0.1 and less than or equal to 0.5, with a default value of 0.2 if the field is left blank.

**1.25.4.1.14 Field: Design Fan Power**

This numeric field contains the fan power in watts at the design (maximum) air flow rate through the tower. A value greater than zero must be specified or this field can be autocalculated. When the field is autocalculated the following input field is used to size the fan power based on nominal capacity.

**1.25.4.1.15 Field: Design Fan Power Per Unit of Nominal Capacity**

This numeric field contains the sizing factor to use when calculating the design fan power from the nominal capacity, in units of Watts per Watt. This field is only used if the previous is set to autocalculate. The default values is 0.0105.

**1.25.4.1.16 Field: Fan Power Modifier Function of Air Flow Rate Ratio Curve Name**

This alpha field contains the name of a curve or table object that describes fan power ratio (fan power/design fan power) as a function of air flow rate ratio (air flow rate/design air flow rate). The curve or table object must be for one independent variable, typically a cubic, and should be normalized to 1.0 at an air flow rate ratio of 1.0. This field is required.

**1.25.4.1.17 Field: Free Convection Regime Air Flow Rate**

This numeric field contains the air flow rate ( $\text{m}^3/\text{s}$ ) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “Design Air Flow Rate”. This field may be autocalculated, in which case it is set to a fraction of the “Design Air Flow Rate” determined in the following input field. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If the user specifies the U-Factor Times Area Value at Free Convection Air Flow Rate or Free Convection Capacity as a value greater than zero, then the free convection air flow rate must be specified greater than 0.0.

**1.25.4.1.18 Field: Free Convection Regime Air Flow Rate Sizing Factor**

This numeric field contains the sizing factor to use when calculating the free convection regime air flow rate. The default is 0.1.

**1.25.4.1.19 Field: Design Air Flow Rate U-Factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (UA) in watts per Kelvin corresponding to the design air and water flow rates specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design tower UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections), assuming a tower water inlet temperature of 35C and tower inlet air at 35C drybulb/25.6C wetbulb. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Nominal Capacity”.

**1.25.4.1.20 Field: Free Convection Regime U-Factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (W/K) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “U-Factor Times Area Value at Design Air Flow Rate”. This field may be autosized, in which case it is set to a fraction of the “U-Factor Times Area Value at Design Air Flow Rate” determined in the following input field. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Free Convection Capacity”.

**1.25.4.1.21 Field: Free Convection U-Factor Times Area Value Sizing Factor**

This numeric field contains the sizing factor to use when calculating the free convection regime U-Factor times area value. The default is 0.1. This field is only used if the previous field is set to autocalculate and the performance input method is UFactorTimesAreaAndDesignWaterFlowRate.

**1.25.4.1.22 Field: U-Factor Times Area Modifier Function of Air Flow Ratio Curve Name**

This alpha field contains the name of a curve or table object that describes how the UA value varies as a function of air flow rate ratio (air flow rate/design air flow rate). The result of this curve is multiplied by the design UA value to adjust for air flow rate, along with the two other modifiers discussed below. The curve or table object must be for one independent variable and should be normalized to 1.0 at an air flow rate ratio of 1.0. This field is required.

**1.25.4.1.23 Field: U-Factor Times Area Modifier Function of Wetbulb Temperature Difference Curve Name**

This alpha field contains the name of a curve or table object that describes how the UA value varies as a function of the current wetbulb temperature. The result of this curve is multiplied by the design UA value to adjust for wetbulb temperatures that differ from design conditions at 25.56°C (78°F), along with the two other modifiers discussed in the previous and following fields. The independent variable is the design wetbulb minus the current outdoor air wetbulb, in units of degrees Celsius. The curve or table

object must be for one independent variable and should be normalized to 1.0 at a wetbulb temperature difference of 0.0. This field is required.

#### **1.25.4.1.24 Field: U-Factor Times Area Modifier Function of Water Flow Ratio Curve Name**

This alpha field contains the name of a curve or table object that describes how the UA value varies as a function of the current water flow rate ratio (water flow rate/design water flow rate). The result of this curve is multiplied by the design UA value to adjust for water flow rates that differ from design level, along with the other two modifiers discussed above. The curve or table object must be for one independent variable and should be normalized to 1.0 at a water flow ratio of 1.0. This field is required

#### **1.25.4.1.25 Field: Design Inlet Air Dry-Bulb Temperature**

This numeric field specifies the design inlet air dry-bulb temperature of the tower. The default is 35.0°C.

#### **1.25.4.1.26 Field: Design Inlet Air Wet-Bulb Temperature**

This numeric field specifies the design inlet air wet-bulb temperature of the tower. The default is 25.6°C.

#### **1.25.4.1.27 Field: Design Approach Temperature**

This numeric field specifies the design approach temperature of the tower corresponding to the design inlet air wet-bulb temperature and the design temperature range. The approach temperature should be the outlet water temperature minus the inlet air wet-bulb temperature at design conditions. This parameter is autosizable and when autosized it is set to 3.9°C.

#### **1.25.4.1.28 Field: Design Temperature Range**

This numeric field specifies the design temperature range of the tower corresponding to the design inlet air wet-bulb temperature and the design approach temperature. The design range should be the inlet water temperature minus the outlet water temperature at design conditions. This parameter is autosizable and when autosized it is set to 5.5°C.

#### **1.25.4.1.29 Field: Basin Heater Capacity**

This numeric field contains the capacity of the tower's electric basin heater in watts per degree Kelvin. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the tower fan is off and water is not flowing through the tower, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **1.25.4.1.30 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the tower fan is off and water is not flowing through the tower. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

#### 1.25.4.1.31 Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the cooling tower fan is off and water is not flowing through the tower.

#### 1.25.4.1.32 Field: Evaporation Loss Mode

This field is used to choose which method is used to model the amount of water evaporated by the cooling tower. There are two options: **LossFactor** or **SaturatedExit**. The default is **SaturatedExit**. The user-defined loss factor is entered in the following field. By assuming that the air leaving the tower is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the cooling tower model (and does not require additional user input).

#### 1.25.4.1.33 Field: Evaporation Loss Factor

This field is used to specify the rate of water evaporated from the cooling tower and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to **LossFactor**. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-degree Kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Typical values are from 0.15 to 0.27 [percent/K]. The default is 0.2.

#### 1.25.4.1.34 Field: Drift Loss Percent

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Typical values for towers with efficient drift eliminators are between 0.002 and 0.2% of the condenser water flow rate. The default value is 0.008%.

#### 1.25.4.1.35 Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options **ConcentrationRatio** or **ScheduledRate**. The choice will determine which of the two models below is used. The default is **ConcentrationRatio**.

#### 1.25.4.1.36 Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the cooling tower as a function of the rate of evaporation. Blowdown is water intentionally drained from the tower in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values for tower operation are 3 to 5. The default value is 3.

#### 1.25.4.1.37 Field: Blowdown Makeup Water Usage Schedule Name

This alpha field contains the name of the schedule used to define the amount of water ( $\text{m}^3/\text{s}$ ) flushed from the basin on a periodic basis to purge the tower of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation Mode is set to **ScheduledRate**. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Typical values range from 0.0002 to 0.0013  $\text{m}^3/\text{s}$  (17.3 to 112.3  $\text{m}^3/\text{day}$ ). This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs

when the basin water contaminant concentration is high, blowdown only occurs when the cooling tower is active and water is flowing through the tower (regardless of the water usage defined by this schedule).

#### 1.25.4.1.38 Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the tower obtains water used for evaporative cooling. If blank or omitted, then the tower will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the tower will obtain its water from that tank. If a tank is specified, the tower will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the tower needs, then the tower will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

#### 1.25.4.1.39 Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the cooling tower. If this field is left blank, the outdoor air conditions entering the cooling tower are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

#### 1.25.4.1.40 Field: Number of Cells

This integer field contains the number of cells in the multi-cell cooling tower. If not entered, the program will assume it is a single-cell cooling tower

#### 1.25.4.1.41 Field: Cell Control

This alpha field specifies the method used to control the number of cells used to meet the load, the two choices are:

**MinimalCell** : the program will use minimal number of cells needed, all other cells will be shut down with no water flow. It will attempt to use as few cells as possible to cool the fluid. In no case, however, will the flow per cell be allowed to exceed its maximum value defined by the *Maximum Water Flow Rate Fraction*.

**MaximalCell**: As many cells as possible will be turned on. In no case, however, will the flow per cell be allowed to drop below its minimum value specified by the *Minimum Water Flow Rate Fraction*.

#### 1.25.4.1.42 Field: Cell Minimum Water Flow Rate Fraction

This numeric field specifies the allowable smallest fraction of the design water flow rate. Flows less than this value will commonly result in fluid distribution problems; the pressure at each nozzle will be too weak for the fluid to be sprayed out in the correct pattern, not all the fill would be wet. If this field is left blank, the default value is 0.33.

#### 1.25.4.1.43 Field: Cell Maximum Water Flow Rate Fraction

This numeric field specifies the allowable largest fraction of the design water flow rate. If this field is left blank, the default value is 2.5.

#### 1.25.4.1.44 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

#### 1.25.4.1.45 Field: End-Use Subcategory

This optional field allows you to specify a user-defined end-use subcategory, e.g., “Process”. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the cooling tower will be assigned to the “General” end-use subcategory.

An example IDF specification follows.

- HVAC,Sum,Cooling Tower Water Evaporation Volume [m3]
- HVAC,Average,Cooling Tower Water Drift Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Drift Volume [m3]
- HVAC,Average,Cooling Tower Water Blowdown Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Blowdown Volume [m3]

IF specified:

- HVAC,Average,Cooling Tower Basin Heater Electricity Rate [W]
- HVAC,Sum,Cooling Tower Basin Heater Electricity Energy [J]

#### **1.25.4.2.1 Cooling Tower Fan Electricity Rate [W]**

#### **1.25.4.2.2 Cooling Tower Fan Electricity Energy [J]**

These outputs are the electric power input to the tower fans. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.25.4.2.3 Cooling Tower Heat Transfer Rate [W]**

This is the rate at which heat is removed from the condenser water loop by the tower.

#### **1.25.4.2.4 Cooling Tower Inlet Temperature [C]**

#### **1.25.4.2.5 Cooling Tower Outlet Temperature [C]**

#### **1.25.4.2.6 Cooling Tower Mass Flow Rate [kg/s]**

These outputs are the tower water inlet and outlet temperatures, and mass flow rate.

**1.25.4.2.7 Cooling Tower Fan Speed Ratio**

This output is the air flow ratio. The current air flow rate divided by the design air flow rate with values from 0.0 to 1.0.

**1.25.4.2.8 Cooling Tower Operating Cells Count []**

This represents the number of cells operating at each time step.

**1.25.4.2.9 Cooling Tower Basin Heater Electricity Rate [W]****1.25.4.2.10 Cooling Tower Basin Heater Electricity Energy [J]**

These outputs are the electric power input to the tower basin heater. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility

**1.25.4.2.11 Cooling Tower Make Up Water Volume Flow Rate [m3/s]****1.25.4.2.12 Cooling Tower Make Up Water Volume [m3]**

These outputs are the water consumed by the wet cooling tower for external water sprays used to augment heat transfer. This is the total of evaporation, drift, and blowdown.

**1.25.4.2.13 Cooling Tower Water Evaporation Volume Flow Rate [m3/s]****1.25.4.2.14 Cooling Tower Water Evaporation Volume [m3]****1.25.4.2.15 Cooling Tower Water Drift Volume Flow Rate [m3/s]****1.25.4.2.16 Cooling Tower Water Drift Volume [m3]****1.25.4.2.17 Cooling Tower Water Blowdown Volume Flow Rate [m3/s]****1.25.4.2.18 Cooling Tower Water Blowdown Volume [m3]**

These outputs provide the breakdown of the different components of water use during cooling tower operation.

**1.25.4.2.19 Cooling Tower Make Up Mains Water Volume [m3]**

This is the volume of water drawn from mains service to feed the cooling tower. If a water storage tank is used to provide water to the tower, then the following output variables will also be available.

**1.25.4.2.20 Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]****1.25.4.2.21 Cooling Tower Storage Tank Water Volume [m3]**

These are the rate and volume of water provided by the Water Storage Tank.

**1.25.4.2.22 Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]**

#### 1.25.4.2.23 Cooling Tower Starved Storage Tank Water Volume [m3]

These are the rate and volume of water the Storage Tank connections was not able to provide. The starved water is assumed to come from the mains. The tower's operation is not affected by a lack of storage tank water.

### 1.25.5 CoolingTower:VariableSpeed

The variable speed tower model is based on empirical curve fits of manufacturer's performance data or field measurements. The user specifies tower performance at design conditions, and empirical curves are used to determine the approach temperature and fan power at off-design conditions. The user defines tower performance by entering the inlet air wet-bulb temperature, tower range, and tower approach temperature at the design conditions. The corresponding water flow rate (within  $\pm 25\%$  of the tower's rated water mass flow rate), air flow rate, and fan power must also be specified. The model will account for tower performance in the "free convection" regime, when the tower fan is off but the water pump remains on and heat transfer still occurs (albeit at a low level). Basin heater operation and makeup water usage (due to evaporation, drift, and blowdown) are also modeled.

The cooling tower seeks to maintain the temperature of the water exiting the cooling tower at (or below) a set point. The set point schedule is defined by the field "Condenser Loop Temperature Setpoint Node Name or Reference" for the **CondenserLoop** object. The model first checks to determine the impact of "free convection" on the tower exiting water temperature. If the exiting water temperature based on "free convection" is at or below the set point, then the variable-speed tower fan is not turned on. If the exiting water temperature is above the set point after "free convection" is modeled, then the variable-speed tower fan is turned on to reduce the exiting water temperature. Tower fan power is calculated based on the tower air flow rate required to achieve the exiting water set point temperature.

Cooling towers here are "wet" and consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the towers. The last six input fields are optional and provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a **WaterUse:Storage** object.

For the operation of multi-cell towers, the first step is to determine the number of cells to operate based on the cell control method – between the minimum number of cells subject to the maximum water flow rate fraction per cell, and maximum number of cells subject to the minimum water flow rate fraction per cell. If the calculated cells do not meet the loads, additional cells will be operating to help meet the loads. Inside each cell, the existing capacity controls still apply.

For multi-cell towers, the following inputs are assumed to be for the entire tower including all cells:

- Design Water Flow Rate; Design Air Flow Rate; Fan Power at Design Air Flow Rate;
- Air Flow Rate in Free Convection Regime; Nominal Capacity; Free Convection Capacity
- BASIN HEATER (we assume that there is a common basin)

#### 1.25.5.1 Inputs

##### 1.25.5.1.1 Field: Name

This alpha field contains the identifying name for the variable speed cooling tower.

##### 1.25.5.1.2 Field: Water Inlet Node Name

This alpha field contains the identifying name for the cooling tower's water inlet node.

### 1.25.5.1.3 Field: Water Outlet Node Name

This alpha field contains the identifying name for the cooling tower's water outlet node.

### 1.25.5.1.4 Field: Model Type

This alpha field contains the type of empirical model used to simulate the tower's thermal performance (approach temperature). Valid choices for this field are "CoolToolsCrossFlow", "CoolToolsUserDefined", "YorkCalc", or "YorkCalcUserDefined". "CoolToolsCrossFlow" and "YorkCalc" are empirical models with the equation form and model coefficients already defined within EnergyPlus. If "CoolToolsUserDefined" or "YorkCalcUserDefined" is selected, the user must specify a valid Model Coefficient Name in the next input field to reference an appropriate **CoolingTowerPerformance:CoolTools** or **CoolingTowerPerformance:YorkCalc** object. If a user-defined model type is selected and the specified Model Coefficient Name is not found in the input data file (idf), then a severe message is issued and the simulation will terminate.

### 1.25.5.1.5 Field: Model Coefficient Name

This alpha field contains the identifying name for the object(s) **CoolingTowerPerformance:CoolTools** or **CoolingTowerPerformance:YorkCalc**. A single model coefficient object may be used to define coefficients for multiple variable speed cooling tower objects (i.e., the same name may be used in this input field for more than one variable speed tower). This field is only used when the field Tower Model Type described above is set to "CoolToolsUserDefined" or "YorkCalcUserDefined", and should be left blank otherwise.

### 1.25.5.1.6 Field: Design Inlet Air Wet-Bulb Temperature

This numeric field specifies the inlet air wet-bulb temperature ( $^{\circ}\text{C}$ ) at design conditions. This design temperature should correspond with the design values for range temperature, approach temperature, water flow rate, and air flow rate specified in the following fields. The minimum value for this field is  $20^{\circ}\text{C}$  and the default value is  $25.6^{\circ}\text{C}$  if this field is left blank.

### 1.25.5.1.7 Field: Design Approach Temperature

This numeric field specifies the tower approach temperature ( $^{\circ}\text{C}$ ) at design conditions. The approach temperature is the outlet water temperature minus the inlet air wet-bulb temperature. The design approach temperature should correspond with the design values for inlet air wet-bulb temperature, range temperature, water flow rate, and air flow rate specified for this tower. The value for this field must be greater than  $0^{\circ}\text{C}$  and the default value is  $3.9^{\circ}\text{C}$  if this field is left blank.

### 1.25.5.1.8 Field: Design Range Temperature

This numeric field specifies the range temperature ( $^{\circ}\text{C}$ ) at design conditions. The range temperature is defined as the inlet water temperature minus the outlet water temperature. The design range temperature should correspond with the design values for inlet air wet-bulb temperature, approach temperature, water flow rate, and air flow rate specified for this tower. The value for this field must be greater than  $0^{\circ}\text{C}$  and the default value is  $5.6^{\circ}\text{C}$  if this field is left blank.

### 1.25.5.1.9 Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the tower in  $\text{m}^3/\text{s}$ . The value entered should be within  $\pm 25\%$  of the tower's rated water mass flow rate as specified by the manufacturer if Model Type is "CoolToolsCrossFlow" or "YorkCalc". This constraint may be different for Model Type "CoolToolsUserDefined" or "YorkCalcUserDefined" (ref. **CoolingTowerPerformance:CoolTools** or **CoolingTowerPerformance:YorkCalc**).

This value is the flow rate of the condenser loop water being cooled by the tower. A value greater than zero must be specified or this field can be autosized. A Plant Sizing object must be defined if the

field is autosized and the design water flow rate is then derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections). The design water flow rate should correspond with the design values specified for the inlet air wet-bulb temperature, approach temperature, range temperature, and air flow rate. When this field is not autosized, the condenser loop flow rate specified in other objects should be within  $\pm 25\%$  of the tower's rated water flow rate (different range is permissible if Model Type is "User Defined").

#### 1.25.5.1.10 Field: Design Air Flow Rate

This numeric field contains the design (maximum) air flow rate through the tower in  $\text{m}^3/\text{s}$ . A value greater than zero must be specified or this field can be autosized. Autosizing of this field does not require a Plant Sizing object since the design air flow rate is assumed to be the design fan power multiplied by a total fan efficiency of 0.5 and divided by a fan pressure rise of 190 Pascals. A correction for altitude is also included as follows:

$$\text{Design Air Flow Rate} = \frac{0.5(\text{Fan power at Design Air Flow Rate})}{190} \left( \frac{101325}{P_{\text{atm}}} \right) \quad (1.99)$$

#### 1.25.5.1.11 Field: Design Fan Power

This numeric field contains the fan power in watts at the design (maximum) air flow rate through the tower. A value greater than zero must be specified or this field can be autosized. If autosized, a Plant Sizing object must be defined and the fan power is calculated as follows:

$$\text{Design fan power} = 0.0105 \cdot \rho_{\text{water}} \cdot C_{p,\text{water}} \cdot \text{Design Water Flow Rate} \cdot \text{Design Loop } \Delta T \quad (1.100)$$

#### 1.25.5.1.12 Field: Fan Power Ratio Function of Air Flow Rate Ratio Curve Name

This alpha field contains the curve object name for fan power ratio (fan power/design fan power) as a function of air flow rate ratio (air flow rate/design air flow rate) [ref. Performance Curves]. The curve object must be a cubic curve and should be normalized to 1.0 at an air flow rate ratio of 1.0. If this field is left blank, a theoretical fan curve is assumed where fan power ratio is directly proportional to the air flow rate ratio cubed.

#### 1.25.5.1.13 Field: Minimum Air Flow Rate Ratio

This numeric field contains the minimum air flow rate ratio. The tower fan is allowed to operate between the ratio defined here and a maximum air flow rate ratio of 1.0 (which corresponds to the design [maximum] tower air flow rate). Below this value, the tower is assumed to operate either in the "free convection" regime with the tower fan off, or the tower fan is cycled on/off to maintain the exiting water set point temperature. The minimum air flow rate ratio must be greater than or equal to 0.2 and less than or equal to 0.5, with a default value of 0.2 if the field is left blank.

#### 1.25.5.1.14 Field: Fraction of Tower Capacity in Free Convection Regime

This numeric field contains the fraction of tower capacity available in the free convection regime (i.e., when the tower fan is off but water continues to flow through the tower). The tower fan does not operate when the free convection tower capacity is able to meet or exceed the exiting water set point temperature. The air flow rate through the tower in the free convection regime is assumed to be this same fraction of the tower design air flow rate. The fraction of tower capacity in free convection regime must be greater than or equal to 0 and less than or equal to 0.2, with a default value of 0.125 if this field is left blank.

**1.25.5.1.15 Field: Basin Heater Capacity**

This numeric field contains the capacity of the tower's electric basin heater in watts per degree Kelvin. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the tower fan is off and water is not flowing through the tower, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

**1.25.5.1.16 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the tower fan is off and water is not flowing through the tower. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

**1.25.5.1.17 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the cooling tower fan is off and water is not flowing through the tower.

**1.25.5.1.18 Field: Evaporation Loss Mode**

This field is used to choose which method is used to model the amount of water evaporated by the cooling tower. There are two options: 'LossFactor' or 'SaturatedExit'. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the tower is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the cooling tower model (and does not require additional user input).

**1.25.5.1.19 Field: Evaporation Loss Factor**

This field is used to specify the rate of water evaporated from the cooling tower and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to LossFactor. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-degree Kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Typical values are from 0.15 to 0.27 [percent/K]. The default is 0.2.

**1.25.5.1.20 Field: Drift Loss Percent**

This numeric field contains the percent (%) of design water flow rate lost to the atmosphere at the design air flow rate due to drift, which is water droplets that are entrained in the airstream as it passes through the tower. Drift is assumed to vary directly with tower air flow rate ratio, and is in addition to the amount of water lost to the atmosphere due to evaporation and/or blowdown. Typical values for water usage due to drift are from 0.05 to 0.2% of the total water circulation rate with currently-available drift eliminators from tower manufacturers. The value entered in this field must be greater than or equal to zero, and the default is zero if the field is left blank.

#### 1.25.5.1.21 Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options ‘ConcentrationRatio’ or ‘ScheduledRate’. The choice will determine which of the two models below is used. The default is ConcentrationRatio.

#### 1.25.5.1.22 Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the cooling tower as a function of the rate of evaporation. Blowdown is water intentionally drained from the tower in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values for tower operation are 3 to 5. The default value is 3.

#### 1.25.5.1.23 Field: Blowdown Makeup Water Usage Schedule Name

This alpha field contains the name of the schedule used to define the amount of water ( $\text{m}^3/\text{s}$ ) flushed from the basin on a periodic basis to purge the condenser loop of mineral scale build-up and other contaminants. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Typical values range from 0.0002 to 0.0013  $\text{m}^3/\text{s}$  (17.3 to 112.3  $\text{m}^3/\text{day}$ ). This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the cooling tower is active and water is flowing through the tower (regardless of the water usage defined by this schedule).

#### 1.25.5.1.24 Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the tower obtains water used for evaporative cooling. If blank or omitted, then the tower will obtain water directly from the mains. If the name of a WaterUser:Storage object is used here, then the tower will obtain its water from that tank. If a tank is specified, the tower will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the tower needs, then the tower will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

#### 1.25.5.1.25 Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the cooling tower. If this field is left blank, the outdoor air conditions entering the cooling tower are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

#### 1.25.5.1.26 Field: Number of Cells

This integer field contains the number of cells in the multi-cell cooling tower. If not entered, the program will assume it is a single-cell cooling tower

#### 1.25.5.1.27 Field: Cell Control

This alpha field specifies the method used to control the number of cells used to meet the load, the two choices are:

**MinimalCell:** the program will use minimal number of cells needed, all other cells will be shut down with no water flow. It will attempt to use as few cells as possible to cool the fluid. In no case, however,

will the flow per cell be allowed to exceed its maximum value defined by the *Maximum Water Flow Rate Fraction*.

**MaximalCel** : As many cells as possible will be turned on. In no case, however, will the flow per cell be allowed to drop below its minimum value specified by the *Minimum Water Flow Rate Fraction*.

#### 1.25.5.1.28 Field: Cell Minimum Water Flow Rate Fraction

This numeric field specifies the allowable smallest fraction of the design water flow rate. Flows less than this value will commonly result in fluid distribution problems; the pressure at each nozzle will be too weak for the fluid to be sprayed out in the correct pattern, not all the fill would be wet. If this field is left blank, the default value is 0.33.

#### 1.25.5.1.29 Field: Cell Maximum Water Flow Rate Fraction

This numeric field specifies the allowable largest fraction of the design water flow rate. If this field is left blank, the default value is 2.5.

#### 1.25.5.1.30 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Design Air Flow Rate;
3. Design Fan Power.

#### 1.25.5.1.31 Field: End-Use Subcategory

This optional field allows you to specify a user-defined end-use subcategory, e.g., “Process”. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Any text may be used here to further subcategorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table. If this field is omitted or blank, the cooling tower will be assigned to the “General” end-use subcategory.

An example IDF specification for this object is shown below:

### 1.25.5.2 Outputs

- HVAC,Average,Cooling Tower Fan Electricity Rate [W]
- HVAC,Sum,Cooling Tower Fan Electricity Energy [J]
- HVAC,Average,Cooling Tower Heat Transfer Rate [W]
- HVAC,Average,Cooling Tower Inlet Temperature [C]
- HVAC,Average,Cooling Tower Outlet Temperature [C]
- HVAC,Average,Cooling Tower Mass Flow Rate [kg/s]
- HVAC,Average,Cooling Tower Fan Part Load Ratio
- HVAC,Average,Cooling Tower Air Flow Rate Ratio
- HVAC,Average,Cooling Tower Operating Cells Count

A tower uses either mains water or storage tank for make-up water.

*When mains water is used:*

- HVAC,Average,Cooling Tower Make Up Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Make Up Water Volume [m3]
- HVAC,Sum,Cooling Tower Make Up Mains Water Volume [m3]

*When storage tank water is used:*

- HVAC,Average,Cooling Tower Make Up Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Make Up Water Volume [m3]
- HVAC,Sum,Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Storage Tank Water Volume [m3]
- HVAC,Sum,Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Starved Storage Tank Water Volume [m3]
- HVAC,Sum,Cooling Tower Make Up Mains Water Volume [m3]
- HVAC,Average,Cooling Tower Water Evaporation Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Evaporation Volume [m3]

- HVAC,Average,Cooling Tower Water Drift Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Drift Volume [m3]
- HVAC,Average,Cooling Tower Water Blowdown Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Blowdown Volume [m3]

IF specified:

- HVAC,Average,Cooling Tower Basin Heater Electricity Rate [W]
- HVAC,Sum,Cooling Tower Basin Heater Electricity Energy [J]

#### 1.25.5.2.1 Cooling Tower Fan Electricity Rate [W]

#### 1.25.5.2.2 Cooling Tower Fan Electricity Energy [J]

These outputs are the electric power input to the tower fan. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

#### 1.25.5.2.3 Cooling Tower Fan Part Load Ratio []

This is the on/off cycling rate of the tower fan when free convection cannot meet the set point temperature and the tower capacity at the minimum air flow rate ratio drives the tower exiting water temperature below the set point temperature. The fan part-load ratio is calculated as the ratio of the exiting water temperature in the free convection regime minus the exiting water temperature set point divided by the exiting water temperature in the free convection regime minus the exiting water temperature at the minimum air flow rate ratio. If tower air flow is at or above the minimum air flow rate ratio, then the tower fan part-load ratio is 1.0.

#### 1.25.5.2.4 Cooling Tower Heat Transfer Rate [W]

This is the rate at which heat is removed from the condenser water loop by the tower.

#### 1.25.5.2.5 Cooling Tower Inlet Temperature [C]

#### 1.25.5.2.6 Cooling Tower Outlet Temperature [C]

#### 1.25.5.2.7 Cooling Tower Mass Flow Rate [kg/s]

These outputs are the tower water inlet and outlet temperatures, and mass flow rate of the circulating condenser water loop.

#### 1.25.5.2.8 Cooling Tower Air Flow Rate Ratio []

This is the ratio of air flow through the tower to the design air flow rate. During times when the tower can maintain the condenser loop set point temperature using free convection (when the fan is not operating), the air flow rate ratio is assumed to be equal to the field Fraction of Tower Capacity in Free Convection Regime. During times when the fan cycles on/off to maintain the outlet water set point temperature, the air flow rate ratio is calculated as the summation of Fan Part-Load Ratio multiplied by the Minimum Air Flow Rate Ratio and (1.0 - Fan Part-Load Ratio) multiplied by the fraction of Tower Capacity in Free Convection Regime.

#### 1.25.5.2.9 Cooling Tower Basin Heater Electricity Rate [W]

**1.25.5.2.10 Cooling Tower Basin Heater Electricity Energy [J]**

These outputs are the electric power input to the tower basin heater. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

**1.25.5.2.11 Cooling Tower Make Up Water Volume Flow Rate [m3/s]****1.25.5.2.12 Cooling Tower Make Up Water Volume [m3]**

These outputs are the water consumed by the wet cooling tower for external water sprays used to augment heat transfer. This is the total of evaporation, drift, and blowdown.

**1.25.5.2.13 Cooling Tower Water Evaporation Volume Flow Rate [m3/s]****1.25.5.2.14 Cooling Tower Water Evaporation Volume [m3]****1.25.5.2.15 Cooling Tower Water Drift Volume Flow Rate [m3/s]****1.25.5.2.16 Cooling Tower Water Drift Volume [m3]****1.25.5.2.17 Cooling Tower Water Blowdown Volume Flow Rate [m3/s]****1.25.5.2.18 Cooling Tower Water Blowdown Volume [m3]**

These outputs provide the breakdown of the different components of water use during cooling tower operation.

**1.25.5.2.19 Cooling Tower Make Up Mains Water Volume [m3]**

This is the volume of water drawn from mains service to feed the cooling tower. If a water storage tank is used to provide water to the tower, then the following output variables will also be available.

**1.25.5.2.20 Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]****1.25.5.2.21 Cooling Tower Storage Tank Water Volume [m3]**

These are the rate and volume of water provided by the Water Storage Tank.

**1.25.5.2.22 Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]****1.25.5.2.23 Cooling Tower Starved Storage Tank Water Volume [m3]**

These are the rate and volume of water the Storage Tank connections was not able to provide. The starved water is assumed to come from the mains. The tower's operation is not affected by a lack of storage tank water.

**1.25.5.2.24 Cooling Tower Operating Cells Count []**

This represents the number of cells operating at each time step.

### 1.25.6 CoolingTowerPerformance:CoolTools

Variable speed cooling towers can be modeled by EnergyPlus with user-selectable performance based on the CoolTools correlation, YorkCalc correlation, or user-defined coefficients for either the CoolTools or YorkCalc correlations. The empirical CoolTools tower correlation uses a set of 35 coefficients to model the thermal performance (approach temperature) of a cooling tower based on four independent variables. If the user specifies Model Type = CoolToolsCrossFlow in the **CoolingTower:VariableSpeed** object, then the 35 coefficients derived for the CoolTools simulation model are used and these coefficients are already defined within EnergyPlus. If the user specifies Model Type = CoolToolsUserDefined, then the user must enter a CoolingTowerPerformance:CoolTools object to define the 35 coefficients that will be used by the CoolTools correlation.

The user must specify a name for the model coefficient object, and this name must be used in the **CoolingTower:VariableSpeed** object (field Model Coefficient Name) to tell the program to use these coefficients. Next, the user enters the minimum and maximum values for inlet air wet-bulb temperature, range temperature, approach temperature, and water mass flow rate ratio to specify the valid range for which the model coefficients were derived. For all of these variables, the program issues warnings if the actual values are beyond the minimum/maximum values specified. For inlet air wet-bulb temperature and water mass flow rate ratio, the values of these variables used in the calculation of approach temperature are limited to be within the valid minimum/maximum range specified. For approach and range, the warnings are issued if the values are beyond the specified minimum/maximum range but the actual values are still used.

The CoolTools correlation has four independent variables: inlet air wet-bulb temperature (Twb), tower range temperature (Tr), water flow rate ratio (FRwater), and air flow rate ratio (FRair). Temperatures are in units of °C and flow rate ratios are dimensionless (actual flow rate divided by design flow rate). Using these independent variables, tower approach temperature (°C) is calculated as follows:

$$\begin{aligned} \text{Approach} = & \text{Coeff}(1) + \text{Coeff}(2) \cdot \text{FRair} + \text{Coeff}(3) \cdot (\text{FRair})^2 + \\ & \text{Coeff}(4) \cdot (\text{FRair})^3 + \text{Coeff}(5) \cdot \text{FRwater} + \\ & \text{Coeff}(6) \cdot \text{FRair} \cdot \text{FRwater} + \text{Coeff}(7) \cdot (\text{FRair})^2 \cdot \text{FRwater} + \\ & \text{Coeff}(8) \cdot (\text{FRwater})^2 + \text{Coeff}(9) \cdot \text{FRair} \cdot (\text{FRwater})^2 + \\ & \text{Coeff}(10) \cdot (\text{FRwater})^3 + \text{Coeff}(11) \cdot \text{Twb} + \text{Coeff}(12) \cdot \text{FRair} \cdot \text{Twb} + \\ & \text{Coeff}(13) \cdot (\text{FRair})^2 \cdot \text{Twb} + \text{Coeff}(14) \cdot \text{FRwater} \cdot \text{Twb} + \\ & \text{Coeff}(15) \cdot \text{FRair} \cdot \text{FRwater} \cdot \text{Twb} + \text{Coeff}(16) \cdot (\text{FRwater})^2 \cdot \text{Twb} + \\ & \text{Coeff}(17) \cdot (\text{Twb})^2 + \text{Coeff}(18) \cdot \text{FRair} \cdot (\text{Twb})^2 + \\ & \text{Coeff}(19) \cdot \text{FRwater} \cdot (\text{Twb})^2 + \text{Coeff}(20) \cdot (\text{Twb})^3 + \text{Coeff}(21) \cdot \text{Tr} + \\ & \text{Coeff}(22) \cdot \text{FRair} \cdot \text{Tr} + \text{Coeff}(23) \cdot \text{FRair} \cdot \text{FRair} \cdot \text{Tr} + \\ & \text{Coeff}(24) \cdot \text{FRwater} \cdot \text{Tr} + \text{Coeff}(25) \cdot \text{FRair} \cdot \text{FRwater} \cdot \text{Tr} + \\ & \text{Coeff}(26) \cdot (\text{FRwater})^2 \cdot \text{Tr} + \text{Coeff}(27) \cdot \text{Twb} \cdot \text{Tr} + \\ & \text{Coeff}(28) \cdot \text{FRair} \cdot \text{Twb} \cdot \text{Tr} + \text{Coeff}(29) \cdot \text{FRwater} \cdot \text{Twb} \cdot \text{Tr} + \\ & \text{Coeff}(30) \cdot (\text{Twb})^2 \cdot \text{Tr} + \text{Coeff}(31) \cdot (\text{Tr})^2 + \text{Coeff}(32) \cdot \text{FRair} \cdot (\text{Tr})^2 + \\ & \text{Coeff}(33) \cdot \text{FRwater} \cdot (\text{Tr})^2 + \text{Coeff}(34) \cdot \text{Twb} \cdot (\text{Tr})^2 + \text{Coeff}(35) \cdot (\text{Tr})^3 \end{aligned}$$

This object allows the user to specify model coefficients for use with the CoolTools correlation shown above. It is recommended that a broad set of cooling tower performance data be used to generate these model coefficients. The data set used to create the model coefficients should cover the entire range of water and air flow rate ratios and inlet air wet-bulb, range, and approach temperatures expected during the simulation.

#### 1.25.6.1 Inputs

##### 1.25.6.1.1 Field: Name

This alpha field contains the identifying name for the variable speed cooling tower model coefficients.

#### **1.25.6.1.2 Field: Minimum Inlet Air Wet-Bulb Temperature**

This numeric field contains the minimum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures less than this value will not be used; instead, the minimum inlet air wet-bulb temperature specified here will be used by the correlation and a warning will be issued.

#### **1.25.6.1.3 Field: Maximum Inlet Air Wet-Bulb Temperature**

This numeric field contains the maximum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures greater than this value will not be used; instead, the maximum inlet air wet-bulb temperature specified here will be used by the correlation and a warning will be issued.

#### **1.25.6.1.4 Field: Minimum Range Temperature**

This numeric field contains the minimum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is less than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

#### **1.25.6.1.5 Field: Maximum Range Temperature**

This numeric field contains the maximum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is greater than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

#### **1.25.6.1.6 Field: Minimum Approach Temperature**

This numeric field contains the minimum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is less than this value then the calculated value is still used but a warning will be issued.

#### **1.25.6.1.7 Field: Maximum Approach Temperature**

This numeric field contains the maximum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is greater than this value then the calculated value is still used but a warning will be issued.

#### **1.25.6.1.8 Field: Minimum Water Flow Rate Ratio**

This numeric field contains the minimum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios less than this value will not be used; instead, the minimum water flow rate ratio specified here will be used by the model and a warning will be issued.

#### **1.25.6.1.9 Field: Maximum Water Flow Rate Ratio**

This numeric field contains the maximum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios greater than this value will not be used; instead, the maximum water flow rate ratio specified here will be used by the model and a warning will be issued.

#### **1.25.6.1.10 Field: Coefficient 1 to 35**

These numeric fields contain the coefficients to be used by the CoolTools approach temperature correlation shown above.

An example IDF specification for this object is shown below:

```

### 1.25.6.2 Outputs

No additional cooling tower output variables are output when this object is used.

### 1.25.7 CoolingTowerPerformance:YorkCalc

Variable speed cooling towers can be modeled by EnergyPlus with user-selectable performance based on the CoolTools correlation, YorkCalc correlation, or user-defined coefficients for either the CoolTools or YorkCalc correlations. The empirical YorkCalc tower correlation uses a set of 27 coefficients to model the thermal performance (approach temperature) of a variable speed cooling tower based on three independent variables. If the user specifies Tower Model Type = YorkCalc in the **CoolingTower:VariableSpeed** object, then the 27 coefficients derived for the YorkCalc simulation model are used and these coefficients are already defined within EnergyPlus. If the user specifies Tower Model Type = YorkCalcUserDefined, then the user must enter a CoolingTowerPerformance:YorkCalc object to define the 27 coefficients that will be used by the YorkCalc correlation.

The user must specify a name for the model coefficient object, and this name must be used in the **CoolingTower:VariableSpeed** object (field Model Coefficient Name) to tell the program to use these coefficients. Next, the user enters the minimum and maximum values for inlet air wet-bulb temperature, range temperature, approach temperature, and water mass flow rate ratio to specify the valid range for which the model coefficients were derived. The user also specifies the maximum valid liquid-to-gas ratio. For all of these variables, the program issues warnings if the actual values are beyond the minimum/maximum values specified. For inlet air wet-bulb temperature and water mass flow rate ratio, the values of these variables used in the calculation of approach temperature are limited to be within the valid minimum/maximum range specified. For approach, range, and liquid-to-gas ratio the warnings are issued if the values are beyond the specified minimum/maximum range but the actual values are still used.

The YorkCalc correlation has three independent variables: inlet air wet-bulb temperature (Twb), tower range temperature (Tr), and the liquid-to-gas ratio (ratio of water flow rate ratio to air flow rate ratio = LGRatio). Temperatures are in units of °C and liquid-to-gas ratio is dimensionless. Using these independent variables, an approach temperature (°C) is calculated as follows:

$$\begin{aligned} \text{Approach} = & \text{Coeff}(1) + \text{Coeff}(2) \cdot \text{Twb} + \text{Coeff}(3) \cdot \text{Twb}^2 + \text{Coeff}(4) \cdot \text{Tr} + \\ & \text{Coeff}(5) \cdot \text{Twb} \cdot \text{Tr} + \text{Coeff}(6) \cdot \text{Twb}^2 \cdot \text{Tr} + \text{Coeff}(7) \cdot \text{Tr}^2 + \\ & \text{Coeff}(8) \cdot \text{Twb} \cdot \text{Tr}^2 + \text{Coeff}(9) \cdot \text{Twb}^2 \cdot \text{Tr}^2 + \text{Coeff}(10) \cdot \text{LGRatio} + \\ & \text{Coeff}(11) \cdot \text{Twb} \cdot \text{LGRatio} + \text{Coeff}(12) \cdot \text{Twb}^2 \cdot \text{LGRatio} + \\ & \text{Coeff}(13) \cdot \text{Tr} \cdot \text{LGRatio} + \text{Coeff}(14) \cdot \text{Twb} \cdot \text{Tr} \cdot \text{LGRatio} + \\ & \text{Coeff}(15) \cdot \text{Twb}^2 \cdot \text{Tr} \cdot \text{LGRatio} + \text{Coeff}(16) \cdot \text{Tr}^2 \cdot \text{LGRatio} + \\ & \text{Coeff}(17) \cdot \text{Twb} \cdot \text{Tr}^2 \cdot \text{LGRatio} + \text{Coeff}(18) \cdot \text{Twb}^2 \cdot \text{Tr}^2 \cdot \text{LGRatio} + \\ & \text{Coeff}(19) \cdot \text{LGRatio}^2 + \text{Coeff}(20) \cdot \text{Twb} \cdot \text{LGRatio}^2 + \\ & \text{Coeff}(21) \cdot \text{Twb}^2 \cdot \text{LGRatio}^2 + \text{Coeff}(22) \cdot \text{Tr} \cdot \text{LGRatio}^2 + \\ & \text{Coeff}(23) \cdot \text{Twb} \cdot \text{Tr} \cdot \text{LGRatio}^2 + \text{Coeff}(24) \cdot \text{Twb}^2 \cdot \text{Tr} \cdot \text{LGRatio}^2 + \\ & \text{Coeff}(25) \cdot \text{Tr}^2 \cdot \text{LGRatio}^2 + \text{Coeff}(26) \cdot \text{Twb} \cdot \text{Tr}^2 \cdot \text{LGRatio}^2 + \\ & \text{Coeff}(27) \cdot \text{Twb}^2 \cdot \text{Tr}^2 \cdot \text{LGRatio}^2 \end{aligned}$$

This object allows the user to specify model coefficients for use with the YorkCalc correlation shown above. It is recommended that a broad set of cooling tower performance data be used to generate these model coefficients. The data set used to create the model coefficients should cover the entire range of water and air flow rate ratios and inlet air wet-bulb, range, and approach temperatures expected during the simulation.

### 1.25.7.1 Inputs

#### 1.25.7.1.1 Field: Name

This alpha field contains the identifying name for the variable speed cooling tower model coefficients.

#### 1.25.7.1.2 Field: Minimum Inlet Air Wet-Bulb Temperature

This numeric field contains the minimum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures less than this value will not be used; instead, the minimum inlet air wet-bulb temperature specified here will be used by the correlation and a warning will be issued.

#### 1.25.7.1.3 Field: Maximum Inlet Air Wet-Bulb Temperature

This numeric field contains the maximum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures greater than this value will not be used; instead, the maximum inlet air wet-bulb temperature specified here will be used by the model and a warning will be issued.

**1.25.7.1.4 Field: Minimum Range Temperature**

This numeric field contains the minimum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is less than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

**1.25.7.1.5 Field: Maximum Range Temperature**

This numeric field contains the maximum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is greater than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

**1.25.7.1.6 Field: Minimum Approach Temperature**

This numeric field contains the minimum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is less than this value then the calculated value is still used but a warning will be issued.

**1.25.7.1.7 Field: Maximum Approach Temperature**

This numeric field contains the maximum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is greater than this value then the calculated value is still used but a warning will be issued.

**1.25.7.1.8 Field: Minimum Water Flow Rate Ratio**

This numeric field contains the minimum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios less than this value will not be used; instead, the minimum water flow rate ratio specified here will be used by the model and a warning will be issued.

**1.25.7.1.9 Field: Maximum Water Flow Rate Ratio**

This numeric field contains the maximum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios greater than this value will not be used; instead, the maximum water flow rate ratio specified here will be used by the model and a warning will be issued.

**1.25.7.1.10 Field: Maximum Liquid to Gas Ratio**

This numeric field contains the maximum liquid-to-gas ratio (ratio of actual water flow rate ratio [capped to be within the minimum/maximum water flow rate ratio defined above as necessary] to actual air flow rate ratio) to be used by the empirical model. If the liquid-to-gas ratio is greater than this value the actual liquid to gas ratio is still passed to the empirical model but a warning will be issued.

**1.25.7.1.11 Field: Coefficient 1 to 27**

These numeric fields contain the coefficients to be used by the YorkCalc approach temperature correlation shown above.

An example IDF specification for this object is shown below:

```
CoolingTowerPerformance:YorkCalc

### 1.25.7.2 Outputs

No additional cooling tower output variables are output when this object is used.

## 1.25.8 EvaporativeFluidCooler:SingleSpeed

Evaporative fluid coolers are components that may be assigned to condenser loops. The Evaporative fluid cooler is modeled as a counter flow heat exchanger with single-speed fans (induced draft configuration). The user must define fluid cooler performance via one of three methods: design heat transfer coefficient-area product (UA) and design water flow rate, or standard fluid cooler design capacity at a specific rating point or design capacity at non standard conditions. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified.

The evaporative fluid cooler seeks to maintain the temperature of the water exiting the evaporative fluid cooler at (or below) a set point. The set point schedule value is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the **CondenserLoop** object. The model first checks to see whether inlet water temperature is at or below the set point. If so, then the fluid cooler fan is not turned on and all the flow goes through bypass. If the inlet water temperature is above the set point then the fluid cooler fan is turned on to reduce the exiting water temperature to the set point. If the capacity control is FanCycling, the model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan on for the entire simulation timestep and fluid cooler fan off for the entire simulation timestep). Cyclic losses are not taken into account. If the capacity control is FluidBypass, the model determines the fraction of water flow to be bypassed while the remaining water goes through the fluid cooler cooling media and gets cooled, then the two water flows mix to meet the setpoint temperature. In this case, the fan runs at full speed for the entire timestep.

Evaporative fluid coolers consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the fluid coolers. For this purpose, the last seven input fields can

either be provided in the input or if nothing is specified then the default values for these fields will be used. These fields provide the methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the building's water system by providing the name of a water storage tanks (i.e. **WaterUse:Storage** objects). The schematic of the system is shown below:

Figure 1.98: Schematic diagram for evaporative fluid cooler

Where,

- $h$  = Enthalpy (j/kg-K)
- $m$  = mass flow rate (kg/s)
- Subscripts

- a = air
- w = water
- wb = wet-bulb
- in = inlet
- out = outlet

### 1.25.8.1 Inputs

#### 1.25.8.1.1 Field: Name

This alpha field contains the identifying name for the fluid cooler.

#### 1.25.8.1.2 Field: Water Inlet Node Name

This alpha field contains the identifying name for the fluid cooler's water inlet node.

#### 1.25.8.1.3 Field: Water Outlet Node Name

This alpha field contains the identifying name for the fluid cooler's water outlet node.

#### 1.25.8.1.4 Field: Design Air Flow Rate

This numeric field contains the design air flow rate induced by the fluid cooler fan in  $\text{m}^3/\text{s}$ . The field must contain a value greater than zero regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering Reference document for autosizing calculations.

#### 1.25.8.1.5 Field: Design Air Flow Rate Fan Power

This numeric field contains the fan power (in watts) at the design air flow rate specified in the previous field. The field must contain a value greater than zero regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering Reference document for autosizing calculations.

#### 1.25.8.1.6 Field: Design Spray Water Flow Rate

This numeric field contains the design spray water flow rate through the fluid cooler in  $\text{m}^3/\text{s}$ . A value greater than zero must be specified regardless of the performance input method,

#### 1.25.8.1.7 Field: Performance Input Method

This alpha field contains the method by which the user will specify fluid cooler performance: "UFactor-TimesAreaAndDesignWaterFlowRate" or "StandardDesignCapacity" or "UserSpecifiedDesignCapacity".

#### 1.25.8.1.8 Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the fluid cooler. If this field is left blank, the outdoor air conditions entering the fluid cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

**1.25.8.1.9 Field: Heat Rejection Capacity and Nominal Capacity Sizing Ratio**

This numeric field contains the value for the ratio of actual tower heat rejection to nominal capacity. This ratio is defined at entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. Historically this ratio has been set at 1.25 based on the assumption that the tower must dissipate 0.25 W of compressor power for every what of heat removed at the chiller evaporator. The default is 1.25.

**1.25.8.1.10 Field: Standard Design Capacity**

This numeric input field contains the heat rejection capacity of the fluid cooler in watts, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be 5.382E-8 m<sup>3</sup>/s per watt of nominal capacity (3 gpm/ton). 125% of this capacity gives the actual fluid cooler heat rejection at these operating conditions (based on historical assumption that the evaporative fluid cooler must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). This field is only used for performance input method = "StandardDesignCapacity". For other input methods this field is ignored. The standard conditions mentioned above for "standard design capacity" are already specified in the EnergyPlus. So the input fields such as design entering water temp., design entering air wet-bulb and dry-bulb temp. and design water flow rate, if provided in the input, will be ignored for the StandardDesignCapacity performance input method. Also, the standard conditions are for water as a fluid type so this performance input method can only be used with water as a fluid type (ref. [CondenserLoop](#) object).

**1.25.8.1.11 Field: Design Air Flow Rate U-factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (UA) in watts per Kelvin corresponding to the design air and water flow rates specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design fluid cooler UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections), the fluid cooler inlet air dry-bulb and wetbulb temperature are taken from the input. This field is only used for performance input method = "UFactorTimesAreaAndDesignWaterFlowRate". For other performance input methods, this field is ignored.

**1.25.8.1.12 Field: Design Water Flow Rate**

This numeric field contains the design water flow rate through the fluid cooler in m<sup>3</sup>/s. This value is the flow rate of the condenser loop water being cooled by the fluid cooler. This field is ignored for the "StandardDesignCapacity" performance input method. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections).

**1.25.8.1.13 Field: User Specified Design Capacity**

This numeric input field contains the heat rejection capacity of the fluid cooler in watts. Design conditions for this capacity i.e. entering air dry-bulb temperature, entering air wet-bulb temperature and entering water temperature must be provided in the input. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

**1.25.8.1.14 Field: Design Entering Water Temperature**

This numeric field contains entering water temperature at nominal conditions in degrees Celsius. The design entering water temperature must be greater than the design entering air temperature. Only used

for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

#### **1.25.8.1.15 Field:Design Entering Air Temperature**

This numeric field contains entering air dry-bulb temperature at nominal conditions in degrees Celsius. The design entering air temperature must be greater than the design entering air wet-bulb temperature. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

#### **1.25.8.1.16 Field:Design Entering Air Wet-bulb Temperature**

This numeric field contains entering air wetbulb temperature at nominal conditions in degrees Celsius. The design entering air wet-bulb temperature must be less than the design entering air (dry-bulb) temperature. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

#### **1.25.8.1.17 Field: Capacity Control**

This alpha field contains the cooling capacity control for the evaporative fluid cooler. Two choices are available: FanCycling and FluidBypass. During part-load conditions, there are two ways to maintain the exiting water temperature at the setpoint: either cycling the evaporative fluid cooler fan, or bypassing portion of the evaporative fluid cooler water with a three-way valve. For FluidBypass, the evaporative fluid cooler fan still runs at full speed for the entire timestep, but only portion of the water flow goes through the evaporative fluid cooler media to get cooled while the remaining portion of the water flow gets bypassed. Two water flows then mix at the common water sump to meet the setpoint temperature.

#### **1.25.8.1.18 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Design Air Flow Rate;
3. Fan Power at Design Air Flow Rate;
4. U-Factor Times Area Value at Design Air Flow Rate;

Note that the U-Factor Times Area Value at Design Air Flow Rate is not multiplied by the Sizing Factor. Instead the design evaporative fluid cooler load is multiplied by the sizing factor and the design UA then calculated as usual.

#### **1.25.8.1.19 Field: Evaporation Loss Mode**

This field is used to choose which method is used to model the amount of water evaporated by the evaporative fluid cooler. There are two options: LossFactor or SaturatedExit. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the evaporative fluid cooler is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the evaporative fluid cooler model (and does not require additional user input).

#### **1.25.8.1.20 Field: Evaporation Loss Factor**

This field is used to specify the rate of water evaporated from the evaporative fluid cooler and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to LossFactor.

The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Empirical correlation is used to calculate default loss factor if it not explicitly specified in the input file.

#### 1.25.8.1.21 Field: Drift Loss Percent

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value.

#### 1.25.8.1.22 Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options `ConcentrationRatio` or `ScheduledRate`. The choice will determine which of the two models below is used. The default is `ConcentrationRatio`.

#### 1.25.8.1.23 Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the evaporative fluid cooler as a function of the rate of evaporation. Blowdown is water intentionally drained from the evaporative fluid cooler in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value.

**1.25.8.1.24 Field: Blowdown Makeup Water Usage Schedule Name**

This alpha field contains the name of the schedule used to define the amount of water (m3/s) flushed from the basin on a periodic basis to purge the evaporative fluid cooler of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation Mode is set to ScheduledRate. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value. This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the evaporative fluid cooler is active and water is flowing through the evaporative fluid cooler (regardless of the water usage defined by this schedule).

#### 1.25.8.1.25 Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the evaporative fluid cooler obtains water used for evaporative cooling. If blank or omitted, then the evaporative fluid cooler will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the evaporative fluid cooler will obtain its water from that tank. If a tank is specified, the evaporative fluid cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the evaporative fluid cooler needs, then the evaporative fluid cooler will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

An IDF specification for this object is shown below:

- HVAC,Sum,Cooling Tower Starved Storage Tank Water Volume [m3]

#### 1.25.8.2.1 Cooling Tower Fan Electricity Rate [W]

The average electric power consumption of the fluid cooler fan in Watts for the timestep being reported.

**1.25.8.2.2 Cooling Tower Fan Electricity Energy [J]**

Fan energy use in Joules. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

**1.25.8.2.3 Cooling Tower Heat Transfer Rate [W]**

This is the average rate, in Watts, at which heat is removed from the condenser water loop by the fluid cooler for the time step being reported.

**1.25.8.2.4 Cooling Tower Inlet Temperature [C]**

The fluid temperature at the fluid cooler inlet in degrees Celsius.

**1.25.8.2.5 Cooling Tower Outlet Temperature [C]**

The fluid temperature at the fluid cooler outlet in degrees Celsius.

**1.25.8.2.6 Cooling Tower Mass Flow Rate [kg/s]**

The average fluid mass flow rate through the fluid cooler in kg/s for the time step being reported.

**1.25.8.2.7 Cooling Tower Bypass Fraction []**

This output is the average fluid bypass fraction for the time step being reported. See Capacity Control input field.

**1.25.8.2.8 Cooling Tower Make Up Water Volume Flow Rate [m3/s]****1.25.8.2.9 Cooling Tower Make Up Water Volume [m3]**

These outputs are the external spray water consumed by the evaporative fluid cooler. This is the total of evaporation, drift, and blowdown.

**1.25.8.2.10 Cooling Tower Water Evaporation Volume Flow Rate [m3/s]****1.25.8.2.11 Cooling Tower Water Evaporation Volume [m3]****1.25.8.2.12 Cooling Tower Water Drift Volume Flow Rate [m3/s]****1.25.8.2.13 Cooling Tower Water Drift Volume [m3]****1.25.8.2.14 Cooling Tower Water Blowdown Volume Flow Rate [m3/s]****1.25.8.2.15 Cooling Tower Water Blowdown Volume [m3]**

These outputs provide the breakdown of the different components of water use during fluid cooler operation.

**1.25.8.2.16 Cooling Tower Make Up Mains Water Volume [m3]**

The volume of make up water provided by the mains in cubic meters. If no Supply Water Storage Tank is specified, then all fluid cooler make up water is provided by the mains (same as Cooling Tower Make Up Water Volume). If a Supply Water Storage Tank is specified, then the make up from the mains only occurs when sufficient water supply is not available from the tank (same as Evaporative Fluid Cooler Water Starved by Storage Tank). This output variable is metered on HeatRejection:MainsWater, MainsWater:Plant and MainsWater:Facility.

**1.25.8.2.17 Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]****1.25.8.2.18 Cooling Tower Storage Tank Water Volume [m3]**

These are the rate and volume of water provided by the Supply Water Storage Tank.

**1.25.8.2.19 Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]****1.25.8.2.20 Cooling Tower Starved Storage Tank Water Volume [m3]**

These are the rate and volume of water the Supply Water Storage Tank was not able to provide. The starved water is assumed to come from the mains. The fluid cooler's operation is not affected by a lack of storage tank water.

**1.25.9 EvaporativeFluidCooler:TwoSpeed**

The two-speed evaporative fluid cooler is modeled in a similar fashion to the single-speed evaporative fluid cooler. The evaporative fluid cooler is modeled as a counter flow heat exchanger with two-speed fan (induced draft configuration. See schematic diagram in [EvaporativeFluidCooler:SingleSpeed](#) section). The user must define fluid cooler performance via one of the three methods: design heat transfer coefficient-area product (UA) and design water flow rate, or standard fluid cooler design capacity at a specific rating point or design capacity at non standard conditions. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified.

The evaporative fluid cooler seeks to maintain the temperature of the water exiting the evaporative fluid cooler at (or below) a set point. The set point schedule value is defined by the field "Condenser Loop Temperature Setpoint Node Name or Reference" for the [CondenserLoop](#) object. The model first checks to see whether inlet water temperature is at or below the set point. If so, then the fluid cooler fan is not turned on and all the flow goes through bypass. If the inlet water temperature is above the set point then the fluid cooler fan is turned on at low speed to reduce the exiting water temperature to the set point. If operating the fluid cooler fan at low speed does not reduce the exiting water temperature to the set point, then the fluid cooler fan is increased to its high speed.

The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan at high speed for the entire simulation timestep and fluid cooler fan at low speed for the entire simulation timestep, or fluid cooler fan at low speed for the entire simulation timestep and fluid cooler fan off for the entire simulation timestep). Cyclic losses are not taken into account.

Evaporative fluid coolers consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the evaporative fluid coolers. For this purpose, the last seven input fields can either be provided in the input or if nothing is specified then the default values for these fields will be used. These fields provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a water storage tanks (i.e. [WaterUse:Storage](#) objects).

**1.25.9.1 Inputs****1.25.9.1.1 Field: Name**

This alpha field contains the identifying name for the fluid cooler.

**1.25.9.1.2 Field: WaterInlet Node Name**

This alpha field contains the identifying name for the fluid cooler's water inlet node.

**1.25.9.1.3 Field: Water Outlet Node Name**

This alpha field contains the identifying name for the fluid cooler’s water outlet node.

**1.25.9.1.4 Field: High Fan Speed Air Flow Rate**

This numeric field contains the fluid cooler air flow rate at high fan speed in  $\text{m}^3/\text{s}$ . A value greater than zero must be defined regardless of fluid cooler performance input method. Alternately, this field can be autosized. See Engineering Reference document for fluid cooler autosizing.

**1.25.9.1.5 Field: High Fan Speed Fan Power**

This numeric field contains the fan power (in Watts) at the high-speed air flow rate specified in the previous field. A value greater than zero must be specified regardless of fluid cooler performance input method, or this field can be autosized. See Engineering Reference document for fluid cooler autosizing.

**1.25.9.1.6 Field: Low Fan Speed Air Flow Rate**

This numeric field contains the fluid cooler air flow rate at low fan speed in  $\text{m}^3/\text{s}$ . This value must be greater than zero, less than the value specified for the field “Air Flow Rate at High Fan Speed”. This field may be autocalculated, in which case it is set to a fraction of the “Air Flow Rate at High Fan Speed” determined in the following field.

**1.25.9.1.7 Field: Low Fan Speed Air Flow Rate Sizing Factor**

This numeric field contains the sizing factor for calculating the low fan speed air flow rate as a fraction of the high fan speed air flow rate. The default is 0.5.

**1.25.9.1.8 Field: Low Fan Speed Fan Power**

This numeric field contains the fan power (in Watts) at the low-speed air flow rate specified in the previous field. This value must be specified greater than zero or the field may be autocalculated, in which case it is set to a fraction of the “Fan Power at High Fan Speed” determined in the following field.

**1.25.9.1.9 Field: Low Fan Speed Fan Power Sizing Factor**

This numeric field contains the sizing factor for calculating the low fan speed fan power as a fraction of the high fan speed fan power. The default is 0.16.

**1.25.9.1.10 Field: Design Spray Water Flow Rate**

This numeric field contains the design spray water flow rate through the fluid cooler in  $\text{m}^3/\text{s}$ . This input field must be specified for all the performance input methods.

**1.25.9.1.11 Field: Performance Input Method**

This alpha field contains the method by which the user will specify fluid cooler performance: “UFactor-TimesAreaAndDesignWaterFlowRate” or “StandardDesignCapacity” or “UserSpecifiedDesignCapacity”.

**1.25.9.1.12 Field: Outdoor Air Inlet Node Name**

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the fluid cooler. If this field is left blank, the outdoor air conditions entering the fluid cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

**1.25.9.1.13 Field: Heat Rejection Capacity and Nominal Capacity Sizing Ratio**

This numeric field contains the value for the ratio of actual tower heat rejection to nominal capacity. This ratio is defined at entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. Historically this ratio has been set at 1.25 based on the assumption that the tower must dissipate 0.25 W of compressor power for every what of heat removed at the chiller evaporator. The default is 1.25.

**1.25.9.1.14 Field: High Speed Standard Design Capacity**

This numeric input field contains the heat rejection capacity of the fluid cooler in watts, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be  $5.382\text{E-}8 \text{ m}^3/\text{s}$  per watt of nominal capacity (3 gpm/ton). The Heat Rejection Capacity and Nominal Capacity Sizing Ratio set in the previous field is applied to this capacity to give the actual fluid cooler heat rejection at these operating conditions. This field is only used for performance input method = "StandardDesignCapacity". For other input methods this field is ignored. The standard conditions mentioned above for "standard design capacity" are already specified in the EnergyPlus. So the input fields such as design entering water temp., design entering air wet-bulb and dry-bulb temp. and design water flow rate, if provided in the input, will be ignored for the StandardDesignCapacity performance input method. Also, the standard conditions are for water as a fluid type so this performance input method can only be used with water as a fluid type (ref. [CondenserLoop](#) object).

**1.25.9.1.15 Field: Low Speed Standard Design Capacity**

This numeric input field contains the heat rejection capacity of the fluid cooler in watts, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be  $5.382\text{E-}8 \text{ m}^3/\text{s}$  per watt of nominal capacity (3 gpm/ton). The Heat Rejection Capacity and Nominal Capacity Sizing Ratio is applied to this capacity to give the actual fluid cooler heat rejection at these operating conditions. This field is only used for performance input method = "StandardDesignCapacity". For other input methods this field is ignored. The standard conditions mentioned above for "standard design capacity" are already specified in the EnergyPlus. So the input fields such as design entering water temp., design entering air wet-bulb and dry-bulb temp. and design water flow rate, if provided in the input, will be ignored for the StandardDesignCapacity performance input method. Also, the standard conditions are for water as a fluid type so this performance input method can only be used with water as a fluid type (ref. [CondenserLoop](#) object). The value specified for this field must be greater than zero but less than the value specified for the field "High-Speed Standard Design Capacity". This field may be autocalculated, in which case it is set to a fraction of the High-Speed Standard Design Capacity determined in the following field.

**1.25.9.1.16 Field: Low Speed Standard Capacity Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Low Speed Standard Design Capacity. The default is 0.5.

**1.25.9.1.17 Field: High Fan Speed U-factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (UA) in watts per Kelvin corresponding to the high speed design air and water flow rates specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a UA value greater than zero but less than or equal to 2,100,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design fluid cooler UA value is derived from the design load to

be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections), the fluid cooler inlet air dry-bulb and wetbulb temperature are taken from the input. This field is only used for performance input method = "UFactorTimesAreaAndDesignWaterFlowRate". For other input methods this field is ignored.

#### **1.25.9.1.18 Field: Low Fan Speed U-factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Kelvin corresponding to the low speed design air and water flow rates specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a UA value greater than zero but less than or equal to 300,000 and less than the value specified for the field "U-Factor Times Area Value at High Fan Speed" must be defined. This field may be autocalculated, in which case it is set to a factor of the "U-Factor Times Area Value at High Fan Speed" determined in the following field. This field is only used for performance input method = "UFactorTimesAreaAndDesignWaterFlowRate". For other input methods this field is ignored.

#### **1.25.9.1.19 Field: Low Fan Speed U-Factor Times Area Sizing Factor**

This field contains the sizing factor to use when calculating the Low Fan Speed U-Factor Times Area Value. The default is 0.6.

#### **1.25.9.1.20 Field: Design Water Flow Rate**

This numeric field contains the design water flow rate through the fluid cooler in m<sup>3</sup>/s. This value is the flow rate of the condenser loop water being cooled by the fluid cooler. This field is ignored for the "StandardDesignCapacity" performance input method. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections).

#### **1.25.9.1.21 Field: High Speed User Specified Design Capacity**

This numeric input field contains the heat rejection capacity of the fluid cooler in watts. Design conditions for this capacity i.e. entering air dry-bulb temperature, entering air wet-bulb temperature and entering water temperature must be provided in the input. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

#### **1.25.9.1.22 Field: Low Speed User Specified Design Capacity**

This numeric input field contains the heat rejection capacity of the fluid cooler in watts. Design conditions for this capacity i.e. entering air dry-bulb temperature, entering air wet-bulb temperature and entering water temperature must be provided in the input. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored. This field may be autocalculated, in which case it is set to a fraction of the "High Speed User Specified Design Capacity" determined in the following field.

#### **1.25.9.1.23 Field: Low Speed User Specified Design Capacity Sizing Factor**

This field contains the sizing factor to use when calculating the Low-Speed User Specified Design Capacity. The default is 0.5.

#### **1.25.9.1.24 Field: Design Entering Water Temperature**

This numeric field contains entering water temperature at nominal conditions in degrees Celsius. The design entering water temperature must be greater than the design entering air temperature. Only used

for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

#### **1.25.9.1.25 Field:Design Entering Air Temperature**

This numeric field contains entering air dry-bulb temperature at nominal conditions in degrees Celsius. The design entering air temperature must be greater than the design entering air wet-bulb temperature. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

#### **1.25.9.1.26 Field:Design Entering Air Wet-bulb Temperature**

This numeric field contains entering air wetbulb temperature at nominal conditions in degrees Celsius. The design entering air wet-bulb temperature must be less than the design entering air (dry-bulb) temperature. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

#### **1.25.9.1.27 Field: High Speed Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Air Flow Rate at High Fan Speed;
3. Fan Power at High Fan Speed;
4. U-Factor Times Area Value at High Fan Speed;
5. Air Flow Rate at Low Fan Speed;
6. Fan Power at Low Fan Speed;
7. U-Factor Times Area Value at Low Fan Speed;

Note that the U-Factor Times Area Value at High Fan Speed is not multiplied by the Sizing Factor. Instead the design evaporative fluid cooler load is multiplied by the sizing factor and the design UA then calculated as usual. The U-Factor Times Area Value at Low Fan Speed is set to Low Fan Speed U-Factor Times Area Sizing Factor times the full load design UA.

#### **1.25.9.1.28 Field: Evaporation Loss Mode**

This field is used to choose which method is used to model the amount of water evaporated by the evaporative fluid cooler. There are two options: LossFactor or SaturatedExit. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the evaporative fluid cooler is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the evaporative fluid cooler model (and does not require additional user input).

#### **1.25.9.1.29 Field: Evaporation Loss Factor**

This field is used to specify the rate of water evaporated from the evaporative fluid cooler and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to LossFactor. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Empirical correlation is used to calculate default loss factor if it not explicitly specified in the input file.

### 1.25.9.1.30 Field: Drift Loss Percent

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value.

### 1.25.9.1.31 Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options ConcentrationRatio or ScheduledRate. The choice will determine which of the two models below is used. The default is ConcentrationRatio.

#### 1.25.9.1.32 Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the evaporative fluid cooler as a function of the rate of evaporation. Blowdown is water intentionally drained from the evaporative fluid cooler in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value.

**1.25.9.1.33** Field: Blowdown Makeup Water Usage Schedule Name

This alpha field contains the name of the schedule used to define the amount of water (m3/s) flushed from the basin on a periodic basis to purge the evaporative fluid cooler of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation Mode is set to ScheduledRate. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value. This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the evaporative fluid cooler is active and water is flowing through the evaporative fluid cooler (regardless of the water usage defined by this schedule).

#### 1.25.9.1.34 Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the evaporative fluid cooler obtains water used for evaporative cooling. If blank or omitted, then the evaporative fluid cooler will obtain water directly from the mains. If the name of a **WaterUse:Storage** object is used here, then the evaporative fluid cooler will obtain its water from that tank. If a tank is specified, the evaporative fluid cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the evaporative fluid cooler needs, then the evaporative fluid cooler will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

Examples of an IDF specification for this object are shown below:

- HVAC,Average,Cooling Tower Water Drift Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Drift Volume [m3]
- HVAC,Average,Cooling Tower Water Blowdown Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Water Blowdown Volume [m3]
- HVAC,Sum,Cooling Tower Make Up Mains Water Volume [m3]

If Supply Water Storage Tank Name is specified:

- HVAC,Average,Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Storage Tank Water Volume [m3]
- HVAC,Average,Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]
- HVAC,Sum,Cooling Tower Starved Storage Tank Water Volume [m3]

#### 1.25.9.2.1 Cooling Tower Fan Electricity Rate [W]

The average electric power consumption of the fluid cooler fan in Watts for the timestep being reported.

**1.25.9.2.2 Cooling Tower Fan Electricity Energy [J]**

Fan energy use in Joules. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

**1.25.9.2.3 Cooling Tower Heat Transfer Rate [W]**

This is the average rate, in Watts, at which heat is removed from the condenser water loop by the fluid cooler for the time step being reported.

**1.25.9.2.4 Cooling Tower Inlet Temperature [C]**

The fluid temperature at the fluid cooler inlet in degrees Celsius.

**1.25.9.2.5 Cooling Tower Outlet Temperature [C]**

The fluid temperature at the fluid cooler outlet in degrees Celsius.

**1.25.9.2.6 Cooling Tower Mass Flow Rate [kg/s]**

The average fluid mass flow rate through the fluid cooler in kg/s for the time step being reported.

**1.25.9.2.7 Cooling Tower Make Up Water Volume Flow Rate [m3/s]****1.25.9.2.8 Cooling Tower Make Up Water Volume [m3]**

These outputs are the external spray water consumed by the evaporative fluid cooler. This is the total of evaporation, drift, and blowdown.

**1.25.9.2.9 Cooling Tower Water Evaporation Volume Flow Rate [m3/s]****1.25.9.2.10 Cooling Tower Water Evaporation Volume [m3]****1.25.9.2.11 Cooling Tower Water Drift Volume Flow Rate [m3/s]****1.25.9.2.12 Cooling Tower Water Drift Volume [m3]****1.25.9.2.13 Cooling Tower Water Blowdown Volume Flow Rate [m3/s]****1.25.9.2.14 Cooling Tower Water Blowdown Volume [m3]**

These outputs provide the breakdown of the different components of water use during fluid cooler operation.

**1.25.9.2.15 Cooling Tower Make Up Mains Water Volume [m3]**

The volume of make up water provided by the mains in cubic meters. If no Supply Water Storage Tank is specified, then all fluid cooler make up water is provided by the mains (same as Cooling Tower Make Up Water Volume). If a Supply Water Storage Tank is specified, then the make up from the mains only occurs when sufficient water supply is not available from the tank (same as Cooling Tower Starved Storage Tank Water Volume). This output variable is metered on HeatRejection:MainsWater, MainsWater:Plant and MainsWater:Facility.

**1.25.9.2.16 Cooling Tower Storage Tank Water Volume Flow Rate [m3/s]**

**1.25.9.2.17 Cooling Tower Storage Tank Water Volume [m3]**

These are the rate and volume of water provided by the Supply Water Storage Tank.

**1.25.9.2.18 Cooling Tower Starved Storage Tank Water Volume Flow Rate [m3/s]****1.25.9.2.19 Cooling Tower Starved Storage Tank Water Volume [m3]**

These are the rate and volume of water the Supply Water Storage Tank was not able to provide. The starved water is assumed to come from the mains. The fluid cooler's operation is not affected by a lack of storage tank water.

**1.25.10 FluidCooler:SingleSpeed**

Fluid coolers are components that may be assigned to condenser loops. The Fluid cooler is modeled as a cross flow heat exchanger (both streams unmixed) with single-speed fans (induced draft configuration). The user must define fluid cooler performance via one of the two methods: design heat transfer coefficient-area product (UA) and design water flow rate, or nominal fluid cooler capacity at a specific rating point. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified.

The fluid cooler seeks to maintain the temperature of the water exiting the fluid cooler at (or below) a set point. The set point schedule value is defined by the field "Condenser Loop Temperature Setpoint Node Name or Reference" for the **CondenserLoop** object. The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan on for the entire simulation timestep and fluid cooler fan off for the entire simulation timestep). Cyclic losses are not taken into account.

**1.25.10.1 Inputs****1.25.10.1.1 Field: Name**

This alpha field contains the identifying name for the Fluid Cooler.

**1.25.10.1.2 Field: Water Inlet Node Name**

This alpha field contains the identifying name for the Fluid Cooler's water inlet node.

**1.25.10.1.3 Field: Water Outlet Node Name**

This alpha field contains the identifying name for the Fluid Cooler's water outlet node.

**1.25.10.1.4 Field: Performance Input Method**

This alpha field contains the method by which the user will specify fluid cooler performance: "UFactorTimesAreaAndDesignWaterFlowRate" or "NominalCapacity".

**1.25.10.1.5 Field: Design Air Flow Rate U-factor Times Area Value**

This numeric field contains the heat transfer coefficient-area product (UA) in watts per Kelvin corresponding to the design air and water flow rates specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design fluid cooler UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections), the fluid cooler inlet air dry-bulb and wetbulb temperature are taken

from the input. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the fluid cooler UA based on the fluid cooler capacity and nominal conditions specified in input file.

#### 1.25.10.1.6 Field: Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the fluid cooler in watts, Nominal conditions i.e. entering air dry-bulb temperature, entering air wet-bulb temperature and Entering water temperature should be provided in the input.

#### 1.25.10.1.7 Field:Design Entering Water Temperature

This numeric field contains entering water temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering water temperature must be greater than the design entering air temperature.

#### 1.25.10.1.8 Field:Design Entering Air Temperature

This numeric field contains entering air dry-bulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air temperature must be greater than the design entering air wet-bulb temperature.

#### 1.25.10.1.9 Field:Design Entering Air Wet-bulb Temperature

This numeric field contains entering air wetbulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air wet-bulb temperature must be less than the design entering air (dry-bulb) temperature.

#### 1.25.10.1.10 Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the fluid cooler in  $\text{m}^3/\text{s}$ . This value is the flow rate of the condenser loop water being cooled by the fluid cooler. A water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections).

#### 1.25.10.1.11 Field: Design Air Flow Rate

This numeric field contains the design air flow rate induced by the fluid cooler fan in  $\text{m}^3/\text{s}$ . A value greater than zero must be defined regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering Reference document for fluid cooler autosizing.

#### 1.25.10.1.12 Field: Design Air Flow Rate Fan Power

This numeric field contains the fan power (in watts) at the design air flow rate specified in the previous field. A value greater than zero must be specified regardless of the performance input method, or this field can be autosized. See Engineering ref. for fluid cooler autosizing.

#### 1.25.10.1.13 Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the fluid cooler. If this field is left blank, the outdoor air conditions entering the fluid cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

An IDF specification for this object is shown below:

```
FluidCooler:SingleSpeed,
    Big FLUIDCOOLER1,           !- Name
    Condenser FLUIDCOOLER 1 Inlet Node, !- Water Inlet Node Name
    Condenser FLUIDCOOLER 1 Outlet Node, !- Water Outlet Node Name
    NominalCapacity,           !- Performance Input Method
    ,                           !- Design Air Flow Rate U-factor Times Area Value {W/K}
    58601.,                     !- Nominal Capacity {W}
    51.67,                      !- Design Entering Water Temperature {C}
    35,                         !- Design Entering Air Temperature {C}
    25.6,                       !- Design Entering Air Wetbulb Temperature {C}
    0.001388,                   !- Design Water Flow Rate{m3/s}
    9.911,                      !- Design Air Flow Rate {m3/s}
    Autosize;                   !- Design Air Flow Rate Fan Power {W}
```

### 1.25.10.2 Outputs

- HVAC,Average,Cooling Tower Fan Electricity Rate [W]
- HVAC,Sum,Cooling Tower Fan Electricity Energy [J]
- Zone,Meter,HeatRejection:Electricity [J]
- HVAC,Average,Cooling Tower Heat Transfer Rate [W]
- HVAC,Average, Cooling Tower Inlet Temperature [C]
- HVAC,Average, Cooling Tower Outlet Temperature [C]
- HVAC,Average,Cooling Tower Mass Flow Rate [kg/s]

#### 1.25.10.2.1 Cooling Tower Fan Electricity Rate [W]

The electric power consumption of the fluid cooler fans.

#### 1.25.10.2.2 Cooling Tower Fan Electricity Energy [J]

Fan energy use. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

#### 1.25.10.2.3 Cooling Tower Heat Transfer Rate [W]

This is the rate at which heat is removed from the condenser water loop by the fluid cooler.

#### 1.25.10.2.4 Cooling Tower Inlet Temperature [C]

The loop temperature at the fluid cooler inlet.

#### 1.25.10.2.5 Cooling Tower Outlet Temperature [C]

The loop temperature at the fluid cooler outlet.

#### 1.25.10.2.6 Cooling Tower Mass Flow Rate [kg/s]

The loop mass flow rate of the circulating condenser water loop.

### 1.25.11 FluidCooler:TwoSpeed

The two-speed fluid cooler is modeled in a similar fashion to the single-speed fluid cooler. The fluid cooler is modeled as a cross flow heat exchanger (both stream unmixed) with two-speed fans (induced draft configuration). The user must define fluid cooler performance via one of two methods: heat transfer coefficient-area product (UA) and design water flow rate, or nominal fluid cooler capacity at a specific rating point. Regardless of which method is chosen, the airflow rate and corresponding fan power at both high and low fan speed must be specified. The Fluid Cooler seeks to maintain the temperature of the water exiting the Fluid Cooler at (or below) a set point. The set point schedule is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the **CondenserLoop** object. The model first runs at low speed and calculates the fluid cooler exiting water temperature. If the exiting water temperature based on “low speed” is at or below the set point, then the fluid cooler fan runs at this speed or below this speed. If the exiting water temperature remains above the set point after “low speed” is modeled, then the fluid cooler fan runs at high speed to reduce the exiting water temperature.

The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan at high speed for the entire simulation timestep and fluid cooler fan at low speed for the entire simulation timestep.). Cyclic losses are not taken into account.

#### 1.25.11.1 Inputs

##### 1.25.11.1.1 Field: Name

This alpha field contains the identifying name for the fluid cooler.

##### 1.25.11.1.2 Field: Water Inlet Node Name

This alpha field contains the identifying name for the fluid cooler’s water inlet node.

##### 1.25.11.1.3 Field: Water Outlet Node Name

This alpha field contains the identifying name for the fluid cooler’s water outlet node.

##### 1.25.11.1.4 Field: Performance Input Method

This alpha field contains the method by which the user will specify fluid cooler performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”.

##### 1.25.11.1.5 Field: High Fan Speed U-factor Times Area Value

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the high-speed air flow rate and design water flow rate specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the fluid cooler UA value at high fan speed is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections), fluid cooler water inlet temperature, fluid cooler inlet air drybulb and wetbulb are provided in the input. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the fluid cooler UA based on the capacity specified in the field “High Speed Nominal Capacity” and nominal conditions.

##### 1.25.11.1.6 Field: Low Fan Speed U-factor Times Area Value

This numeric field contains the heat transfer coefficient-area product (UA) in watts per Kelvin corresponding to the design water flow rate and low-speed air flow rate specified above. If the input field

“Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, this value must be greater than zero but less than or equal to 300,000, less than the value specified for the field “U-factor Times Area Value at High Fan Speed”. This field may be autocalculated, in which case it is set to a factor of the “U-factor Times Area Value at High Fan Speed” determined in the following field. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the fluid cooler UA based on the fluid cooler capacity specified in the field “Low Speed Nominal Capacity”.

#### **1.25.11.1.7 Field: Low Fan Speed U-Factor Times Area Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Low Fan Speed U-factor Times Area Value. The default is 0.6.

#### **1.25.11.1.8 Field: High Speed Nominal Capacity**

This numeric input field contains the “nominal” heat rejection capacity of the fluid cooler in watts under high-speed fan operation, with nominal (design) inputs entering water temperature, entering air temperature and entering air wet-bulb temperature. The design water flow rate is also provided in the input.

#### **1.25.11.1.9 Field: Low Speed Nominal Capacity**

This numeric input field contains the “nominal” heat rejection capacity of the Fluid Cooler in watts under low-speed fan operation, with nominal (design) inputs entering water temperature, entering air temperature and entering air wet-bulb temperature. The design water flow rate is also provided in the input. The value specified for this field must be greater than zero but less than the value specified for the field “High Speed Nominal Capacity”. This field may be autocalculated, in which case it is set to a fraction of the “High Speed Nominal Capacity” determined in the following field.

#### **1.25.11.1.10 Field: Low Speed Nominal Capacity Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Low Speed Nominal Capacity. The default is 0.5.

#### **1.25.11.1.11 Field: Design Entering Water Temperature**

This numeric field contains entering water temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering water temperature must be greater than the design entering air temperature.

#### **1.25.11.1.12 Field: Design Entering Air Temperature**

This numeric field contains entering air dry-bulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air temperature must be greater than the design entering air wet-bulb temperature.

#### **1.25.11.1.13 Field: Design Entering Air Wet-bulb Temperature**

This numeric field contains entering air wet-bulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air wet-bulb temperature must be less than the design entering air (dry-bulb) temperature.

**1.25.11.1.14 Field: Design Water Flow Rate**

This numeric field contains the design water flow rate through the fluid cooler in  $\text{m}^3/\text{s}$ . This value is the flow rate of the condenser loop water being cooled by the fluid cooler. A water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing sections).

**1.25.11.1.15 Field: High Fan Speed Air Flow Rate**

This numeric field contains the fluid cooler air flow rate at high fan speed in  $\text{m}^3/\text{s}$ . A value greater than zero must be defined regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering ref. for fluid cooler autosizing.

**1.25.11.1.16 Field: High Fan Speed Fan Power**

This numeric field contains the fan power (in Watts) at the high-speed air flow rate specified in the previous field. A value greater than zero must be specified regardless of the fluid cooler performance input method, or this field can be autosized. See Engineering ref. for fluid cooler autosizing.

**1.25.11.1.17 Field: Low Fan Speed Air Flow Rate**

This numeric field contains the fluid cooler air flow rate at low fan speed in  $\text{m}^3/\text{s}$ . This value must be greater than zero, less than the value specified for the field “Air Flow Rate at High Fan Speed”. This field may be autocalculated, in which case it is set to a fraction of the “Air Flow Rate at High Fan Speed” determined in the following field.

**1.25.11.1.18 Field: Low Fan Speed Air Flow Rate Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Low Fan Speed Air Flow Rate. The default is 0.5.

**1.25.11.1.19 Field: Low Fan Speed Fan Power**

This numeric field contains the fan power (in Watts) at the low-speed air flow rate specified in the previous field. This value must be specified greater than zero or the field may be autocalculated, in which case it is set to a fraction of the “Fan Power at High Fan Speed” determined in the following field.

**1.25.11.1.20 Field: Low Fan Speed Fan Power Sizing Factor**

This numeric field contains the sizing factor to use when calculating the Low Fan Speed Fan Power. The default is 0.16.

**1.25.11.1.21 Field: Outdoor Air Inlet Node Name**

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the Fluid Cooler. If this field is left blank, the outdoor air conditions entering the Fluid Cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an **OutdoorAir:NodeList** object where the outdoor air conditions are taken directly from the weather data.

Examples of an IDF specification for this object are shown below:

```
FluidCooler:TwoSpeed,
    Big FLUIDCOOLER1,           !- Name
    Condenser FLUIDCOOLER 1 inlet Node, !- Water Inlet Node Name
    Condenser FLUIDCOOLER 1 Outlet Node, !- Water Outlet Node Name
```

### 1.25.11.2 Outputs

- HVAC,Average,Cooling Tower Fan Electricity Rate [W]
- HVAC,Sum,Cooling Tower Fan Electricity Energy [J]
- HVAC,Average,Cooling Tower Heat Transfer Rate [W]
- HVAC,Average, Cooling Tower Inlet Temperature [C]
- HVAC,Average, Cooling Tower Outlet Temperature [C]
- HVAC,Average,Cooling Tower Mass Flow Rate [kg/s]

#### 1.25.11.2.1 Cooling Tower Fan Electricity Rate [W]

Average fan electric power consumed.

#### 1.25.11.2.2 Cooling Tower Fan Electricity Energy [J]

Total energy used by the fan. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

#### 1.25.11.2.3 Cooling Tower Heat Transfer Rate [W]

This is the rate at which heat is removed from the condenser water loop by the fluid cooler.

#### 1.25.11.2.4 Cooling Tower Inlet Temperature [C]

Loop temperature at the fluid cooler inlet.

#### 1.25.11.2.5 Cooling Tower Outlet Temperature [C]

Loop temperature at the fluid cooler outlet.

#### 1.25.11.2.6 Cooling Tower Mass Flow Rate [kg/s]

Loop mass flow rate through the fluid cooler.

### 1.25.12 GroundHeatExchanger:System

The EnergyPlus ground loop heat exchanger is a condenser component which serves the condenser supply side in addition to the cooling towers and other condensing components. Figure 1.99 shows the Ground Heat Exchanger in the simulation environment.

The heat exchanger response is defined by a g-function which is a non-dimensional function that is used to calculate the response to square heat pulses of different duration. (This function is not the same as ‘G-factors’ referred to in the ASHRAE Applications Handbook). This continuous function is specified by a series of data pairs (LNTTS $i$ , GFNC $i$ ) where,

- LNTTS $i$  is the non-dimensional time:  $\ln(T/T_s)$
- GFNC $i$  is the g-function value

The g-function is different for each borehole field configuration (i.e. a  $4 \times 4$  field has a different response than a  $80 \times 80$  field). It is also dependent on the ratio of borehole spacing to depth. g-function values, for accurate simulation, have to be computed for each specific heat exchanger design. The GroundHeatExchanger:System object will accept three different types of input in order to define the g-functions necessary for the ground heat exchanger calculations.

1. Use the **GroundHeatExchanger:Vertical:Array** object to define a rectangular borehole field. EnergyPlus will compute and cache the g-functions for reuse again in future simulations.
2. Use one or more **GroundHeatExchanger:Vertical:Single** objects to define a vertical borehole field with the boreholes located arbitrarily. EnergyPlus will compute and cache the g-functions for reuse again in future simulations.
3. Use a third-party tool, such as GLHEPro, to compute the g-functions and pass them to EnergyPlus using the **GroundHeatExchanger:ResponseFactors** object.

A small number of reference datasets containing example input data for  $1 \times 2$ ,  $4 \times 4$  and  $8 \times 8$  configurations and for both standard and thermally enhanced grout are provided as well.

Definitions for the input fields are provided below.

#### 1.25.12.1 Inputs

##### 1.25.12.1.1 Field: Name

This alpha field contains the identifying name for the ground heat exchanger (GHE).

##### 1.25.12.1.2 Field: Inlet Node Name

This alpha field contains the ground heat exchanger inlet node name.

##### 1.25.12.1.3 Field: Outlet Node Name

This alpha field contains the ground heat exchanger outlet node name.

##### 1.25.12.1.4 Field: Design Flow Rate

This numeric field contains the GHE design flow rate in cubic meters per second  $\{\text{m}^3/\text{s}\}$ . The flow rate specified is the total flow rate for the entire borehole field. Flow will be assumed to be evenly distributed across all boreholes.

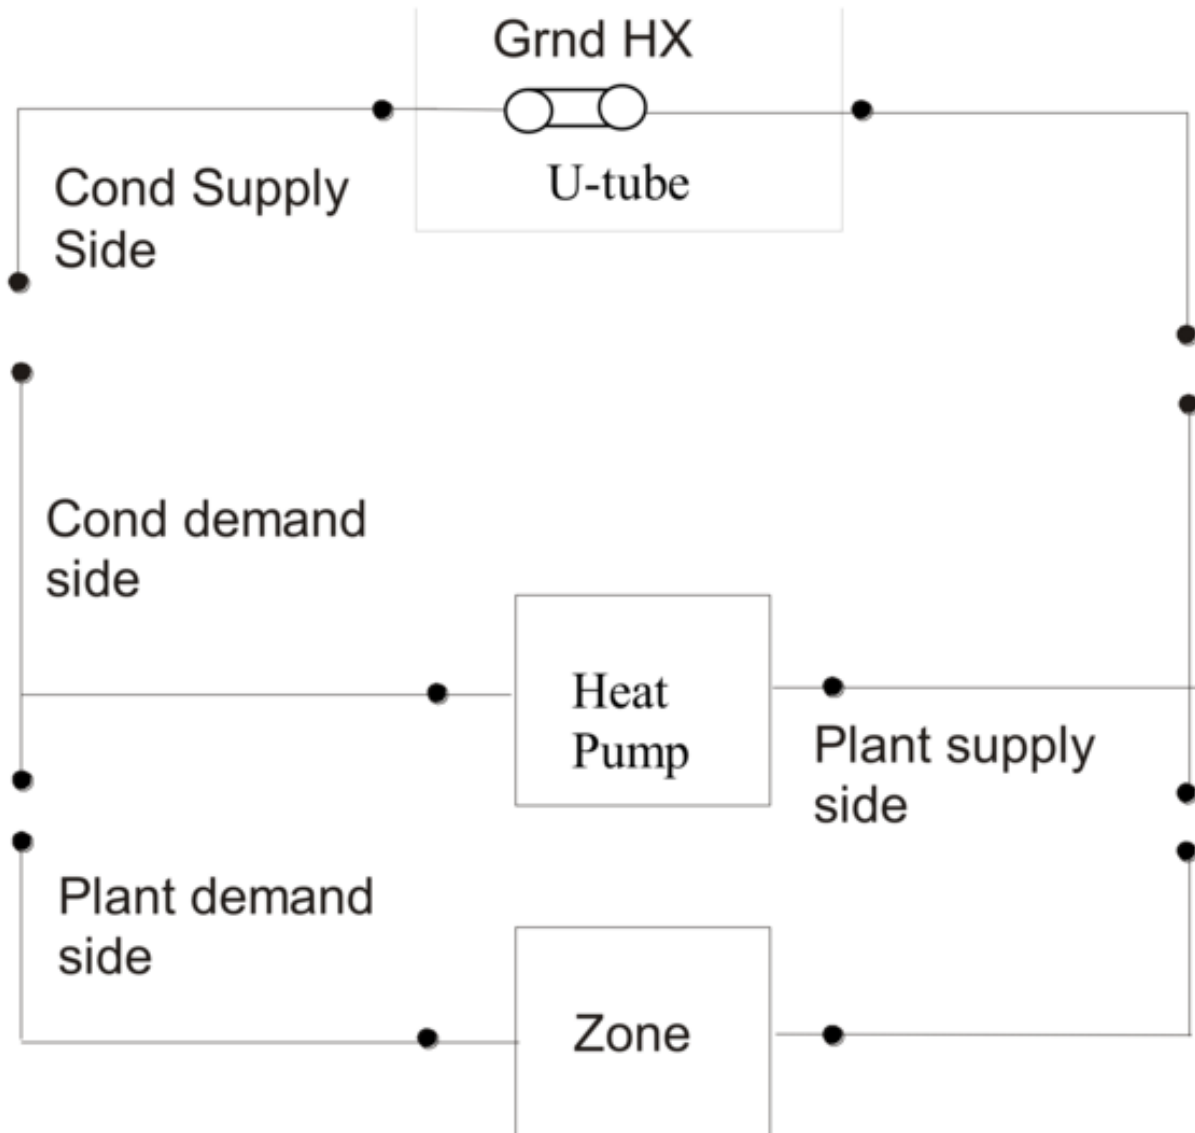

Figure 1.99: Schematic of EnergyPlus Ground Loop Heat Exchanger

**1.25.12.1.5 Field: Type of Undisturbed Ground Temperature Object**

The type of undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.25.12.1.6 Field: Name of Undisturbed Ground Temperature Object**

The name of the undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.25.12.1.7 Field: Ground Thermal Conductivity**

This numeric field contains the thermal conductivity of the ground in W/m-K.

**1.25.12.1.8 FieldSet: Ground Thermal Heat Capacity**

This numeric field contains the thermal heat capacity of the ground in J/m<sup>3</sup>-K.

**1.25.12.1.9 Field: GHE:ResponseFactors object name**

The unique name of the **GroundHeatExchanger:ResponseFactors** object used to define the third-party response factors. If present, the GHE:Vertical:Array and GHE:Vertical:Single objects defined will be ignored.

**1.25.12.1.10 Field: GHE:Vertical:Array object name**

The unique name of the **GroundHeatExchanger:Vertical:Array** object used to define a rectangular borehole field. If present, the GHE:Vertical:Single objects will be ignored.

**1.25.12.1.11 Field: GHE:Vertical:Single names**

The unique names of all single, vertical GLHE objects which are used to define and arbitrarily shaped GHE array. This field is exensible.

The following is are example inputs corresponding to the input variations allowed which were described previously. The first example uses the **GroundHeatExchanger:Vertical:Array** object. The g-functions will be generated automatically by EnergyPlus and cached for later use.

### 1.25.12.2 Outputs

- HVAC,Average,Ground Heat Exchanger Average Borehole Temperature [C]
- HVAC,Average,Ground Heat Exchanger Heat Transfer Rate [W]
- HVAC,Average,Ground Heat Exchanger Inlet Temperature [C]
- HVAC,Average,Ground Heat Exchanger Outlet Temperature [C]
- HVAC,Average,Ground Heat Exchanger Mass Flow Rate [kg/s]
- HVAC,Average,Ground Heat Exchanger Average Fluid Temperature [C]
- HVAC,Average,Ground Heat Exchanger Farfield Ground Temperature [C]

#### 1.25.12.2.1 Ground Heat Exchanger Average Borehole Temperature [C]

This is the model result for the average temperature of the borehole heat exchanger.

#### 1.25.12.2.2 Ground Heat Exchanger Heat Transfer Rate [W]

This is the rate of heat transfer between the working fluid and the ground heat exchanger, in Watts.

#### 1.25.12.2.3 Ground Heat Exchanger Inlet Temperature [C]

This is the temperature of the working fluid entering the ground heat exchanger.

**1.25.12.2.4 Ground Heat Exchanger Outlet Temperature [C]**

This is the temperature of the working fluid leaving the ground heat exchanger.

**1.25.12.2.5 Ground Heat Exchanger Mass Flow Rate [kg/s]**

This is the mass flow rate of the working fluid through the heat exchanger.

**1.25.12.2.6 Ground Heat Exchanger Average Fluid Temperature [C]**

This is the average temperature of the working fluid inside the heat exchanger.

**1.25.12.2.7 Ground Heat Exchanger Farfield Ground Temperature**

This is the farfield temperature used by the object which is provided by the undisturbed ground temperature object. The temperature is the average of the 5 evenly spaced points between the top of the borehole and the bottom of the borehole.

**1.25.13 GroundHeatExchanger:Vertical:Properties**

This object defines several borehole parameters.

**1.25.13.1 Inputs****1.25.13.1.1 Field: Name**

This alpha field indicates the unique name of the object.

**1.25.13.1.2 Field: Depth of Top of Borehole**

This numeric field indicates the depth of the top of the borehole below the ground surface, in meters. The depth measured from the ground surface downward is positive.

**1.25.13.1.3 Field: Borehole Length**

This numeric field indicates the active length of the borehole, referenced from the starting location (potentially below the ground surface), to the end of the borehole, in meters.

**1.25.13.1.4 Field: Borehole Diameter**

This numeric field indicates the diameter of the borehole, in meters.

**1.25.13.1.5 Field: Grout Thermal Conductivity**

This numeric field contains the thermal conductivity of the filler material in W/m-K.

**1.25.13.1.6 Field: Grout Thermal Heat Capacity**

This numeric field contains the thermal heat capacity of the grout in J/m<sup>3</sup>-K.

**1.25.13.1.7 Field: Pipe Thermal Conductivity**

This numeric field contains the thermal conductivity of the pipe in W/m-K.

**1.25.13.1.8 Field: Pipe Thermal Heat Capacity**

This numeric field contains the thermal heat capacity of the pipe in J/m<sup>3</sup>-K.

**1.25.13.1.9 Field: Pipe Outer Diameter**

This numeric field contains the outer diameter of the U-tube (pipe) in meters {m}.

**1.25.13.1.10 Field: Pipe Thickness**

This numeric field contains the outer diameter of the U-tube (pipe) in meters.

**1.25.13.1.11 Field: U-Tube Distance**

This numeric field contains the distance between the two legs of the U-tube in meters {m}. Distance is measured from the u-tube pipe center.

An example object is shown below.

```
GroundHeatExchanger:Vertical:Properties,
  GHE-1 Props,      !- Name
  1,                !- Depth of Top of Borehole {m}
  100,              !- Borehole Length {m}
  0.114,            !- Borehole Diameter {m}
  0.7443,           !- Grout Thermal Conductivity {W/m-K}
  3.90E+06,         !- Grout Thermal Heat Capacity {J/m3-K}
  0.3895,           !- Pipe Thermal Conductivity {W/m-K}
  1.77E+06,         !- Pipe Thermal Heat Capacity {J/m3-K}
  0.03341,          !- Pipe Outer Diameter {m}
  0.002984,         !- Pipe Thickness {m}
  0.04913;          !- U-Tube Distance {m}
```

---

**1.25.14 GroundHeatExchanger:Vertical:Array**

This object defines the borehole locations for a rectangular array of boreholes.

**1.25.14.0.1 Field: Name**

This alpha field indicates the unique name of the object.

**1.25.14.0.2 Field: Properties**

This alpha field indicates the name of the [GroundHeatExchanger:Vertical:Properties](#) object referenced by the boreholes in the array.

**1.25.14.0.3 Field: Number of Boreholes in the X-Direction**

This numeric field indicates the number of boreholes in one axis of the rectangular borehole field.

**1.25.14.0.4 Field: Number of Boreholes in the Y-Direction**

This numeric field indicates the number of boreholes in the other axis of the rectangular borehole field.

**1.25.14.0.5 Field: Borehole Spacing**

This numeric field indicates the center-to-center borehole spacing, in meters, which is applied to the rectangular borehole field.

An example object is shown below.

```
GroundHeatExchanger:Vertical:Array,
  GHE-Array,        !- Name
  GHE-1 Props,      !- GHE Properties
  2,                !- Number of Boreholes in X Direction
  2,                !- Number of Boreholes in Y Direction
  5;                !- Borehole Spacing {m}
```

---

**1.25.15 GroundHeatExchanger:Vertical:Single**

This object defines a single borehole heat exchanger.

### 1.25.15.1 Inputs

#### 1.25.15.1.1 Field: Name

This alpha field indicates the unique name of the object.

#### 1.25.15.1.2 Field: Properties

This alpha field indicates the name of the `GroundHeatExchanger:Vertical:Properties` object referenced by the borehole.

#### 1.25.15.1.3 Field: X-Location

This numeric field indicates the x-location of this borehole.

#### 1.25.15.1.4 Field: Y-Location

This numeric field indicates the y-location of this borehole.

```
GroundHeatExchanger:Vertical:Single,
  GHE-1,           !- Name
  GHE-1 Props,     !- GHE Properties
  0,               !- X Location {m}
  0;               !- Y Location {m}
```

---

## 1.25.16 GroundHeatExchanger:ResponseFactors

This object is used to provide third-party g-functions which are generated by other tools.

### 1.25.16.1 Inputs

#### 1.25.16.1.1 Field: Name

This alpha field indicates the unique name of the object.

#### 1.25.16.1.2 Field: Properties

This alpha field indicates the name of the `GroundHeatExchanger:Vertical:Properties` object referenced g-function response factors.

#### 1.25.16.1.3 Field: G-Function Reference Ratio

The G-Functions may be formulated slightly differently based on the program which generated them. The original g-functions as defined by Eskilson are based on an borehole radius to active length ratio of 0.0005. If the physical ratio is different from this, a correction must be applied. EnergyPlus will apply the correction, based on the reference ratio entered in this field. Therefore, there are two possible input configurations.

- If the g-functions have not had a correction applied, then the g-functions are still based on a reference of 0.0005, so use a value of 0.0005 in this field. EnergyPlus will adjust the g-functions internally to create the properly referenced g-function.
- If the correction has already been applied, then the input g-functions are based on a reference to the actual (physical) radius/length ratio, so enter the physical radius/length in this field. Entering the actual value will nullify any internal corrections, which will avoid re-basing the g-function set.

The software GLHEPro has been making this “pre-correction” to the data sets since version 3.1 of that software, so this input field should match the actual (physical) radius/length ratio.

**1.25.16.1.4 Field: g-function  $\ln(t/t_s)$  Value <x>**

This numeric field contains the natural log of time/steady state time:  $\ln(t/t_s)$ . Field is extensible.

**1.25.16.1.5 Field: g-function ‘g’ Value <x>**

This numeric field contains the g-function value of the corresponding LNTTS. Field is extensible.

An example object is shown below.

```
GroundHeatExchanger:ResponseFactors,
  GHE-1 g-functions,      !- Name
  GHE-1 Props,           !- GHE Properties

  1.679000;              !- G-Function  $\ln(T/T_s)$  Value 73
```

**1.25.17 GroundHeatExchanger:Slinky**

The GroundHeatExchanger:Slinky use the g-functions to calculate the GHX temperature response, similar to the GroundHeatExchanger:Vertical model, however for this model g-functions are automatically calculated by EnergyPlus without the need of external software or data.

Horizontal slinky-loop ground heat exchangers (GHXs) consist of coiled tubing, with the individual rings spread out along the direction of the trench either horizontally or vertically, as shown in [Figure](#). A schematic of a slinky GHX can be seen in [Figure](#). Compared to conventional straight tube horizontal GHXs, slinky loops have a higher tube density; hence, with the same cooling/heating loads, slinky-loop GHXs require less land area and excavation work than straight tube HGHXs.

Figure: Slinky Ground Heat Exchanger Configurations.

Figure: Schematic of Slinky HX.

An example GroundHeatExchanger:Slinky object is shown below.

```

### 1.25.17.1 Inputs

#### 1.25.17.1.1 Field: Name

Alpha field used as identifying field for heat exchanger

#### 1.25.17.1.2 Field: Inlet Node

This alpha field is the name of the inlet node of the component on a plant loop.

#### 1.25.17.1.3 Field: Outlet Node

This alpha field is the name of the outlet node of the component on a plant loop.

#### 1.25.17.1.4 Field: Design Flow Rate

This numeric field is the design flow rate in m<sup>3</sup>/s for the heat exchanger. The plant loop will attempt to meet this request based on loop and flow conditions.

#### 1.25.17.1.5 Field: Soil Thermal Conductivity

This numeric field is the thermal conductivity of the soil, in W/m-K.

#### 1.25.17.1.6 Field: Soil Density

This numeric field is the density of the soil, in kg/m<sup>3</sup>.

#### 1.25.17.1.7 Field: Soil Specific Heat

This numeric field is the specific heat of the soil, in J/kg-K.

#### 1.25.17.1.8 Field: Pipe Thermal Conductivity

This numeric field is the thermal conductivity of the heat exchanger pipe.

#### 1.25.17.1.9 Field: Pipe Density

This numeric field is the density of the heat exchanger pipe, in kg/m<sup>3</sup>.

#### 1.25.17.1.10 Field: Pipe Specific Heat

This numeric field is the specific heat of the heat exchanger pipe, in J/kg-K.

#### 1.25.17.1.11 Field: Pipe Outside Diameter

This numeric field is the outside pipe diameter, in meters.

#### 1.25.17.1.12 Field: Pipe Wall Thickness

This numeric field is the pipe wall thickness, in meters.

#### 1.25.17.1.13 Field: Heat Exchanger Configuration

This alpha field is heat exchanger configuration, either Vertical or Horizontal.

**1.25.17.1.14 Field: Coil Diameter**

This numeric is the diameter of the slinky coil, in meters.

**1.25.17.1.15 Field: Coil Pitch**

This numeric field is the center-to-center distance between heat exchanger coils, in meters.

**1.25.17.1.16 Field: Trench Depth**

This numeric field is the distance from the bottom of the trench to the ground surface, in meters.

**1.25.17.1.17 Field: Trench Length**

This numeric field is the length of the heat exchanger trench, in meters. This assumes the heat exchanger runs the full length of the trench.

**1.25.17.1.18 Field: Number of Parallel Trenches**

This numeric field is the number of parallel trenches. Design flow rate will be equally divided among all parallel trenches.

**1.25.17.1.19 Field: Trench Spacing**

This numeric field is the center-to-center distance in between parallel trenches, in meters.

**1.25.17.1.20 Field: Type of Undisturbed Ground Temperature Object**

The type of undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.25.17.1.21 Field: Name of Undisturbed Ground Temperature Object**

The name of the undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.25.17.1.22 Field: Maximum Length of Simulation**

This numeric field contains the maximum number of years of simulation to be carried out.

**1.25.17.2 Outputs**

The following output variables are available.

- HVAC,Average,Ground Heat Exchanger Average Borehole Temperature [C]
- HVAC,Average,Ground Heat Exchanger Heat Transfer Rate [W]
- HVAC,Average,Ground Heat Exchanger Inlet Temperature [C]
- HVAC,Average,Ground Heat Exchanger Outlet Temperature [C]
- HVAC,Average,Ground Heat Exchanger Mass Flow Rate [kg/s]
- HVAC,Average,Ground Heat Exchanger Average Fluid Temperature [C]

**1.25.17.2.1 Ground Heat Exchanger Average Borehole Temperature [C]**

This is the model result for the average temperature of the borehole heat exchanger.

**1.25.17.2.2 Ground Heat Exchanger Heat Transfer Rate [W]**

This is the rate of heat transfer between the working fluid and the ground heat exchanger, in Watts.

**1.25.17.2.3 Ground Heat Exchanger Inlet Temperature [C]**

This is the temperature of the working fluid entering the ground heat exchanger.

**1.25.17.2.4 Ground Heat Exchanger Outlet Temperature [C]**

This is the temperature of the working fluid leaving the ground heat exchanger.

**1.25.17.2.5 Ground Heat Exchanger Mass Flow Rate [kg/s]**

This is the mass flow rate of the working fluid through the heat exchanger.

**1.25.17.2.6 Ground Heat Exchanger Average Fluid Temperature [C]**

This is the average temperature of the working fluid inside the heat exchanger.

**1.25.18 GroundHeatExchanger:Pond**

The pond heat exchanger model represents a shallow pond with submerged hydronic tubes through which the heat transfer fluid is circulated. The model represents a ‘shallow’ pond in that no attempt is made to model any stratification effects that may be present in deeper ponds.

This type of heat exchanger is intended to be connected to the supply side of a condenser loop, and can be used with any type of plant loop. The pond may be specified as the only heat exchanger on the condenser loop (as shown in Figure 1.102) or it may be connected in parallel with other condenser loop heat exchangers (such as cooling towers, ground surface heat exchangers) as shown in the second figure below.

Figure 1.102: Example of Pond Ground Heat Exchanger as only heat exchanger on condenser loop

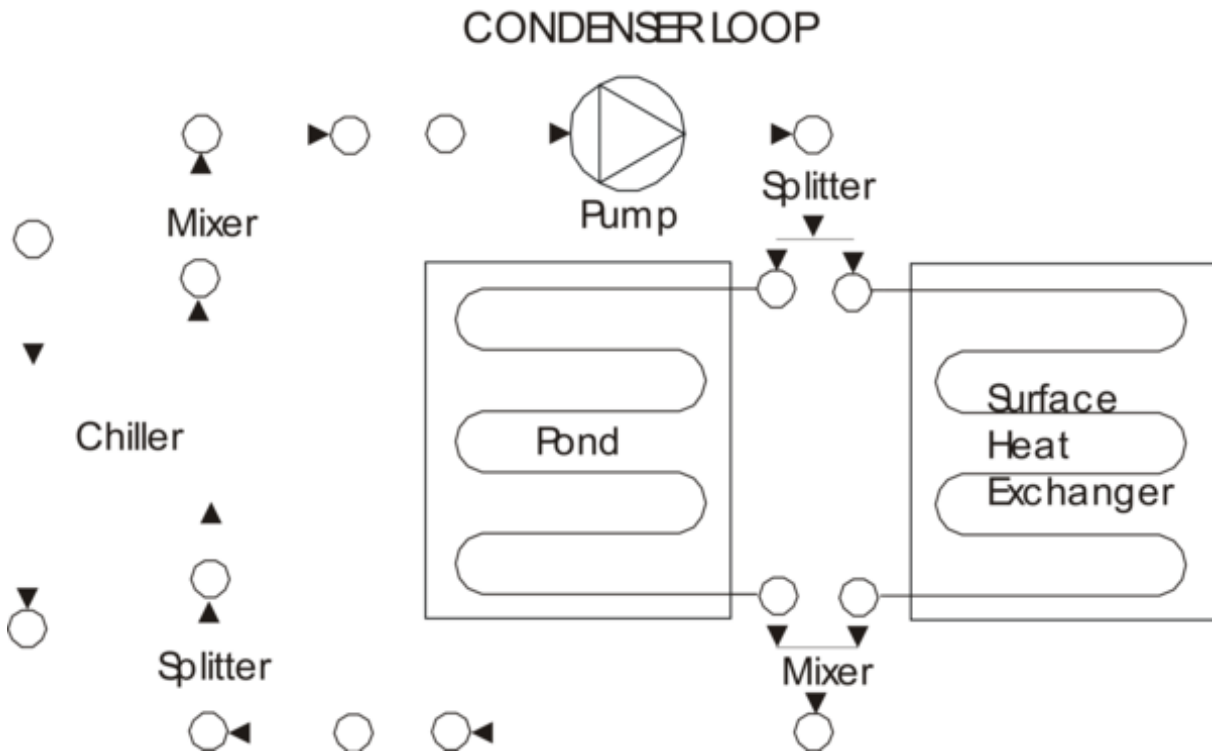

Figure 1.103: Pond Ground Heat Exchanger with other heat exchangers on condenser loop

### 1.25.18.1 Inputs

#### 1.25.18.1.1 Field: Name

This alpha field contains the identifying name for the outside pond heat exchanger.

#### 1.25.18.1.2 Field: Fluid Inlet Node Name

This alpha field contains the fluid inlet node name.

#### 1.25.18.1.3 Field: Fluid Outlet Node Name

This alpha field contains the fluid outlet node name.

#### 1.25.18.1.4 Field: Pond Depth

This numeric field contains the pond depth {m}.

#### 1.25.18.1.5 Field: Pond Area

This numeric field contains the pond area  $\text{m}^2$ .

#### 1.25.18.1.6 Field: Hydronic Tubing Inside Diameter

This numeric field contains the hydronic tubing inside diameter {m}.

#### 1.25.18.1.7 Field: Hydronic Tubing Outside Diameter

This numeric field contains the hydronic tubing outside diameter {m}.

#### 1.25.18.1.8 Field: Hydronic Tubing Thermal Conductivity

This numeric field contains the hydronic tubing thermal conductivity in  $\text{W/mK}$ .

**1.25.18.1.9 Field: Ground Thermal Conductivity**

This numeric field contains the ground thermal conductivity in W/m<sup>2</sup>K.

**1.25.18.1.10 Field: Number of Tubing Circuits**

This numeric field contains the number of hydronic tubing circuits, total in parallel in this pond..

**1.25.18.1.11 Field: Length of Each Tubing Circuit**

This numeric field contains length {m} of each hydronic tubing circuit.

An example of the IDF is shown below.

```
GroundHeatExchanger:Pond,
  Pond 1,                !- Name
  Condenser Tower 1 Inlet Node, !- Fluid Inlet Node Name
  Condenser Tower 1 Outlet Node, !- Fluid Outlet Node Name
  2.0,                    !- Pond Depth {m}
  1000.0,                  !- Pond Area {m2}
  0.02,                    !- Hydronic Tubing Inside Diameter {m}
  0.025,                   !- Hydronic Tubing Outside Diameter {m}
  0.4,                     !- Hydronic Tubing Thermal Conductivity {W/m-K}
  1.0,                     !- Ground Thermal Conductivity {W/m2-K}
  10,                      !- Number of Tubing Circuits
  50.0;                    !- Length of Each Tubing Circuit {m}
```

**1.25.18.2 Outputs**

- HVAC,Average,Pond Heat Exchanger Heat Transfer Rate [W]
- HVAC,Sum,Pond Heat Exchanger Heat Transfer Energy [J]
- HVAC,Average,Pond Heat Exchanger Mass Flow Rate [kg/s]
- HVAC,Average,Pond Heat Exchanger Inlet Temperature [C]
- HVAC,Average,Pond Heat Exchanger Outlet Temperature [C]
- HVAC,Average,Pond Heat Exchanger Bulk Temperature [C]

**1.25.18.2.1 Pond Heat Exchanger Heat Transfer Rate [W]****1.25.18.2.2 Pond Heat Exchanger Heat Transfer Energy [J]**

These outputs are the pond ground heat exchanger heat transfer rate and total energy exchange for the timestep.

**1.25.18.2.3 Pond Heat Exchanger Mass Flow Rate [kg/s]****1.25.18.2.4 Pond Heat Exchanger Inlet Temperature [C]****1.25.18.2.5 Pond Heat Exchanger Outlet Temperature [C]**

These outputs are the pond fluid inlet and outlet temperatures and mass flow rate.

**1.25.18.2.6 Pond Heat Exchanger Bulk Temperature [C]**

This output is the pond bulk temperature.

### 1.25.19 GroundHeatExchanger:Surface

The surface heat exchanger model is to simulate hydronic surface ground heat exchangers. This includes pavement surfaces with embedded pipes for snow-melting or heat rejection from hybrid ground source heat pump systems.

The heat exchanger may be ground coupled or not. In the latter case the bottom surface is exposed to the wind but not solar gains. This type of heat exchanger is intended to be connected to the supply side of a condenser loop, and can be used with any type of plant loop. The surface heat exchanger may be specified as the only heat exchanger on the condenser loop (as shown in the first figure below) or it may be connected in parallel with other condenser loop heat exchangers (such as cooling towers, ground surface heat exchangers) as shown in the second figure below.

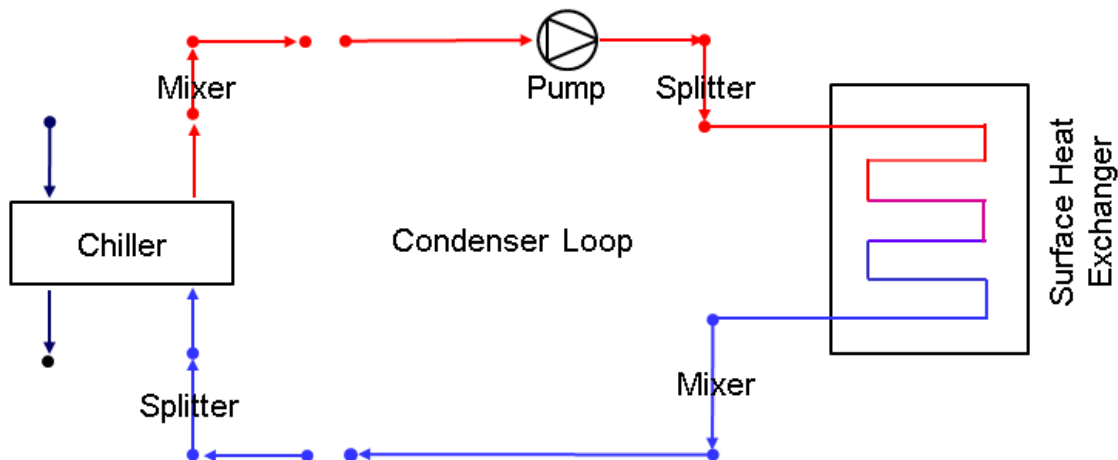

Figure 1.104: Example of Surface Ground Heat Exchanger as only heat exchanger on condenser loop

#### 1.25.19.1 Inputs

##### 1.25.19.1.1 Field: Name

This alpha field contains the identifying name for the outside panel heat exchanger.

##### 1.25.19.1.2 Field: Construction Name

This alpha field contains the construction name. It must contain a valid “Construction” name that is usual for Surfaces. (Ref: Group – Surface Construction Elements).

##### 1.25.19.1.3 Field: Fluid Inlet Node Name

This alpha field contains the fluid inlet node name.

##### 1.25.19.1.4 Field: Fluid Outlet Node Name

This alpha field contains the fluid outlet node name.

##### 1.25.19.1.5 Field: Hydronic Tubing Inside Diameter

This numeric field contains the hydronic tubing inside diameter in m.

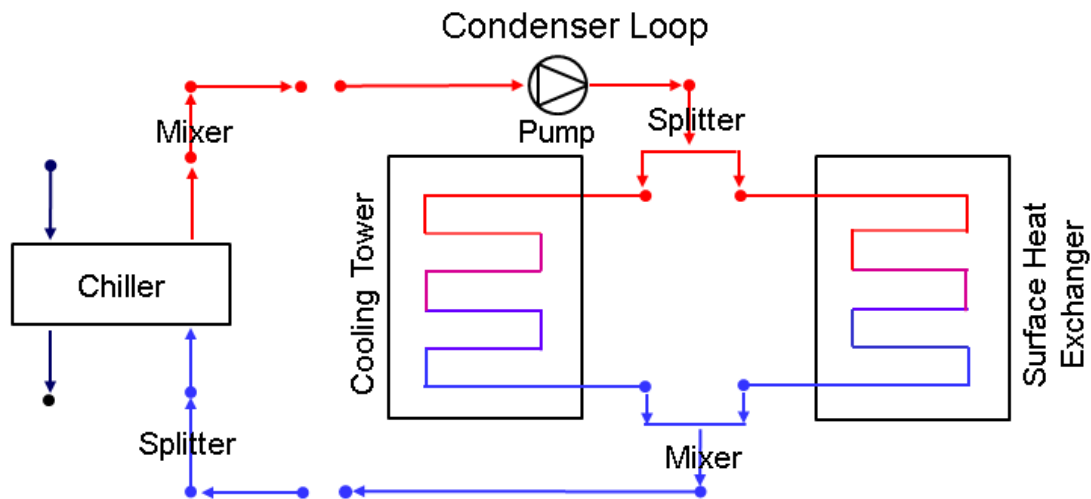

Figure 1.105: Surface Ground Heat Exchanger with other heat exchangers on condenser loop

#### 1.25.19.1.6 Field: Number of Tubing Circuits

This numeric field contains the number of hydronic tubing circuits.

#### 1.25.19.1.7 Field: Hydronic Tube Spacing

This numeric field contains the hydronic tube spacing in m.

#### 1.25.19.1.8 Field: Surface Length

This numeric field contains the surface length in m.

#### 1.25.19.1.9 Field: Surface Width

This numeric field contains the surface width in m.

#### 1.25.19.1.10 Field: Lower Surface Environment

This alpha field expresses the lower surface exposure: Exposed or Ground.

An example of this statement in an IDF is shown below:

```
GroundHeatExchanger:Surface,
  SURFACE 1,                !- Name
  Outside Surface Construction, !- Construction Name
  Condenser Tower 1 Inlet Node, !- Fluid Inlet Node Name
  Condenser Tower 1 Outlet Node, !- Fluid Outlet Node Name
  0.02,                      !- Hydronic Tubing Inside Diameter {m}
  10.0,                      !- Number of Tubing Circuits
  0.3,                      !- Hydronic Tube Spacing {m}
  100.0,                    !- Surface Length {m}
  100.0,                    !- Surface Width {m}
  GROUND;                   !- Lower Surface Environment
```

### 1.25.19.2 Outputs

- HVAC,Average,Ground Heat Exchanger Heat Transfer Rate [W]
- HVAC,Average,Ground Heat Exchanger Surface Heat Transfer Rate [W]

- HVAC,Sum,Ground Heat Exchanger Heat Transfer Energy [J]
- HVAC,Average,Ground Heat Exchanger Mass Flow Rate [kg/s]
- HVAC,Average,Ground Heat Exchanger Inlet Temperature [C]
- HVAC,Average,Ground Heat Exchanger Outlet Temperature [C]
- HVAC,Average,Ground Heat Exchanger Top Surface Temperature [C]
- HVAC,Average,Ground Heat Exchanger Bottom Surface Temperature [C]
- HVAC,Average,Ground Heat Exchanger Top Surface Heat Transfer Energy per Area [J/m<sup>2</sup>]
- HVAC,Average,Ground Heat Exchanger Bottom Surface Heat Transfer Energy per Area [J/m<sup>2</sup>]
- HVAC,Sum,Ground Heat Exchanger Surface Heat Transfer Energy [J]
- HVAC,Average,Ground Heat Exchanger Source Temperature [C]

#### **1.25.19.2.1 Ground Heat Exchanger Heat Transfer Rate [W]**

#### **1.25.19.2.2 Ground Heat Exchanger Surface Heat Transfer Rate [W]**

#### **1.25.19.2.3 Ground Heat Exchanger Heat Transfer Energy [J]**

These outputs are the source heat transfer rate, surface heat transfer rate and the total source energy input for the timestep.

#### **1.25.19.2.4 Ground Heat Exchanger Mass Flow Rate [kg/s]**

#### **1.25.19.2.5 Ground Heat Exchanger Inlet Temperature [C]**

#### **1.25.19.2.6 Ground Heat Exchanger Outlet Temperature [C]**

These outputs are the surface heat exchanger fluid inlet and outlet temperatures and mass flow rate.

#### **1.25.19.2.7 Ground Heat Exchanger Top Surface Temperature [C]**

#### **1.25.19.2.8 Ground Heat Exchanger Bottom Surface Temperature [C]**

These outputs are the surface heat exchanger top and bottom surface temperatures.

#### **1.25.19.2.9 Ground Heat Exchanger Top Surface Heat Transfer Energy per Area [J/m<sup>2</sup>]**

#### **1.25.19.2.10 Ground Heat Exchanger Bottom Surface Heat Transfer Energy per Area [J/m<sup>2</sup>]**

These outputs are the surface heat exchanger top and bottom surface flux.

#### **1.25.19.2.11 Ground Heat Exchanger Surface Heat Transfer Energy [J]**

This is the total surface energy exchange for the timestep.

**1.25.19.2.12 Ground Heat Exchanger Source Temperature [C]**

This is the surface heat exchanger source temperature.

**1.25.20 GroundHeatExchanger:HorizontalTrench**

The horizontal trench ground heat exchanger object provides an alternate interface to the detailed PipingSystem:Underground:\* objects. The same underlying simulation algorithm is utilized, providing a transient numerical simulation of soil with buried pipes and a detailed surface heat balance. The input syntax is much smaller and useful for simple applications. For full flexibility, use the PipingSystem:Underground:\* objects to build a detailed simulation domain and piping circuit. For information regarding the simulation algorithms, see the engineering reference document section covering the buried piping system objects.

**Field: Name**

This alpha field is used as an identifying field for the ground heat exchanger.

**Field: Inlet Node Name**

This alpha field is the name of the inlet node of this component on a plant loop, and must match other topology definitions such as branch objects.

**Field: Outlet Node Name**

This alpha field is the name of the outlet node of this component on a plant loop, and must match other topology definitions such as branch objects.

**Field: Design Flow Rate [m<sup>3</sup>/s]**

This numeric field is the designed flow rate for this heat exchanger; the plant loop solver will attempt to meet this request based on flow and loop conditions.

**Field: Trench Length in Pipe Axial Direction [m]**

This numeric field represents the axial length of each pipe trench. Each pipe defined for this ground heat exchanger will have the same length. If different pipes have different lengths, they must use separate GroundHeatExchanger:HorizontalTrench objects with different lengths.

**Field: Number of Trenches**

This integer field is the number of trenches for this heat exchanger. Since each trench has a single pipe, this defines the number of “pipe segments” for this overall heat exchanger. The total piping length is then calculated as the trench length times the number of trenches.

**Field: Horizontal Spacing Between Pipes [m]**

This numeric field represents the horizontal spacing (pipe centroid to pipe centroid) between pipes/trenches.

**Field: Pipe Inner Diameter [m]**

This numeric field is the inner diameter of the pipe. The same pipe properties are used for all pipes in this heat exchanger.

**Field: Pipe Outer Diameter [m]**

This numeric field is the outer diameter of the pipe. The same pipe properties are used for all pipes in this heat exchanger.

**Field: Burial Depth [m]**

This numeric field is the burial depth of each pipe, from ground surface to pipe cross section centroid. The same pipe depth is used for all pipes in this heat exchanger.

**Field: Soil Thermal Conductivity [W/mK]**

This numeric field is the soil thermal conductivity.

**Field: Soil Density [kg/m<sup>3</sup>]**

This numeric field is the soil density.

**Field: Soil Specific Heat [J/kgK]**

This numeric field is the nominal soil specific heat, but is corrected for moisture content and in freezing conditions.

**Field: Pipe Thermal Conductivity [W/mK]**

This numeric field is the pipe thermal conductivity.

**Field: Pipe Density [kg/m<sup>3</sup>]**

This numeric field is the pipe density.

**Field: Pipe Specific Heat [J/kgK]**

This numeric field is the pipe specific heat.

**Field: Soil Moisture Content Percent [%]**

This numeric field represents the volume fraction, in percent, of water content in the soil.

**Field: Soil Moisture Content Percent at Saturation [%]**

This numeric field represents the volume fraction, in percent, of water content in the soil which results in saturation.

### 1.25.20.1 Inputs

#### 1.25.20.1.1 Field: Type of Undisturbed Ground Temperature Object

The type of undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

#### 1.25.20.1.2 Field: Name of Undisturbed Ground Temperature Object

The name of the undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**Field: Evapotranspiration Ground Cover Parameter [-]**

This numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, non-permeable ground surface) to 1.5 (wild growth).

An example of this statement in an IDF is shown below:

```

### 1.25.20.2 Outputs

- HVAC,Average,Ground Heat Exchanger Mass Flow Rate [kg/s]
- HVAC,Average,Ground Heat Exchanger Inlet Temperature [C]
- HVAC,Average,Ground Heat Exchanger Outlet Temperature [C]

- HVAC,Average,Ground Heat Exchanger Fluid Heat Transfer Rate [W]

#### 1.25.20.2.1 Ground Heat Exchanger Mass Flow Rate [kg/s]

The output provides the mass flow rate currently being sent through the heat exchanger.

#### 1.25.20.2.2 Ground Heat Exchanger Inlet Temperature [C]

#### 1.25.20.2.3 Ground Heat Exchanger Outlet Temperature [C]

Temperature of fluid at the inlet and outlet of the heat exchanger.

#### 1.25.20.2.4 Ground Heat Exchanger Fluid Heat Transfer Rate [W]

Heat transfer rate for the heat exchanger, defined as positive for *fluid heat loss*.

### 1.25.21 HeatExchanger:FluidToFluid

A fluid-to-fluid heat exchanger designed to couple the supply side of one plant or condenser loop to the demand side of another plant or condenser loop. This heat exchanger is fairly general and can be configured for use in any application where any two loops need to be connected together. The only constraints are that that one side must be connected to the supply side of one loop and the other side connected to the demand side of a different loop.

Because the heat exchanger is intended to be generic, its two sides are distinguished by the nature of loop side being connected. One side is called **Loop Supply Side** to indicate the heat exchanger is situated on the supply side of a loop. The other side is called **Loop Demand Side** to indicate it is on the demand side of a loop. The heat exchanger is intended to act as a supply component for the loop connected to it as the “Loop Supply Side” and as a demand component for the loop connected to it as the “Loop Demand Side.” From the point of view of the heat exchanger model itself, the Loop Demand Side fluid serves as the source/sink to supply heating/cooling to the fluid in the Loop Supply Side.

This heat exchanger can be used for a wide variety of applications including chilled water, hot water, condenser, ground source, primary-secondary systems, etc. Heat transfer is calculated and reported using a sign convention from chilled water applications where **positive heat transfer indicates energy was extracted from the Loop Supply Side and added to the Loop Demand Side**.

**Note:** Only hydronic “plant” fluids are allowed (excepting Fluid Type ”Steam”), no air-side connections are possible with this heat exchanger.

**Various options are available for the heat exchanger model.**

- The heat transfer between the two sides can be modeled using one of seven different models for different types of heat exchangers.
- There are also eleven options for different ways to control the heat exchanger.
  - One general type of control is **OnOff** where the flow through the heat exchanger is either fully on or fully off.
  - Another type of control is **Modulated** where the flow through the Loop Demand Side is controlled to try and meet a target setpoint or load on the Loop Supply Side.

As of Version 8.0, **this object replaces three separate objects that were available prior to version 8.0 of EnergyPlus.**

Figure 1.106: Plant Fluid-to-Fluid Heat Exchanger

- The former **HeatExchanger:Hydronic** object corresponds to a situation where the Loop Demand Side is the demand side of condenser loop, the Loop Supply Side is a the supply side of a chilled water loop, the control type is “CoolingSetpointOnOffWithComponentOverride”, and the remote override component is a chiller.
- The former **HeatExchanger:WatersideEconomizer** object corresponds to a situation where the Loop Demand Side is the demand side of condenser loop, the Loop Supply Side is a the supply side of a chilled water loop, and the control type is “CoolingDifferentialOnOff.”
- The former **HeatExchanger:Plate** object corresponds to a situation where the Loop Demand Side is the demand side of a condenser loop, the Loop Supply Side is the supply side of a second condenser loop, and the control type is “UncontrolledOn.”

### 1.25.21.1 Inputs

#### 1.25.21.1.1 Field: Name

This alpha field provides the unique identifying name for this heat exchanger.

#### 1.25.21.1.2 Field: Availability Schedule Name

This field specifies the name of an availability schedule that can be used for supervisory control of the device. If blank, the default is that heat exchanger is always available. If a scheduled is named here, then the heat exchanger is available for use whenever the schedule value is greater than zero. The heat exchanger is not available whenever the schedule value is zero or less.

#### 1.25.21.1.3 Field: Loop Demand Side Inlet Node Name

This field specifies the name of a plant system node that connects an inlet of the heat exchanger to the demand side of a loop. This node must be on a branch located on the demand side of a plant or condenser loop.

#### 1.25.21.1.4 Field: Loop Demand Side Outlet Node Name

This field specifies the name of a plant system node that connects an outlet of the heat exchanger to the demand side of a loop. This node must be on a branch located on the demand side of a plant or condenser loop.

#### 1.25.21.1.5 Field: Loop Demand Side Design Flow Rate

This field specifies the design flow rate, in  $\text{m}^3/\text{s}$ , of the hydronic fluid passing through the heat exchanger on the Loop Demand Side. This field is autosizable. When autosized, this design flow rate is set to equal the design flow rate for the Loop Supply Side.

#### 1.25.21.1.6 Field: Loop Supply Side Inlet Node Name

This field specifies the name of a plant system node that connects an inlet of the heat exchanger to the supply side of a loop. This node must be on a branch located on the supply side of a plant or condenser loop.

#### 1.25.21.1.7 Field: Loop Supply Side Outlet Node Name

This field specifies the name of a plant system node that connects an outlet of the heat exchanger to the supply side of a loop. This node must be on a branch located on the supply side of a plant or condenser loop.

#### 1.25.21.1.8 Field: Loop Supply Side Design Flow Rate

This field specifies the design flow rate, in  $\text{m}^3/\text{s}$ , of the fluid passing through the heat exchanger on the Loop Supply Side. This field is autosizable. When autosized, this design flow rate is set equal to the overall design flow rate of the loop that is connected. If a sizing factor is entered in the field below, then it is multiplied to modify the design flow rate.

#### 1.25.21.1.9 Field: Heat Exchange Model Type

This alpha field identifies the nature of heat exchanger. Heat exchanger model type is specified by one of the following four key word choices:

**CrossFlowBothUnMixed** Specifies a single-pass, cross-flow heat exchanger. The effectiveness will be calculated using a cross-flow heat exchanger correlation for both streams unmixed.

**CrossFlowBothMixed** Specifies a single-pass, cross-flow heat exchanger. The effectiveness will be calculated using a cross-flow heat exchanger correlation for both streams mixed.

**CrossFlowSupplyMixedDemandUnMixed** Specifies a single-pass, cross-flow heat exchanger. The effectiveness will be calculated using a cross-flow heat exchanger correlation for flow mixed on the Loop Supply side and flow unmixed on the Loop Demand Side.

**CrossFlowSupplyUnMixedDemandMixed** Specifies a single-pass, cross-flow heat exchanger. The effectiveness will be calculated using a cross-flow heat exchanger correlation for flow unmixed on the Loop Supply side and flow mixed on the Loop Demand Side.

**CounterFlow** Specifies a counter-flow shell and tube heat exchanger (one fluid has the opposite direction to the other fluid). The effectiveness will be calculated using a counter-flow shell and tube heat exchanger correlation.

**ParallelFlow** Specifies a parallel-flow shell and tube heat exchanger (both fluids have the same direction). The effectiveness will be calculated using a parallel-flow shell and tube heat exchanger correlation.

**Ideal** Specifies an ideal heat exchanger. The effectiveness will be set to '1.0' and the specified UA will be ignored. The heat transfer rate will be calculated as the maximum possible heat transfer rate.

For effectiveness of each heat exchanger model type in detail, See "Heat Exchangers: Plant Loop Fluid-to-Fluid Heat Exchanger" Section in Engineering Reference.

#### 1.25.21.1.10 Field: Heat Exchanger U-Factor Times Area Value

This numerical field is used to specify the overall U-Factor Times Area (UA)  $\{\text{W/K}\}$  for use in the calculation of the heat exchanger effectiveness using the appropriate D-NTU correlation. If **Ideal** is specified as the heat exchanger type, the effectiveness will be set to 1.0. When set to autosize Heat Exchanger U-Factor Times Area Value is calculated based on an effectiveness of 1.0 where capacity is such that the temperatures in the **Sizing:Plant** objects for the two loops can be maintained.

#### 1.25.21.1.11 Field: Control Type

This field is used to specify how the heat exchanger is to be controlled during operation. Different applications for connecting two loops will require different control behavior and different control options are needed depending on the desired behavior. There are the following eleven key choice options to choose from:

- **UncontrolledOn.** This control mode is applicable to situations where the heat exchanger is passively running all the time and always transfers as much heat as possible between the fluid streams. However there is one aspect of control in that it will only request flow on the Loop Demand Side when there is non-zero flow into the heat exchanger on the Loop Supply Side. This control mode corresponds to that available in the HeatExchanger:Plate object prior to version 8.0.
- **OperationSchemeModulated.** This control mode is applicable to situations where the heat exchanger is controlled by an operation scheme (see objects called PlantEquipmentOperationScheme or **CondenserEquipmentOperationSchemes**). When using this control mode the heat exchanger must be listed in **PlantEquipmentList** or a **CondenserEquipmentList** and it serves as a supply component. The operation scheme will dispatch a load request to the heat exchanger which it will try meet by conditioning the fluid stream connected as the Loop Supply Side. If the heat exchanger could exceed the load request, then the flow through the fluid stream connected as the Loop Demand Side will be modulated to just meet the load request.
- **OperationSchemeOnOff.** This control mode is applicable to situations where the heat exchanger is controlled by an operation scheme (see objects called PlantEquipmentOperationScheme or **CondenserEquipmentOperationSchemes**). When using this control mode the heat exchanger must be listed in **PlantEquipmentList** or a **CondenserEquipmentList** and it serves as a supply component. The operation scheme will dispatch a load request to the heat exchanger which it will use as an on/off signal to decide if the heat exchange should run or not. If it runs, it will run at full capacity and may exceed the load request.
- **HeatingSetpointModulated.** This control mode is applicable to situations where the Loop Demand Side can provide useful heating to the Loop Supply Side. A heating setpoint is obtained from a node named in the following field. If the setpoint and inlet temperatures are such that heat exchanger could transfer heat from the Loop Demand Side to the Loop Supply Side to meet the heating setpoint, then the heat exchanger will run. The inlet temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. If the heat exchanger could overshoot the setpoint, then the flow through the fluid stream connected as the Loop Demand Side will be modulated to just meet the setpoint.
- **HeatingSetpointOnOff.** This control mode is applicable to situations where the Loop Demand Side can provide useful heating to the Loop Supply Side. A heating setpoint is obtained from a node named in the following field. If the setpoints and inlet temperatures are such that heat exchanger could transfer heat from the Loop Demand Side to the Loop Supply Side to meet the heating setpoint, then the heat exchanger will run. The inlet temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. If it runs, it will run at full capacity and may overshoot the setpoint.
- **CoolingSetpointModulated.** This control mode is applicable to situations where the Loop Demand Side can provide useful cooling to the Loop Supply Side. A cooling setpoint is obtained from a node named in the following field. If the setpoints and inlet temperatures are such that heat exchanger could transfer heat from the Loop Supply Side to the Loop Demand Side to meet the cooling setpoint, then the heat exchanger will run. The inlet temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. If the heat exchanger could undershoot the setpoint, then the flow through the fluid stream connected as the Loop Demand Side will be modulated to just meet the setpoint.

- **CoolingSetpointOnOff.** This control mode is applicable to situations where the Loop Demand Side can provide useful cooling to the Loop Supply Side. A cooling setpoint is obtained from a node named in the following field. If the setpoints and inlet temperatures are such that heat exchanger could transfer heat from the Loop Supply Side to the Loop Demand Side to meet the cooling setpoint, then the heat exchanger will run. The inlet temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. If it runs, it will run at full capacity and may undershoot the setpoint. This control mode corresponds to that available in the HeatExchanger:WatersideEconomizer object prior to version 8.0.
- **DualDeadbandSetpointModulated.** This control mode is applicable to situations where the Loop Demand Side can provide either useful cooling or heating to the Loop Supply Side. A dual deadband setpoint is obtained from a node named in the following field. If the setpoints and inlet temperatures are such that heat exchanger could transfer heat from the Loop Demand Side to the Loop Supply Side to meet the lower setpoint, then the heat exchanger will run. If the setpoints and inlet temperatures are such that heat exchanger could transfer heat from the Loop Supply Side to the Loop Demand Side to meet the high setpoint, then the heat exchanger will run. The inlet temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. If the heat exchanger could overshoot the lower setpoint, or undershoot the higher setpoint, then the flow through the fluid stream connected as the Loop Demand Side will be modulated to just meet the deadband setpoint.
- **DualDeadbandSetpointOnOff.** This control mode is applicable to situations where the Loop Demand Side can provide either useful cooling or heating to the Loop Supply Side. A dual deadband setpoint is obtained from a node named in the following field. If the setpoints and inlet temperatures are such that heat exchanger could transfer heat from the Loop Demand Side to the Loop Supply Side to meet the lower setpoint, then the heat exchanger will run. If the setpoints and inlet temperatures are such that heat exchanger could transfer heat from the Loop Supply Side to the Loop Demand Side to meet the high setpoint, then the heat exchanger will run. The inlet temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. If the heat exchanger runs, it will run at full capacity and may overshoot the lower setpoint or undershoot the higher setpoint.
- **CoolingDifferentialOnOff.** This control mode is applicable to situations where the Loop Demand Side can provide useful cooling to the Loop Supply Side. This mode is similar to CoolingSetpointOnOff except that it ignores any cooling setpoint and its control is based only on the temperature difference between Loop Demand Side and the Loop Supply Side. The inlet temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. This control mode corresponds to that available in the HeatExchanger:WatersideEconomizer object prior to version 8.0.
- **CoolingSetpointOnOffWithComponentOverride.** This control mode is applicable to situations where the heat exchanger operation is integrated with the operation of a specific chiller. Typically the heat exchanger and chiller are in parallel on separate branches. When conditions are favorable for the heat exchanger to provide cooling to the Loop Supply Side, the heat exchanger is run and the integrated chiller is turned off. When conditions are not favorable, the heat exchanger is completely off and the chiller is allowed to run as usual. A cooling setpoint is obtained from a node named in the following field. If it runs it will run at full capacity and may undershoot the setpoint. The chiller that is integrated with the heat exchanger is identified by entering the names of the chiller's inlet nodes in the input fields below. The control decision can be based on one of three different temperature signals selected in the field below called Component Override

Cooling Control Temperature Mode. The setpoint and control signal temperatures must differ by more than the value set in the field called Minimum Temperature Difference to Activate Heat Exchanger for the heat exchanger to operate. This control mode corresponds to that available in the HeatExchanger:Hydronic object prior to version 8.0.

#### 1.25.21.1.12 Field: Heat Exchanger Setpoint Node Name

This field specifies the name of a plant system node located on loop attached to the Loop Supply Side. This field is used and required when the previous field is set to one of the “Setpoint” control types. The node must have a temperature setpoint placed on it by a setpoint manager (or EMS actuator).

If the previous field is set to DualDeadbandSetpointModulated or DeadbandSetpointOnOff then there must be a setpoint manager that places both a high and low setpoint on the node named in this field. (see [SetpointManager:Scheduled:DualSetpoint](#)).

#### 1.25.21.1.13 Field: Minimum Temperature Difference to Activate Heat Exchanger

This field specifies the value of a temperature tolerance used in control decisions, in deg. Celsius. Whenever the control logic needs to compare two temperatures, the value entered in this field is used as a threshold for comparisons.

#### 1.25.21.1.14 Field: Heat Transfer Metering End Use Type

This field specifies how the metering for heat transfer will be accounted with respect to end uses. Although the heat exchanger consumes no energy that needs to be metered, there are also meters for heat transfers that apply to the model. The nature of the end use may vary depending on the application that the heat exchanger is being used for. The available choices are FreeCooling, HeatRecovery, HeatRejection, HeatRecoveryForCooling, HeatRecoveryForHeating, and LoopToLoop.

#### 1.25.21.1.15 Field: Component Override Loop Supply Side Inlet Node Name

This field specifies the name of an inlet node for the remote component that will be integrated with this heat exchanger. This inlet should be on the supply side of a loop – typically chilled water inlet or return for a chiller. This field and the next two are only used for the control type called CoolingSetpointOnOffWithComponentOverride.

#### 1.25.21.1.16 Field: Component Override Loop Demand Side Inlet Node Name

This field specifies the name of an inlet node for the remote component that will be integrated with this heat exchanger. This inlet should be on the demand side of a loop – typically condenser water inlet or return for a water-cooled chiller. This field is only used for the control type called CoolingSetpointOnOffWithComponentOverride.

#### 1.25.21.1.17 Field: Component Override Cooling Control Temperature Mode

This field specifies which type of temperature is used to control a heat exchanger that uses the control type called CoolingSetpointOnOffWithComponentOverride. There are three options: Loop, WetBulbTemperature, and DryBulbTemperature. The option called “Loop” directs the program to use the inlet fluid temperature at the Loop Demand Side connection of heat exchanger for the temperature used as a signal to be compared with the setpoint. The option call “WetBulbTemperature” uses the outdoor air wetbulb temperature as the signal. The option called “DryBulbTemperature” uses the outdoor air drybulb temperature as the signal.

### 1.25.21.1.18 Field: Sizing Factor

This optional field can be used to modify the results of autosize calculations. This sizing factor is used for this heat exchanger and modifies sizing results by multiplying them by the factor entered here. This factor is applied to the Loop Supply Side Design Flow rate and in turn affects the heat exchanger UA and the loop demand side flow rate which are derived from that flow rate. This allows fine control over the size of the heat exchanger when using autosize in those fields.

### 1.25.21.1.19 Field: Operation Minimum Temperature Limit

This optional field can be used to provide supervisory control of the heat exchanger. If either of the inlet temperatures are below this limit (°C), the heat exchanger will not operate.

### 1.25.21.1.20 Field: Operation Maximum Temperature Limit

This optional field can be used to provide supervisory control of the heat exchanger. If either of the inlet temperatures are above this limit (°C), the heat exchanger will not operate.

Some example IDF input objects follow.

## 1.25.21.2 Outputs

### 1.25.21.2.1 Fluid Heat Exchanger Heat Transfer Rate [W]

### 1.25.21.2.2 Fluid Heat Exchanger Heat Transfer Energy [J]

These outputs are the rate and energy transferred from the Loop Supply Side to the Loop Demand Side. The sign convention is taken from cooling or heat rejection applications such that positive values indicate cooling of the Loop Supply Side.

**1.25.21.2.3 Fluid Heat Exchanger Loop Supply Side Mass Flow Rate [kg/s]**

This is the system mass flow of fluid through the heat exchanger side connected as the Loop Supply Side, in kg/s.

**1.25.21.2.4 Fluid Heat Exchanger Loop Supply Side Inlet Temperature [C]**

This is the temperature, in degrees Celsius, of the fluid entering the heat exchanger on the side connected as the Loop Supply Side.

**1.25.21.2.5 Fluid Heat Exchanger Loop Supply Side Outlet Temperature [C]**

This is the temperature, in degrees Celsius, of the fluid leaving the heat exchanger on the side connected as the Loop Supply Side.

**1.25.21.2.6 Fluid Heat Exchanger Loop Demand Side Mass Flow Rate [kg/s]**

This is the system mass flow of fluid through the heat exchanger side connected as the Loop Demand Side, in kg/s.

**1.25.21.2.7 Fluid Heat Exchanger Loop Demand Side Inlet Temperature [C]**

This is the temperature, in degrees Celsius, of the fluid entering the heat exchanger on the side connected as the Loop Demand Side.

**1.25.21.2.8 Fluid Heat Exchanger Loop Demand Side Outlet Temperature [C]**

This is the temperature, in degrees Celsius, of the fluid leaving the heat exchanger on the side connected as the Loop Demand Side.

**1.25.21.2.9 Fluid Heat Exchanger Operation Status [0 = off, 1 = on]**

This output is a numeric flag that indicates whether or not the heat exchanger was operating or not. If the value is 0, then the heat exchanger was not operating. If the value is 1, then the heat was operating.

**1.25.21.2.10 Fluid Heat Exchanger Effectiveness []**

This output is the calculated heat exchanger effectiveness (non-dimensional). It is an intermediate value in the NTU model calculations for heat flow rate. Values range between 0 and 1.0. A value of 1.0 indicates ideal heat transfer.

## 1.26 Group – Plant-Condenser Flow Control

The connector list described earlier determines how the branches of a particular loop will be hooked together. These connections can be classified either as a separation of a single stream into several outlet streams (splitter) or the merging of several streams into a single outlet stream (mixer). Due to the limitation per branch of a single splitter and a single mixer, the connector list can only have two pieces of equipment as a maximum. The names defined for either/both the splitter or/and the mixer refer then to “component” definitions as described below.

### 1.26.1 Connector:Splitter, Connector:Mixer

The format of both the **Connector:Splitter** and **Connector:Mixer** statements is similar. Both begin with an identifying name followed by the branch name of the “single side” of the component. In the case of the splitter, this is the inlet since the inlet stream is broken into several outlet streams. In the case of the

mixer, this is the outlet since several streams are mixed together to form a single outlet. The remaining list of up to 50 names is simply the branch names of the outlet legs in the case of the splitter and inlet legs in the case of the mixer. No control logic is assume in these components—a determination of how much air to split in which direction using the splitter must be defined by other components.

## 1.26.2 Connector:Splitter

### 1.26.2.1 Inputs

#### 1.26.2.1.1 Field: Name

This alpha field contains the identifying name for the Splitter.

#### 1.26.2.1.2 Field: Inlet Branch Name

This alpha field contains the identifying name for the Splitter Inlet Branch.

#### 1.26.2.1.3 Field: Outlet Branch <x> Name

This alpha field contains the identifying names for the Splitter Outlet Branches and you enter as many outlet branches as needed.

## 1.26.3 Connector:Mixer

### 1.26.3.1 Inputs

#### 1.26.3.1.1 Field: Name

This alpha field contains the identifying name for the Mixer.

#### 1.26.3.1.2 Field: Outlet Branch Name

This alpha field contains the identifying name for the Mixer Outlet Branch.

#### 1.26.3.1.3 Field: Inlet Branch <x> Name

This alpha field contains the identifying names for the Mixer Inlet Branches and you enter as many inlet branch names as needed..

An example of these statements in an IDF is:

```
Connector:Splitter,
    CW Loop Splitter,
    CW Pump Branch,
    Little Chiller Branch,
    Big Chiller Branch,
    Purchased Cooling Branch,
    Supply Bypass Branch;
Connector:Mixer,
    CW Loop Mixer,
    Cooling Supply Outlet,
    Little Chiller Branch,
    Big Chiller Branch,
    Purchased Cooling Branch,
    Supply Bypass Branch;
```

---

### 1.26.4 TemperingValve

This object is used for special cases where plant flow control is needed to make efficient use of thermal storage. In certain solar hot water and heat recovery situations, a thermal storage tank may become warmer than is necessary or allowable for safe use of the hot water. Although real installations of a tempering, or anti-scald valve, would more commonly mix a new stream of mains water with the hot water to achieve a desired outlet temperature, this is difficult to model directly within EnergyPlus because plant loops need to be closed circuits. For many installations where the water entering the splitter is directly from the mains, such as make up water entering a water heater tank, the modeling provided with this object should be thermodynamically equivalent.

The TemperingValve object models a temperature-controlled diversion valve. It models a valve on a bypass pipe that can open to divert flow around one or more plant components. It can only be used on one of two branches between a Splitter and a Mixer. The figure below shows the use of the tempering valve with a Water Heater:Mixed component on “Stream 2.” The tempering valve acts to divert flow through the branch it is on in order to adjust the temperature at the outlet of the mixer. If the temperature at Stream 2 Source Node is warmer than the setpoint and the inlet flow is cooler than the setpoint, then a controller determines how much flow should bypass the storage tank to achieve the desired setpoint.

Figure 1.107: Tempering Valve Schematic

The TemperingValve is an **Active** component and the other path should have only **Passive** components. Passive components are ones that can make a flow request but will passively accept whatever flow

is provided by the loop. Active components specifically set the flow. When using the `TemperingValve`, only two paths can be used in the splitter/mixer; bypasses are not allowed. No other `Connector:Splitter` and `Connector:Mixer` pair can be used on the supply side of the plant loop.

### 1.26.4.1 Inputs

#### 1.26.4.1.1 Field: Name

This field should contain an unique name for each `TemperingValve` object

#### 1.26.4.1.2 Field: Inlet Node Name

This field should contain the name of node which is the inlet for the valve.

#### 1.26.4.1.3 Field: Outlet Node Name

This field should contain the name of node which is the outlet for the valve

#### 1.26.4.1.4 Field: Stream 2 Source Node Name

This field should contain the name of node that is the inlet to the Mixer object for the second stream containing the component whose flow is being diverted.

#### 1.26.4.1.5 Field: Temperature Setpoint Node Name

This field should contain the name of a node that has a temperature setpoint assigned to it. A separate set point manager object is needed to provide a set point on the node listed here.

#### 1.26.4.1.6 Field: Pump Outlet Node Name

This field should contain the name of the node that is the outlet for the pump that is on the same plant loop. This node is used to sense the total flow rate.

This object is demonstrated in the example file called `SolarCollectorFlatPlateWater.idf`. An example of this object is:

```
TemperingValve,
    DHW Anti-Scald Diverter,
    DHW Anti-Scald Inlet Node, ! Inlet Node Name
    DHW Anti-Scald Outlet Node, ! Outlet Node Name
    SHW Storage Tank Use Outlet Node, ! Stream 2 Source Node Name
    DHW Instantaneous Boost Outlet Node, ! Temperature Setpoint Node Name
    DHW Use Side Pump Outlet; ! pump outlet node
```

### 1.26.4.2 Outputs

Use output variables for System Nodes for flow and temperature results.

## 1.27 Group – Air Distribution

### 1.27.1 AirLoopHVAC

Air loops along with zone equipment form the entire forced air heating and cooling system (air side). The main statement for defining an air loop is the *AirLoopHVAC* object described here. As with the main plant and condenser statements, several of the items in the `AirLoopHVAC` object definition are actually names that refer to other objects in the input file. After the `AirLoopHVAC` object name, four such list pointers are encountered: for controllers, system availability, branches, and connectors. The Controller List defines

how the air loop will respond due to various inputs (control signals). The Availability Manager List refers to methods for controlling when a system is operational. This may be as simple as a schedule to define when the system is shutdown. The Branch List lists the branches that comprise the primary air system. Finally, the Connector List lists the connections between the branches. The branches and connections together define the primary air system topology.

The only numeric input is the design primary air flow rate. This item is input just before the **BranchList** name.

The next series of names refer to nodes for the various inlet and outlet points of the air loop. The air loop starts where the zone equipment ends. This is a single point consisting of the return air duct once all of the zone return air streams have been collected (if the loop has a return path). While in reality, there is really only one point, for clarity within the simulation components and consistency with the other HVAC loop sections, this point in the systems is defined as two points: one that resides with the zone equipment simulation and one that is acted upon by the air loop simulation. Both node names must be entered into the input file (if the loop has a return path), and both nodes must have unique names. Similarly, the end points of the air loop that also correspond to the beginning points of the zone equipment loop must also be defined. These consist of names referencing lists of up to three pairs of node names as shown below. Up to three air loop outlets are allowed to accommodate the simulation of three deck systems.

**1.27.1.0.1 Schedules And Availability Manager** Regarding component schedules, the general rule is don't schedule any components except the supply fan and the corresponding availability manager(s). Beyond that, every component should always be available and let the controls determine what runs or doesn't run. If a component other than the supply fan is scheduled off, then it will remain off even if the night cycle manager turns on the system.

### 1.27.1.1 Inputs

#### 1.27.1.1.1 Field: Name

This field is a unique, user assigned name for a single instance of an AirLoopHVAC object. Any other object referencing this AirLoopHVAC will use this name.

#### 1.27.1.1.2 Field: Controller List Name

This field is the name of a ControllerList object. A Controller List is simply a list of controllers giving both controller name and type. This Controller List specifies all the controllers that will act on this primary air loop. The order of the controllers in the list is significant: controllers are simulated sequentially in the order given in the Controller List.

#### 1.27.1.1.3 Field: Availability Manager List Name

This field is the name of a AvailabilityManagerList object. An Availability Manager List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this primary air loop. That is, they determine when and if this air loop is on or off, overriding the control provided by the central fan on/off schedule.

#### 1.27.1.1.4 Field: Design Supply Air Flow Rate

This is the system primary air design volumetric flow rate in cubic meters per second.

#### 1.27.1.1.5 Field: Branch List Name

This field is the object name of a **BranchList** object (see **BranchList** and **Branch**). The **BranchList** named here specifies all the branches composing the primary air system. These branches, together with the Connectors listed in the **ConnectorList**, define the primary air system topology.

#### 1.27.1.1.6 Field: Connector List Name

This field is the name of `ConnectorList` object. This `ConnectorList` object lists all the Connectors (by type and name) that are included in this primary air system. These Connectors, together with the Branches in the `BranchList`, define the topology of the primary air system.

#### 1.27.1.1.7 Field: Supply Side Inlet Node Name

The name of the air entrance node of this primary air system. If this air loop has a return path, then this is the inlet node for return air for this air system. If this air loop does not have a return path, then this node is where outdoor air or other air enters the supply side.

#### 1.27.1.1.8 Field: Demand Side Outlet Node Name

The name of the air outlet node for the zone equipment group (`ZoneHVAC:EquipmentConnections` objects) attached to the primary air system. This should be the outlet node of a `AirLoopHVAC:ZoneMixer` or `AirLoopHVAC:ReturnPlenum` in the `AirLoopHVAC:ReturnPath` for the zone equipment group attached to this primary air system. Leave this field blank if this air loop does not have a return path.

#### 1.27.1.1.9 Field: Demand Side Inlet Node Names

This field can be the name of a node which is the air inlet node for the zone equipment group (see `ZoneHVAC:EquipmentConnections` objects) attached to this primary air system. Or, this field can be the name of a node list containing one or more nodes (up to 3). These nodes should be the inlet nodes to the `AirLoopHVAC:ZoneSplitter` or `AirLoopHVAC:SupplyPlenum` in each of the `AirLoopHVAC:SupplyPaths` for the zone equipment groups attached to this primary air system. For single duct systems, there is only one node name in this list. For two and three duct systems, the order of the nodes in this list must correspond with the order of the nodes in the Supply Side Outlet Node Names list.

#### 1.27.1.1.10 Field: Supply Side Outlet Node Names

This field can be the name of a node which is the air outlet node for each supply duct of this primary air system. Or, this field can be the name of a node list containing one or more nodes (up to 3). The list can contain the names of up to three nodes. For single duct systems, there is only one node name in this list. For two and three duct systems, the order of the nodes in this list must correspond with the order of the nodes in the Demand Side Inlet Node Names list.

#### 1.27.1.1.11 Field: Design Return Air Flow Fraction of Supply Air Flow

This field specifies the design air loop return air flow rate as a fraction of the supply flow rate when there is no exhaust flow. It may be used to set zero return air flow for a DOAS system or to model a pressurized system where the return flow is a fraction of the supply flow. The return air flow rate will never be greater than the current supply air flow rate multiplied by this fraction. It may be less if there is unbalanced exhaust from any zones served by this airloop. The default is 1.0. If the air loop has no return path, then this field is ignored.

An example of this statement in an IDF is:

```
AirLoopHVAC,
  Main Dual Duct Air Loop,          !- Name
  Dual Duct System 1 Controllers,    !- Controller List Name
  Dual Duct System 1 Schedule List , !- Availability Manager List Name
  1.3 ,                             !- Design Supply Air Flow Rate {m3/s}
  Dual Duct Air Loop Branches ,      !- Branch List Name
  Dual Duct Connectors ,            !- Connector List Name
  Supply Fan Inlet Node ,           !- Supply Side Inlet Node Name
  Return Air Mixer Outlet ,         !- Demand Side Outlet Node Name
  Zone Equipment Inlet Node List ,   !- Demand Side Inlet Node Names
```

Air Loop Outlet Node List, 1.0;	!- Supply Side Outlet Node Names !- Design Return Air Flow Fraction of Supply Air Flow

---

### 1.27.1.2 Outputs

- HVAC,Average,Air System Simulation Cycle On Off Status
- HVAC,Sum,HVAC System Solver Iteration Count []
- HVAC,Sum,Air System Solver Iteration Count []
- HVAC,Sum,Air System Simulation Maximum Iteration Count []
- HVAC,Sum,Air System Simulation Iteration Count []
- HVAC,Sum,Air System Component Model Simulation Calls []

#### 1.27.1.2.1 Air System Simulation Cycle On Off Status

This field is the availability status of an AirLoopHVAC. This status flag is a result of the calculations made by the System Availability Manager(s) listed in a System Availability Manager List. When a single availability manager is used in a System Availability Manager List, this is also the availability status reported by the specific availability manager (Ref. System Availability Manager Outputs). When multiple availability managers are used in a System Availability Manager List, the loop availability status is determined by the rules associated with AirLoopHVACs (see rules described for Group – System Availability Managers). The control status outputs are represented using integers 0 through 3.. These integers represent *NoAction* (0), *ForceOff* (1), *CycleOn* (2), and *CycleOnZoneFansOnly* (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

**1.27.1.2.2 HVAC System Solver Iteration Count []** This field reports the total number of HVAC System solver iterations in the current system time step or the maximum iterations possible for this solver if the simulation has not yet converged before it reached the maximum iterations.

**1.27.1.2.3 Air System Solver Iteration Count []** This field reports the total number of Air System solver iterations in the current system time step or the maximum iterations possible for this solver if the simulation has not yet converged before it reached the maximum iterations.

**1.27.1.2.4 Air System Simulation Maximum Iteration Count []** This field reports the maximum number of iterations possible for an Air System simulation.

**1.27.1.2.5 Air System Simulation Iteration Count []** This field reports the total number of Air System iterations in the current system time step or the maximum iterations possible for this solver if the simulation has not yet converged before it reached the maximum iterations.

#### 1.27.1.2.6 Air System Component Model Simulation Calls []

These variables are simply counters of how many iterations were executed. The count for any given HVAC time step will be the iterations executed before convergence was achieved, or the max allowed in which case the simulation throws a warning and proceeds to the next time step.

### 1.27.1.3 Outputs

This section provides more detailed information on the reporting available for outdoor air ventilation. Sixteen cooling and heating load variables and eight energy summary variables are available that report the impact of system outdoor air on zone loads, system demand and total energy use. The representative air system shown in the diagram below shows outdoor air (OA), return air (RA), supply air (SA) and mixed air (MA).

Figure 1.108: Example System for Ventilation Loads Report

The overall effect of outdoor air on the system shown above can be summarized by considering the mixing box. In this system, part or all of the return air is replaced by outdoor air. The presence of any heat recovery will already be taken into account and thus will automatically be accounted for by using the outdoor air inlet conditions to the mixing box (point OA in the diagram) rather than actual outdoor air conditions. Thus, the overall energy impact of outdoor air (ventilation) on a particular system can be evaluated by multiplying the outdoor air mass flow rate by the enthalpy difference between the outdoor air entering the mixing box (OA) and the return air entering the mixing box (RA') as shown in the following equation.

$$\dot{q}_{OA} = \dot{m}_{OA} (h_{OA} - h_{RA'}) = \dot{m}_{sys} (h_{MA} - h_{RA'}) \quad (1.101)$$

#### 1.27.1.3.1 Ventilation Flow Outputs

The fresh air flow into each zone are reported using the ventilation flow output variables. The total outdoor air flow in a primary air system is divided to each zone based on the fraction of flow each zone is supplied. There are six variables which deals with the mechanical ventilation flow reporting. Those six variables are:

##### 1.27.1.3.2 Zone Mechanical Ventilation Mass Flow Rate [kg/s]

Reports the average outdoor air mass flow rate to any zone over the reporting interval.

##### 1.27.1.3.3 Zone Mechanical Ventilation Mass [kg]

Reports the total outdoor air mass that has been supplied to any zone over the reporting interval.

##### 1.27.1.3.4 Zone Mechanical Ventilation Standard Density Volume Flow Rate [m3/s]

Reports the average outdoor air volume flow rate to any zone over the reporting interval, calculated using a standard density for air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

##### 1.27.1.3.5 Zone Mechanical Ventilation Standard Density Volume [m3]

Reports the total outdoor air volume that has been supplied to a zone over the reporting interval, calculated using a standard density for air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

##### 1.27.1.3.6 Zone Mechanical Ventilation Current Density Volume Flow Rate [m3/s]

Reports the average outdoor air volume flow rate to any zone over the reporting interval, calculated using the current density for zone air.

##### 1.27.1.3.7 Zone Mechanical Ventilation Current Density Volume [m3]

Reports the total outdoor air volume that has been supplied to a zone over the reporting interval, calculated using the current density for zone air.

##### 1.27.1.3.8 Zone Mechanical Ventilation Air Changes per Hour [ach]

Reports the air changes per hour in the zone due to the outside fresh air supplied by mechanical ventilation system.

**1.27.1.3.9 Zone Target Voz Ventilation Flow Rate [m3/s]** The target ventilation flow rate  $V_{oz-dyn}$  at standard density at the current timestep as defined by the zone Design Specification Outdoor Air Object ([DesignSpecification:OutdoorAir](#)).

**1.27.1.3.10 Zone Ventilation Below Target Voz Time [hr]** The time that the zone total ventilation rate (mechanical ventilation plus natural ventilation) is more than 1% below the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.11 Zone Ventilation At Target Voz Time [hr]** The time that the zone total ventilation rate (mechanical ventilation plus natural ventilation) is within 1% of the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.12 Zone Ventilation Above Target Voz Time [hr]** The time that the zone total ventilation rate (mechanical ventilation plus natural ventilation) is more than 1% above the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.13 Zone Ventilation When Unoccupied Time [hr]** The time that the zone total ventilation rate (mechanical ventilation plus natural ventilation) is greater than zero when the zone is unoccupied.

**1.27.1.3.14 Facility Any Zone Ventilation Below Target Voz Time [hr]** The time that any zone's total ventilation rate (mechanical ventilation plus natural ventilation) is more than 1% below the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.15 Facility All Zones Ventilation At Target Voz Time [hr]** The time that every zone's total ventilation rate (mechanical ventilation plus natural ventilation) is within 1% of the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.16 Facility Any Zone Ventilation Above Target Voz Time [hr]** The time that any zone's total ventilation rate (mechanical ventilation plus natural ventilation) is more than 1% above the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.17 Facility Any Zone Ventilation When Unoccupied Time [hr]** The time that any zone's total ventilation rate (mechanical ventilation plus natural ventilation) is greater than zero when the zone is unoccupied.

**1.27.1.3.18 Air System Mechanical Ventilation Flow Rate [m3/s]** The current airloop mechanical ventilation flow rate at standard density.

**1.27.1.3.19 Air System Natural Ventilation Flow Rate [m3/s]** The sum of the natural ventilation flow rate at standard density at the current timestep for each zone on the airloop. If any zone terminal unit has a Design Specification Air Terminal Sizing Object ([DesignSpecification:AirTerminal:Sizing](#)) then the natural ventilation rate for that zone is scaled by the Fraction of Minimum Outdoor Air Flow value.

**1.27.1.3.20 Air System Target Voz Ventilation Flow Rate [m3/s]** The sum of the target ventilation flow rates  $V_{oz-dyn}$  at standard density at the current timestep for each zone on the airloop. If any zone terminal unit has a Design Specification Air Terminal Sizing Object ([DesignSpecification:AirTerminal:Sizing](#)) then the target ventilation rate for that zone is scaled by the Fraction of Minimum Outdoor Air Flow value.

**1.27.1.3.21 Air System Ventilation Below Target Voz Time [hr]** The time that the airloop total ventilation rate (mechanical ventilation plus natural ventilation) is more than 1% below the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.22 Air System Ventilation At Target Voz Time [hr]** The time that the airloop total ventilation rate (mechanical ventilation plus natural ventilation) is within 1% of the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.23 Air System Ventilation Above Target Voz Time [hr]** The time that the airloop total ventilation rate (mechanical ventilation plus natural ventilation) is more than 1% above the *Zone Target Voz Ventilation Flow Rate*.

**1.27.1.3.24 Air System Ventilation When Unoccupied Time [hr]** The time that the air-loop total ventilation rate (mechanical ventilation plus natural ventilation) is greater than zero when all of the zones on the airloop are unoccupied.

The example syntax below shows the basic ventilation flow variables reported on an hourly basis.

- Output:Variable,\*,Zone Mechanical Ventilation Mass Flow Rate,Hourly;
- Output:Variable,\*,Zone Mechanical Ventilation Mass,Hourly;
- Output:Variable,\*,Zone Mechanical Ventilation Standard Density Volume Flow Rate,Hourly;
- Output:Variable,\*,Zone Mechanical Ventilation Standard Density Volume,Hourly;

- Output:Variable,\*, Air System Ventilation Above Target Voz Time,Hourly;
- Output:Variable,\*, Air System Ventilation When Unoccupied Time,Hourly;

### 1.27.1.3.25 Ventilation Load Reports

The impact of system outdoor air on a particular zone may be calculated by summing the mass flow weighted  $\dot{q}_{OA}$  over the supply air paths (both cooling and heating) serving the zone as follows:

$$\dot{q}_{OA,Zone\ 1} = \sum_{n=1}^{AirPathNum} \dot{q}_{OA} \frac{\dot{m}_n}{\dot{m}_{sys}} \quad (1.102)$$

Four output variables each for cooling and heating report the impact of the ventilation air on the zone load in the absence of ventilation air system interactions. The ventilation load output variables are:

### 1.27.1.3.26 Zone Mechanical Ventilation Cooling Load Increase Due to Overheating Energy [J]

### 1.27.1.3.27 Zone Mechanical Ventilation Heating Load Increase Due to Overcooling Energy [J]

The cooling/heating load that would occur once ventilation air met the zone cooling/heating load and continued to overcool/overheat the zone. No system effects are accounted for.

### 1.27.1.3.28 Zone Mechanical Ventilation Cooling Load Decrease Energy [J]

### 1.27.1.3.29 Zone Mechanical Ventilation Heating Load Decrease[J]

The decrease in zone cooling/heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

### 1.27.1.3.30 Zone Mechanical Ventilation No Load Heat Removal Energy [J]

### 1.27.1.3.31 Zone Mechanical Ventilation No Load Heat Addition Energy [J]

The addition or removal of heat to a zone with no load. The heat addition or removal is due to mechanical ventilation while the zone thermostat is in the deadband.

To summarize:

#### Cooling:

#### 1. Zone Mechanical Ventilation No Load Heat Removal Energy [J]

Cooling that would be provided directly to zone by ventilation air. Ventilation occurred with no zone load.

#### 2. Zone Mechanical Ventilation Cooling Load Increase Energy [J]

The increase in zone cooling load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

#### 3. Zone Mechanical Ventilation Cooling Load Increase Due to Overheating Energy [J]

The cooling load that would occur once ventilation air met the zone heating load and continued to overheat the zone. No system effects are accounted for.

#### 4. Zone Mechanical Ventilation Cooling Load Decrease Energy [J]

The decrease in zone cooling load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

#### Heating:

#### 1. Zone Mechanical Ventilation No Load Heat Addition Energy [J]

Heating that would be provided directly to zone by ventilation air. Ventilation occurred with no zone load.

#### 2. Zone Mechanical Ventilation Heating Load Increase Energy [J]

The increase in zone heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

**3. Zone Mechanical Ventilation Heating Load Increase Due to Overcooling Energy [J]**

The heating load that would occur once ventilation air met the zone cooling load and continued to overcool the zone. No system effects are accounted for.

**4. Zone Mechanical Ventilation Heating Load Decrease Energy [J]**

The decrease in zone heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

The output variables are calculated by comparing the zone ventilation load with the zone cooling or heating load. ‘Ventilation cooling’ decreases the zone cooling load until the cooling load has been eliminated. The remaining ‘ventilation cooling’ is reported as ‘overcooling’. ‘Overheating’ is calculated in the same manner. The actual system operation, which determines whether or not an ‘overcooling’ or ‘overheating’ load actually results in increased energy consumption, is not considered in the calculation of these output variables.

The ventilation zone load output variables are shown in Table 1.45. The variables report the maximum potential “cost” or “benefit” of ventilation air introduced directly into the zone.

Table 1.45: Ventilation Load Output Variables

	No Zone Load	Zone Cooling Load	Zone Heating Load
Ventilation Cooling	Zone Mechanical Ventilation No Load Heat Removal Energy	Zone Mechanical Ventilation Cooling Load Decrease Energy	Zone Mechanical Ventilation Heating Load Increase Energy
Zone Mechanical Ventilation Heating Load Increase Due to Overcooling Energy			
Ventilation Heating	Zone Mechanical Ventilation No Load Heat Addition Energy	Zone Mechanical Ventilation Cooling Load Increase Energy	Zone Mechanical Ventilation Heating Load Decrease Energy
Zone Mechanical Ventilation Cooling Load Increase Due to Overheating Energy			

The example syntax below shows the basic ventilation load variables reported on a monthly basis.

- Output:Variable,\*,Zone Mechanical Ventilation Heating Load Increase Energy,monthly;
- Output:Variable,\*,Zone Mechanical Ventilation Heating Load Decrease Energy,monthly;
- Output:Variable,\*,Zone Mechanical Ventilation No Load Heat Addition Energy,monthly;
- Output:Variable,\*,Zone Mechanical Ventilation Cooling Load Increase Energy,monthly;
- Output:Variable,\*,Zone Mechanical Ventilation Cooling Load Decrease Energy,monthly;
- Output:Variable,\*,Zone Mechanical Ventilation No Load Heat Removal Energy,monthly;

Reporting on a timestep or hourly level would produce a detailed report with variables intermingled with the other output variables that might be requested in the input file.

Another method will more easily encapsulate the report:

```
OutputControl:Table:Style, HTML;      !- ColumnSeparator

Output:Table:Monthly,
  Ventilation Loads,      !- Name
  ,                      !- DigitsAfterDecimal
Zone Mechanical Ventilation No Load Heat Removal Energy,
  SumOrAverage,
Zone Mechanical Ventilation Cooling Load Increase Due to Overheating Energy,
  SumOrAverage,
Zone Mechanical Ventilation Cooling Load Decrease Energy,
  SumOrAverage,
Zone Mechanical Ventilation Cooling Load Increase Energy,
  SumOrAverage,
Zone Mechanical Ventilation No Load Heat Addition Energy,
  SumOrAverage,
Zone Mechanical Ventilation Heating Load Increase Due to Overcooling Energy,
  SumOrAverage,
Zone Mechanical Ventilation Heating Load Decrease Energy,
  SumOrAverage,
Zone Mechanical Ventilation Heating Load Increase Energy,
  SumOrAverage;
```

This combination will report the ventilation loads on a monthly basis in a HTML style report that can be easily read in a web browser. Review the `Output:Table:Monthly` object for other methods of display or further options on this report item.

## 1.27.2 Systems Level Reporting

Most output variables are a single entity reporting. Meters are a combination of like variables – specifically for Energy Consumption. This section introduces a slightly different concept – where output variables described herein are a combination of several similar items – specifically targeted at HVAC/System level reporting. This reporting is coupled with an Air Loop (ref: [AirLoopHVAC](#))

All items shown in this section are typical “output variables” and can be reported with the `Output:Variable` object.

Or, as is shown by example here, perhaps a more readable form is to generate them in Tabular Form with the “`Output:Table:Monthly`” object.

## 1.27.3 System Loads Outputs

In this category, the total system load is reported. Two aspects are reported here: Heating and Cooling. The following two variables report the heat energy that system components (including packaged equipment, fans, main coils, reheat coils, humidifiers, desiccant dehumidifiers, evaporative coolers and heat exchangers) add or remove from the air loop. Each variable within these grouping wil

### 1.27.3.1 Air System Total Heating Energy

Heat Addition to the Air Loop (Sum of all components) in Joules

### 1.27.3.2 Air System Total Cooling Energy

Heat Removal from the Air Loop (Sum of all components) in Joules

In ‘`Output:Table:Monthly`’ format shown below.

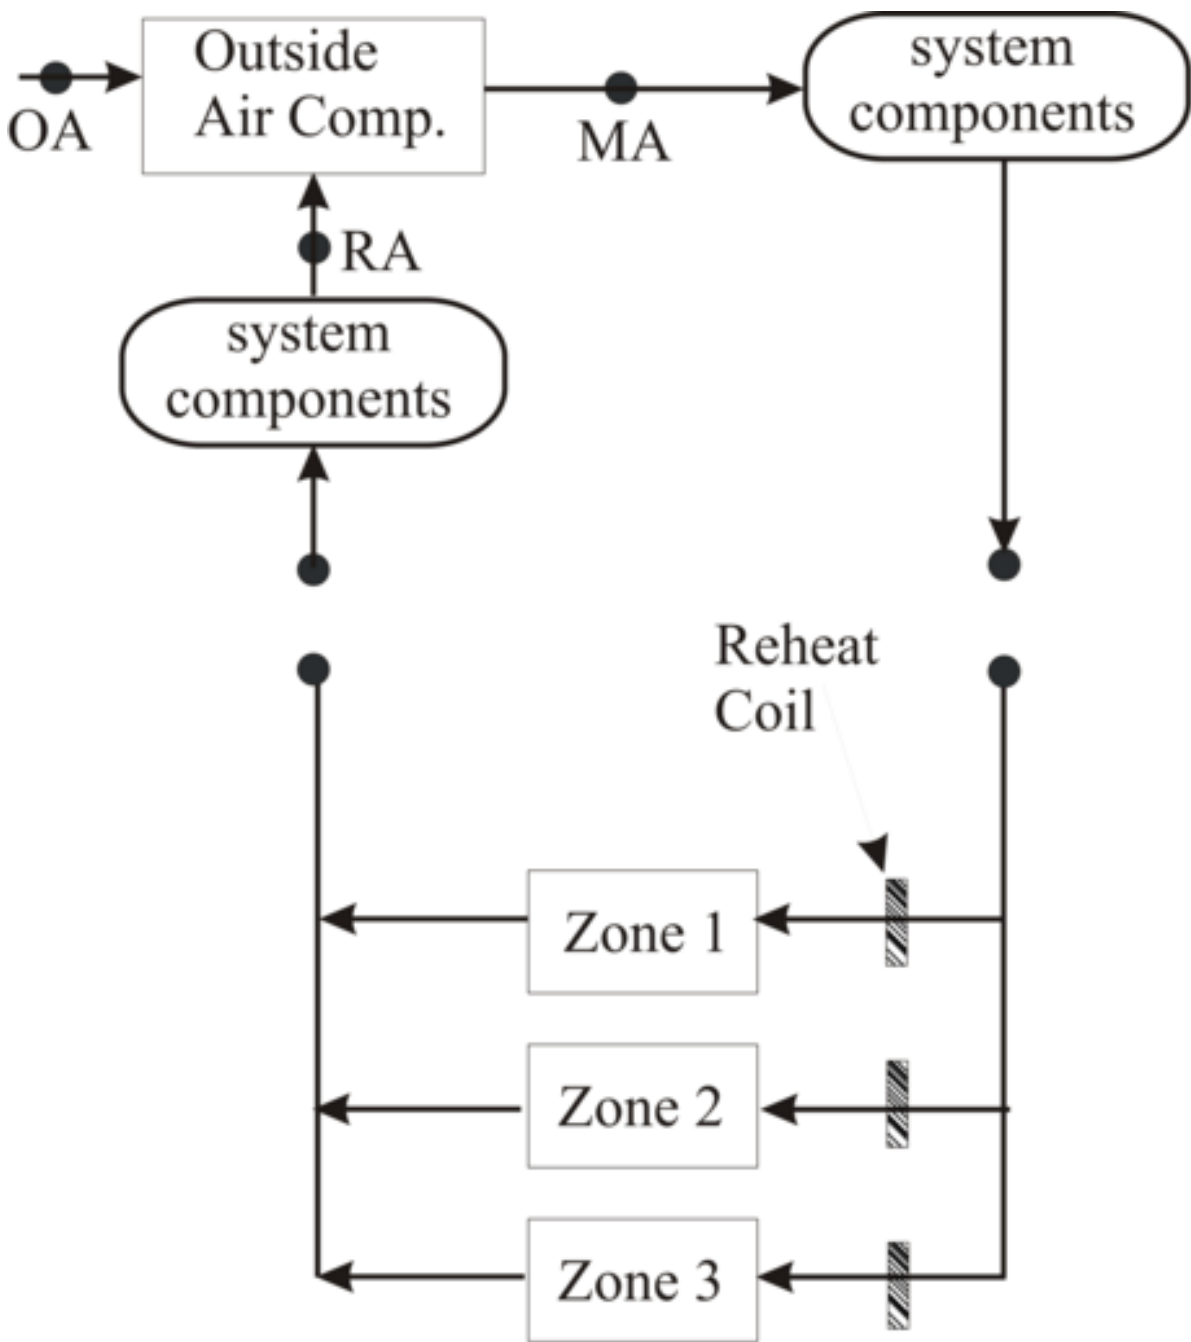

Figure 1.109: View of System Level Reporting

```

OutputControl:Table:Style,HTML;

Output:Table:Monthly,
  System Loads,          !- Name
                        !- DigitsAfterDecimal
  Air System Total Heating Energy, SumOrAverage,
  Air System Total Cooling Energy, SumOrAverage;

```

---

### 1.27.4 System Energy Use Outputs

System Energy Use consists of six output variables that report the total energy (in Joules) and water consumption (in m<sup>3</sup>) for all system components and including packaged equipment, fans, main coils, reheat coils, humidifiers, desiccant dehumidifiers, and evaporative coolers. The output variables shown below show hot and cold water, steam, electric and gas energy. Hot and cold water energy includes all ‘district cooling’ and ‘district heating’ energy.

#### 1.27.4.1 Air System Hot Water Energy

Hot Water Consumption for the system (Joules).

#### 1.27.4.2 Air System Steam Energy

Steam Consumption for the system (Joules).

#### 1.27.4.3 Air System Chilled Water Energy

Chilled Water Consumption for the system (Joules).

#### 1.27.4.4 Air System Electricity Energy

Electric Consumption for the system (Joules).

#### 1.27.4.5 Air System NaturalGas Energy

Natural Gas Consumption for the system (Joules).

#### 1.27.4.6 Air System Propane Energy

Propane Consumption for the system (Joules).

#### 1.27.4.7 Air System Water Volume

Water Consumption for the system (humidifiers and evaporative coolers) (m<sup>3</sup>).

The Standard reports file includes these variables reporting in the Tabular report form as “Air Loop System Energy and Water Use”.

```

OutputControl:Table:Style,HTML;

Output:Table:Monthly,
  Air Loop System Energy and Water Use,          !- Name
                        !- DigitsAfterDecimal
  Air System Hot Water Energy , SumOrAverage,
  Air System Steam Energy , SumOrAverage,
  Air System Chilled Water Energy, SumOrAverage,

```

```
Air System Electricity Energy, SumOrAverage,
Air System NaturalGas Energy, SumOrAverage,
Air System Water Volume, SumOrAverage;
```

---

### 1.27.5 System Component Loads Outputs

Reporting System Component Loads shows the energy transferred to or extracted from the air loop by system component type. Fans, Cooling Coils, Heating Coils, Heat exchangers, humidifiers, evaporative coolers, and desiccant dehumidifiers show heat transfer rates in Joules. The components may be located in outdoor air systems bundled with packaged equipment or specified as stand-alone components. The reporting accounts for both main branch and reheat coils.

The Standard reports file includes these variables reporting in the Tabular report form as “Air Loop System Component Loads”.

---

#### 1.27.5.1 Air System Fan Air Heating Energy

Energy added to the air loop by Fans (Joules)

#### 1.27.5.2 Air System Cooling Coil Total Cooling Energy

Energy removed from air loop by Cooling Coils (Joules)

#### 1.27.5.3 Air System Heating Coil Total Heating Energy

Energy added to air loop by Heating Coils (Joules)

#### 1.27.5.4 Air System Heat Exchanger Total Heating Energy

Energy added to air loop by air-to-air heat recovery heat exchangers (Joules)

#### 1.27.5.5 Air System Heat Exchanger Total Cooling Energy

Energy removed from air loop by air-to-air heat recovery heat exchangers (Joules)

#### 1.27.5.6 Air System Humidifier Total Heating Energy

Energy added to air loop by humidifiers (Joules)

**1.27.5.7 Air System Evaporative Cooler Total Cooling Energy**

Energy removed from air loop by evaporative coolers (Joules)

**1.27.5.8 Air System Desiccant Dehumidifier Total Cooling Energy**

Energy removed from air loop by desiccant dehumidifiers (Joules)

**1.27.5.9 Air System Solar Collector Total Heating Energy**

Energy added to air loop by solar collectors (Joules)

**1.27.5.10 Air System Solar Collector Total Cooling Energy**

Energy removed from air loop by solar collectors (Joules)

**1.27.5.11 Air System User Defined Air Terminal Total Heating Energy**

Energy added to air loop by user defined air terminal units (Joules)

**1.27.5.12 Air System User Defined Air Terminal Total Cooling Energy**

Energy removed from air loop by user defined air terminal units (Joules)

**1.27.6 System Component Energy Use Outputs**

Reporting System Component Energy Use consists of eleven output variables that report the total energy consumption (in Joules) of system components by energy type and coil type. Electric energy consumption is reported for fans, heating and cooling coils in packaged (DX) systems, electric resistance heating coils, humidifiers, evaporative coolers and desiccant dehumidifiers.

**1.27.6.1 Air System Fan Electricity Energy**

Electric consumption for fans. (Joules)

**1.27.6.2 Air System Heating Coil Hot Water Energy**

Consumption for heating coil hot water (both purchased and plant supplied) (Joules)

**1.27.6.3 Air System Cooling Coil Chilled Water Energy**

Consumption for cooling coil chilled water (both purchased and plant supplied) (Joules)

**1.27.6.4 Air System DX Heating Coil Electricity Energy**

Compressor plus condenser fan electricity use. (Joules)

**1.27.6.5 Air System DX Cooling Coil Electricity Energy**

Compressor plus condenser fan electricity use. (Joules)

**1.27.6.6 Air System Heating Coil Electricity Energy**

Electricity consumption for the heating coil. (Joules)

**1.27.6.7 Air System Heating Coil NaturalGas Energy**

Natural Gas consumption for the heating coil. (Joules)

**1.27.6.8 Air System Heating Coil Propane Energy**

Propane consumption for the heating coil. (Joules)

**1.27.6.9 Air System Heating Coil Steam Energy**

Steam consumption for the heating coil (steam coils). (Joules)

**1.27.6.10 Air System Humidifier Electricity Energy**

Electricity consumption for the humidifiers. (Joules)

**1.27.6.11 Air System Evaporative Cooler Electricity Energy**

Electricity consumption for the evaporative coolers. (Joules)

**1.27.6.12 Air System Desiccant Dehumidifier Electricity Energy**

Electricity consumption for the desiccant dehumidifiers. (Joules)

The Standard reports file includes these variables reporting in the Tabular report form as “Air Loop System Component Energy Use”.

**1.27.7 Overall Air Loop Syntax**

A map for Air Loop input syntax is shown in the following diagram.

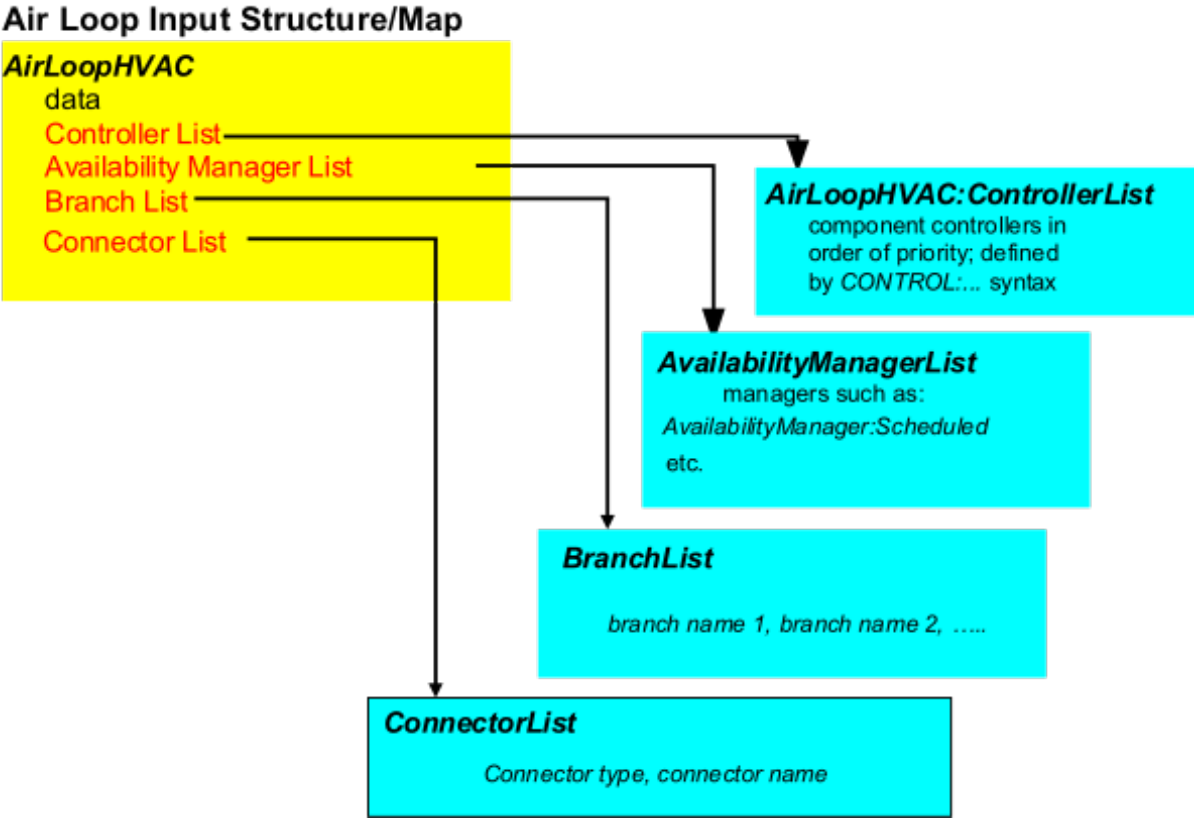

Figure 1.110: Air Loop Input Syntax Map

### 1.27.8 AirLoopHVAC:ControllerList

The syntax for the AirLoopHVAC:ControllerList definition is shown below. As with other lists in Energy-Plus input, the object title and identifying name are followed by type-name pairs. In this case, the types are controller types. The order in which controllers appear on this list also define the priority as described below. The identifying name refers back to the name recorded in the **AirLoopHVAC** statement.

#### 1.27.8.1 Inputs

##### 1.27.8.1.1 Field: Name

The user designated unique name of an instance of a Controller List. Any object referencing this Controller List will do so using this name.

##### 1.27.8.1.2 Field Set (Object Type, Controller Name) up to 8

After the identifying name, input for the controller list consists of up to 8 pairs of data items: a controller type and a controller name. The first controller listed has the highest priority, the second the second highest priority, and so forth.

##### 1.27.8.1.3 Field: Controller <x> Object Type

The type of controller. This should be a key word defining a class of controllers such as **Controller:WaterCoil**.

##### 1.27.8.1.4 Field: Controller <x> Name

The name of a controller object (such as a **Controller:WaterCoil**) defined elsewhere in the input file. An example of this statement in an IDF is:

```
AirLoopHVAC:ControllerList,
    Dual Duct System 1 Controllers,
    Controller:WaterCoil, Main Cooling Coil Controller,
    Controller:WaterCoil, Main Heating Coil Controller;
```

### 1.27.9 AvailabilityManagerAssignmentList

The AvailabilityManagerAssignmentList defines the applicable managers used for an **AirLoopHVAC** or **PlantLoop**. The priority of availability managers is based on a set of rules and are specific to the type of loop. The output from each Availability Manager is an availability status flag. This flag can have the values *NoAction*, *ForceOff*, *CycleOn*, or *CycleOnZoneFansOnly* (used only for air loops). The availability status flags for the Availability Managers referenced by an air or plant loop are used to set the availability status flag for each loop. For the air loops, *ForceOff* takes precedence: if any of the loop's availability managers are showing status *ForceOff*, the loop status will be *ForceOff*. Next in precedence is *CycleOnZoneFansOnly*, followed by *CycleOn*, and *NoAction*. For the plant loops, there is no precedence among the Availability Manager status flag values. Instead, the first availability manager giving a status flag value other than *NoAction* sets the status for the loop. The Availability Managers are executed in Availability Manager List order.

Special rules also apply for which managers may be listed in an Availability Manager list. The Hybrid Ventilation Control Manager (object: **AvailabilityManager:HybridVentilation**) is a special type of manager and is never specified in an Availability Manager List (it is used stand-alone for a specific air loop). All other types of availability managers may be listed in the Availability Manager List used for **AirLoopHVACs**. For Plant Loops, the Night Cycle and Night Ventilation managers (objects: **AvailabilityManager:NightCycle** and **AvailabilityManager:NightVentilation**) are not allowed in the Availability Manager List.

### 1.27.9.1 Inputs

#### 1.27.9.1.1 Field: Name

The name of the `AvailabilityManagerAssignmentList` object. This is referenced by `AirLoopHVAC` and `PlantLoop` objects.

#### 1.27.9.1.2 Field Set (Availability Manager Object Type, Name)

Managers are listed by pairs of data items: *Availability Manager Object Type* and *Availability Manager Name*. The managers are simulated down the list and calculate a control status for use by the `AirLoopHVAC` or `PlantLoop`. The priority of each manager used for a specific loop is based on the rules described above. Availability managers are not currently used for condenser loops. The availability managers, along with the `AirLoopHVAC` and `PlantLoop` object, report the control status calculated each simulation timestep. These output variables can be used to prioritize the managers according to the required control strategy. Six managers are accommodated in the list by default, however, this IDD specification is extensible. Additional pairs may be added by directly editing the IDD.

#### 1.27.9.1.3 Field: Availability Manager <x> Object Type

The key word defining the type of manager, e.g. `AvailabilityManager:NightCycle`.

#### 1.27.9.1.4 Field: Availability Manager<x> Name

The name of a `AvailabilityManager` object defined elsewhere in the input file.

An example of this statement in an IDF is:

```
AvailabilityManagerAssignmentList,
Collector Loop Availability Manager List,  !- Name
AvailabilityManager:HighTemperatureTurnOff,  !- System Availability Manager Type 1
High Temperature Turn Off Availability Manager,  !- System Availability Manager Name 1
AvailabilityManager:LowTemperatureTurnOn ,  !- System Availability Manager Type 2
Low Temperature Turn On Availability Manager,  !- System Availability Manager Name 2
AvailabilityManager:DifferentialThermostat,  !- System Availability Manager Type 3
Differential Thermostat Availability Manager;  !- System Availability Manager Name 3
```

## 1.27.10 AirLoopHVAC:OutdoorAirSystem

The Outside Air System (object `AirLoopHVAC:OutdoorAirSystem`) is a subsystem of an `AirLoopHVAC`. It handles the mixed air portion of the primary air system: the system relief air, the outside air inlet, and any components and controllers associated with the system relief air and outside air streams. From the perspective of the primary air loop the Outside Air System is treated as a single component. As a subsystem, it can contain one or more components and controllers.

The input for the Outside Air System consists of a system name, a controller list name, an equipment list name, and an availability manager list name. The controller list simply lists, by type and unique name, all the controllers in the subsystem. The controllers will be simulated in list order. The equipment list lists all the components in the subsystem, by type and name. The equipment is simulated in list order. Finally, the availability manager list gives the type and name of the availability managers used by the subsystem.

The equipment inlet/outlet must be sequential with no loops - the simulation can only handle a straight-through air path, both on the primary air side and on the secondary air side, if any. Heat exchanger secondary air inlets need to be independent of the primary air stream – usually relief air is used.

The Outside Air System (object `AirLoopHVAC:OutdoorAirSystem`) can also be defined as a subsystem of an `AirLoopHVAC:DedicatedOutdoorAirSystem`. When this subsystem is referred in `AirLoopHVAC:DedicatedOutdoorAirSystem`, the `Controller:OutdoorAir` can not be listed in the `AirLoopHVAC:ControllerList`, because the outdoor air flow rate will not be determined by `Controller:OutdoorAir`.

Instead, the outdoor air flow rate will be specified by `AirLoopHVAC:DedicatedOutdoorAirSystem`. In addition, the `OutdoorAir:Mixer` will not be allowed in the `AirLoopHVAC:OutdoorAirSystem:EquipmentList` as a component, because no mix is needed due to 100% outdoor incoming airflow determined by `AirLoopHVAC:DedicatedOutdoorAirSystem`.

### 1.27.10.1 Inputs

#### 1.27.10.1.1 Field: Name

The unique, user assigned name for a single instance of an Outside Air System. Any other object referencing this Outside Air System will use this name.

#### 1.27.10.1.2 Field: Name: Controller List Name

This field is the name of a `AirLoopHVAC:ControllerList` object. A `AirLoopHVAC:ControllerList` is simply a list of controllers giving both controller name and type. This Controller List specifies all the controllers that will act on this outside air system. The order of the controllers in the list is significant: controllers are simulated sequentially in the order given in the Controller List. Typically the Controller List would contain a `Controller:OutdoorAir`. If there are chilled water or hot water coils in the outdoor air system, each such coil will need a `Controller:WaterCoil`.

When this object is referred in `AirLoopHVAC:DedicatedOutdoorAirSystem`, the `Controller:OutdoorAir` will not be allowed in the list, because `AirLoopHVAC:DedicatedOutdoorAirSystem` does not need `Controller:OutdoorAir` to determine the amount of outdoor air flow rate.

#### 1.27.10.1.3 Field: Outdoor Air Equipment List Name

This field is the name of an `AirLoopHVAC:OutdoorAirSystem:EquipmentList` object. An `AirLoopHVAC:OutdoorAirSystem:EquipmentList` is simply a list of components giving both component name and type. This Outdoor Air Equipment List specifies all the components that will be simulated in this outside air system. The order of the components in the list is significant: components are simulated sequentially in the order given in the Outdoor Air Equipment List. Typically the equipment list would contain at least an `OutdoorAir:Mixer`. If there is more than one component, the components must be listed in order from the outside air to the `OutdoorAir:Mixer` (the `OutdoorAir:Mixer` is last).

When this object is referred in `AirLoopHVAC:DedicatedOutdoorAirSystem`, the `OutdoorAir:Mixer` will not be allowed as a component, because all the incoming airflow is from outdoor, and no mixing is needed.

#### 1.27.10.1.4 Field: Availability Manager List Name

This field is the name of a `AvailabilityManagerAssignmentList` object. An Availability Manager List is a list of Availability Managers giving both Availability Manager Object Type and Name. **Use of this input is optional.** This field may be omitted; it is not currently used by the program.

An IDF example, including the `AirLoopHVAC`, and the controller and equipment lists.

```
AirLoopHVAC,Typical Terminal Reheat 1,
    Reheat System 1 Controllers,
    Reheat System 1 Avail List,
    1.3,
    Air Loop Branches,
    Air Loop Inlet Node, Return Air Mixer Outlet,

```

---

### 1.27.10.2 Outputs

The impact of using outside air/mechanical ventilation is described in the section: Outdoor Air Ventilation Outputs.

## 1.27.11 AirLoopHVAC:OutdoorAirSystem:EquipmentList

Used to specify the components in the outdoor air system. The components will be simulated in the order in which they occur in the list.

The following HVAC equipment types are allowed as outdoor air system equipment. The component matrix (Figure 1.111) shows which coils and fans are allowed with which equipment models.

### 1.27.11.1 Inputs

#### 1.27.11.1.1 Field: Name

The user designated unique name of an instance of an Air Loop Equipment List. Any object referencing this Air Loop Equipment List will do so using this name.

#### 1.27.11.1.2 Field Set (Component Object Type,, Component Name) up to 8

After the identifying name, the list consists of up to 8 pairs of data items:

#### 1.27.11.1.3 Field: Component <x> Object Type

This field specifies the keyword for the type of component used.

#### 1.27.11.1.4 Field: Component <x> Name

This field is the unique name of the component specified in the previous field. This named object must appear in the IDF.

  OA Sys 1 Equipment,
  HeatExchanger:AirToAir:FlatPlate,OA Heat Recovery 1,
  OutdoorAir:Mixer, OA Mixing Box 1;
```

### 1.27.12 OutdoorAir:Node

The `OutdoorAir:Node` object declares an HVAC system node for outdoor air conditions. The program automatically sets the air conditions at these nodes to correspond to the ambient environmental conditions at the beginning of every timestep. The outdoor air node is typically used as the inlet air node to an HVAC component such as the `OutdoorAir:Mixer` object. Multiple `OutdoorAir:Node` objects can be used in an input file, however, duplicate node names are not allowed.

The *Height Above Ground* field is used to adjust the weather file air conditions, e.g., outdoor dry-bulb and wet-bulb air temperatures, for atmospheric variation with height. This variation can become a significant factor when modeling tall buildings. See the Engineering Reference section on Atmospheric Variation for a description of the algorithm for variation of atmospheric properties with height. A blank entry or a value less than zero for this field indicates that the height will be ignored and the weather file conditions will be used.

`OutdoorAir:Node` and `OutdoorAir:NodeList` both set a node to outdoor air conditions. `OutdoorAir:Node` modifies the weather file conditions if a height has been specified. `OutdoorAir:NodeList` does not have a height input and always uses the weather file conditions without modification. The same node name may not be used with both of these objects.

When declared in surface property objects `SurfaceProperty:LocalEnvironment`, in zone property objects `ZoneProperty:LocalEnvironment`, or as an external node in the airflow network calculation linking to a surface node `AirflowNetwork:Multizone:Surface`, the object can also be used to define

local outdoor air conditions for surfaces, zones or air loop components. The local outdoor air conditions would be used in the EnergyPlus calculations for:

1. Convection coefficients used in the exterior surface heat balance

If the user declares a local surface outdoor air node to overwrite the surface level environmental data, the convection coefficients would be calculated based on the local outdoor air node data accordingly based on surface level outdoor dry-bulb temperature, humidity ratio and wind speed.

2. Zone air infiltration and simple ventilation

If the user declares a local zone outdoor air node to overwrite zone level environmental data, global environmental variables used in the subroutines for infiltration and ventilation calculation, including outdoor air temperature, humidity ratio, enthalpy, wind speed and direction, would be overwritten accordingly with zone level data.

3. External air nodes used in the AirFlowNetwork

When used in the airflow network for wind pressure calculation, global environmental variables used in the subroutines for wind pressure calculation, including outdoor air temperature, humidity ratio, air density, wind speed and direction, would be overwritten accordingly with local data.

When used in these cases, optional schedule inputs of local ambient air conditions, including dry-bulb temperature, wet-bulb temperature, wind velocity, and wind direction, can be defined in the optional fields. When used in the airflow network for wind pressure calculation, the wind pressure coefficient curve name and calculation details should also be defined.

### **1.27.12.1 Inputs**

#### **1.27.12.1.1 Field: Name**

The unique name for this outdoor air node.

#### **1.27.12.1.2 Field: Height Above Ground**

The height [m] of the node above ground level. A value greater than zero allows the weather file conditions, e.g., outdoor dry-bulb and wet-bulb air temperatures, to be adjusted according to atmospheric variation with height.

A blank entry or value less than zero indicates that the height will be ignored and the weather file conditions will be used.

#### **1.27.12.1.3 Field: Drybulb Temperature Schedule Name**

This field is used to supply a schedule name of the local dry bulb temperature of this node. When the field is left blank, global values would be used in calculation.

#### **1.27.12.1.4 Field: Wetbulb Temperature Schedule Name**

This field is used to supply a schedule name of the local wet bulb temperature of this node. When the field is left blank, global values would be used in calculation.

#### **1.27.12.1.5 Field: Wind Speed Schedule Name**

This field is used to supply a schedule name of the local wind speed of this node. When the field is left blank, global values would be used in calculation.

**1.27.12.1.6 Field: Wind Direction Schedule Name**

This field is used to supply a schedule name of the local wind direction of this node. When the field is left blank, global values would be used in calculation.

**1.27.12.1.7 Field: Wind Pressure Coefficient Curve Name**

The name of a specific **AirflowNetwork:MultiZone:WindPressureCoefficientValues** object (which gives wind pressure coefficients for the façade as a function of angle of wind incident on the façade).

**1.27.12.1.8 Field: Symmetric Wind Pressure Coefficient Curve**

This field is used to specify whether the pressure curve is symmetric or not. **Yes** for curves that should be evaluated from 0 to 180 degrees. **No** for curves that should be evaluated from 0 to 360 degrees.

**1.27.12.1.9 Field: Wind Angle Type**

This field is used to specify whether the angle used to compute the wind pressure coefficient is absolute or relative. **Relative** for computing the angle between the wind direction and the surface azimuth. **Absolute** for using the wind direction angle directly.

An example IDF:

```
OutdoorAir:Node,
  OA Node 1;  !- Name

OutdoorAir:Node,
  Floor 10 Outdoor air Inlet Node,  !- Name
  30.0;  !- Height Above Ground {m}

OutdoorAir:Node,
  LocalOutdoorAirNode:0001,      !- Name
  ,                               !- Height Above Ground
  OutdoorAirNodeDryBulb:0001,    !- Drybulb Temperature Schedule Name
  OutdoorAirNodeWetBulb:0001,    !- Wetbulb Temperature Schedule Name
  OutdoorAirNodeWindSpeed:0001,  !- Wind Speed Schedule Name
  OutdoorAirNodeWindDir:0001;    !- Wind Direction Schedule Name
  NFacade_WPCValue,             !- Wind Pressure Coefficient Curve Name
  No,                           !- Symmetric Wind Pressure Coefficient Curve
  Absolute;                     !- Wind Angle Type
```

**1.27.13 Outdoor Air Node outputs:**

The ambient dry-bulb, wet-bulb air temperature, wind speed and direction, and flow rate at the outdoor air node can be monitored using the system node output variables:

- HVAC,Average,System Node Temperature [C]
- HVAC,Average,System Node Wetbulb Temperature [C]
- HVAC,Average,System Node Wind Speed [m/s]
- HVAC,Average,System Node Wind Direction [degree]
- HVAC,Average,System Node Mass Flow Rate [kg/s]

e.g.

```
Output:Variable,
  Floor 10 Outdoor air Inlet Node,
  System Node Temperature,
  Hourly;
```

### 1.27.14 OutdoorAir:NodeList

The program needs to know which HVAC system nodes are inlets for outdoor air. Knowing this, the program can set the conditions at these nodes to the outdoor conditions at the start of each major timestep. The **OutdoorAir:NodeList** provides the means for specifying which nodes are outdoor air nodes.

The input is flexible: there may be one or more **OutdoorAir:NodeList** in each input file. Each list contains up to 25 names. The names can be the name of a unique HVAC system node, or the name of a Node List which will contain the actual node names. Duplicate node names are ignored.

**OutdoorAir:Node** and **OutdoorAir:NodeList** both set a node to outdoor air conditions. **OutdoorAir:Node** modifies the weather file conditions if a height has been specified. **OutdoorAir:NodeList** does not have a height input and always uses the weather file conditions without modification. The same node name may not be used with both of these objects.

#### 1.27.14.1 Inputs

##### 1.27.14.1.1 Field: Node or NodeList name

The name of an HVAC system node or of a **NodeList** object. There can be up to 25 names.

An example IDF:

```
OutdoorAir:NodeList,
    OutsideAirInletNodes;

NodeList,OutsideAirInletNodes,
    Outdoor air Inlet Node;
```

---

### 1.27.15 OutdoorAir:Mixer

The OutdoorAir:Mixer is the most common component used in an outdoor air system. The outdoor air mixer has 2 inlet air streams: the system return air and the outdoor air. It has 2 outlet air streams: the system relief air and the mixed air. This is a passive component. It takes the inlet mass flows and conditions plus the relief air mass flow and calculates the mixed air flow rate and conditions (as well as the relief air conditions). The inlet and relief mass flow must be set outside the component – most commonly by an outdoor air controller. The OutdoorAir:Mixer can also be used in compound components such as a fan coil unit.

Input for this object is very simple: a unique name plus the node names of the 2 inlet nodes and the 2 outlet nodes.

#### 1.27.15.1 Inputs

##### 1.27.15.1.1 Field: Name

A unique user assigned name for a particular outdoor air mixer component. Any reference to this component by another object will use this name.

##### 1.27.15.1.2 Field: Mixed Air Node Name

The name of the HVAC system node which is the outlet for the mixed air stream.

##### 1.27.15.1.3 Field: Outdoor Air Stream Node Name

The name of the HVAC system node which is the inlet for the outdoor air stream.

##### 1.27.15.1.4 Field: Relief Air Stream Node Name

The name of the HVAC system node which is the outlet for the system relief air.

### 1.27.15.1.5 Field: Return Air Stream Node Name

The name of the HVAC system node which is the inlet for the return air stream.

An IDF example:

```
OutdoorAir:Mixer,
  Zone1WindACOAMixer,          ! name
  Zone1WindACOAMixerOutletNode, ! mixer outlet node
  Zone1WindACOAMixerInNode,    ! mixer OA node
  Zone1WindACExhNode,          ! mixer relief node
  Zone1WindACAirInletNode;     ! mixer inlet node
```

---

## 1.28 Group – Airflow Network

### 1.28.1 Overview

The Airflow Network model provides the ability to simulate multizone airflows driven by wind and also by forced air distribution systems. The model can also simulate the heat and moisture gains or losses from the air distribution system itself (e.g., ductwork). When modeling air distribution systems, the current version of the Airflow Network model is allowed to simulate multiple forced air systems (i.e., **AirLoopHVAC** object). Each forced air system allows a constant volume supply air fan (**Fan:ConstantVolume** or **Fan:OnOff**), a VAV supply air fan (**Fan:VariableVolume**), or a fan system model (**Fan:SystemMode**). The capabilities of the model are to:

- Simulate zone pressures due to envelope leakage and forced air distribution during HVAC system fan operation
- Simulate node pressures in a forced air distribution system during HVAC system fan operation
- Calculate multizone airflows due to forced air, wind, and surface leakage, including adjacent zones and outdoors, during HVAC system fan operation
- Simulate distribution system airflows, including supply and return air leaks, during HVAC system fan operation
- Simulate air distribution system node temperatures and humidity ratios during HVAC system fan operation
- Calculate duct conduction losses during HVAC system fan operation
- Calculate vapor diffusion losses of ducts during HVAC system fan operation
- Calculate sensible and latent loads on the surrounding zones due to supply and return air leaks in the air distribution system during HVAC system fan operation
- Simulate zone pressures due to envelope leakage driven by wind when the HVAC system fan is off or if no air distribution system is specified
- Calculate multizone airflows due to wind and surface leakage, including adjacent zones and outdoors when the HVAC system fan is off or if no air distribution system is specified
- Allow zone exhaust fans to be included as part of the airflow network

- For airflow networks with a forced air distribution system, calculate zone sensible and latent loads for two different supply air fan operation modes as required: cycling fan, cycling compressor (CyclingFanAndCompressor) and continuous fan, cycling compressor (ContinuousFanWithCyclingCompressor)
- When multiple forced air systems (AirloopHVAC) are present in the idf, all systems must be used in the Airflow Network model.

### 1.28.2 Summary of Objects

Before describing the Airflow Network input objects in detail, we list all of the objects and then give a short description of what the objects do.

The Airflow Network input objects are:

**AirflowNetwork:SimulationControl**  
**AirflowNetwork:MultiZone:Zone**  
**AirflowNetwork:MultiZone:Surface**  
**AirflowNetwork:MultiZone:Component:SimpleOpening**  
**AirflowNetwork:MultiZone:Component:DetailedOpening**  
**AirflowNetwork:MultiZone:Component:HorizontalOpening**  
**AirflowNetwork:MultiZone:Surface:Crack**  
**AirflowNetwork:MultiZone:ReferenceCrackConditions**  
**AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea**  
**AirflowNetwork:MultiZone:Component:ZoneExhaustFan**  
**AirflowNetwork:MultiZone:ExternalNode**  
**AirflowNetwork:MultiZone:WindPressureCoefficientArray**  
**AirflowNetwork:MultiZone:WindPressureCoefficientValues**  
**AirflowNetwork:IntraZone:Node**  
**AirflowNetwork:IntraZone:Linkage**  
**AirflowNetwork:Distribution:Node**  
**AirflowNetwork:Distribution:Component:Leak**  
**AirflowNetwork:Distribution:Component:LeakageRatio**  
**AirflowNetwork:Distribution:Component:Duct**  
**AirflowNetwork:Distribution:Component:ConstantPressureDrop**  
**AirflowNetwork:Distribution:Component:Fan**  
**AirflowNetwork:Distribution:Component:Coil**  
**AirflowNetwork:Distribution:Component:HeatExchanger**  
**AirflowNetwork:Distribution:Component:TerminalUnit**  
**AirflowNetwork:Distribution:Component:OutdoorAirFlow**  
**AirflowNetwork:Distribution:Component:ReliefAirFlow**  
**AirflowNetwork:Distribution:Linkage**

- **AirflowNetwork:SimulationControl** defines basic run parameters for the air flow calculations and specifies whether wind pressure coefficients are input by the user or, for rectangular buildings, calculated by the program.
- The **AirflowNetwork:MultiZone:Zone** object specifies the ventilation control that applies to all of the openable exterior and interior windows and doors in the corresponding thermal zone. Surface-level ventilation control can be used to override the zone-level ventilation control if required (see AirflowNetwork: MultiZone:Surface object below).

- **AirflowNetwork:MultiZone:Surface** object indicates whether a heat transfer surface (wall, window, etc.) has a crack or opening and references an object in the list below that gives the air flow characteristics of that crack, opening, or zone exhaust fan. The **AirflowNetwork:MultiZone:Surface** object can also be used to specify individual ventilation control for openable exterior and interior windows and doors.
  - **AirflowNetwork:MultiZone:Surface:Crack**
  - **AirflowNetwork:Multi-Zone:Surface:EffectiveLeakageArea**
  - **AirflowNetwork:MultiZone:Component:SimpleOpening**
  - **AirflowNetwork:Multi-Zone:Component:DetailedOpening**
  - **AirflowNetwork:MultiZone:Component:HorizontalOpening**
  - **AirflowNetwork:Multi-Zone:Component:ZoneExhaustFan**
- **AirflowNetwork:MultiZone:ReferenceCrackConditions** is used to normalize crack information that is based on measurements of crack air flow.
- **AirflowNetwork:Distribution:Node** represents air distribution system nodes for the AirflowNetwork model. A set of an **AirLoopHVAC** and **ZoneHVAC:EquipmentList** nodes is a subset of the **AirflowNetwork:Distribution:Nodes**.
- **AirflowNetwork:Distribution:Component** objects consist of **Leak**, **LeakageRatio**, **Duct**, **ConstantPressureDrop**, **Fan**, **Coil**, **TerminalUnit**, **OutdoorAirFlow** and **ReliefAirFlow**. The components provide a relationship between pressure and airflow. The **Leak** and **LeakageRatio** components can be used to simulate supply and/or return leaks in an air distribution system. The **Duct** and **ConstantPressureDrop** components can be used to deliver forced air into conditioned spaces. The components **Fan**, **Coil**, and **TerminalUnit** reference normal EnergyPlus objects. **OutdoorAirFlow**, and **ReliefAirFlow** specify the outdoor air flow rate set by the **Controller:OutdoorAir** object in the model. The Airflow Network model gets information from these objects to perform an airflow network simulation.
- **AirflowNetwork:Distribution:Linkage** object represents a connection between two node objects and an AirflowNetwork component. The node objects can be an **AirflowNetwork:Distribution:Node**, **AirflowNetwork:MultiZone:ExternalNode** or **AirflowNetwork:MultiZone:Zone**.

If you input wind pressure coefficients, **AirflowNetwork:MultiZone:Surface** also has an associated **AirflowNetwork:MultiZone:ExternalNode**, that, via the **AirflowNetwork:MultiZone:WindPressureCoefficientArray** and **AirflowNetwork:MultiZone:WindPressureCoefficientValues** objects, gives the wind pressure distribution vs. wind direction for that node and, implicitly, for the cracks and openings in the exterior surfaces associated with that node.

Figure 1.112 shows the relationships among **AirflowNetwork:MultiZone** objects and between **AirflowNetwork:MultiZone** objects and regular EnergyPlus objects. In this figure an arrow from object A to object B means A references B, i.e., one of the inputs in A is the name of object B. For example, one input for **AirflowNetwork:MultiZone:Surface** is the name of a heat transfer surface, and another is the name of a crack or opening object. The arrow between **AirflowNetwork:MultiZone:Surface** and **AirflowNetwork:MultiZone:ExternalNode** is shown dashed to indicate that this reference is not used when wind pressure coefficients are calculated by the program rather than being input by the user.

Figure 1.112 also shows the relationships among **AirflowNetwork:Distribution** objects and between **AirflowNetwork:Distribution** objects and regular EnergyPlus objects. The **AirflowNetwork:Distribution:Linkage** objects link two nodes from **AirflowNetwork:Distribution:Node** and/or

**AirflowNetwork:MultiZone:Zone** objects with a component defined in the object **AirflowNetwork:Distribution:Component**. The solid arrows show a reference from object A to object B. The dashed arrows indicate the components which can be used in a linkage object. The red arrows pointing to the Zone object indicate the components that interact with the zone air. For example, the temperature in a zone where a supply leak terminates is used to calculate duct leakage energy loss. The temperature in a zone where a duct component is located is also used to calculate duct conduction loss.

Much of the information needed for the air flow calculation is automatically extracted from the building description for thermal modeling. This includes things like the volume and neutral height of the zones, and the orientation and location of the building surfaces that contain cracks or openings through which air flows. From all of this information the program creates a “pressure-flow network” that is solved each timestep using iterative solution methods to obtain the unknown pressures and air flows.

Figure 1.113 shows a plan view of a very simple air flow network that you can construct using the above **AirflowNetwork** objects. There are three thermal zones, Zone-1, Zone-2 and Zone-3. There are openable exterior windows—Window-1, Window-2 and Window-3—and openable interior doors—Door-12 and Door-23. Two External Nodes are indicated. ExternalNode-1 is associated with the façade that contains Window-1 and Window-2. ExternalNode-2 is associated with the façade containing Window-3.

One possible air flow pattern is shown in this figure. The actual air flow pattern in a particular timestep, and the size of the flows, depends on many factors, such as (1) What is the wind pressure distribution seen by the exterior windows? (2) Are the exterior windows open or closed, and if open, how far are they open? (3) Are the interior doors open or closed? (4) What are the air temperature differences between zones and between zones and the outdoor air (which affect buoyancy flows)?

Figure 1.113 shows a possible air flow pattern in which all of the windows and doors are open. Associated with the external nodes are wind pressure coefficient distributions as a function of wind direction that are input using two **AirflowNetwork:MultiZone:Wind Pressure Coefficient** objects. The nature of the air flows through the windows and doors is specified using **AirflowNetwork:MultiZone:Component:DetailedOpening** and **AirflowNetwork:MultiZone:Component:SimpleOpening** objects. The Airflow Network model calculates the flows each system timestep depending on various factors, including wind direction and speed, size and vertical position of openings, outdoor air temperature, and zone air temperatures.

### 1.28.3 Airflow Network Example Files (included in the installation)

### 1.28.4 What the Airflow Network Model Can and Cannot Do

Here is a list of some of the things that the Airflow Network calculation can and cannot model.

#### 1.28.4.1 Can Do

1. Air flow through cracks in exterior or interzone surfaces.
2. Air flow through cracks around windows and doors when closed.
3. Natural ventilation (i.e., air flow through open or partially open exterior windows and doors).
4. Zone level control of natural ventilation (all windows/doors in a zone that are defined with a component opening object have identical controls).
5. Individual surface control of natural ventilation for a subsurface (window, door, or glassdoor).
6. Modulation of natural ventilation to prevent large zone air temperature swings.
7. Interzone air flow (i.e., air flow through open interzone windows and doors, and through cracks in interzone surfaces).
8. Dependence of air flow on buoyancy effects and wind pressure.
9. Dependence of wind pressure on wind speed, wind direction and surface orientation.
10. Supply and return air leaks in an air distribution system.
11. Account for the effect of supply-air and/or return-air leakage on zone pressure when a forced air distribution system is present and is operating.
12. When duct leakage is modeled and the HVAC system is on, interzone airflow or infiltration/exfiltration can occur due to changes in zone pressure.
13. Bi-directional flow through large openings. See discussion below under [AirflowNetwork:MultiZone:Component:Door](#), [AirflowNetwork:MultiZone:Component:HorizontalOpening](#), and [AirflowNetwork:MultiZone:Component:SimpleOpening](#).
14. Calculate air flows and pressures in ducts or other components of a forced air distribution system.
15. Calculate zone loads when the supply air fan cycles on and off during a system timestep using the [CyclingFanAndCompressor](#) fan operation mode ([Fan:OnOff](#)).
16. Determine the impact of zone exhaust fans on air flows, pressures, air temperatures/humidity levels and energy consumption.

#### 1.28.4.2 Cannot Do or Restricted

1. The model is restricted to using a constant volume or variable volume fan ([Fan:ConstantVolume](#), [Fan:OnOff](#), and [Fan:VariableVolume](#)).
2. Air circulation and/or air temperature stratification within a thermal zone. For example, you should not try to divide a high space, such as an atrium, into subzones separated by artificial horizontal surfaces that have cracks or openings with the expectation that [AirflowNetwork](#) will give you a realistic temperature in each subzone and/or a realistic air flow between subzones.

3. The model is restricted to eleven types of coils that can be in the air distribution system (Coil:Cooling:DX:SingleSpeed, Coil:Heating:Fuel, Coil:Heating:Electric, Coil:Heating:DX:SingleSpeed, Coil:Cooling:Water, Coil:Heating:Water, Coil:Cooling:Water:DetailedGeometry, Coil:Cooling:DX:TwoStageWithCommonReturn, Coil:Cooling:DX:MultiSpeed, Coil:Heating:DX:MultiSpeed, and Coil:Heating:Desuperheater).
4. The model is restricted to two types of air distribution equipment terminal units (AirTerminal:SingleDuct:ConstantVolume:Reheat and AirTerminal:SingleDuct:VAV:Reheat).
5. Supply and return leaks are not allowed in an AirLoopHVAC. They can only be modeled in the Zone Equipment portion of the air loop (i.e., return leaks may be modeled between the zone return node and the zone mixer inlet or the zone mixer outlet and the zone equipment loop outlet; and supply leaks may be modeled between the zone equipment loop inlet and the AirLoopHVAC:ZoneSplitter inlet node or the AirLoopHVAC:ZoneSplitter outlet node and the zone supply node).
6. An air distribution system must be located inside the building (i.e., the ducts must pass through zones within the building).
7. Zone exhaust fans must be defined in ZoneHVAC:EquipmentConnections objects.

The input specifications consist of five main sections: **AirflowNetwork:SimulationControl** object, **AirflowNetwork multizone data objects**, **AirflowNetwork distribution node objects**, **AirflowNetwork distribution component objects**, and **AirflowNetwork distribution linkage objects**. Each of these object types is described in detail below.

### 1.28.5 AirflowNetwork:SimulationControl

The basic run parameters for this model are defined in this unique object which has the following input specifications:

#### 1.28.5.1 Inputs

##### 1.28.5.1.1 Field: Name

This is a unique character string associated with this instance of the AirflowNetwork:SimulationControl object. At this time, only one AirflowNetwork:SimulationControl object can be specified in an input data file (idf).

##### 1.28.5.1.2 Field: AirflowNetwork Control

The following selections are available to control the Airflow Network simulation:

**MultiZoneWithDistribution:** MultiZone air flow calculations are performed during all simulation timesteps, including the impacts of the air distribution system when a HVAC system fan is operating. Any **ZoneInfiltration:\***, **ZoneVentilation:\***, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are not simulated.

**MultiZoneWithoutDistribution:** MultiZone air flow calculations are performed during all simulation timesteps, but the air distribution system portion of the network is not modeled even if it is specified in the input data file. Any **ZoneInfiltration:\***, **ZoneVentilation:\***, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are not simulated.

**MultiZoneWithDistributionOnlyDuringFanOperation:** MultiZone air flow calculations, including the impacts of the air distribution system, are only performed when the HVAC system fan is operating. Any **ZoneInfiltration:\***, **ZoneVentilation:\***, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are used when the HVAC system fan is OFF (if none are specified, then no air flow calculations are performed when the fan is OFF).

**NoMultiZoneOrDistribution:** No multizone air flow calculations (with or without the air distribution system portion of the network) are performed during the simulation. Any **ZoneInfiltration:\***, **ZoneVentilation:\***, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are simulated (if none are specified, then no air flow calculations are performed). Note: Having an input data file with no AirflowNetwork:SimulationControl objects gives the same impact – no multizone air flow calculations. However, this choice is provided as a convenience to the user to easily disable the multizone air flow calculations for an input data file that already contains AirflowNetwork objects.

**Note:** A **ZoneInfiltration:\*** object indicates any one of **ZoneInfiltration:DesignFlowRate**, **ZoneInfiltration:EffectiveLeakageArea**, and **ZoneInfiltration:FlowCoefficient** objects. A **ZoneVentilation:\*** object indicates any one of **ZoneVentilation:DesignFlowRate** and **ZoneVentilation:WindandStackOpenArea** objects.

#### 1.28.5.1.3 Field: Wind Pressure Coefficient Type

Determines whether the wind pressure coefficients are input by the user or calculated. The choices are **Input** or **SurfaceAverageCalculation**, with the default being SurfaceAverageCalculation.

If **INPUT**, you must enter an **AirflowNetwork:MultiZone:WindPressureCoefficientArray** object, one or more **AirflowNetwork:MultiZone:ExternalNode** objects, and one or more **AirflowNetwork:MultiZone:WindPressureCoefficientValues** objects.

The second choice, SurfaceAverageCalculation, should only be used for **rectangular** buildings. In this case surface-average wind pressure coefficients vs. wind direction are calculated by the program for the four vertical façades and the roof based on user entries for “Building Type,” “Azimuth Angle of Long Axis of Building,” and “Ratio of Building Width Along Short Axis to Width Along Long Axis” (see description of these fields below). With this choice you do **not** have to enter any of the following objects: AirflowNetwork:MultiZone: Wind Pressure Coefficient Array, **AirflowNetwork:MultiZone:ExternalNode** and **AirflowNetwork:MultiZone:WindPressureCoefficientValues**.

#### 1.28.5.1.4 Field: Height Selection for Local Wind Pressure Calculation

Determines whether the local wind pressure is calculated based on either given external node heights or surface opening heights. The choices are **ExternalNode** or **OpeningHeight**, with the default being OpeningHeight. The local outdoor wind speed calculation procedure is given in the section of “Local Wind Speed Calculation” in the Engineering Reference. The calculation procedure requires the height input.

If **ExternalNode**, the heights given in the **AirflowNetwork:MultiZone:ExternalNode** objects are used to calculate local wind pressures based on the given height local wind speed. Used only if Wind Pressure Coefficient Type = INPUT (see description of previous field).

If **OpeningHeight**, the number of the **AirflowNetwork:MultiZone:ExternalNode** objects has to be equal to the number of external surfaces defined in the **AirflowNetwork:MultiZone:Surface** objects. The centroids in the z direction of the **AirflowNetwork:MultiZone:Surface** objects are the heights used in the local wind pressure calculation with the given height wind speed. The input is required if Wind Pressure Coefficient Type = INPUT (see description of previous field).

If Wind Pressure Coefficient Type = **SurfaceAverageCalculation**, a value in this field is not required and a blank may be entered. The default choice is used internally to generate the **AirflowNetwork:MultiZone:ExternalNode** objects

#### 1.28.5.1.5 Field: Building Type

Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The choices for Building Type are LowRise and HighRise, with the default being LowRise.

LowRise corresponds to a rectangular building whose height is less than three times the width of the footprint ( $w_{short}$  in Figure 1.114) and is less than three times the length of the footprint ( $w_{long}$  in the same figure).

HighRise corresponds to a rectangular building whose height is more than three times the width of the footprint ( $w_{short}$  in Figure 1.114) or is more than three times the length of the footprint ( $w_{long}$  in the same figure).

#### 1.28.5.1.6 Field: Maximum Number of Iterations

The maximum number of iterations allowed in finding an AirflowNetwork solution. If the number of iterations at each simulation timestep is above the maximum number of iterations defined by this field, the program could not find the solution and a Severe error is issued and the program is aborted. The default value is 500.

#### 1.28.5.1.7 Field: Initialization Type

Designates which method is used for AirflowNetwork initialization. The choices for Initialization Type are LinearInitializationMethod and ZeroNodePressures, with the default being ZeroNodePressures.

#### 1.28.5.1.8 Field: Relative Airflow Convergence Tolerance

The solution is assumed to have converged when  $\left| \sum \dot{m}_i \right| / \sum \left| \dot{m}_i \right|$  is less than the value specified for this input field. This convergence criteria is equivalent to the ratio of the absolute value of the sum of all network airflows ( $\left| \sum \dot{m}_i \right|$ ) to the sum of network airflow magnitudes ( $\sum \left| \dot{m}_i \right|$ ). The default value is  $1.0 \times 10^{-4}$ .

#### 1.28.5.1.9 Field: Absolute Airflow Convergence Tolerance

The solution is assumed to have converged when the summation of the absolute value of all network airflows ( $\left| \sum \dot{m}_i \right|$ ) is less than the value specified for this input field. The default value is  $1.0 \times 10^{-6}$ .

#### 1.28.5.1.10 Field: Convergence Acceleration Limit

If the ratio of successive pressure corrections is less than this limit, use Steffensen acceleration algorithm (Ref. AirflowNetwork Model in the EnergyPlus Engineering Reference). The range for this field is -1 to 1, with the default value being -0.5.

#### 1.28.5.1.11 Field: Azimuth Angle of Long Axis of Building

Gives the orientation of a rectangular building for calculating wind pressure coefficients. This is the smaller of the angles, measured clockwise, between North and the long axis of the building (see Figure 1.114). Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The range for this input is 0 to 180, with the default value being 0.

#### 1.28.5.1.12 Field: Ratio of Building Width Along Short Axis to Width Along Long Axis

This is the aspect ratio of a rectangular footprint. It is given by the width of the footprint along its short axis divided by the width along the long axis (see Figure 1.114). If the footprint is square, the value of this field is 1.0. Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The range for this input is  $> 0$  to 1, with the default value being 1.

#### 1.28.5.1.13 Field: Height Dependence of External Node Temperature

This is an optional field. Input is Yes or No. The default is No. Yes is that external node temperature is dependent on node height. No means that external node temperature is calculated with zero height.

Figure 1.114: Footprint of a rectangular building showing variables used by the program to calculate surface-average wind pressure coefficients. The angle  $a$  is the “Azimuth Angle of Long Axis of Building.”  $w_{short}/w_{long}$  is the “Ratio of Building Width Along Short Axis to Width Along Long Axis.”

#### 1.28.5.1.14 Field: Allow Unsupported Zone Equipment

This is an optional field. Input is Yes or No. The default is No. Set this input to Yes to have zone equipment that are currently unsupported in the AirflowNetwork model allowed in the simulation. Setting this field to Yes, allows the following equipment to be modeled along an AirflowNetwork model: ZoneHVAC:Dehumidifier, ZoneHVAC:EnergyRecoveryVentilator, WaterHeater:HeatPump:\*. The AirflowNetwork model will exclude mass balance in these equipment objects and assume the mass flows are self-balanced in the equipment objects.

An IDF example is shown below:

```

AirflowNetwork:MultiZone data objects are used to calculate multizone airflows. This section describes the input requirements for the following objects:

- [AirflowNetwork:MultiZone:Zone](#)

AirflowNetwork:MultiZone data objects are used to calculate multizone airflows. This section describes the input requirements for the following objects:

- [AirflowNetwork:MultiZone:Zone](#)
- [AirflowNetwork:MultiZone:Surface](#)
- [AirflowNetwork:MultiZone:Surface:Crack](#)
- [AirflowNetwork:MultiZone:ReferenceCrackConditions](#)
- [AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea](#)
- [AirflowNetwork:MultiZone:Component:DetailedOpening](#)
- [AirflowNetwork:MultiZone:Component:SimpleOpening](#)
- [AirflowNetwork:MultiZone:Component:HorizontalOpening](#)
- [AirflowNetwork:MultiZone:Component:ZoneExhaustFan](#)
- [AirflowNetwork:MultiZone:ExternalNode](#)
- [AirflowNetwork:MultiZone:WindPressureCoefficientArray](#)
- [AirflowNetwork:MultiZone:WindPressureCoefficientValues](#)

A detailed description for each of these objects is provided below.

### 1.28.6 AirflowNetwork:MultiZone:Zone

This object allows control of natural ventilation through exterior and interior openings in a zone, where “opening” is defined as an openable window or door. (Note that only window, door or glass door subsurfaces in a zone that are specified using [AirflowNetwork:MultiZone:Component:DetailedOpening](#), [AirflowNetwork:MultiZone:Component:HorizontalOpening](#) or [AirflowNetwork:MultiZone:Component:SimpleOpening](#) and have an associated [AirflowNetwork:MultiZone:Surface](#) object are considered to be openings). The control will be applied in the same way to all of the openings in the zone.

This object is required to perform Airflow Network calculations. Note that ventilation control for all openings is provided at the zone level as default and individual ventilation control of a surface opening can be used to override the zone-level control (see the [AirflowNetwork:MultiZone:Surface](#) object description below).

#### 1.28.6.1 Field: Zone Name

The name of the EnergyPlus thermal zone corresponding to the AirflowNetwork zone.

#### 1.28.6.2 Field: Ventilation Control Mode

Specifies the type of zone-level natural ventilation control.

Let  $T_{out}$  equal the outdoor air temperature,  $T_{zone}$  equal the previous timestep’s zone air temperature,  $T_{set}$  equal the Vent Temperature Schedule value,  $H_{zone}$  equal the specific enthalpy of zone air from the previous timestep, and  $H_{out}$  equal the specific enthalpy of outdoor air. Then the four allowed choices for Ventilation Control Mode are:

**NoVent:** All of the zone’s openable windows and doors are closed at all times independent of indoor or outdoor conditions. The Venting Availability Schedule is ignored in this case. This is the default value for this field.

**Temperature:** All of the zone’s openable windows and doors are opened if  $T_{zone} > T_{out}$  **and**  $T_{zone} > T_{set}$  **and** Venting Availability Schedule (see below) allows venting.

**Enthalpy:** All of the zone’s openable windows and doors are opened if  $H_{zone} > H_{out}$  **and**  $T_{zone} > T_{set}$  **and** Venting Availability Schedule allows venting.

**Constant:** Whenever this object’s Venting Availability Schedule allows venting, all of the zone’s openable windows and doors are open, independent of indoor or outdoor conditions. Note that “Constant” here means that the size of each opening is fixed while venting; the air flow through each opening can, of course, vary from timestep to timestep.

**ASHRAE55Adaptive:** All of the zone’s operable windows and doors are opened if the operative temperature is greater than the comfort temperature (central line) calculated from the ASHRAE Standard 55-2010 adaptive comfort model and Venting Availability Schedule allows venting.

**CEN15251Adaptive:** All of the zone’s operable windows and doors are opened if the operative temperature is greater than the comfort temperature (central line) calculated from the CEN15251 adaptive comfort model and Venting Availability Schedule allows venting.

#### 1.28.6.3 Field: Ventilation Control Zone Temperature Setpoint Schedule Name

The name of a schedule of zone air temperature set points that controls the opening of windows and doors in the thermal zone to provide natural ventilation. This setpoint is the temperature above which all the openable windows and doors in the zone will be opened if the conditions described in the previous field Ventilation Control Mode are met.

The Ventilation Control Zone Temperature Setpoint Schedule Name applies only to windows and doors in the zone that are specified using [AirflowNetwork:MultiZone:Component:DetailedOpening](#), [AirflowNet-](#)

work:MultiZone:Component:HorizontalOpening or AirflowNetwork:MultiZone:Component:SimpleOpening and have an associated AirflowNetwork:MultiZone:Surface object.

(The discussion under the field Window/Door Opening Factor in the AirflowNetwork:MultiZone:Surface object describes how the actual opening area of a window or door in a particular timestep is determined.)

#### *Modulation of Openings*

The following five fields can be used to modulate the window/door openings when Ventilation Control Mode = Temperature or Enthalpy. These fields determine a factor between 0 and 1 that multiplies the opening factor of each window and door in the zone according to the control action shown in Figure 1.116 for Ventilation Control Mode = Temperature and in Figure 1.117 for Ventilation Control Mode = Enthalpy. Modulation of the openings can reduce the large temperature swings that can occur if the windows/doors are open too far when they are venting, especially when there is a large inside-outside temperature difference.

The modulation takes the following form when Ventilation Control Mode = Temperature:

**if**  $T_{zone} - T_{out} \leq$  [Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor] **then** Multiplication factor = 1.0

**if** [Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor]  $< T_{zone} - T_{out} <$  [Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor] **then** Multiplication factor varies linearly from 1.0 to [Limit Value on Multiplier for Modulating Venting Open Factor]

**if**  $T_{zone} - T_{out} \geq$  [Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor] **then** Multiplication factor = [Limit Value on Multiplier for Modulating Venting Open Factor]

One way of “tuning” the following modulation control parameters is to perform a sensitivity analysis for winter and/or summer design days to determine what combination of values causes the biggest reduction in zone air temperature fluctuations due to venting.

Note that the default values for the following fields are such that, if none of the fields are specified, the default values are assigned.

#### **1.28.6.4 Field: Minimum Venting Open Factor**

See Figure 1.116 or Figure 1.117. This field applies only if Ventilation Control Mode = Temperature or Enthalpy. This value may be from zero to 1.0, with the default being 0.0.

#### **1.28.6.5 Field: Indoor and Outdoor Temperature Difference Lower Limit For Maximum Venting Open Factor**

See Figure 1.116. This field applies only if Ventilation Control Mode = Temperature. This value may be from zero to less than 100 °C, with the default being 0 °C. The value for this field must be less than the value specified for the following field.

#### **1.28.6.6 Field: Indoor and Outdoor Temperature Difference Upper Limit for Minimum Venting Open Factor**

See Figure 1.116. This field applies only if Ventilation Control Mode = Temperature. This value must be greater than 0 °C, with the default being 100 °C. The value for this field must be greater than the value specified for the previous field..

#### 1.28.6.7 Field: Indoor and Outdoor Enthalpy Difference Lower Limit For Maximum Venting Open Factor

See Figure 1.117. This field applies only if Ventilation Control Mode = Enthalpy. This value may be from zero to less than 300,000 J/kg, with the default being 0 J/kg. The value for this field must be less than the value specified for the following field.

#### 1.28.6.8 Field: Indoor and Outdoor Enthalpy Difference Upper Limit for Minimum Venting Open Factor

See Figure 1.117. This field applies only if Ventilation Control Mode = Enthalpy. This value must be greater than zero, with the default being 300,000 J/kg. The value for this field must be greater than the value specified for the previous field.

#### 1.28.6.9 Field: Venting Availability Schedule Name

The name of a schedule that specifies when venting is available. A zero or negative schedule value means venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by Ventilation Control Mode and Vent Temperature Schedule Name) are satisfied. This schedule name should not be confused with Vent Temperature Schedule Name.

If a Venting Availability Schedule Name is not specified, it is assumed that venting is always available.

Using Venting Availability Schedule allows you to turn off venting at certain times of the day (at night, for example), of the week (on weekends, for example), or of the year (during the winter, for example).

If used with Ventilation Control Mode = Constant, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero.

If Ventilation Control Mode = NoVent, this schedule has no effect.

#### 1.28.6.10 Field: Single Sided Wind Pressure Coefficient Algorithm

Specifies the type of single sided wind pressure coefficient algorithm to be used for the zone. This field is optional and is only used if Wind Pressure Coefficient Type is set to SurfaceAverageCalculation. The default is Standard and the two valid choices are:

**Standard:** A single wind pressure coefficient is applied to all openings in the zone, as calculated using SurfaceAverageCalculation.

**Advanced:** EnergyPlus calculates modified wind pressure coefficients for the two openings in the zone. This model is only valid for zones with two openings, both of which are on a single façade (i.e. are coplanar). For zones with more than two openings, consider combining the openings into two. The modified wind pressure coefficients account for wind direction and turbulence effects on single sided ventilation rates. See the Engineering Reference for a detailed description of the Advanced algorithm. When the Advanced algorithm is selected, the difference between the two modified wind pressure coefficients are output to the .eio file.

#### 1.28.6.11 Field: Façade Width

This is the whole building width along the direction of the facade of this zone, or  $W_F$  in Figure 1.115. This field is used in the Single Sided Wind Pressure Coefficient Algorithm. This field is optional and is only used if the Single Sided Wind Pressure Coefficient Algorithm is set to Advanced. The value must be greater than 0.0 m, with the default being 10 m.

Figure 1.115: Footprint of a rectangular building showing  $W_F$ , the “Façade Width”, used by the Single Sided Wind Pressure Coefficient Algorithm.

#### 1.28.6.12 Field: Occupant Ventilation Control Name

The name of an `AirflowNetwork:OccupantVentilationControl` object. The object is used to perform advanced window opening control based on occupant conditions. When an object name is given, advanced window opening control is performed and, the ventilation control defined in the Ventilation Control Mode field will be overridden.

**Note:** The Occupant Ventilation Control object can be assigned to a zone (`AirflowNetwork:MultiZone:Zone`) or a surface (`AirflowNetwork:MultiZone:Surface`). When the object is assigned to a zone, the Occupant Ventilation Control is assigned to the surfaces belonging to the zone automatically. The surface objects must have an associated `AirflowNetwork:MultiZone:Component:DetailedOpening`, `AirflowNetwork:MultiZone:Component:HorizontalOpening`, or `AirflowNetwork:MultiZone:Component:SimpleOpening` component specified in the field of Leakage Component Name. All output variables will be shown under surface names only, and not under zone names.

**Note:** In order to establish an airflow network, each `AirflowNetwork:MultiZone:Zone` object must have at least two surfaces defined with `AirflowNetwork:MultiZone:Surface` objects, so that air can flow from one zone into other zones (or to outdoors) through the network (air mass flow conserved). In addition, for all `AirflowNetwork:MultiZone:Surface` objects facing the same Zone (ref. `BuildingSurface:Detailed`), at least two different environments must be defined for the other side of these surfaces (e.g., an external node and an adjacent zone, two adjacent zones, or two external nodes).

An IDF example is shown below:

```

VentingSched;  !- Venting Availability Schedule Name

```

### 1.28.7 AirflowNetwork:MultiZone:Surface

The `AirflowNetwork:MultiZone:Surface` object specifies the properties of a surface “linkage” through which air flows. This linkage is always associated with a building surface (wall, roof, floor, or a ceiling) or subsurface (door, glass door, or window) with both faces exposed to air. The linkage specifies two connected nodes: two zone nodes defined in `AirflowNetwork:MultiZone:Zone` objects based on inside and outside face environment for an interior surface, or a zone node defined in an `AirflowNetwork:MultiZone:Zone` object based on inside face environment and an external node defined in an `AirflowNetwork:MultiZone:ExternalNode` object for an exterior surface. The associated leakage component for this surface can be a crack (or surface effective leakage area) in an exterior or interior heat transfer surface or subsurface, or an exterior or interior window, door or glass door (heat transfer subsurface) that can be opened to allow air flow. The allowed surface air leakage components are:

- `AirflowNetwork:MultiZone:Surface:Crack`
- `AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea`
- `AirflowNetwork:MultiZone:Component:DetailedOpening`

Figure 1.117: Modulation of venting area according to inside-outside enthalpy difference.

- `AirflowNetwork:MultiZone:Component:HorizontalOpening`
- `AirflowNetwork:MultiZone:Component:SimpleOpening`
- `AirflowNetwork:MultiZone:Component:ZoneExhaustFan`

The three “opening” components are used to modulate openness based on required conditions.

The `AirflowNetwork:MultiZone:Surface` object allows a heat transfer surface or subsurface to have one crack (or one surface effective leakage area object), or a subsurface (i.e., window, door or glass door) to have one opening (detailed, simple, or horizontal).

An interior heat transfer surface (`BuildingSurface:Detailed`) whose surface name is used as the input for the Outside Boundary Condition Object field is adiabatic and is not allowed as an `AirflowNetwork:MultiZone:Surface`. A heat transfer surface defined in the `BuildingSurface:Detailed:ExteriorNaturalVentedCavity` is also not allowed.

When a non-rectangular subsurface is used, the model will automatically convert it into a rectangular subsurface using equivalent width and height based on an entered choice from the Equivalent Rectangle Method field or a default choice.

When an air boundary surface or subsurface is used (`Construction:AirBoundary`), all types of leakage component are allowed except `AirflowNetwork:MultiZone:Component:ZoneExhaustFan`. The only allowed venting control type for an air boundary surface is Constant, and the venting schedule is ignored (which means the opening is always fully open at the specified Window/Door Opening Factor, or Crack Factor). EnergyManagementSystem:Actuator “AirFlow Network Window/Door Opening” is available for special applications where control of the air boundary opening is required.

### 1.28.7.1 Field: Surface Name

This is the name of the corresponding surface (wall, roof, ceiling, floor, window, door or glass door).

Information on this surface is used by the program as follows:

- For a linkage associated with an exterior heat transfer surface: air flow through this linkage is between the outside environment and the thermal zone to which the surface belongs.
- For a linkage associated with an interior (i.e., interzone) heat transfer surface: air flow through this linkage is between the thermal zones separated by the surface (i.e., the thermal zone associated with the inside face environment and the thermal zone associated with the outside face environment).
- This heat transfer surface determines the height of the linkage, which is used in calculating buoyancy-related flow through the linkage.
- The surface may be an air boundary surface or subsurface (`Construction:AirBoundary`).

**Note:** It is possible to define an interzone surface twice in EnergyPlus, once in each of the zones that the surface separates. Previously this was a requirement of EnergyPlus (prior to version 2.0), but now it is optional and the user also has the option of only defining the surface once (EnergyPlus defines the second surface automatically within the program). For each interzone surface, use only one (of possible two) interzone surface names in the `AirflowNetwork:MultiZone:Surface` object for “Surface Name.” **Do not** enter two `AirflowNetwork:MultiZone:Surface` objects corresponding to the two possible interzone names. This would cause the air flow through the surface to be counted twice.

### 1.28.7.2 Field: Leakage Component Name

The name of the `AirflowNetwork:MultiZone:Surface:Crack`, `AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea`, `AirflowNetwork:MultiZone:Component:SimpleOpening`, `AirflowNetwork:MultiZone:Component:HorizontalOpening`, `AirflowNetwork:MultiZone:Component:DetailedOpening` or `AirflowNetwork:MultiZone:Component:ZoneExhaustFan` object associated with this air flow linkage.

If the name of an opening component (i.e. `AirflowNetwork:MultiZone:Component:DetailedOpening`, `AirflowNetwork:MultiZone:Component:HorizontalOpening`, or `AirflowNetwork:MultiZone:Component:SimpleOpening`) is given here, then the Surface Name in the previous field must be that of a window, door or glass door heat transfer subsurface or a building surface which is an air boundary. Otherwise an error message will be reported.

If the name of an `AirflowNetwork:MultiZone:Surface:Crack` object or `AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea` object is given here, the program will position the crack at the average height of the associated heat transfer surface or subsurface. The user can define multiple heat transfer surfaces (e.g., split a wall into several surfaces) to be more precise in establishing the crack location. Similarly, the user can define multiple heat transfer surfaces if a wall, for example, has multiple cracks or openings that need to be defined individually.

If the name of an `AirflowNetwork:MultiZone:Component:ZoneExhaustFan` is given here, then the Surface Name in the previous field must be that of an exterior heat transfer surface. The zone name defined in the Zone Name field for this heat transfer surface must be the same zone name defined in the `ZoneHVAC:EquipmentConnections` object (which references a `ZoneHVAC:EquipmentList` containing the name of the corresponding zone exhaust fan). Otherwise an error message will be reported. When this zone exhaust fan is operating for a simulation timestep, all surface-level controls described below are ignored for that timestep.

### 1.28.7.3 Field: External Node Name

The name of the associated `AirflowNetwork:MultiZone:ExternalNode` object, which determines the wind pressure coefficients for the heat transfer surface. Used only if Surface Name is for an exterior surface.

If Wind Pressure Coefficient Type = SurfaceAverageCalculation in the `AirflowNetwork:SimulationControl` object, this field is not used and a blank may be entered. If the surface is an interior (i.e., interzone) surface, leave this field blank.

When there is an input object of either `ZoneProperty:LocalEnvironment` or `SurfaceProperty:LocalEnvironment`, LocalEnvironment is enable, so that entered names of `OutdoorAir:Node` can be used as inputs for this field. More description of use can be found in `OutdoorAir:Node`.

### 1.28.7.4 Field: Window/Door Opening Factor, or Crack Factor

If this linkage is associated with an `AirflowNetwork:MultiZone:Component:DetailedOpening` or `AirflowNetwork:MultiZone:Component:SimpleOpening` object (which means it is an openable window or door), then this field is called “Window/Door Opening Factor” and represents the value of the Opening Factor that is in effect when the Vent Temperature Schedule (defined in the `AirflowNetwork:MultiZone:Zone` object) indicates that this window or door is open.

The AirflowNetwork model uses a combination of factors to determine the actual opening area for a window or door when it is venting. For example, consider a window that is 1.5m high and 2.0m wide (excluding frame). Assume that the `AirflowNetwork:MultiZone:Component:DetailedOpening` for this window has Type of Large Vertical Opening = 1 (non-pivoting window), Height Factor = 0.5 and Width Factor = 0.8. Then when the window is fully open, the opening area = height of opening (0.5x1.5) times width of opening (0.8x2.0) = 0.75x1.6 = 1.2 m<sup>2</sup>. If the Window/Door Opening Factor is 0.75, then the opening area = 0.75x1.2 = 0.9 m<sup>2</sup>.

If, in addition, the window is in a thermal zone for which opening modulation has been specified (ref: [AirflowNetwork:MultiZone:Zone](#)) and the multiplication factor due to modulation is 0.3 in a particular timestep, then the actual opening factor that timestep =  $0.3 \times 0.75 = 0.225$  and the actual opening area that timestep =  $0.3 \times 0.9 = 0.27 \text{ m}^2$ .

If this linkage is associated with an [AirflowNetwork:MultiZone:Surface:Crack](#) object, the following crack air flow equation is used.

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n \quad (1.103)$$

Where

$Q$  is the air mass flow (kg/s)

$C_Q$  is the air mass flow coefficient (kg/s @ 1 Pa)

$C_T$  is the reference condition temperature correction factor (dimensionless). See [AirflowNetwork:MultiZone:Surface:Crack](#) object.

$\Delta P$  is the pressure difference across crack (Pa)

$n$  is the air flow exponent (dimensionless)

*The following fields control venting. They are used only when Name of Associated Heat Transfer Surface is that of an openable exterior or interior window, door or glass door. They only apply to openings, and do not apply to surface cracks, effective leakage area or zone exhaust fans. If none of these fields is specified, or if Ventilation Control Mode = ZoneLevel, venting is controlled by the [AirflowNetwork:MultiZone:Zone](#) object for the thermal zone containing the window or door (ref: [AirflowNetwork:MultiZone:Zone](#) Data).*

### 1.28.7.5 Field: Ventilation Control Mode

Specifies the type of surface-level natural ventilation control.

Let  $T_{out}$  equals the outdoor air temperature,  $T_{zone}$  equals the previous timestep's zone air temperature,  $T_{set}$  equals the Vent Temperature Schedule value,  $H_{zone}$  equals the specific enthalpy of zone air from the previous timestep, and  $H_{out}$  equals the specific enthalpy of outdoor air. Then the four allowed choices for Ventilation Control Mode are:

**NoVent:** The openable window or door associated with this surface is closed at all times independent of indoor or outdoor conditions. The Venting Availability Schedule is ignored in this case.

**Temperature:** The openable window or door associated with this surface is opened if  $T_{zone} > T_{out}$  and  $T_{zone} > T_{set}$  and Venting Availability Schedule (see below) allows venting.

**Enthalpy:** The openable window or door associated with this surface is opened if  $H_{zone} > H_{out}$  and  $T_{zone} > T_{set}$  and Venting Availability Schedule allows venting.

**Constant:** Whenever this object's Venting Availability Schedule allows venting, the openable window or door associated with this surface is open, independent of indoor or outdoor conditions. Note that "Constant" here means that the size of this opening is fixed while venting; the air flow through this opening can, of course, vary from timestep to timestep. If the surface is an air boundary ([Construction:AirBoundary](#)) then Constant is the only valid option (other options will throw a warning and be reset to Constant).

**ASHRAE55Adaptive:** The openable window or door associated with this surface is opened if the operative temperature is greater than the comfort temperature (central line) calculated from the ASHRAE Standard 55-2010 adaptive comfort model and Venting Availability Schedule allows venting.

**CEN15251Adaptive:** The openable window or door associated with this surface is opened if the operative temperature is greater than the comfort temperature (central line) calculated from the CEN15251 adaptive comfort model and Venting Availability Schedule allows venting.

**ZoneLevel:** Venting of the window or door is not controlled individually, but is controlled instead at the zone level. This means that the venting is determined by the [AirflowNetwork:MultiZone:Zone](#) object for the thermal zone containing the window or door (ref: [AirflowNetwork:MultiZone:Zone](#) object). This is the default value for this field.

**AdjacentTemperature:** This choice is used for an interior surface only. The openable interior window or door associated with this surface is opened if  $T_{zone} > T_{adjacent\ zone}$  **and**  $T_{zone} > T_{set}$  **and** Venting Availability Schedule (see below) allows venting, where  $T_{adjacent\ zone}$  is the adjacent zone temperature.

**AdjacentEnthalpy:** This choice is also used for an interior surface only. The interior openable window or door associated with this surface is opened if  $H_{zone} > H_{adjacent\ zone}$  **and**  $T_{zone} > T_{set}$  **and** Venting Availability Schedule allows venting, where  $H_{adjacent\ zone}$  is the adjacent zone specific enthalpy.

#### 1.28.7.6 Field: Ventilation Control Zone Temperature Setpoint Schedule Name

The name of a schedule of zone air temperature set points that controls the opening of a window or door associated with this surface to provide natural ventilation. This setpoint is the temperature above which this openable window or door will be opened if the conditions described in the previous field Ventilation Control Mode are met.

The Ventilation Control Zone Temperature Setpoint Schedule applies only to a window or door attached to this surface that is specified using **AirflowNetwork:MultiZone:Component:DetailedOpening** or **AirflowNetwork:MultiZone:Component:SimpleOpening**.

(The discussion under the field Window/Door Opening Factor in this object describes how the actual opening area of a window or door in a particular timestep is determined.)

##### *Modulation of Openings*

The following five fields can be used to modulate this window/door opening when Ventilation Control Mode = Temperature or Enthalpy. These fields determine a factor between 0 and 1 that multiplies the opening factor of this window or door according to the control action shown in Figure 1.116 for Ventilation Control Mode = Temperature and in Figure 1.117 for Ventilation Control Mode = Enthalpy. Modulation of this opening can reduce the large temperature swings that can occur if the window/door is open too far when it is venting, especially when there is a large inside-outside temperature difference.

The modulation takes the following form when Ventilation Control Mode = Temperature:

**if**  $T_{zone} - T_{out} < =$  [Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor] **then** Multiplication factor = 1.0

**if** [Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor]  $< T_{zone} - T_{out} <$  [Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor] **then** Multiplication factor varies linearly from 1.0 to [Limit Value on Multiplier for Modulating Venting Open Factor]

**if**  $T_{zone} - T_{out} > =$  [Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor] **then** Multiplication factor = [Limit Value on Multiplier for Modulating Venting Open Factor]

One way of “tuning” the following modulation control parameters is to perform a sensitivity analysis for winter and/or summer design days to determine what combination of values causes the biggest reduction in zone air temperature fluctuations due to venting.

Note that the default values for the following fields are such that, if none of the fields are specified, modulation will not occur.

#### 1.28.7.7 Field: Minimum Venting Open Factor

See Figure 1.116 or Figure 1.117. This field applies only if Ventilation Control Mode = Temperature or Enthalpy. This value may be from zero to 1.0, with the default being 0.0.

#### 1.28.7.8 Field: Indoor and Outdoor Temperature Difference Lower Limit For Maximum Venting Open Factor

See Figure 1.116. This field applies only if Ventilation Control Mode = Temperature. This value may be from zero to less than 100°C, with the default being 0°C. The value for this field must be less than the value specified for the following field.

#### 1.28.7.9 Field: Indoor and Outdoor Temperature Difference Upper Limit for Minimum Venting Open Factor

See Figure 1.116. This field applies only if Ventilation Control Mode = Temperature. This value must be greater than 0°C, with the default being 100°C. The value for this field must be greater than the value specified for the previous field.

#### 1.28.7.10 Field: Indoor and Outdoor Enthalpy Difference Lower Limit For Maximum Venting Open Factor

See Figure 1.117. This field applies only if Ventilation Control Mode = Enthalpy. This value may be from zero to less than 300,000 J/kg, with the default being 0 J/kg. The value for this field must be less than the value specified for the following field.

#### 1.28.7.11 Field: Indoor and Outdoor Enthalpy Difference Upper Limit for Minimum Venting Open Factor

See Figure 1.117. This field applies only if Ventilation Control Mode = Enthalpy. This value must be greater than zero, with the default being 300,000 J/kg. The value for this field must be greater than the value specified for the previous field.

#### 1.28.7.12 Field: Venting Availability Schedule Name

The name of a schedule that specifies when venting is available. A zero or negative schedule value means venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by Ventilation Control Mode and Vent Temperature Schedule Name) are satisfied. This schedule name should not be confused with Vent Temperature Schedule Name. If the surface is an air boundary (**Construction:AirBoundary**) then this field is ignored and venting is always available.

If a Venting Availability Schedule Name is not specified, it is assumed that venting is always available.

Using Venting Availability Schedule allows you to turn off venting at certain times of the day (at night, for example), week (on weekends, for example), or year (during the winter, for example).

If used with Ventilation Control Mode = Constant, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero.

If Ventilation Control Mode = NoVent, this schedule has no effect.

**Note:** In order to establish an airflow network, each **AirflowNetwork:MultiZone:Zone** object must have at least two surfaces defined with **AirflowNetwork:MultiZone:Surface** objects, so that air can flow from one zone into other zones (or to outdoors) through the network (air mass flow conserved). In addition, for all **AirflowNetwork:MultiZone:Surface** objects facing the same Zone Name (ref. **BuildingSurface:Detailed**), at least two different environments must be defined for the other side of these surfaces (e.g., an external node and an adjacent zone, two adjacent zones, or two external nodes).

### 1.28.7.13 Field: Occupant Ventilation Control Name

The name of an AirflowNetwork:OccupantVentilationControl object. The object is used to perform advanced window opening control based on occupant conditions. When an object name is given, advanced window opening control is performed and, the Ventilation Control defined in the Ventilation Control Mode field will be overridden.

### 1.28.7.14 Field: Equivalent Rectangle Method

This field is applied to a non-rectangular window or door. The equivalent rectangular surface has the same area as the non-rectangular one. The valid choices are: PolygonHeight, BaseSurfaceAspectRatio, and UserDefinedAspectRatio, with the default of PolygonHeight. When PolygonHeight is entered, the equivalent width is equal to the area divided by the PolygonHeight for a non-horizontal surface. When a surface is horizontal with the same height for all vertices, the model will automatically switch a choice to BaseSurfaceAspectRatio if a base surface is rectangular, or UserDefinedAspectRatio with the default value if a base surface is non-rectangular. When BaseSurfaceAspectRatio is entered for a rectangular base surface, the equivalent height is equal to Square Root of Area divided by the base surface aspect ratio. The equivalent width is equal to the equivalent height times the base surface aspect ratio. When a base surface is non-rectangular, the model will automatically switch the choice to PolygonHeight for a non-horizontal base surface, and UserDefinedAspectRatio with the default value if a base surface is horizontal. When UserDefinedAspectRatio is entered, the equivalent height is equal to Square Root of Area divided by UserDefinedAspectRatio. The equivalent width is equal to the equivalent height times the user-defined aspect ratio.

### 1.28.7.15 Field: Equivalent Rectangle Aspect Ratio

This field applies only if Equivalent Rectangle Method = UserDefinedAspectRatio. This value must be greater than zero, with the default being 1.0.

## 1.28.8 AirflowNetwork:MultiZone:ReferenceCrackConditions

This object specifies the reference conditions for temperature, humidity, and pressure which correspond to the [AirflowNetwork:MultiZone:Surface:Crack](#) object.

### 1.28.8.1 Inputs

#### 1.28.8.1.1 Field: Name

The name of this Reference Crack Conditions object. This name is referenced by an [AirflowNetwork:MultiZone:Surface:Crack](#) object.

#### 1.28.8.1.2 Field: Reference Temperature

The reference temperature in °C under which the Surface Crack Data were obtained. The default value is 20°C.

#### 1.28.8.1.3 Field: Reference Barometric Pressure

The reference barometric pressure in Pa under which the Surface Crack Data were obtained. The default value is 101325 Pa.

#### 1.28.8.1.4 Field: Reference Humidity Ratio

The reference humidity ratio in kgWater/kgDryAir under which the Surface Crack Data were obtained. The default value is 0 kgWater/kgDryAir.

An IDF example is provided below:

---

```

AirflowNetwork:MultiZone:ReferenceCrackConditions,
  ReferenceCrackConditions,    !- Name of Reference Crack Conditions
  20.0,                       !- Reference Temperature for Crack Data {C}
  101325,                     !- Reference Barometric Pressure for Crack Data {Pa}
  0.0;                        !- Reference Humidity Ratio for Crack Data {kgWater/kgDryAir}

```

---

## 1.28.9 AirflowNetwork:MultiZone:Surface:Crack

This object specifies the properties of air flow through a crack and the associated measurement conditions. The following power law form is used that gives air flow through the crack as a function of the pressure difference across the crack:

$$Q = (Crack\ Factor) * C_T * C_Q (\Delta P)^n \quad (1.104)$$

Where

$Q$  = air mass flow (kg/s)

$C_Q$  = air mass flow coefficient (kg/s-Pa<sup>n</sup> @ 1 Pa)

$C_T$  = reference condition temperature correction factor (dimensionless)

$\Delta P$  = pressure difference across crack (Pa)

$n$  = air flow exponent (dimensionless)

$$C_T = \left[ \frac{\rho_o}{\rho} \right]^{n-1} \left[ \frac{\nu_o}{\nu} \right]^{2n-1} \quad (1.105)$$

where

$\rho$  = Air density at the specific air temperature and humidity ratio conditions [kg/m<sup>3</sup>]

$\nu$  = Air kinetic viscosity at the specific air temperature condition [m<sup>2</sup>/s]

$\rho_o$  = Air density at the reference air conditions provided by the object `AirflowNetwork:MultiZone:ReferenceCrackConditions` specified in the field Reference Crack Conditions [kg/m<sup>3</sup>]

$\nu_o$  = Air kinetic viscosity at the reference air temperature provided by the object `AirflowNetwork:MultiZone:ReferenceCrackConditions` specified in the field Reference Crack Conditions [m<sup>2</sup>/s]

Note: The correction factor shown above is use for this particular component as specified.

### 1.28.9.1 Inputs

#### 1.28.9.1.1 Field: Name

This is a name for this `AirflowNetwork:MultiZone:Surface:Crack` object. It is referenced by an `AirflowNetwork:MultiZone:Surface` object.

#### 1.28.9.1.2 Field: Air Mass Flow Coefficient at Reference Conditions

The value of the air mass flow coefficient,  $C_Q$ , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero.

#### 1.28.9.1.3 Field: Air Mass Flow Exponent

The value of the exponent,  $n$ , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.

#### 1.28.9.1.4 Field: Reference Crack Conditions

The name of the `AirflowNetwork:MultiZone:ReferenceCrackConditions` object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one `AirflowNetwork:MultiZone:ReferenceCrackConditions` object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one `AirflowNetwork:MultiZone:ReferenceCrackConditions` objects are defined in the input data file, then the default conditions for the `AirflowNetwork:MultiZone:ReferenceCrackConditions` object will be used.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Surface:Crack,
CR-1,                !- Name of Surface Crack Component
0.01,                !- Air Mass Flow Coefficient at Reference Conditions {kg/s}
0.667,              !- Air Mass Flow Exponent {dimensionless}
ReferenceCrackConditions; !- Reference Crack Conditions
```

## 1.28.10 AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea

The effective leakage area (ELA) object is used to define surface air leakage. It has five fields. The relationship between pressure and airflow may be expressed as:

$$\dot{m} = ELA * C_d \sqrt{2\rho} * (\Delta P_r)^{0.5-n} (\Delta P)^n \quad (1.106)$$

where

$\dot{m}$  = Air mass flow rate [kg/s]

ELA = Effective leakage area [m<sup>2</sup>]

$\rho$  = Air density [kg/m<sup>3</sup>]  
 $\Delta P_r$  = Reference pressure difference [Pa]  
 $\Delta P$  = Pressure difference across this component [Pa]  
 $C_d$  = Discharge coefficient [dimensionless]  
 $n$  = Air mass flow exponent [dimensionless]

### 1.28.10.1 Inputs

#### 1.28.10.1.1 Field: Name

This is a name for this `AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea` object. It is referenced by an `AirflowNetwork:MultiZone:Surface` object.

#### 1.28.10.1.2 Field: Effective Leakage Area

This numeric field is used to input the effective leakage area in square meters. The effective leakage area is used to characterize openings for infiltration calculations (ASHRAE Handbook of Fundamentals, 1997, pp 25.18). This value must be greater than zero.

#### 1.28.10.1.3 Field: Discharge Coefficient

This numeric field is used to input the discharge coefficient. This value must be greater than zero, with a default value of 1.0.

#### 1.28.10.1.4 Field: Reference Pressure Difference

This numeric field is used to input the reference pressure difference [Pa]. This value must be greater than zero, with a default value of 4.0 Pa.

#### 1.28.10.1.5 Field: Air Mass Flow Exponent

This numeric field is used to input the pressure difference exponent. The valid range of the exponent is from 0.5 to 1.0, with a default value of 0.65.

Note: There are two common sets of reference conditions:  $C_d = 1.0$  and  $\Delta P = 4$  Pa, or  $C_d = 0.6$  and  $\Delta P = 10$  Pa

An IDF example is shown below:

```

AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea,
  SurfaceELR,           !- Name of surface effective leakage area component
  0.07,                 !- Effective leakage area {dimensionless}
  1.00,                 !- Discharge coefficient {dimensionless}
  4.0,                  !- Reference pressure difference {Pa}
  0.65;                 !- Air mass flow exponent {dimensionless}
  
```

## 1.28.11 AirflowNetwork:MultiZone:Component:DetailedOpening

This object specifies the properties of air flow through windows and doors (window, door and glass door heat transfer subsurfaces) when they are closed or open. The fields are similar to those for `AirflowNetwork:MultiZone:SurfaceCrack` object when the window or door is closed, but additional fields are required to describe the air flow characteristics when the window or door is open. These additional fields include opening type, opening dimensions, degree of opening, and opening schedule.

The `AirflowNetwork` model assumes that open windows or doors are vertical or close to vertical; for this reason they are called “Large Vertical Openings.” Such openings can have air flow moving simultaneously

in two different directions depending on stack effects and wind conditions (for example, flow from inside to outside at the top of a window and from outside to inside at the bottom). AirflowNetwork models such two-directional flow, but only for vertical openings.

It is assumed that the air flow through a window opening is unaffected by the presence of a shading device such as a shade or blind on the window. Also, the calculation of conductive heat transfer and solar gain through a window or door assumes that the window or door is closed.

The AirflowNetwork model does not have a model for bi-directional flow through large horizontal openings in exterior surfaces. For this reason, **AirflowNetwork:MultiZone:Component:Detailed-Opening should not be used for exterior horizontal openings**. The best modeling technique in this case is to put an AirflowNetwork:MultiZone:Surface:Crack object in a horizontal surface and use a large air mass flow coefficient. Crack flow is assumed to be uni-directional in any given timestep (but can reverse flow direction from timestep to timestep).

For large horizontal openings in interior surfaces, see AirflowNetwork:MultiZone:Component:-HorizontalOpening.

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

### 1.28.11.1 Inputs

#### 1.28.11.1.1 Field: Name

The name of this AirflowNetwork:MultiZone:Component:DetailedOpening object. It is referenced by an AirflowNetwork:Multizone:Surface object.

#### 1.28.11.1.2 Field: Air Mass Flow Coefficient When Opening is Closed

Crack flow is assumed when the window or door is closed. The units for this air mass flow coefficient ( $C_{Q, unit\ length}$ ) are different from the units for  $C_Q$  (kg/s at 1 Pa pressure difference) defined in an AirflowNetwork:MultiZone:Surface:Crack object. There is no default but the entered value must be greater than zero. The program will automatically generate four cracks around the perimeter of the window or door—one along the bottom, one along the top, and one on each side. The temperature correction factor used in the AirflowNetwork:MultiZone:Surface:Crack object is not used for this component to calculate air mass flow rate.

#### 1.28.11.1.3 Field: Air Mass Flow Exponent When Opening Is Closed

Crack flow is assumed when the window or door is closed. In this case, the value of this field is the exponent,  $n$ , in the crack air flow equation. The valid range for this exponent is 0.5 to 1.0, with the default value being 0.65. Mass Flow Rate = Air Mass Flow Coefficient ( $\Delta P$ ) Air Mass Flow Exponent.

#### 1.28.11.1.4 Field: Type of Rectangular Large Vertical Opening (LVO)

This alpha field specifies the type of rectangular window or door. (Open windows or doors are also called Large Vertical Openings (LVOs). The choices for the opening type are **NonPivoted** (LVO Type 1) and **HorizontallyPivoted** (LVO Type 2) with the default being **NonPivoted**. The NonPivoted type represents a regular window or door. The HorizontallyPivoted type represents a window with a horizontal axis (i.e., a horizontally-pivoting window) and cannot be used for a door.

#### 1.28.11.1.5 Field: Extra Crack Length or Height of Pivoting Axis

Specifies window or door characteristics that depend on the LVO type.

For LVO Type 1 (rectangular non-pivoted windows and doors) this field is the extra crack length in meters due to multiple openable parts, if present. “Extra” here means in addition to the length, calculated by the program, of the cracks on the top, bottom and sides of the window/door.

For LVO Type 2 (rectangular horizontally-pivoted windows) this field gives the height of the pivoting axis measured from the bottom of the glazed part of the window (m).

#### 1.28.11.1.6 Field: Number of Sets of Opening Factor Data

This is the number of the following sets of data for opening factor, discharge coefficient, width factor, height factor, and start height factor. From two to four of these sets must be defined. The first set should be for Opening Factor = 0.0 and the last set should be for Opening Factor = 1.0. For example, if only two sets are defined, the first set should be for Opening Factor = 0.0 and the second set should be for Opening Factor = 1.0, as shown below in the IDF example below.

An “opening factor” refers to the amount that a window or door is opened. The program linearly interpolates each timestep between the values of discharge coefficient, width factor, etc., in these sets using the opening factor for the window or door for the timestep. (See discussion under the field Window/Door Opening Factor in the AirflowNetwork:Multizone:Zone object for a description of how the AirflowNetwork model determines the time-step value of the opening factor.)

#### 1.28.11.1.7 Field Group: Opening Factor, Discharge Coefficient, Width Factor, Height Factor, Start Height Factor

Each field is described for as many groups as required in the previous field (number of sets of opening factor data). As the final field has specific requirements, this field (n) will be described.

#### 1.28.11.1.8 Field: Opening Factor 11

The first opening factor of a window or door. This value must be 0.0. The default value is also 0.0.

For LVO Type 1 (rectangular non-pivoted window or door), the Opening Factor corresponds to the fraction of window or door that is opened.

For LVO Type 2 (rectangular horizontally-pivoted windows), the Opening Factor is determined by the window opening angle. For example, an opening angle of 45° corresponds to an Opening Factor of 0.50 since the maximum opening angle is 90°.

#### 1.28.11.1.9 Field: Discharge Coefficient for Opening Factor 1

The discharge coefficient of the window or door for Opening Factor 1. The range is greater than 0.0 to less than or equal to 1.0. The default value is 0.001. The Discharge Coefficient indicates the fractional effectiveness for air flow through a window or door at that Opening Factor.

**Note:** In the following, “window width” and “window height” are glazing dimensions; they do not include the frame, if present.

#### 1.28.11.1.10 Field: Width Factor for Opening Factor 1

The Width Factor of the rectangular window or door for Opening Factor 1. The Width Factor is the opening width divided by the window or door width (see Figure 1.118). The range is 0.0 to 1.0. The default value is 0.0. Note that the width factor applies to rectangular windows or doors where the width is assumed constant along the entire height of the opening.

#### 1.28.11.1.11 Field: Height Factor for Opening Factor 1

The Height Factor of the rectangular window or door for Opening Factor 1. The Height Factor is the opening height divided by the window or door height (see Figure 1.118). The range is 0.0 to 1.0. The

default value is 0.0. Note that the height factor applies to rectangular windows or doors where the height is assumed constant along the entire width of the opening.

**1.28.11.1.12 Field: Start Height Factor for Opening Factor 1**

The Start Height Factor of the window or door for Opening Factor 1. The Start Height Factor is the Start Height divided by the window or door height (see Figure 1.118). The range is 0.0 to 1.0. The default is 0. Start Height is the distance between the bottom of the window or door and the bottom of the window or door opening. The sum of the Height Factor and the Start Height Factor must be less than 1.0 in order to have the opening within the window or door dimensions.

Figure 1.118: Window (or door) showing geometrical factors associated with an opening through which air flows.

**1.28.11.1.13 Field: Opening Factor <n>**

When Number of Sets of Opening Factor Data = n, the value of Opening Factor n must be set to 1.0.

**1.28.11.1.14 Field: Discharge Coefficient for Opening Factor <n>**

The discharge coefficient of the window or door for Opening Factor n. The range is greater than 0.0 to less than or equal to 1.0. The default value is 1.0.

**1.28.11.1.15 Field: Width Factor for Opening Factor <n>**

The Width Factor of the rectangular window or door for Opening Factor n. The Width Factor is the opening width divided by the window or door width (see Figure 1.118). The range is 0.0 to 1.0. The default value is 1.0.

**1.28.11.1.16 Field: Height Factor for Opening Factor <n>**

The Height Factor of the rectangular window or door for Opening Factor n. The Height Factor is the opening height divided by the window or door height (see Figure 1.118). The range is 0.0 to 1.0. The default value is 1.0.

### 1.28.11.1.17 Field: Start Height Factor for Opening Factor <n>

The Start Height Factor of the window or door for Opening Factor *n*. The Start Height Factor is the Start Height divided by the window or door height (see Figure 1.118). The range is 0.0 to 1.0. The default is 0.

When the opening factor value (as described under the field Window/Door Opening Factor in the **AirflowNetwork:MultiZone:Surface** object) is between two Opening Factor field values, the values of Discharge Coefficient, Width Factor, Height Factor, and Start Height Factor are linearly interpolated.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Component:DetailedOpening,
    W1Open1,           !- Detailed Opening Name
    0.001,              !- Air Mass Flow Coefficient When Opening is Closed {kg/s-m}
    0.667,              !- Air Mass Flow Exponent When Opening is Closed {dimensionless}
    NonPivoted,         !- Type of Large Vertical Opening (LVO)
    0.0,                !- Extra crack length for LVO type 1 with multiple openable parts,
                        !- or Height of pivoting axis for LVO type 2 {m}
    2,                  !- Number of Sets of Opening Factor Data
    0.0,                !- Opening factor 1 {dimensionless}
    0.5,                !- Discharge coefficient for opening factor 1 {dimensionless}
    0.0,                !- Width factor for opening factor 1 {dimensionless}
    1.0,                !- Height factor for opening factor 1 {dimensionless}
    0.0,                !- Start height factor for opening factor 1 {dimensionless}
    1.0, 0.6, 1.0, 1.0, 0.0; !- Set of values for opening factor 2
```

## 1.28.12 AirflowNetwork:MultiZone:Component:HorizontalOpening

This object specifies the properties of air flow through windows, doors and glass doors (heat transfer subsurfaces defined as a subset of **FenestrationSurface:Detailed** objects) when they are closed or open. This AirflowNetwork model assumes that these openings are horizontal or close to horizontal and are interzone surfaces. The second and third input fields are similar to those for **AirflowNetwork:MultiZone:Surface:Crack**, when the window or door is closed, but additional information is required to describe the air flow characteristics when the window or door is open. This additional information is specified in the last two input fields. The airflow across the opening consists of two types of flows: forced and buoyancy. The forced flow is caused by the pressure difference between two zones, while the buoyancy flow only occurs when the air density in the upper zone is greater than the air density in the lower zone. This opening also allows for the possibility of two-way flow when forced and buoyancy flows co-exist. This object's openness can also be modulated based on the same opening factor control as an **AirflowNetwork:MultiZone:Component:DetailedOpening** object. However, the opening factor is only applied to the subsurface width. The opening width is equal to opening factor multiplied by the subsurface width.

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

### 1.28.12.1 Inputs

#### 1.28.12.1.1 Field: Name

This is a name for this AirflowNetwork:MultiZone:Component:HorizontalOpening object. It is referenced by an **AirflowNetwork:MultiZone:Surface** object.

#### 1.28.12.1.2 Field: Air Mass Flow Coefficient When Opening is Closed

The value of the air mass flow coefficient,  $C_{Q, unit\ length}$ , in the horizontal opening air flow equation. It has units of kg/s-m at 1Pa. The temperature correction factor is not applied to the mass flow calculation. This is a required input field and the entered value must be greater than zero.

### 1.28.12.1.3 Field: Air Mass Flow Exponent When Opening is Closed

The value of the exponent,  $n$ , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.

### 1.28.12.1.4 Field: Sloping Plane Angle

This numeric field is used to represent the angle between the horizontal plane and a sloped plane under the horizontal opening. Sloping plane angle = 90 is equivalent to fully open. The valid range is >0 to 90, with the default value being 90.

### 1.28.12.1.5 Field: Discharge Coefficient

This numeric field is used to input the discharge coefficient. This is a required field and the entered value must be greater than zero.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Component:HorizontalOpening,
    HrOpen,                !- Name
    0.001,                  !- Air Mass Flow Coefficient When Opening is Closed {kg/s-m}
    0.667,                  !- Air Mass Flow Exponent When Opening is Closed {dimensionless}
    90.0,                   !- Sloping Plane Angle
    0.2;                    !- Discharge Coefficient
```

## 1.28.13 AirflowNetwork:MultiZone:Component:SimpleOpening

This object specifies the properties of air flow through windows, doors and glass doors (heat transfer subsurfaces) when they are closed or open. The AirflowNetwork model assumes that open windows or doors are vertical or close to vertical. The second and third fields are similar to those for [AirflowNetwork:MultiZone:Surface:Crack](#), when the window or door is closed, but additional information is required to describe the air flow characteristics when the window or door is open. This additional information is specified in the last two fields. Compared to the object [AirflowNetwork:MultiZone:Component:DetailedOpening](#), which requires more inputs at different opening factors, this object needs comparatively less inputs. For this reason it is called a simple opening. This opening also allows for the possibility of two-way flow due to temperature and resulting density differences. Therefore, it is possible to have a positive pressure difference at the top of the opening, and a negative pressure difference at the bottom (or vice versa) when the neutral height is between the bottom and top heights of the associated surface. This object's openness can also be modulated based on the same opening factor control as an [AirflowNetwork:MultiZone:Component:DetailedOpening](#) object. However, the opening factor is only applied to the subsurface width. The opening width is equal to opening factor multiplied by the subsurface width.

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

### 1.28.13.1 Inputs

#### 1.28.13.1.1 Field: Name

This is a name for this AirflowNetwork:MultiZone:Component:SimpleOpening object. It is referenced by an [AirflowNetwork:MultiZone:Surface](#) object.

#### 1.28.13.1.2 Field: Air Mass Flow Coefficient When Opening is Closed

The value of the air mass flow coefficient,  $C_{Q, unit\ length}$ , in the simple opening air flow equation. It has units of kg/s-m at 1Pa. The temperature correction factor is not applied for mass flow calculation.

**1.28.13.1.3 Field: Air Mass Flow Exponent When Opening is Closed**

The value of the exponent,  $n$ , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.  $\text{Mass Flow Rate} = \text{Air Mass Flow Coefficient} (\Delta P)^{\text{Air Mass Flow Exponent}}$ .

**1.28.13.1.4 Field: Minimum Density Difference for Two-Way Flow**

This numeric field is used to input the minimum density difference above which two-way or one way flow may occur due to stack effect with the window being open. Two-way flow occurs only when the neutral plane is within the opening. Density differences less than this value result in one-way flow only with the window being closed. The minimum value for this field is greater than zero.

**1.28.13.1.5 Field: Discharge Coefficient**

This numeric field is used to input the discharge coefficient. This value must be greater than zero.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Component:SimpleOpening,
    WiOpen2,           !- Simple Opening Name
    0.001,              !- Air Mass Flow Coefficient When Opening Is Closed {kg/s-m}
    0.650,              !- Air Mass Flow Exponent When Opening Is Closed {dimensionless}
    0.0001,             !- Minimum density difference for two-way flow (kg/m3)
    1.0;               !- Discharge coefficient (dimensionless)
```

**1.28.14 AirflowNetwork:MultiZone:Component:ZoneExhaustFan**

This object specifies the properties of air flow through an exterior heat transfer surface with a zone exhaust fan. The zone exhaust fan turns on or off based on the availability schedule defined in the corresponding **Fan:ZoneExhaust** object. When the exhaust fan mass flow rate is greater than zero, the airflow network model treats this object as a constant volume fan. When the fan is off based on the availability schedule, the model treats this object as a crack.

When the fan is on, the air mass flow rate modeled for the airflow network is based on the value defined in the MaximumFlow Rate field of the **Fan:ZoneExhaust** object. The airflow direction is from the corresponding zone to outdoors.

When the fan is off, the following power law form is used that gives air flow through the crack as a function of the pressure difference across the crack:

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n \quad (1.107)$$

Where

$Q$  = air mass flow (kg/s)

$C_Q$  = air mass flow coefficient (kg/s-Pa<sup>n</sup> @ 1 Pa)

$C_T$  = reference condition temperature correction factor (dimensionless)

$\Delta P$  = pressure difference across crack (Pa)

$n$  = air flow exponent (dimensionless)

$$C_T = \left[ \frac{\rho_o}{\rho} \right]^{n-1} \left[ \frac{\nu_o}{\nu} \right]^{2n-1} \quad (1.108)$$

where

$\rho$  = Air density at the specific air temperature and humidity ratio conditions [kg/m<sup>3</sup>]

$\nu$  = Air kinetic viscosity at the specific air temperature condition [m<sup>2</sup>/s]

$\rho_o$  = Air density at the reference air conditions provided by the object AirflowNetwork:MultiZone:-ReferenceCrackConditions specified in the field Reference Crack Conditions [kg/m<sup>3</sup>]

$\nu_o$  = Air kinetic viscosity at the reference air temperature provided by the object `AirflowNetwork:MultiZone:ReferenceCrackConditions` specified in the field Reference Crack Conditions [m<sup>2</sup>/s]

Note: The correction factor shown above is used when the exhaust fan is off. The airflow direction is based on the pressure difference between the zone and outdoors.

### 1.28.14.1 Inputs

#### 1.28.14.1.1 Field: Name

This is the name for this instance of the `AirflowNetwork:MultiZone:Component:ZoneExhaustFan` object. This name must be the same name defined in the `Fan:ZoneExhaust` object. It is referenced by an `AirflowNetwork:Multizone:Surface` object.

#### 1.28.14.1.2 Field: Air Mass Flow Coefficient When the Zone Exhaust Fan is Off at Reference Conditions

The value of the air mass flow coefficient,  $C_Q$ , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero. The value is used when the fan is off.

#### 1.28.14.1.3 Field: Air Mass Flow Exponent When the Zone Exhaust Fan is Off

The value of the exponent,  $n$ , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65. The value is used when the fan is off.

#### 1.28.14.1.4 Field: Reference Crack Conditions

The name of the `AirflowNetwork:MultiZone:ReferenceCrackConditions` object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one `AirflowNetwork:MultiZone:ReferenceCrackConditions` object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one `AirflowNetwork:MultiZone:ReferenceCrackConditions` objects are defined in the input data file, then the default conditions for the `AirflowNetwork:MultiZone:ReferenceCrackConditions` object will be used.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Component:ZoneExhaustFan,

```

## 1.28.15 AirflowNetwork:MultiZone:ExternalNode

External nodes in the `AirflowNetwork` model define environmental conditions outside of the building. These conditions include wind pressure coefficients that vary from façade to façade and can be highly dependent on the building geometry.

`AirflowNetwork:MultiZone:ExternalNode` objects do **not** have to be entered if Wind Pressure Coefficient Type = SurfaceAverageCalculation in the `AirflowNetwork:SimulationControl` object.

### 1.28.15.1 Inputs

#### 1.28.15.1.1 Field: Name

The external node name is associated with a particular building façade. This name is referenced by the External Node Name field of an `AirflowNetwork:MultiZone:Surface` object.

### 1.28.15.1.2 Field: External Node Height

Designates the reference height, in meters, used to calculate relative pressure. The default value is 0 meters.

### 1.28.15.1.3 Field: Wind Pressure Coefficient Curve Name

The name of a specific `AirflowNetwork:MultiZone:WindPressureCoefficientValues` object, curve, or table (which gives wind pressure coefficients for the façade as a function of angle of wind incident on the façade). Curves or tables should have the domain of 0 to 180 degrees or 0 to 360 degrees, depending upon the symmetry field (see below).

**1.28.15.1.4 Field: Symmetric Wind Pressure Coefficient Curve** Specifies the symmetry of the above named curve. The default is No, meaning that the curve will be evaluated from 0 to 360 degrees. Specify Yes for a curve that is symmetric about zero and is evaluated only up to 180 degrees. For this type of curve, an angle of 270 degrees is passed to the curve as 90 degrees.

**1.28.15.1.5 Field: Wind Angle Type** Specifies which wind angle should be used to calculate the wind pressure coefficient. The default is Absolute, meaning that the absolute wind direction angle will be used. Specifying Relative means that the angle will be relative to the surface normal. For a surface facing due east, the angle 0 corresponds to wind blowing perpendicular to and at the surface with absolute direction 90 degrees, while 90 degrees corresponds to wind blowing parallel to the surface from the right (facing outward) with an absolute direction of 180 degrees.

IDF examples are provided below:

```
AirflowNetwork:MultiZone:ExternalNode,
    NFacade,                !- Name
    1.524,                  !- External Node Height {m}
    NFacade_WPCValue;       !- Wind Pressure Coefficient Curve Name

AirflowNetwork:MultiZone:ExternalNode,
    EFacade,                !- Name
    1.524,                  !- External Node Height {m}
    EFacade_WPCValue;       !- Wind Pressure Coefficient Curve Name

AirflowNetwork:MultiZone:ExternalNode,
    SFacade,                !- Name
    1.524,                  !- External Node Height {m}
    SFacade_WPCValue;       !- Wind Pressure Coefficient Curve Name

AirflowNetwork:MultiZone:ExternalNode,
    WFacade,                !- Name
    1.524,                  !- External Node Height {m}
    WFacade_WPCValue;       !- Wind Pressure Coefficient Curve Name

AirflowNetwork:MultiZone:ExternalNode,
    Horizontal,             !- Name
    3.028,                  !- External Node Height {m}
    Horizontal_WPCValue;    !- Wind Pressure Coefficient Curve Name
```

## 1.28.16 AirflowNetwork:MultiZone:WindPressureCoefficientArray

The reference height and wind directions are first specified under the `AirflowNetwork:MultiZone:WindPressureCoefficientArray` object. The user may specify up to 36 different wind directions in ascending order. These are then referenced by `AirflowNetwork:MultiZone:WindPressureCoefficientValues` objects defined for each `AirflowNetwork:MultiZone:ExternalNode`.

The `AirflowNetwork:MultiZone:WindPressureCoefficientArray` object is unique and needs to be entered only if Wind Pressure Coefficient Type = INPUT in the `AirflowNetwork:SimulationControl` object. If Wind Pressure Coefficient Type = SurfaceAverageCalculation, this object is not required.

### 1.28.16.1 Inputs

#### 1.28.16.1.1 Field: Name

The name of this `AirflowNetwork:MultiZone:WindPressureCoefficientArray` object. This name is referenced by each `AirflowNetwork:MultiZone:WindPressureCoefficientValues` object which, for each `AirflowNetwork:MultiZone:ExternalNode`, gives the wind pressure coefficients at each of the wind directions listed in the `AirflowNetwork:MultiZone:WindPressureCoefficientArray`. This name is also referenced by the `AirflowNetwork:SimulationControl` object, indicating that this `AirflowNetwork:MultiZone:WindPressureCoefficientArray` and the pressure coefficients in the associated `AirflowNetwork:MultiZone:WindPressureCoefficientValues` objects will be used in the air flow simulation.

#### 1.28.16.1.2 Field: Wind Direction 1-Wind Direction N

Each field references the wind direction corresponding to the first through the Nth WPC value in each of the `AirflowNetwork:MultiZone:WindPressureCoefficientValues` objects.  $N$  can be as high as 36.

An IDF example is provided below:

```
AirflowNetwork:MultiZone:WindPressureCoefficientArray,
  Every 30 Degrees,      !- WPC Array Name
  0,                    !- Wind Direction #1 {deg}
  30,                   !- Wind Direction #2 {deg}
  60,                   !- Wind Direction #3 {deg}
  90,                   !- Wind Direction #4 {deg}
  120,                  !- Wind Direction #5 {deg}
  150,                  !- Wind Direction #6 {deg}
  180,                  !- Wind Direction #7 {deg}
  210,                  !- Wind Direction #8 {deg}
  240,                  !- Wind Direction #9 {deg}
  270,                  !- Wind Direction #10 {deg}
  300,                  !- Wind Direction #11 {deg}
  330;                  !- Wind Direction #12 {deg}
```

---

## 1.28.17 AirflowNetwork:MultiZone:WindPressureCoefficientValues

This object specifies up to 36 wind pressure coefficients (WPCs) for an `AirflowNetwork:MultiZone:ExternalNode`. These coefficients are defined for each of the wind directions defined in the unique `AirflowNetwork:MultiZone:WindPressureCoefficientArray` object. In the air flow calculation, interpolation of the specified WPC values is done for time-step values of wind direction.

`AirflowNetwork:MultiZone:WindPressureCoefficientValues` objects need to be entered only if the Wind Pressure Coefficient Type = INPUT in the `AirflowNetwork:SimulationControl` object. If Wind Pressure Coefficient Type = SurfaceAverageCalculation, this object is not required and is not used.

### 1.28.17.1 Inputs

#### 1.28.17.1.1 Field: Name

The name of this `WindPressureCoefficientValues` object. This name can be referenced by multiple `AirflowNetwork:MultiZone:ExternalNode` objects.

### 1.28.17.1.2 Field: WindPressureCoefficientArray Name

Name of the associated `AirflowNetwork:MultiZone:WindPressureCoefficientArray`, which lists the wind direction corresponding to each wind pressure coefficient value in this `AirflowNetwork:MultiZone:WindPressureCoefficientValues` object.

### 1.28.17.1.3 Field: Wind Pressure Coefficient Value 1 to Wind Pressure Coefficient Value N

The WPC (wind pressure coefficient) value for the building façade indicated by the External Node Name field above. This WPC value corresponds to the first wind direction in the `AirflowNetwork:MultiZone:WindPressureCoefficientArray`. Note that WPC values can be positive, negative or zero.

### 1.28.17.1.4 Obtaining WPC values

WPC values can be obtained from wind tunnel measurements, CFD calculations, or from published values for different building shapes.

For **rectangular buildings** EnergyPlus will automatically calculate surface-averaged  $C_p$  values for the walls and roof of the building if you specify Wind Pressure Coefficient Type = SurfaceAverageCalculation in the `AirflowNetwork:SimulationControl` object. In this case you do not have to enter any `AirflowNetwork:MultiZone:WindPressureCoefficientValues` objects.

Wind pressure coefficients are reported in the `eplusout.eio` either from inputs using “INPUT” as the choice for the Wind Pressure Coefficient Type field defined in the `AirflowNetwork:SimulationControl` object, or from internal calculation using SurfaceAverageCalculation as the choice for the Wind Pressure Coefficient Type field defined in the same object. Below is an output example from the `eplusout.eio` file:

```
AirflowNetwork Model:Wind Direction, 0.0,30.0,60.0,90.0,120.0,150.0,180.0,210.0,240.0,270.0,300.0,330.0
! <AirflowNetwork Model:Wind Pressure Coefficients, WPC Name, Wind Pressure Coefficients #1 to n (
  dimensionless)>

```

## 1.28.18 AirflowNetwork:OccupantVentilationControl

The `AirflowNetwork:OccupantVentilationControl` object provides control options with minimum opening and closing time checks and opening and closing probability values. In general, the probability values

could be a constant or a specific function. Due to lack of real data, two schedules are selected to represent probability values. If real data are available, this object may be modified to adopt new data.

### 1.28.18.1 Inputs

#### 1.28.18.1.1 Field: Name

This is the name of the object.

#### 1.28.18.1.2 Field: Minimum Opening Time

The field represents the minimum time that windows will remain open. If a window has been open for a time less than this value, the window will remain open.

#### 1.28.18.1.3 Field: Minimum Closing Time

The field represents the minimum time that windows will remain closed. If a window has been closed for a time less than this value, the window will remain closed.

#### 1.28.18.1.4 Field: Thermal Comfort Low Temperature Curve Name

This alpha field defines the name of a curve to be used for thermal comfort temperature calculation at low outdoor dry-bulb temperature. This curve is a linear or quadratic equation using outdoor dry-bulb temperatures as an independent variable. This performance curve can be used to describe the thermal comfort temperature at low outdoor dry-bulb temperature. It allows maximum two curves to describe the thermal comfort temperature in two different outdoor dry-bulb temperature regions. If a single curve is used, blanks are entered in the following two fields.

#### 1.28.18.1.5 Field: Thermal Comfort Temperature Boundary Point

When there are two piecewise curves to represent thermal comfort temperature calculation, this field represents a boundary point of outdoor dry-bulb temperature. The low temperature curve and the high temperature curve should have the same values at the boundary point. If a single curve is used, this field may be left blank.

#### 1.28.18.1.6 Field: Thermal Comfort High Temperature Curve Name

This alpha field defines the name of a curve to be used for thermal comfort temperature calculation at high outdoor dry-bulb temperature. This curve is a linear or quadratic equation using outdoor dry-bulb temperatures as an independent variable. This performance curve can be used to describe the thermal comfort temperature at high outdoor dry-bulb temperature. It allows maximum two curves to describe the thermal comfort temperature in two different outdoor dry-bulb temperature regions. If a single curve is used, blanks are entered in this field.

#### 1.28.18.1.7 Field: Maximum Threshold for Persons Dissatisfied PPD

This field is used to calculate the comfort band as a function of predicted percentage of dissatisfied (PPD). The default value is 10%. The equation is based on curve fit and is valid between 0% and 35%.

$$\Theta = -0.0028(100 - PPD)^2 + 0.3419(100 - PPD) - 6.6275 \quad (1.109)$$

where

- $\Theta$  is the comfort band (degC)
- PPD is predicted percentage person of dissatisfied (%)

**1.28.18.1.8 Field: Occupancy Check**

Input is Yes or No. The default is No. If Yes, an occupancy check is performed used in the opening probability check. If No, the occupancy check is bypassed.

**1.28.18.1.9 Field: Opening Probability Schedule Name**

The name of a schedule of opening probability that controls the opening of windows and doors in the thermal zone to provide natural ventilation. If the probability value is greater a random number, windows are allowed to open. Otherwise, the output will be false. This control will occur when minimum time checks for both opening and closing are satisfied.

**1.28.18.1.10 Field: Closing Probability Schedule Name**

The name of a schedule of closing probability that controls the closing of windows and doors in the thermal zone to reduce natural ventilation. If the probability value is greater a random number, windows are allowed to be closed. Otherwise, the output will be false. This control will occur when minimum time checks for both opening and closing are satisfied.

An IDF example is provided below:

```
AirflowNetwork:OccupantVentilationControl,
VentilationControl,          !- Name
5.0,                         !- Minimum Opening Time
5.0,                         !- Minimum Opening Time
ComfortLowTempCurve,        !- Thermal Comfort Low Temperature Curve Name
10.0,                       !- Thermal Comfort Temperature Boundary Point
ComfortHighTempCurve,       !- Thermal Comfort High Temperature Curve Name
10.0,                       !- Maximum Threshold for Persons Dissatisfied PPD
Yes,                         !- Occupancy Check
OpeningProbabilitySch,       !- Opening Probability Schedule Name
ClosingProbabilitySch;       !- Closing Probability Schedule Name
```

**1.28.19 AirflowNetwork:ZoneControl:PressureController**

The AirflowNetwork:ZoneControl:PressureController object is used to control a zone to a specified indoor level of pressure using the AirflowNetwork model. The specified pressure setpoint is used to calculate the required zone exhaust fan flow rate in a controlled zone or relief air flow rate in an AirLoop.

The object has a similar function as **ZoneControl:Thermostat**. When an AirLoop serves multiple zones, the controlled zone will reach the specified setpoint, while other zones will not be controlled precisely.

**1.28.19.1 Inputs****1.28.19.1.1 Field: Name**

Unique identifying name for the AirflowNetwork:ZoneControl:PressureController.

**1.28.19.1.2 Field: Control Zone Name**

Name of the zone that is being controlled.

**1.28.19.1.3 Field: Control Object Type**

This field specifies the control type to be used for pressure control. Available control types are: **AirflowNetwork:MultiZone:Component:ZoneExhaustFan** and **AirflowNetwork:Distribution:Component:ReliefAirFlow**.

**1.28.19.1.4 Field: Control Object Name**

The corresponding control object name.

#### 1.28.19.1.5 Field: Pressure Control Availability Schedule Name

This field contains the name of a schedule that determines whether or not the `AirflowNetwork:ZoneControl:PressureController` is available. When the schedule value is zero, the `AirflowNetwork:ZoneControl:PressureController` is bypassed (not available to operate). When the schedule value is greater than zero, the `AirflowNetwork:ZoneControl:PressureController` is available to perform pressure control. When `AirflowNetwork:Distribution:Component:ZoneExhaustFan` is entered in the Control Object Type field, the model will calculate the required zone exhaust fan airflow rate to reach the pressure setpoint. When an `AirflowNetwork:Distribution:Component:ReliefAirFlow` is entered in the Control Object Type field, the model will calculate the central relief flow rate in an outdoor air mixer. If this field is left blank, the schedule has a value of 1 for all time periods. Schedule values must be between 0 and 1.

#### 1.28.19.1.6 Field: Pressure Setpoint Schedule Name

This field contains the name of a schedule that contains the zone air pressure setpoint as a function of time. The units for pressure setpoint are Pascal. The setpoint values in the schedule must be between -50 and 100 Pascal.

An IDF example is provided below:

```
AirflowNetwork:ZoneControl:PressureController,
  Pressure Controller1,          !- Name
  EAST ZONE,                     !- Controlled Zone Name
  AirflowNetwork:MultiZone:Component:ZoneExhaustFan, !- Control Object type
  East Zone Exhaust Fan,         !- Control Object Name
  PressureAvailSchedule,         !- Pressure Control Availability Schedule Name
  PressureSetpointSchedule;      !- Pressure Setpoint Schedule Name
```

### 1.28.20 AirflowNetwork with RoomAir Models

The next two objects of `AirflowNetwork:IntraZone:Node` and `AirflowNetwork:IntraZone:Linkage` are used with `RoomAir:Node:AirflowNetwork` objects together to simulate multiple internal airflows via multiple intrazone nodes and linkages in a thermal zone. The mixed-air assumption for zone air conditions is not always appropriate. EnergyPlus includes several RoomAir models that can model the implications for different flow patterns on variations in temperature within the zone. However none of them are generalized enough for different types of air flow situations and none are coupled tightly with AirflowNetwork. A general RoomAir model based on pressure network solver will allow modeling a variety of spaces types not currently covered by existing models such as tall spaces.

Recent advancements have been made to AirflowNetwork to model large horizontal openings. This new development makes AirflowNetwork useful for not only modeling air movement between zones (and outdoors), but also within individual thermal zones.

The possible combination will allow the EnergyPlus to simulate a thermal zone using a network approach by assuming internal nodes connected by user-defined patterns of temperatures and airflows. It should be pointed out that the new model works when the `MultiZoneWithoutDistribution` is selected in the field of AirflowNetwork Control of the `AirflowNetwork:SimulationControl` object. The model cannot work with other choices.

### 1.28.21 AirflowNetwork:IntraZone:Node

This object allows users to input multiple nodes in a zone. A single object represent a node. If there is only one node per zone, then use the `AirflowNetwork:MultiZone:Zone` input object. The zone node is not defined in this object.

**1.28.21.1 Field: Name**

The name identifies the node for later reference and in the output listing. Each node should have a unique name. This name can be referenced as `AirflowNetworkNodeNames`.

**1.28.21.2 Field: RoomAir:Node:AirflowNetwork Name**

The name of a `RoomAir:Node:AirflowNetwork` object, which is also defined in a `RoomAirSettings:AirflowNetwork` object (zone based).

**1.28.21.3 Field: Zone Name**

The name of a zone object, which is also defined in a `AirflowNetwork:MultiZone:Zone` object (zone based).

**1.28.21.4 Field: Node Height**

This field requires input of node height in meters.

An IDF example is provided below:

VentilationControl, !- Name

```
AirflowNetwork:IntraZone:Node,
LeftUpper,                !- Name
LeftUpper,                !- RoomAir:Node:AirflowNetwork Name
NORTH_ZONE,               !- Zone Name
4.572;                    !- Node Height {m}
```

**1.28.22 AirflowNetwork:IntraZone:Linkage**

The input object specifies a connection between two `AirflowNetwork:IntraZone:Node` objects and an `AirflowNetwork` component defined elsewhere. The object also allow users to specify a connection between an `AirflowNetwork:IntraZone:Node` and an adjacent zone defined in an `AirflowNetwork:MultiZone:Zone` object. This object provides flexibility to define a linkage either in the same zone or in two different zones.

**1.28.22.1 Field: Name**

The name identifies the linkage for later reference and in the output listing. Each linkage should have a unique name.

**1.28.22.2 Field: Node 1 Name**

The input designates a node name where airflow starts. The node name should be defined in an `AirflowNetwork:IntraZone:Node` object or an `AirflowNetwork:MultiZone:Zone` object.

**1.28.22.3 Field: Node 2 Name**

The input designates a node name where airflow ends. The node name should be defined in an `AirflowNetwork:IntraZone:Node` object or an `AirflowNetwork:MultiZone:Zone` object.

Note: One of Node 1 and Node 2 should be defined as an `AirflowNetwork:IntraZone:Node` object. In other words, both nodes cannot be defined as `AirflowNetwork:MultiZone:Zone` object. This type of connection should be defined as an `AirflowNetwork:MultiZone:Surface` object.

#### 1.28.22.4 Field: Component Name

The input designates an `AirflowNetwork:MultiZone:Component` name associated with the two nodes. The component name should be one of the `AirflowNetwork:MultiZone:Component` object names. The component is used for intrazone node connection only. If the next field is specified, the input of this field could be a blank.

It should be pointed out that an `AirflowNetwork:MultiZone:Surface` object allows following five `AirflowNetwork:MultiZone:Component` objects:

- `AirflowNetwork:MultiZone:Component:DetailedOpening`,
- `AirflowNetwork:MultiZone:Component:SimpleOpening`,
- `AirflowNetwork:MultiZone:Surface:Crack`,
- `AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea`,
- `AirflowNetwork:MultiZone:Component:HorizontalOpening`

However, an `AirflowNetwork:IntraZone:Linkage` object without a surface connection has connection with two intrazone nodes in the same zone and allows two `AirflowNetwork:MultiZone:Component` objects due to lack of geometry inputs.

- `AirflowNetwork:MultiZone:Surface:Crack`,
- `AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea`,

#### 1.28.22.5 Field: Connection Surface

The input specifies an `AirflowNetwork:MultiZone:Surface` object name, when the nodes defined above are not located in the same zone. The surface linkage will be connected by the above two nodes, instead of zone nodes in normal definition. In other words, the connection defined in an `AirflowNetwork:MultiZone:Surface` is removed. Instead, this new connection replaces the the connection specified before. A warning message is issued to let users be aware of the changes. Since each `AirflowNetwork:MultiZone:Surface` object has its own component defined in the Leakage Component Name field, the input of the Component Name field in this object will be ignored.

An IDF example is provided below:

```
AirflowNetwork:IntraZone:Linkage,
  IntraZoneMiddleUpperLink, !- Name
  LeftUpper,                !- Node 1 Name
  CentralUpper,              !- Node 2 Name
  CR-1;                      !- Component Name

AirflowNetwork:IntraZone:Linkage,
  IntraZoneLeftUpperLink,
  LeftUpper,                !- Node 1 Name
  EAST_ZONE_T,              !- Node 2 Name
  CR-1,                     !- Component Name
  Surface_11_T;             !- Surface Name
```

The previous sections of this `AirflowNetwork` model discussion describe input objects used for multi-zone airflow calculations. The following sections describe input objects used for air distribution system simulations. These objects work when control option “MultiZone with Distribution” or “MultiZone with Distribution Only During Fan Operation” is defined in the `AirflowNetwork:SimulationControl` object.

The first section presents the input object for distribution system nodes. Although thermal zones are required to perform air distribution system simulations, the thermal zones are already defined in the multizone input section (described previously), so that there is no need to repeat the inputs for thermal zones when modeling an air distribution system. The same is also true for surface air leakage. This section has only one object: `AirflowNetwork:Distribution:Node`.

### 1.28.23 AirflowNetwork:Distribution:DuctViewFactors

The AirflowNetwork:Distribution:DuctViewFactors object is used to represent the information needed for simplified surface-to-duct radiation heat transfer. View factors from each duct object to each referenced surface are provided by the user. EnergyPlus calculates the heat gain to the duct from the referenced surfaces. If the object is included, radiation is calculated for the referenced duct; radiation is neglected of the object is omitted.

#### 1.28.23.1 Field: Name of Linkage

Name of the linkage object in which the view factors are applied.

#### 1.28.23.2 Field: Surface Exposure Fraction

The fraction, range 0 to 1, of the duct surface that is exposed to the zone for a partially buried duct (dimensionless).

#### 1.28.23.3 Field: Surface Emittance

The air duct surface emittance factor in the range 0 to 1 based on the material properties (dimensionless).

#### 1.28.23.4 Field: Surface 1 Name

This field specifies the name of the surface seen by the duct. Field is extensible to accommodate as many surfaces as required.

#### 1.28.23.5 Field: View Factor 1

This field specifies the view factor from the duct to surface 1. Field is extensible to accommodate as many surfaces as required.

An IDF example is provided below:

```
AirflowNetwork:Distribution:DuctViewFactors,
  Main Link 1,           !- Name of linkage
  0.5,                   !- Surface exposure fraction
  0.9,                   !- Duct surface emittance
  Lshaped Zone:Wall 1,   !- To Surface 1

```

### 1.28.24 AirflowNetwork:Distribution:Node

The AirflowNetwork:Distribution:Node object is used to represent air distribution system nodes for the AirflowNetwork model. The EnergyPlus nodes defined in an **AirLoopHVAC** are a subset of the nodes used to simulate the distribution system using the AirflowNetwork model. For example, the inlet node of a fan and the outlet node of a coil defined in an **AirLoopHVAC** must be defined as nodes using the AirflowNetwork:Distribution:Node object. A set of EnergyPlus Zone Equipment nodes is also a subset of the AirflowNetwork:Distribution:Nodes. For example, zone inlet and outlet nodes must be defined as nodes using the AirflowNetwork:Distribution: Node object. In addition, although mixers

and splitters are defined as objects with inlet and outlet nodes within EnergyPlus, the `AirflowNetwork:Distribution:Node` object treats mixers and splitters as single nodes. The node objects are referenced by `AirflowNetwork:Distribution:Linkage` objects.

In summary, all nodes used to define an `AirLoopHVAC` (except splitters, mixers, and outdoor air systems which are treated as single nodes) and its connections to a thermal zone must be specified as `AirflowNetwork:Distribution:Nodes`. If distribution system air leaks are to be modeled, additional `AirflowNetwork:Distribution:Nodes` may be defined along with `AirflowNetwork:Distribution:Components` (e.g., leak or leak ratio) to define the air leakage characteristics.

Note: Supply and return leaks are not allowed in an `AirLoopHVAC`. They can only be modeled in the Zone Equipment Loop (i.e., return leaks may be modeled between the zone return node and the zone mixer inlet or the zone mixer outlet and the zone equipment loop outlet; and supply leaks may be modeled between the zone equipment loop inlet and the `AirLoopHVAC:ZoneSplitter` inlet node or the `AirLoopHVAC:ZoneSplitter` outlet node and the zone supply node).

### 1.28.24.1 Inputs

#### 1.28.24.1.1 Field: Name

The name of an air distribution system node. This node name is referenced by an `AirflowNetwork:Distribution:Linkage` and in the output listing. Each node should have a unique name within the `AirflowNetwork:Distribution:Node` objects (however, the node name may be used elsewhere as regular EnergyPlus node names such as the fan inlet node or coil outlet node).

#### 1.28.24.1.2 Field:Component Name or Node Name

Designates node names defined in another EnergyPlus object, so that the `AirflowNetwork:Distribution:Node` object is able to get input parameters and node conditions from the associated EnergyPlus node or object. The actual node name is entered here and represents a node already defined in an `AirLoopHVAC` or zone equipment loop. This field is left blank if the EnergyPlus Node Type field below is entered as Mixer, Splitter, Outdoor air System, or Other.

#### 1.28.24.1.3 Field: Component Object Type or Node Type

This choice field distinguishes the node type for the EnergyPlus node or object name defined above. Five node types are available:

- **`AirLoopHVAC:ZoneMixer`**: Represents an `AirLoopHVAC:ZoneMixer` object defined in EnergyPlus
- **`AirLoopHVAC:ZoneSplitter`**: Represents an `AirLoopHVAC:ZoneSplitter` object defined in EnergyPlus
- **`AirLoopHVAC:OutdoorAirSystem`**: Represents an `AirLoopHVAC:OutdoorAirSystem` object used in EnergyPlus
- **`OAMixerOutdoorAirStreamNode`**: Represents an external node name specified as an Outdoor Air Stream Node Name in the `OutdoorAir:Mixer` object when the `AirLoopHVAC:OutdoorAirSystem` object is used.
- **`OutdoorAir:NodeList`**: Represents an external node name defined in the `OutdoorAir:NodeList` object when the `AirLoopHVAC:OutdoorAirSystem` object and an exhaust energy recovery system (air-to-air heat exchanger) are used.

- **OutdoorAir:** Represents an external node name defined in the **OutdoorAir:Node** object when the **AirLoopHVAC:OutdoorAirSystem** and an exhaust energy recovery system (air-to-air heat exchanger) are used.
- **Other:** Represents a type not already defined above.

Note: Both the **OutdoorAir:NodeList** and **OutdoorAir:Node** node types represent a node to outdoor air conditions. Either one of these node types can be used to represent an external node when an air-to-air heat exchanger is used to recover energy from the exhaust air stream as part of an **AirLoopHVAC:OutdoorAirSystem** object. Node type **OAMixerOutdoorAirStreamNode** does not represent an external node when an **OutdoorAir:NodeList** or **OutdoorAir:Node** object is specified. If no exhaust heat recovery system (i.e., air-to-air heat exchanger) is specified in the **AirLoopHVAC:OutdoorAirSystem**, the node type **OAMixerOutdoorAirStreamNode** represents an external node.

#### 1.28.24.1.4 Field: Node Height

Designates the reference height in meters used to calculate relative pressure. The default value is 0 meters.

IDF examples are provided below:

```
AirflowNetwork:Distribution:Node,
    EquipmentInletNode,      !- Name
    Zone Equipment Inlet Node, !- Component Name or Node Name
    Other,                   !- Component Object Type or Node Type
    3.0;                     !- Node Height {m}

AirflowNetwork:Distribution:Node,
    SupplyMainNode,          !- Name
    ,                        !- Component Name or Node Name
    Other,                   !- Component Object Type or Node Type
    3.0;                     !- Node Height {m}

AirflowNetwork:Distribution:Node,
    MainSplitterNode,        !- Name
    ,                        !- Component Name or Node Name
    AirLoopHVAC:ZoneSplitter, !- Component Object Type or Node Type
    3.0;                     !- Node Height {m}

AirflowNetwork:Distribution:Node,
    MainSplitterNode,        !- Name of Node
    ,                        !- Name of Associated EnergyPlus Node or Object
    AirLoopHVAC:ZoneSplitter, !- EnergyPlus Object or Node Type
    3.0;                     !- Node Height {m}
```

The next section describes AirflowNetwork Distribution Components, with 7 available types listed below. All required fields for each component represent a relationship between pressure difference and airflow. The components are referenced in **AirflowNetwork:Distribution:Linkage** objects.

- **AirflowNetwork:Distribution:Component:Leak**
- **AirflowNetwork:Distribution:Component:LeakageRatio**
- **AirflowNetwork:Distribution:Component:Duct**
- **AirflowNetwork:Distribution:Component:Fan**
- **AirflowNetwork:Distribution:Component:Coil**

- [AirflowNetwork:Distribution:Component:HeatExchanger](#)
- [AirflowNetwork:Distribution:Component:TerminalUnit](#)
- [AirflowNetwork:Distribution:Component:ConstantPressureDrop](#)

### 1.28.25 AirflowNetwork:Distribution:Component:Leak

This component may be also called a power law component and is used to represent a supply or return air leak in an air distribution system. Its relationship between pressure difference and airflow may be expressed as:

$$\dot{m} = C_T C (\Delta P)^n \quad (1.110)$$

where

$\dot{m}$  = Air mass flow rate through the component [kg/s]

$C$  = Air mass flow coefficient (kg/s at 1 Pa pressure difference)

$\Delta P$  = Total pressure loss across the element [Pa]

$n$  = Air mass flow exponent

$C_T$  = Temperature correction factor

$$C_T = \left[ \frac{\rho_o}{\rho} \right]^{n-1} \left[ \frac{\nu_o}{\nu} \right]^{2n-1} \quad (1.111)$$

where

$\rho$  = Air density at the specific air temperature and humidity ratio conditions [kg/m<sup>3</sup>]

$\nu$  = Air kinetic viscosity at the specific air temperature condition [m<sup>2</sup>/s]

$\rho_o$  = Air density at air conditions of 20°C, 0 kg/kg and 101325 Pa [kg/m<sup>3</sup>]

$\nu_o$  = Air kinetic viscosity at an air temperature of 20°C [m<sup>2</sup>/s]

Note: The correction factor shown above is use for this particular component as specified.

#### 1.28.25.1 Inputs

##### 1.28.25.1.1 Field: Name

A unique name identifying a supply or return air leak in an air distribution system. This unique name will be referenced by an [AirflowNetwork:Distribution:Linkage](#) object to represent a component leak.

##### 1.28.25.1.2 Field: Air Mass Flow Coefficient

This numeric field is defined as the air mass flow coefficient at 1 Pa pressure difference across this component. Valid entries must be greater than zero.

##### 1.28.25.1.3 Field: Air Mass Flow Exponent

This numeric field is defined as the pressure difference exponent across the component. Valid entries are from 0.5 to 1.0, with the default value being 0.65.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:Leak,
  MainSupplyLeak,      !- Name of Supply or Return Leak
  0.0001,              !- Air Mass Flow Coefficient {kg/s}
  0.65;               !- Air Mass Flow Exponent {dimensionless}

AirflowNetwork:Distribution:Component:Leak,
  ZoneSupplyLeak,      !- Name of Supply or Return Leak
  0.01,                !- Air Mass Flow Coefficient {kg/s}
  0.65;               !- Air Mass Flow Exponent {dimensionless}
```

### 1.28.26 AirflowNetwork:Distribution:Component:LeakageRatio

The leakage ratio component is generally used to define supply and return leaks with respect to a constant fan flow. This object requires 5 inputs. The relationship between pressure and airflow may be expressed as a power law element:

$$\dot{m} = C_{equ}(\Delta P)^n \quad (1.112)$$

where

$\rho$  = Air density [kg/m<sup>3</sup>]

$\Delta P$  = Total pressure loss across the element [Pa]

$n$  = Air mass flow exponent

$C_{equ}$  = Equivalent air mass flow coefficient

$$C_{equ} = r * Q_r * \rho * (\Delta P_r)^{-n} \quad (1.113)$$

where

$\rho$  = Effective leakage ratio [dimensionless]

$Q_r$  = Maximum airflow rate [m<sup>3</sup>/s]

$\Delta P_r$  = Reference pressure difference [Pa]

$n$  = Air mass flow exponent [dimensionless]

The above calculation is valid only for a HVAC system using a constant volume supply fan: **Fan:ConstantVolume** or **Fan:OnOff**.

#### 1.28.26.1 Inputs

##### 1.28.26.1.1 Field: Name

A unique name identifying a supply or return air leak (ratio with respect to the constant volume fan flow rate) in an air distribution system. This unique name will be referenced in an **AirflowNetwork:Distribution:Linkage** object to represent a component.

##### 1.28.26.1.2 Field: Effective Leakage Ratio

This numeric field is used to input the effective leakage ratio. This value must be greater than zero and less than or equal to 1. The effective leakage ratio is used to characterize supply and return leaks with respect to the constant fan flow (supply or return air leak flow rate divided by the maximum air flow rate for the fan). When a VAV system is used with Supply Fan Object Type = **Fan:VariableVolume** in the **AirflowNetwork:Distribution:Component:Fan** object, the ratio for a supply leak is defined as the value of supply air leak flow rate divided by the supply fan air flow rate at the current time step. The inputs of the rest of 3 fields are not used.

##### 1.28.26.1.3 Field: Maximum Flow Rate

This numeric field is used to input the maximum flow rate for a constant volume fan [m<sup>3</sup>/s]. This value must be greater than 0 m<sup>3</sup>/s. When a VAV system is used with Supply Fan Object Type = **Fan:VariableVolume** in the **AirflowNetwork:Distribution:Component:Fan** object, this input is not used, because the real supply fan flow rate at the current time step is used to calculate the amount of a supply leak.

#### 1.28.26.1.4 Field: Reference Pressure Difference

This numeric field is used to input the reference pressure difference [Pa]. This value must be greater than 0 Pa. When a VAV system is used with Supply Fan Object Type = **Fan:VariableVolume** in the **AirflowNetwork:Distribution:Component:Fan** object, this input is not used, because the real supply fan flow rate at the current time step is used to calculate the amount of a supply leak.

#### 1.28.26.1.5 Field: Air Mass Flow Exponent

This numeric field is used to input the pressure difference exponent. The value of the exponent can be from 0.5 to 1.0, with the default value being 0.65. When a VAV system is used with Supply Fan Object Type = **Fan:VariableVolume** in the **AirflowNetwork:Distribution:Component:Fan** object, this input is not used, because the real supply fan flow rate at the current time step is used to calculate the amount of a supply leak.

Note: The reference pressure difference is defined as the difference between pressures of originate and terminate nodes for supply and return leaks. In general, it may require that a simulation be performed with an initial guess for reference pressure difference using design day conditions. After obtaining pressures at the leakage nodes, more realistic reference pressure differences can be entered. It should be pointed out that since pressures at the nodes vary with temperature and other conditions, the effective leakage ratio is only an estimate. In other words, the exact leakage ratio may not be available.

When a VAV system is used with Supply Fan Object Type = **Fan:VariableVolume** in the **AirflowNetwork:Distribution:Component:Fan** object, the **AirflowNetwork:Distribution:Component:LeakageRatio** object has to be used to define a supply leak. The other components cannot be used. In addition, the first node in a **AirflowNetwork:Distribution:Linkage** to define a supply leak has to be the node in the duct to originate a supply leak, and the second node has to be the node of a zone to terminate a supply leak. In other words, the supply leak has to flow from node 1 to node 2. When this object is used to define a return leak, the first node in a **AirflowNetwork:Distribution:Linkage** has to be a thermal zone to originate a leak, and the second node has to be the node of a duct to terminate a leak.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:LeakageRatio,
Zone1SupplyLeakELA,      !- Name of Effective Leakage Ratio
0.043527,                !- Effective Leakage Ratio {dimensionless}
1.0,                    !- Maximum Flow Rate {m3/s}
20.0,                   !- Reference Pressure Difference {Pa}
0.65;                   !- Air Mass Flow Exponent {dimensionless}
```

### 1.28.27 AirflowNetwork:Distribution:Component:Duct

This object represents a duct component and requires 9 input fields, one alpha field and 8 numeric fields. An additional two fields can be used to define the convection coefficients on the inner and outer surfaces of the duct. The relationship between pressure and airflow across the component may be expressed as (2001 ASHRAE Handbook of Fundamentals, Chapter 34):

$$\dot{m} = \sqrt{\frac{2\rho A^2 \Delta P}{fL/D + \sum C_d}} \quad (1.114)$$

where

$\dot{m}$  = Mass flow rate of air through the component [kg/s]

$\rho$  = Air density [kg/m<sup>3</sup>]

$A$  = Cross sectional area [m<sup>2</sup>]

$\Delta P$  = Total pressure loss across the component [Pa]

L = Duct length [m]

D = Hydraulic diameter [m]

C<sub>d</sub> = Dynamic loss coefficient due to fitting [dimensionless]

f = Friction factor

The friction factor can be calculated using the nonlinear Colebrook equation (ASHRAE Handbook of Fundamentals, 1997. p. 2.9, Eq. 29b)

$$\frac{1}{\sqrt{f}} = 1.44 + 2 * \log \left( \frac{D}{\varepsilon} \right) - 2 * \log \left( 1 + \frac{9.3}{\text{Re} * \varepsilon / D * \sqrt{f}} \right) \quad (1.115)$$

where

e = Surface roughness [m]

Re = Reynolds number =  $\frac{\rho V D}{\mu}$

### 1.28.27.1 Inputs

#### 1.28.27.1.1 Field: Name

A unique name for an AirflowNetwork duct component in an air distribution system. This unique name will be referenced by an **AirflowNetwork:Distribution:Linkage** object to represent a component.

#### 1.28.27.1.2 Field: Duct Length

This numeric field is used to input duct length [m]. This value must be greater than zero.

#### 1.28.27.1.3 Field: Hydraulic Diameter

This numeric field is used to input hydraulic diameter, which is defined as:

$$D_h = \frac{4A}{P} \quad (1.116)$$

where

D<sub>h</sub> = Hydraulic diameter [m]

A = Duct cross sectional area [m<sup>2</sup>]

P = Perimeter of cross section [m]

#### 1.28.27.1.4 Field: Cross Section Area

This numeric field is used to input cross section area [m<sup>2</sup>]. The model assumes that this element has no area change along its length. Otherwise, effective cross sectional area is required.

#### 1.28.27.1.5 Field: Surface Roughness

This numeric field is used to input surface roughness [m]. This value must be greater than zero, and the default value is 0.0009 m.

#### 1.28.27.1.6 Field: Coefficient for Local Dynamic Loss Due to fitting

This numeric field is defined as a coefficient for dynamic loss [dimensionless]. It represents dynamic loss due to fittings (such as an elbow).

#### 1.28.27.1.7 Field: Heat Transmittance Coefficient (U-Factor) for Duct Wall Construction

This numeric field defines the heat transmittance coefficient (U value, W/m<sup>2</sup>-K) for the duct wall construction. Film coefficients are calculated automatically, unless directly specified below.

### 1.28.27.1.8 Field: Overall Moisture Transmittance Coefficient from Air to Air

This numeric field is defined as the overall moisture transmittance coefficient ( $\text{kg/m}^2$ ) from air to air, including film coefficients at both surfaces.

### 1.28.27.1.9 Field: Outside Convection Coefficient

This numeric field defines the outside convection coefficient ( $\text{W/m}^2\text{-K}$ ). If the field is omitted, the film coefficient is calculated automatically as described in ASTM C1340.

### 1.28.27.1.10 Field: Inside Convection Coefficient

This numeric field defines the inside convection coefficient ( $\text{W/m}^2\text{-K}$ ). If the field is omitted, the film coefficient is calculated automatically as described in ASTM C1340.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:Duct,
  MainTruck1,           !- Name of Duct Component
  3.0,                  !- Duct Length {m}
  0.6,                  !- Hydraulic Diameter {m}
  0.2827,               !- Cross Section Area {m2}
  0.0009,               !- Surface Roughness {m}
  0.01,                 !- Coefficient for local dynamic loss due to fitting {dimensionless}
  0.772,                !- Heat Transmittance Coefficient (U-Factor) for Duct Wall Construction {W
/m2-K}
  0.0001;               !- Overall moisture transmittance coefficient from air to air {kg/m2}
```

## 1.28.28 AirflowNetwork:Distribution:Component:Fan

This component represents a constant or variable volume fan in the air distribution system (**AirLoopHVAC**). The air flow rate and air conditions (temperature and humidity) are obtained from the associated **Fan:ConstantVolume**, **Fan:OnOff**, **Fan:VariableVolume**, or **Fan:SystemModel** object.

### 1.28.28.1 Inputs

#### 1.28.28.1.1 Field: Fan Name

The name identifying an AirflowNetwork constant volume fan in an air distribution system. This name must be the same as the name of the associated **Fan:ConstantVolume**, **Fan:OnOff**, **Fan:VariableVolume**, or **Fan:SystemModel** object. This name will be referenced by an **AirflowNetwork:Distribution:Linkage** object to represent a component.

#### 1.28.28.1.2 Field: Supply Fan Object Type

This choice field defines the type of fan. The only valid choices are **Fan:OnOff**, **Fan:ConstantVolume**, **Fan:VariableVolume**, and **Fan:SystemModel** with the default being **Fan:ConstantVolume**. Both cycling and continuous fan operating modes are allowed for **Fan:OnOff**. Only the continuous fan operating mode is allowed for **Fan:ConstantVolume** with constant volume and **Fan:VariableVolume** with variable volume, respectively. An advanced fan model for **Fan:SystemModel** is also allowed.

Note: Make sure that the volumetric air flow rates for the fan, coils, and parent components (e.g., unitary system or furnace) are the same so that fan energy and air distribution system losses/gains are properly calculated.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:Fan,
  Supply Fan 1,          !- Name of Constant Volume Fan
  Fan:ConstantVolume;    !- Supply fan type
```

### 1.28.29 AirflowNetwork:Distribution:Component:Coil

This component represents a cooling or heating coil. The main purpose for this object is to get calculated values (air flow and temperature/humidity conditions) from the associated coil models.

#### 1.28.29.1 Inputs

##### 1.28.29.1.1 Field: Coil Name

The name identifying an AirflowNetwork cooling coil or heating coil defined in an air loop. This name must be the same name as the associated coil object. This unique name will be referenced by an [AirflowNetwork:Distribution:Linkage](#) object to represent a component.

##### 1.28.29.1.2 Field: Coil Object Type

This field requires input of the coil type used in the AirflowNetwork model. The available choices are:

- [Coil:Cooling:DX:SingleSpeed](#)
- [Coil:Heating:Fuel](#)
- [Coil:Heating:Electric](#)
- [Coil:Heating:DX:SingleSpeed](#)
- [Coil:Cooling:Water](#)
- [Coil:Heating:Water](#)
- [Coil:Cooling:Water:DetailedGeometry](#)
- [Coil:Cooling:DX:TwoStageWithHumidityControlMode](#)
- [Coil:Cooling:DX:MultiSpeed](#)
- [Coil:Heating:DX:MultiSpeed](#)
- [Coil:Heating:Desuperheater](#)

##### 1.28.29.1.3 Field: Air Path Length

This numeric field is used to input air path length for the coil [m]. This value must be greater than 0 meters.

##### 1.28.29.1.4 Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter of a coil's air path, which is defined as:

$$D_h = \frac{4A}{P} \quad (1.117)$$

where

$D_h$  = Hydraulic diameter [m]

$A$  = Duct cross section area [m<sup>2</sup>]

$P$  = Perimeter of cross section [m]

For this component, the relationship between airflow and pressure is similar to the component [AirflowNetwork:Distribution:Component:Duct](#). However, the model assumes very small surface roughness

( $10^{-4}$ ) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings is ignored.

Note: Make sure that the volumetric air flow rates for the fan, coils, and parent components (e.g., unitary system or furnace) are the same so that fan energy and air distribution system losses/gains are properly calculated.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:Coil,
  ACDXCoil 1,           !- Name of Associated EnergyPlus Coil
  Coil:Cooling:DX:SingleSpeed, !- EnergyPlus Coil Type
  0.1,                 !- Air Path Length {m}
  1.00;                !- Air Path Hydraulic Diameter {m}

AirflowNetwork:Distribution:Component:Coil,
  HP Heating Coil 1,    !- Name of Associated EnergyPlus Coil
  Coil:Heating:DX:SingleSpeed, !- EnergyPlus Coil Type
  0.1,                 !- Air Path Length {m}
  1.00;                !- Air Path Hydraulic Diameter {m}
```

### 1.28.30 AirflowNetwork:Distribution:Component:HeatExchanger

This component represents an air-to-air heat exchanger typically used in combination with a cooling coil to enhance dehumidification or in an outside air system to recover energy from exhaust air to pretreat incoming outdoor ventilation air. The cooling coils with enhanced dehumidification are defined in the two objects `CoilSystem:Cooling:DX:HeatExchangerAssisted` and `CoilSystem:Cooling:Water:HeatExchangerAssisted` using one of three heat exchanger objects specified below. The exhaust air energy recovery system also has the same restriction using the one of three heat exchanger objects. The main purpose for this object is to obtain calculated values (air flow and temperature/humidity conditions) from the associated heat exchanger models for the airflow network calculations.

#### 1.28.30.1 Inputs

##### 1.28.30.1.1 Field: Heat Exchanger Name

The name identifying an AirflowNetwork heat exchanger defined in an air loop. This name must be the same name that is used in the associated heat exchanger object. This unique name will be referenced by an `AirflowNetwork:Distribution:Linkage` object to represent a component.

##### 1.28.30.1.2 Field: Heat Exchanger Object Type

This field requires input of the heat exchanger type. The available choices are:

- `HeatExchanger:AirToAir:FlatPlate`
- `HeatExchanger:AirToAir:SensibleAndLatent`
- `HeatExchanger:Desiccant:BalancedFlow`

##### 1.28.30.1.3 Field: Air Path Length

This numeric field is used to input air path length for the heat exchanger coil [m]. This value must be greater than 0 meters.

### 1.28.30.1.4 Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter of a heat exchanger coil's air path, which is defined as:

$$D_h = \frac{4A}{P} \quad (1.118)$$

where

$D_h$  = Hydraulic diameter [m]

$A$  = Duct cross section area [m<sup>2</sup>]

$P$  = Perimeter of cross section [m]

For this component, the relationship between airflow and pressure is similar to the component **AirflowNetwork:Distribution:Component:Duct**. However, the model assumes very small surface roughness ( $10^{-4}$ ) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings are ignored.

Note: When a heat exchanger is used as a component of either **CoilSystem:Cooling:DX:HeatExchangerAssisted** or **CoilSystem:Cooling:Water:HeatExchangerAssisted**, the heat exchanger acts as two components in an air primary loop. For example, an air-to-air heat exchanger has a component connected to the supply air side (equivalent to a supply coil) and a component connected to exhaust air side (equivalent to an exhaust coil). The desiccant heat exchanger has a component connected to regeneration air side (equivalent to a regeneration air coil) and a component connected to process air side (equivalent to a process air coil). Therefore, each air-to-air heat exchanger used in this configuration requires two linkage objects (instead of only one linkage object as required for other AirflowNetwork components).

When a heat exchanger is used in an exhaust air energy recovery system (i.e., in an **AirLoopHVAC:OutdoorAirSystem** object to recover waste heat from exhaust air to pretreat incoming outdoor ventilation air), the heat exchanger is treated as a single component. The AirflowNetwork model only connects the two nodes associated with the incoming outdoor ventilation air, while the two exhaust nodes are not defined as part of the AirflowNetwork model. Therefore, each heat exchanger component used in an exhaust air energy recovery system has only one linkage object, similar to AirflowNetwork coil components.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:HeatExchanger,
  OA Heat Recovery 1,      !- HeatExchanger Name
  HeatExchanger:AirToAir:SensibleAndLatent, !- HeatExchanger Object Type
  0.1,                    !- Air Path Length {m}
  1.00;                   !- Air Path Hydraulic Diameter {m}

AirflowNetwork:Distribution:Component:HeatExchanger,
  Desiccant Heat Exchanger 1, !- HeatExchanger Name
  HeatExchanger:Desiccant:BalancedFlow, !- HeatExchanger Object Type
  0.1,                    !- Air Path Length {m}
  1.00;                   !- Air Path Hydraulic Diameter {m}
```

## 1.28.31 AirflowNetwork:Distribution:Component:TerminalUnit

This component represents a terminal unit for reheating the incoming supply air. The main purpose is to get calculated values from the terminal unit models.

### 1.28.31.1 Inputs

#### 1.28.31.1.1 Field: Terminal Unit Name

A name identifying an AirflowNetwork terminal unit defined in a zone equipment list. This name must be the same as the associated terminal unit object. This unique name will be referenced by an `AirflowNetwork:Distribution:Linkage` object to represent a component.

#### 1.28.31.1.2 Field: Terminal Unit Object Type

This field requires input of the terminal unit type used in the AirflowNetwork model. The available types are `AirTerminal:SingleDuct:ConstantVolume:Reheat` and `AirTerminal:SingleDuct:VAV:Reheat`. The `AirTerminal:SingleDuct:ConstantVolume:Reheat` type is used when the Supply Fan Object Type in the `AirflowNetwork:Distribution:Component:Fan` is either `Fan:ConstantVolume` or `Fan:OnOff`. The `AirTerminal:SingleDuct:VAV:Reheat` type is used when the Supply Fan Object Type in the `AirflowNetwork:Distribution:Component:Fan` is `Fan:VariableVolume` only.

#### 1.28.31.1.3 Field: Air Path Length

This numeric field is used to input the air path length for the terminal unit [m]. This value must be greater than 0 meters.

#### 1.28.31.1.4 Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter for the terminal unit's air path, which is defined as:

$$D_h = \frac{4A}{P} \quad (1.119)$$

where

$D_h$  = Hydraulic diameter [m]

A = Duct cross section area [m<sup>2</sup>]

P = Perimeter of cross section [m]

It should be noted that the relationship for this component between airflow and pressure is similar to the component `AirflowNetwork:Distribution:Component:Duct`. However, the model assumes very small surface roughness ( $10^{-4}$ ) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings is ignored.

Note: The `AirflowNetwork:Distribution:Component:TerminalUnit` object is used to represent an `AirTerminal:SingleDuct:ConstantVolume:Reheat` or an `AirTerminal:SingleDuct:VAV:Reheat` object in an AirflowNetwork simulation. The `AirflowNetwork:Distribution:Component:TerminalUnit` should not be used to represent any other air terminal unit types. When the `ZoneHVAC:EquipmentList` object specifies an `Air:Terminal:SingleDuct:ConstantVolume:NoReheat` object, the `AirflowNetwork:Distribution:Component:Duct` object should be used instead.

The `AirTerminal:SingleDuct:VAV:Reheat` object has two components: a damper and a reheat coil. When the `AirTerminal:SingleDuct:VAV:Reheat` type is used, two objects of `AirflowNetwork:Distribution:Linkage` have to be used to make two links, one of which is a link to connect two nodes for a damper, and the other is a link to connect two nodes for a reheat coil.

When a VAV system is used with Supply Fan Object Type = `Fan:VariableVolume` in the `AirflowNetwork:Distribution:Component:Fan` object, the type of all terminals has to be `AirTerminal:SingleDuct:VAV:Reheat`. The object of `Air:Terminal:SingleDuct:ConstantVolume:NoReheat` is not allowed.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:TerminalUnit,
    Reheat Zone 1,                !- Name of Associated Energyplus Terminal Unit
    AirTerminal:SingleDuct:ConstantVolume:Reheat, !- EnergyPlus Terminal Unit Type
    0.1,                          !- Air Path Length {m}
```

---

```
0.44;                                !- Air Path Hydraulic Diameter {m}
```

---

### 1.28.32 AirflowNetwork:Distribution:Component:ConstantPressureDrop

This component represents a constant pressure drop component. It is generally used to simulate a constant pressure drop filter. The mathematical equation may be written as:

$$\Delta P = \text{const} \quad (1.120)$$

#### 1.28.32.1 Inputs

##### 1.28.32.1.1 Field: Name

A unique name identifying an AirflowNetwork constant pressure drop component in an air distribution system. This unique name will be referenced by an AirflowNetwork: Distribution:Linkage object to represent a component.

##### 1.28.32.1.2 Field: Pressure Difference across the Component

This numeric field is used to input the pressure difference across the element [Pa].

Note: This object should be used with caution. Each node connected to this object cannot be a node for a mixer or splitter, a node in an **AirLoopHVAC**, or a node in a zone configuration loop. It is recommended that duct components be specified at both ends of this object.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:ConstantPressureDrop,
  SupplyCPDComp, ! Name of Constant Pressure Drop Component
  1.0;           ! Pressure Difference Across the Component [Pa]
```

---

### 1.28.33 AirflowNetwork:Distribution:Component:OutdoorAirFlow

The AirflowNetwork:Distribution:Component:OutdoorAirFlow object is used to allow the AirflowNetwork model to include the outdoor air flow rate in the airflow network. When the outdoor air mass flow rate is greater than zero, the airflow network model treats this object as a constant volume fan and the flow rate is provided by the **Controller:OutdoorAir** object. When there is no outdoor air flow rate, the model treats this object as a crack and a power law is assumed.

#### 1.28.33.1 Inputs

##### 1.28.33.1.1 Field: Name

This is the name for this instance of the AirflowNetwork:Distribution:Component:OutdoorAirFlow object.

##### 1.28.33.1.2 Field: Outdoor Air Mixer Name

The name identifying an AirflowNetwork OutdoorAirFlow defined in an air loop as an **OutdoorAir:Mixer** object. This name must be the same name as the associated **OutdoorAir:Mixer** object.

### 1.28.33.1.3 Field: Air Mass Flow Coefficient When No Outdoor Air Flow at Reference Conditions

The value of the air mass flow coefficient,  $C_Q$ , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero. The value is used when the outdoor mass flow rate is zero from the `Controller:OutdoorAir` object.

### 1.28.33.1.4 Field: Air Mass Flow Exponent When No Outdoor Air Flow

The value of the exponent,  $n$ , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65. The value is used when the outdoor mass flow rate is zero from the `Controller:OutdoorAir` object.

### 1.28.33.1.5 Field: Reference Crack Conditions

The name of the `AirflowNetwork:MultiZone:ReferenceCrackConditions` object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one `AirflowNetwork:MultiZone:ReferenceCrackConditions` object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one `AirflowNetwork:MultiZone:ReferenceCrackConditions` objects are defined in the input data file, then the default conditions for the `AirflowNetwork:MultiZone:ReferenceCrackConditions` object will be used.

IDF examples are provided below:

```
AirflowNetwork:MultiZone:Component:OutdoorAirFlow,
  OAFlow,                !- Name
  OA Mixer 1,             !- Outdoor Air Mixer Name
  0.01,                   !- Air Mass Flow Coefficient When No Outdoor Air Flow at Reference Conditions
  {kg/s}
  0.667;                  !- Air Mass Flow Exponent When No Outdoor Air Flow {dimensionless}

AirflowNetwork:Distribution:Node,

  ,                       !- Component Name or Node Name
  AirLoopHVAC:OutdoorAirSystem, !- Component Object Type or Node Type
  3.0;                    !- Node Height {m}

AirflowNetwork:Distribution:Node,
  OA Inlet Node,          !- Name
  Outside Air Inlet Node, !- Component Name or Node Name
  OAMixerOutdoorAirStreamNode, !- Component Object Type or Node Type
  1.5;                    !- Node Height {m}

AirflowNetwork:Distribution:Linkage,
  OASystemFanLink,        !- Name
  OA Inlet Node,          !- Node 1 Name
  OA System Node,         !- Node 2 Name
  OAFlow;                 !- Component Name
```

## 1.28.34 AirflowNetwork:Distribution:Component:ReliefAirFlow

The `AirflowNetwork:Distribution:Component:ReliefAirFlow` object is used to allow the `AirflowNetwork` model to perform pressure control by varying the amount of relief air flow rate between 0 and the flow rate specified by the `Controller:OutdoorAir` object. When the outdoor air mass flow rate is greater than zero, the airflow network model treats this object as a constant volume fan and the flow rate is varied to reach pressure control. When there is no outdoor air flow rate, the model treats this object as a crack and a power law is assumed.

### 1.28.34.1 Inputs

#### 1.28.34.1.1 Field: Name

This is the name for this instance of the `AirflowNetwork:Distribution:Component:ReliefAirFlow` object.

#### 1.28.34.1.2 Field: Outdoor Air Mixer Name

The name identifying an `AirflowNetwork OutdoorAirFlow` defined in an air loop as an `OutdoorAir:Mixer` object. This name must be the same name as the associated `OutdoorAir:Mixer` object.

#### 1.28.34.1.3 Field: Air Mass Flow Coefficient When No Outdoor Air Flow at Reference Conditions

The value of the air mass flow coefficient,  $C_Q$ , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero. The value is used when the outdoor mass flow rate is zero from the `Controller:OutdoorAir` object.

#### 1.28.34.1.4 Field: Air Mass Flow Exponent When No Outdoor Air Flow

The value of the exponent,  $n$ , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65. The value is used when the outdoor mass flow rate is zero from the `Controller:OutdoorAir` object.

#### 1.28.34.1.5 Field: Reference Crack Conditions

The name of the `AirflowNetwork:MultiZone:ReferenceCrackConditions` object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one `AirflowNetwork:MultiZone:ReferenceCrackConditions` object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one `AirflowNetwork:MultiZone:ReferenceCrackConditions` objects are defined in the input data file, then the default conditions for the `AirflowNetwork:MultiZone: Reference Crack Conditions` object will be used.

IDF examples are provided below:

```
AirflowNetwork:ZoneControl:PressureController,
  Pressure Controller1,          !- Name
  EAST ZONE,                     !- Controlled Zone Name
  AirflowNetwork:Distribution:Component:ReliefAirFlow, !- Control Object type
  ReliefFlow,                   !- Control Name
  PressureAvailSchedule,        !- Pressure Control Availability Schedule Name
  PressureSetpointSchedule;      !- Pressure Setpoint Schedule Name

AirflowNetwork:MultiZone:Component:ReliefAirFlow,
  ReliefFlow,                   !- Name
  OA Mixer 1,                   !- Outdoor Air Mixer Name
  0.01,                         !- Air Mass Flow Coefficient When No Outdoor Air Flow at Reference
    Conditions {kg/s}
  0.667;                        !- Air Mass Flow Exponent When No Outdoor Air Flow {dimensionless}

AirflowNetwork:Distribution:Node,
  OA System Node,              !- Name
  ,                             !- Component Name or Node Name
  AirLoopHVAC:OutdoorAirSystem, !- Component Object Type or Node Type
  3.0;                         !- Node Height {m}

AirflowNetwork:Distribution:Node,
  OA Inlet Node,               !- Name
  Outside Air Inlet Node,      !- Component Name or Node Name
  OAMixerOutdoorAirStreamNode, !- Component Object Type or Node Type
  1.5;                         !- Node Height {m}

AirflowNetwork:Distribution:Linkage,
```

---

```

OASystemFanLink,      !- Name
OA System Node,       !- Node 1 Name
OA Inlet Node,        !- Node 2 Name
ReliefFlow;           !- Component Name

```

---

### 1.28.35 AirflowNetwork:Distribution:Linkage

The AirflowNetwork:Distribution:Linkage represents a connection between two AirflowNetwork:Distribution:Node objects and an AirflowNetwork component defined above. In addition, the relative height from node height to linkage height for each node is required.

#### 1.28.35.1 Inputs

##### 1.28.35.1.1 Field: Name

The name identifies the linkage for later reference and in the output listing. Each linkage should have a unique name.

##### 1.28.35.1.2 Field: Node 1 Name

Designates a node name where airflow starts. The node name should be defined in an AirflowNetwork:Distribution:Node object.

##### 1.28.35.1.3 Field: Node 2 Name

Designates a node name where airflow ends. The node name should be defined in an AirflowNetwork:Distribution:Node object.

##### 1.28.35.1.4 Field: Component Name

Designates an AirflowNetwork component name associated with the two nodes. The component name should be one of the AirflowNetwork:Distribution:Component... object names.

##### 1.28.35.1.5 Field: Thermal Zone Name

Designates a thermal zone where the linkage is located. The information provides the ambient conditions for duct elements to calculate duct conduction losses (only used if component is AirflowNetwork:Distribution:Component:Duct).

An IDF example is provided below:

---

```

AirflowNetwork:Distribution:Linkage,
  Main Link 1,          !- Name of Linkage
  EquipmentInletNode,   !- Node 1 Name
  SupplyMainNode,      !- Node 2 Name
  MainTruck1,           !- Component Name
  Attic Zone;           !- Thermal Zone Name

```

---

#### 1.28.35.2 Outputs

The AirflowNetwork nodes in the following output variables includes zones defined in AirflowNetwork:MultiZone:Zone objects, external nodes defined in AirflowNetwork:MultiZone:ExternalNode objects, and nodes defined in AirflowNetwork:Distribution:Node objects.

The AirflowNetwork linkage used in following output variables includes surfaces defined in AirflowNetwork:MultiZone:Surface objects, and linkages defined in AirflowNetwork:Distribution:Linkage objects. The surface linkages represent airflows through surface cracks or openings between two zones or between a zone and outdoors. The distribution linkages represent airflows in an air distribution system.

- HVAC,Average,AFN Surface Closing Probability Status []

The following are reported only when an integrated model of RoomAir and AirflowNetwork is used:

- HVAC,Average, RoomAirflowNetwork Node Total Pressure [Pa]
- HVAC,Average, RoomAirflowNetwork Node Temperature [C]
- HVAC,Average, RoomAirflowNetwork Node Humidity Ratio [kgWater/kgDryAir]

#### 1.28.35.2.1 AFN Node Temperature [C]

This is the AirflowNetwork node temperature output in degrees C. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the temperature when the fan is operating (ON).

#### 1.28.35.2.2 AFN Node Humidity Ratio [kgWater/kgDryAir]

This is the AirflowNetwork node humidity ratio output in kgWater/kgDryAir. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the humidity ratio when the fan is operating (ON).

#### 1.28.35.2.3 AFN Node Total Pressure [Pa]

This is the AirflowNetwork node total pressure in Pa with respect to outdoor barometric pressure. The total pressure is the sum of static pressure, dynamic pressure, and elevation impact at the node's relative height. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, the value for AirflowNetwork:Distribution:Node objects reflects the total pressure when the fan is operating (ON). The total pressures for nodes associate with AirflowNetwork:MultiZone:Zone objects are reported in different output variables (below).

#### 1.28.35.2.4 AFN Node CO2 Concentration [ ppm]

This is the AirflowNetwork node carbon dioxide concentration level in parts per million (ppm). When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the carbon dioxide when the fan is operating (ON).

#### 1.28.35.2.5 AFN Node Generic Air Contaminant Concentration [ppm]

This is the AirflowNetwork node generic contaminant concentration level in parts per million (ppm). When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the carbon dioxide when the fan is operating (ON).

#### 1.28.35.2.6 AFN Zone Average Pressure [Pa]

This is the AirflowNetwork average zone total pressure in Pa with respect to outdoor barometric pressure. This output is only available when a Fan:OnOff object is used in the air distribution system. The average zone pressure is weighted by the system fan part-load ratio using the calculated zone pressures during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Average zone pressure = (Zone pressure during on cycle \* Part-load ratio) + Zone pressure during off cycle \* (1.0 – Part-load ratio)

**1.28.35.2.7 AFN Zone On Cycle Pressure [Pa]**

This is the AirflowNetwork zone total pressure in Pa with respect to outdoor barometric pressure when the air distribution system fan is operating (ON). This output is only available when a Fan:OnOff object is used in the air distribution system. When the fan part-load ratio is equal to 0.0, this pressure value will be zero because the air distribution system is not simulated when the fan is off for the entire timestep.

**1.28.35.2.8 AFN Zone Off Cycle Pressure [Pa]**

This is the AirflowNetwork zone total pressure in Pa with respect to outdoor barometric pressure when the air distribution system fan is not operating (OFF). This output is only available when a Fan:OnOff object is used in the air distribution system. Even if the fan part-load ratio is equal to 1.0, the pressure calculated as if the fan were not operating (OFF) is reported.

**1.28.35.2.9 AFN Node Wind Pressure [Pa]**

This is the AirflowNetwork wind pressure output in Pa. The wind pressure depends on several factors, including wind speed, wind direction, the wind-pressure coefficient ( $C_p$ ) values for the AirflowNetwork:MultiZone:ExternalNode associated with the heat transfer surface and the site wind conditions.

When Wind Pressure Coefficient Type = “Input” in the AirflowNetwork:SimulationControl object, the output represents external node pressures driven by wind defined in an AirflowNetwork:MultiZone:ExternalNode object. When Wind Pressure Coefficient Type = “SurfaceAverageCalculation” in AirflowNetwork:SimulationControl, the program assumes five external nodes:

- FACADE1      Representing north orientation
- FACADE2      Representing east orientation
- FACADE3      Representing south orientation
- FACADE4      Representing west orientation
- ROOF          Representing horizontal orientation

In this case, the output represents the wind pressures for the five external nodes defined above.

**1.28.35.2.10 AFN Linkage Node 1 to Node 2 Mass Flow Rate [kg/s]**

This is the AirflowNetwork linkage mass flow rate output in kg/s in the direction from Node 1 to Node 2. It reports surface airflows through a crack or opening, and through linkages defined in an AirflowNetwork:Distribution:Linkage object. The surface linkage is divided into two types of surfaces, exterior surface and interior surface. Node 1 for an exterior surface linkage is a thermal zone and Node 2 is an external node. The value of AFN Linkage Node 1 to Node 2 Mass Flow Rate represents the flow rate from a thermal zone to outdoors. The flow direction through an interior surface crack or opening is defined from a thermal zone defined by a surface’s Zone Name (Node 1) to an adjacent thermal zone defined by a surface’s OutsideFaceEnvironment (Node 2). For an AirflowNetwork:Distribution:Linkage object, the value represents the air mass flow rate flowing from Node 1 to Node 2.

It should be pointed out that in general, each linkage has one directional flow at any given time, either from Node 1 to 2 or from Node 2 to 1. However, there are three components which may have flows in both directions simultaneously: AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening.

When a Fan:OnOff object is used, the air mass flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air mass flow rates when the fan is off are zero for the distribution system air linkage objects. The air mass flow rates for the AirflowNetwork:MultiZone:Surface object are reported in different output variables (below).

**1.28.35.2.11 AFN Linkage Node 2 to Node 1 Mass Flow Rate [kg/s]**

This is the AirflowNetwork linkage mass flow rate output in kg/s in the direction from Node 2 to Node 1. It reports airflows from surfaces through a crack or opening, and from linkages defined in an AirflowNetwork:Distribution:Linkage object. Node 1 and Node 2 for a surface or subsurface are defined in the same manner as AFN Linkage Node 1 to Node 2 Mass Flow Rate.

When a Fan:OnOff object is used, the air mass flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air mass flow rates when the fan is off are zero for the distribution system air linkage objects. The air mass flow rates for the AirflowNetwork:MultiZone:Surface object are reported in different output variables (below).

**1.28.35.2.12 AFN Linkage Node 1 to 2 Average Mass Flow Rate [kg/s]**

This is the AirflowNetwork linkage average mass flow rate in kg/s in the direction from Node 1 to Node 2 defined in the AirflowNetwork:MultiZone:Surface objects. This output is only available when a Fan:OnOff object is used in the air distribution system. The average mass flow rate is weighted by the system fan part-load ratio using the calculated air mass flow rates during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Average surface mass flow rate = (Surface mass flow rate during on cycle \* Part-load ratio) + Surface mass flow rate during off cycle \* (1.0 – Part-load ratio)

**1.28.35.2.13 AFN Linkage Node 2 to 1 Average Mass Flow Rate [kg/s]**

This is the AirflowNetwork linkage average mass flow rate in kg/s in the direction from Node 2 to Node 1 defined in the AirflowNetwork:MultiZone:Surface objects. This output is only available when a Fan:OnOff object is used in the air distribution system. The average mass flow rate is weighted by the system fan part-load ratio using the calculated air mass flow rates during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

**1.28.35.2.14 AFN Linkage Node 1 to Node 2 Volume Flow Rate [m<sup>3</sup>/s]**

This is the AirflowNetwork linkage volume flow rate output in m<sup>3</sup>/s in the direction from the Node 1 to Node 2. It is defined in the same manner as AFN Linkage Node 1 to Node 2 Mass Flow Rate.

When a Fan:OnOff object is used, the air volume flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air volume flow rates when the fan is off are zero for the distribution system air linkage objects. The air volume flow rates for the AirflowNetwork:MultiZone:Surface object are reported in different output variables (below).

**1.28.35.2.15 AFN Linkage Node 2 to Node 1 Volume Flow Rate [m<sup>3</sup>/s]**

This is the AirflowNetwork linkage volume flow rate output in m<sup>3</sup>/s in the direction from Node 2 to Node 1. It is defined in the same manner as AFN Linkage Node 2 to Node 1 Mass Flow Rate.

When a Fan:OnOff object is used, the air volume flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air volume flow rates when the fan is off are zero for the distribution system air linkage objects. The air volume flow rates for the AirflowNetwork:MultiZone:Surface object are reported in different output variables (below).

**1.28.35.2.16 AFN Linkage Node 1 to 2 Average Volume Flow Rate [m<sup>3</sup>/s]**

This is the AirflowNetwork linkage average volume flow rate in m<sup>3</sup>/s in the direction from Node 1 to Node 2 defined in the AirflowNetwork:MultiZone:Surface objects. This output is only available when a Fan:OnOff object is used. The average volume flow rate is weighted by the system fan part-load ratio using the calculated air volume flow rates during the fan on and off periods for the system timestep.

Average surface volume flow rate = (Surface volume flow rate during on cycle \* Part-load ratio) + Surface volume flow rate during off cycle \* (1.0 – Part-load ratio)

**1.28.35.2.17 AFN Linkage Node 2 to 1 Average Volume Flow Rate [m<sup>3</sup>/s]**

This is the AirflowNetwork linkage average volume flow rate in m<sup>3</sup>/s in the direction from Node 2 to Node 1 defined in the AirflowNetwork:MultiZone:Surface objects. This output is only available when a Fan:OnOff object is used. The average volume flow rate is weighted by the system fan part-load ratio using the calculated air volume flow rates during the fan on and off periods for the system timestep.

**1.28.35.2.18 AFN Linkage Node 1 to Node 2 Pressure Difference [Pa]**

This is the pressure difference across a linkage in Pa. The linkage includes both objects: AirflowNetwork:MultiZone:Surface and AirflowNetwork: Distribution:Linkage.

When a Fan:OnOff object is used, the pressure differences reported for the AirflowNetwork:Distribution:Linkage objects are the values calculated when the fan is operating (ON). It is assumed that the pressure differences when the fan is off are zero for the distribution system air linkage objects. The pressure differences defined in the AirflowNetwork:MultiZone:Surface are reported in different output variables (below).

**1.28.35.2.19 AFN Surface Average Pressure Difference [Pa]**

This is the average pressure difference across a linkage in Pa for the AirflowNetwork:MultiZone:Surface objects only when a Fan:OnOff object is used. The average pressure difference is weighted by the system fan part-load ratio using the calculated pressure differences during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Surface Average Pressure Difference = (Surface Average Pressure Difference during on cycle \* Part-load ratio) + Surface Average Pressure Difference during off cycle \* (1.0 - Part-load ratio)

**1.28.35.2.20 AFN Surface On Cycle Pressure Difference [Pa]**

This is the pressure difference across a linkage in Pa for the AirflowNetwork:MultiZone:Surface objects only when the air distribution system fan is operating (ON). This output is only available when a Fan:OnOff object is used. When the fan part-load ratio is equal to 0.0, this pressure difference value will be zero because the air distribution system is not simulated when the fan is off for the entire timestep.

**1.28.35.2.21 AFN Surface Off Cycle Pressure Difference [Pa]**

This is the pressure difference across a linkage in Pa for the AirflowNetwork:MultiZone:Surface objects only when the air distribution system fan is not operating (OFF). This output is only available when a Fan:OnOff object is used. Even if the fan part-load ratio is equal to 1.0, the pressure difference calculated as if the fan were not operating (OFF) is reported.

**1.28.35.2.22 AFN Surface Venting Window or Door Opening Factor []**

The current time-step value of the venting opening factor for a particular window or door. When the window or door is venting, this is the input value of the opening factor (see AirflowNetwork:MultiZone:Surface, Window/Door Opening Factor) times the multiplier for venting modulation (see

description of next output variable, “Opening Factor Multiplier for AirflowNetwork Venting Modulation”). For example, if the input Window/Door opening factor is 0.5 and the modulation multiplier is 0.7, then the value of this output variable will be  $0.5 \times 0.7 = 0.35$ .

#### 1.28.35.2.23 AFN Surface Venting Window or Door Opening Modulation Multiplier []

This is the multiplier on a window or door opening factor when venting modulation is in effect. See “Modulation of Openings” under AirflowNetwork:MultiZone:Zone for a description of how the multiplier is determined.

When modulation is in effect the value of the multiplier is between 0.0 and 1.0. When modulation does not apply the value of the multiplier may be  $-1.0$ . When modulation applies but the surface is not venting, the value is  $-1.0$ . This is summarized in the following table. In this table, “Zone” means a thermal zone for which AirflowNetwork:MultiZone:Zone has been specified. See object AirflowNetwork: MultiZone:Zone for definition of “Ventilation Control Mode.”

Table 1.46: Value of opening factor multiplier for different venting conditions

Is surface in a Zone?	Ventilation Control Mode	Is surface venting?	Value of opening factor multiplier
Yes	Temperature	Yes	0.0 to 1.0
		No	-1.0
	Enthalpy	Yes	0.0 to 1.0
		No	-1.0
	Constant	Yes	1.0
	NoVent	No	-1.0

#### 1.28.35.2.24 AFN Surface Venting Inside Setpoint Temperature [C]

The time-step value of the venting setpoint temperature for the zone to which the surface belongs. This setpoint is determined from the Vent Temperature Schedule input (ref: AirflowNetwork:MultiZone:Zone).

#### 1.28.35.2.25 AFN Surface Venting Availability Status []

A value of 1.0 means venting through the surface can occur if venting control conditions are satisfied. A value of 0.0 means venting through the surface cannot occur under any circumstances. This value is determined by the Venting Availability Schedule input (ref: AirflowNetwork:MultiZone:Zone or AirflowNetwork:MultiZone:Surface).

#### 1.28.35.2.26 AFN Zone Infiltration Sensible Heat Gain Rate [W]

The average convective sensible heat gain rate, in Watts, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, this reported value is weighted by the system run time fraction using the calculated infiltration sensible gain rate during the system on and off cycles for the reporting period:

Infiltration Sensible Gain Rate = (Infiltration Sensible Gain Rate during on cycle \* Run time fraction) + Infiltration Sensible Gain Rate during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.27 AFN Zone Infiltration Sensible Heat Gain Energy [J]

The average convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible gain during the system on and off cycles for the reporting period:

Infiltration Sensible Gain = (Infiltration Sensible Gain during on cycle \* Run time fraction) + Infiltration Sensible Gain during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.28 AFN Zone Infiltration Sensible Heat Loss Rate [W]

The average convective sensible heat loss rate, in Watts, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible loss rate during the system on and off cycles for the reporting period:

Infiltration Sensible Loss Rate = (Infiltration Sensible Loss Rate during on cycle \* Run time fraction) + Infiltration Sensible Loss Rate during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.29 AFN Zone Infiltration Sensible Heat Loss Energy [J]

The average convective sensible heat loss, in Joules, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible loss rate during the system on and off cycles for the reporting period:

Infiltration Sensible Loss = (Infiltration Sensible Loss during on cycle \* Run time fraction) + Infiltration Sensible Loss during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.30 AFN Zone Infiltration Latent Heat Gain Rate [W]

The average convective latent heat gain rate, in Watts, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only averaged over the reporting period, when the outdoor humidity ratio is higher than the zone air humidity ratio.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent gain rate during the system on and off cycles for the reporting period:

Infiltration Latent Gain Rate = (Infiltration Latent Gain Rate during on cycle \* Run time fraction) + Infiltration Latent Gain Rate during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.31 AFN Zone Infiltration Latent Heat Gain Energy [J]

The total convective latent heat gain, in Joules, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent gain during the system on and off cycles for the reporting period:

Infiltration Latent Gain = (Infiltration Latent Gain during on cycle \* Run time fraction) + Infiltration Latent Gain during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.32 AFN Zone Infiltration Latent Heat Loss Rate [W]

The average convective latent heat loss rate, in Watts, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent loss rate during the system on and off cycles for the reporting period:

Infiltration Latent Loss Rate = (Infiltration Latent Gain Loss Rate during on cycle \* Run time fraction) + Infiltration Latent Loss Rate during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.33 AFN Zone Infiltration Latent Heat Loss Energy [J]

The total convective latent heat loss, in Joules, to the zone air corresponding to the Zone Infiltration flows from both AirflowNetwork:MultiZone:Surface:Crack and AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea only summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent loss during the system on and off cycles for the reporting period:

Infiltration Latent Loss = (Infiltration Latent Gain Loss during on cycle \* Run time fraction) + Infiltration Latent Loss during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.34 AFN Zone Ventilation Sensible Heat Gain Rate [W]

The average convective sensible heat gain rate, in Watts, to the zone air corresponding to the Zone Ventilation flows from AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, this reported value is weighted by the system run time fraction using the calculated ventilation sensible gain rate during the system on and off cycles for the reporting period:

Ventilation Sensible Gain Rate = (Ventilation Sensible Gain Rate during on cycle \* Run time fraction) + Ventilation Sensible Gain Rate during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.35 AFN Zone Ventilation Sensible Heat Gain Energy [J]

The average convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Ventilation flows from AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated ventilation sensible gain during the system on and off cycles for the reporting period:

Ventilation Sensible Gain = (Ventilation Sensible Gain during on cycle \* Run time fraction) + Ventilation Sensible Gain during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.36 AFN Zone Ventilation Sensible Heat Loss Rate [W]

The average convective sensible heat loss rate, in Watts, to the zone air corresponding to the Zone Ventilation flows from AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated ventilation sensible loss rate during the system on and off cycles for the reporting period:

Ventilation Sensible Loss Rate = (Ventilation Sensible Loss Rate during on cycle \* Run time fraction) + Ventilation Sensible Loss Rate during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.37 AFN Zone Ventilation Sensible Heat Loss Energy [J]

The average convective sensible heat loss, in Joules, to the zone air corresponding to the Zone Ventilation flows from AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated Ventilation sensible loss rate during the system on and off cycles for the reporting period:

Ventilation Sensible Loss = (Ventilation Sensible Loss during on cycle \* Run time fraction) + Ventilation Sensible Loss during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.38 AFN Zone Ventilation Latent Heat Gain Rate [W]

The average convective latent heat gain rate, in Watts, to the zone air corresponding to the Zone Ventilation flows from AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only averaged over the reporting period, when the outdoor humidity ratio is higher than the zone air humidity ratio.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated Ventilation latent gain rate during the system on and off cycles for the reporting period:

Ventilation Latent Gain Rate = (Ventilation Latent Gain Rate during on cycle \* Run time fraction) + Ventilation Latent Gain Rate during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.39 AFN Zone Ventilation Latent Heat Gain Energy [J]

The total convective latent heat gain, in Joules, to the zone air corresponding to the Zone Ventilation flows from AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated ventilation latent gain during the system on and off cycles for the reporting period:

Ventilation Latent Gain = (Ventilation Latent Gain during on cycle \* Run time fraction) + Ventilation Latent Gain during off cycle \* (1.0 – Run time fraction)

#### 1.28.35.2.40 AFN Zone Ventilation Latent Heat Loss Rate [W]

The average convective latent heat loss rate, in Watts, to the zone air corresponding to the Zone Ventilation flows from AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated Ventilation latent loss rate during the system on and off cycles for the reporting period:

Ventilation Latent Loss Rate = (Ventilation Latent Gain Loss Rate during on cycle \* Run time fraction) + Ventilation Latent Loss Rate during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.41 AFN Zone Ventilation Latent Heat Loss Energy [J]**

The total convective latent heat loss, in Joules, to the zone air corresponding to the Zone Ventilation flows from both AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening only summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated Ventilation latent loss during the system on and off cycles for the reporting period:

Ventilation Latent Loss = (Ventilation Latent Gain Loss during on cycle \* Run time fraction) + Ventilation Latent Loss during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.42 AFN Zone Mixing Sensible Heat Gain Rate [W]**

The average convective sensible heat gain rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period. The mixing-volume is defined as incoming volume flow from other adjacent zones where the air temperature is higher than the temperature in this zone. For example, there are two zones (Zone 2 and Zone 3) adjacent to this zone (Zone 1). Zone 1 receives airflows from both Zone 2 and Zone 3. The air temperature is 21°C in Zone 1. The air temperatures are 20°C in Zone 2 and 22°C in Zone 3. The sensible gain rate only includes heat gain from Zone 3 with respect to Zone 1. The energy received from Zone 2 is considered as a sensible loss, instead of a gain, because the air temperature in Zone 2 is lower than in Zone 1.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible gain rate during the system on and off cycles for the reporting period:

Mixing Sensible Gain Rate = (Mixing Sensible Gain Rate during on cycle \* Run time fraction) + Mixing Sensible Gain Rate during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.43 AFN Zone Mixing Sensible Heat Loss Rate [W]**

The average convective sensible heat loss rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible loss rate during the on and off cycles for the reporting period:

Mixing Sensible Loss Rate = (Mixing Sensible Loss Rate during on cycle \* Run time fraction) + Mixing Sensible Loss Rate during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.44 AFN Zone Mixing Sensible Heat Gain Energy [J]**

The total convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible gain during the on and off cycles for the reporting period:

Mixing Sensible Gain = (Mixing Sensible Gain during on cycle \* Run time fraction) + Mixing Sensible Gain during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.45 AFN Zone Mixing Sensible Heat Loss Energy [J]**

The total convective sensible heat loss, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible loss during the on and off cycles for the reporting period:

Mixing Sensible Loss = (Mixing Sensible Loss during on cycle \* Run time fraction) + Mixing Sensible Loss during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.46 AFN Zone Mixing Latent Heat Gain Rate [W]**

The average convective latent heat gain rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent gain rate during the on and off cycles for the reporting period:

Mixing Latent Gain Rate = (Mixing Latent Gain Rate during on cycle \* Run time fraction) + Mixing Latent Gain Rate during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.47 AFN Zone Mixing Latent Heat Gain Energy [J]**

The total convective latent heat gain, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent gain during the on and off cycles for the reporting period:

Mixing Latent Gain = (Mixing Latent Gain during on cycle \* Run time fraction) + Mixing Latent Gain during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.48 AFN Zone Mixing Latent Heat Loss Rate [W]**

The average convective latent heat loss rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent loss rate during the on and off cycles for the reporting period:

Mixing Latent Loss Rate = (Mixing Latent Loss Rate during on cycle \* Run time fraction) + Mixing Latent Loss Rate during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.49 AFN Zone Mixing Latent Heat Loss Energy [J]**

The total convective latent heat loss, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent loss during the on and off cycles for the reporting period:

Mixing Latent Loss = (Mixing Latent Loss during on cycle \* Run time fraction) + Mixing Latent Loss during off cycle \* (1.0 – Run time fraction)

**1.28.35.2.50 AFN Zone Mixing CO2 Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from adjacent zones multiplied by the corresponding zone carbon dioxide concentration level to the receiving zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing mass flow rate calculated during the fan on and off periods for the simulation timestep.

**1.28.35.2.51 AFN Zone Mixing Generic Air Contaminant Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from adjacent zones multiplied by the corresponding zone generic contaminant concentration level to the receiving zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing mass flow rate calculated during the fan on and off periods for the simulation timestep.

**1.28.35.2.52 AFN Zone Duct Leaked Air Sensible Heat Gain Rate [W]**

This is the average sensible heat gain rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system. This value is averaged over the reporting period. A sensible heat gain occurs when duct air is warmer than zone air. It should be pointed out that when multiple supply air leaks

are present in a single zone, the output value is the summation of all the supply air leak gains in this zone. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.53 AFN Zone Duct Leaked Air Sensible Heat Gain Energy [J]**

This is the total sensible heat gain, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.54 AFN Zone Duct Leaked Air Sensible Heat Loss Rate [W]**

This is the average sensible heat loss rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system. This value is averaged over the reporting period. A sensible heat loss occurs when duct air is cooler than zone air. It should be pointed out that when multiple supply air leaks are present in this zone, the output value is the summation of all the supply air leak losses in this zone. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.55 AFN Zone Duct Leaked Air Sensible Heat Loss Energy [J]**

This is the total sensible heat loss, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.56 AFN Zone Duct Leaked Air Latent Heat Gain Rate [W]**

This is the average latent heat gain rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system for the reported time period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.57 AFN Zone Duct Leaked Air Latent Heat Gain Energy [J]**

This is the total latent heat gain, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.58 AFN Zone Duct Leaked Air Latent Heat Loss Rate [W]**

This is the average latent heat loss rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system for the reported time period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.59 AFN Zone Duct Leaked Air Latent Heat Loss Energy [J]**

This is the total latent heat loss, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.60 AFN Zone Duct Conduction Sensible Heat Gain Rate [W]**

This is the average sensible heat gain rate, in Watts, of duct conduction to a specific zone where the ducts are located. This value is averaged over the reporting period. A sensible heat gain occurs when duct air is warmer than the zone air. It should be pointed out that when ducts are located in different zones, the total duct conduction loss should be the summation of the duct conduction losses in these zones. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.61 AFN Zone Duct Conduction Sensible Heat Gain Energy [J]**

This is the total sensible heat gain, in Joules, to a specific zone due to duct conduction summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.62 AFN Zone Duct Conduction Sensible Heat Loss Rate [W]**

This is the average sensible heat loss rate, in Watts, of duct conduction to a specific zone where the ducts are located. This value is averaged over the reporting period. A sensible heat loss occurs when duct air is cooler than the zone air. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.63 AFN Zone Duct Conduction Sensible Heat Loss Energy [J]**

This is the total sensible heat loss, in Joules, to a specific zone due to duct conduction summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.64 AFN Zone Duct Diffusion Latent Heat Gain Rate [W]**

This is the average latent heat gain rate, in Watts, of vapor diffusion through the walls of the air distribution system to a specific zone where the ducts are located. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.65 AFN Zone Duct Diffusion Latent Heat Gain Energy [J]**

This is the total latent heat gain, in Joules, to a specific zone due to duct vapor diffusion summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.66 AFN Zone Duct Diffusion Latent Heat Loss Rate [W]**

This is the average latent heat loss rate, in Watts, of duct vapor diffusion to a specific zone where the ducts are located. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.67 AFN Zone Duct Diffusion Latent Heat Loss Energy [J]**

This is the total latent heat loss, in Joules, to a specific zone due to duct vapor diffusion summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.68 AFN Distribution Sensible Heat Gain Rate [W]**

This is the average total sensible heat gain rate, in Watts, in a specific zone caused by the forced air distribution system. The total sensible gain rate is the sum of duct leakage sensible gain rate and duct conduction sensible gain rate. This value is averaged over the reporting period. The multizone airflow sensible gain rate is excluded in this output variable. The output of multizone airflow sensible gain is reported in the previously-described output variables AFN Zone Infiltration Sensible Heat Gain Rate and AFN Zone Mixing Sensible Heat Gain Rate. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.69 AFN Distribution Sensible Heat Gain Energy [J]**

This is the total sensible heat gain, in Joules, in a specific zone caused by the forced air distribution system. The total sensible gain is the sum of duct leakage sensible gain and duct conduction sensible gain. This value is summed over the reporting period. The multizone airflow sensible gain is excluded in this output variable. The output of multizone airflow sensible gain is reported in the previously-described output variables AFN Zone Infiltration Sensible Heat Gain Energy and AFN Zone Mixing Sensible Heat Gain Energy. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.70 AFN Distribution Sensible Heat Loss Rate [W]**

This is the average total sensible heat loss rate, in Watts, in a specific zone caused by the forced air distribution system. The total sensible loss rate is the sum of duct leakage sensible loss rate and duct conduction sensible loss rate. This value is averaged over the reporting period. The multizone airflow sensible loss rate is excluded in this output variable. The output of multizone airflow sensible loss rate is reported in the previously-described output variables AFN Zone Infiltration Sensible Heat Loss Rate and AFN Zone Mixing Sensible Heat Loss Rate. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.71 AFN Distribution Sensible Heat Loss Energy [J]**

This is the total sensible heat loss, in Joules, in a specific zone caused by the forced air distribution system. The total sensible loss is the sum of duct leakage sensible loss and duct conduction sensible loss. This value is summed over the reporting period. The multizone airflow sensible loss is excluded in this output variable. The output of multizone airflow sensible loss is reported in the previously-described output variables AFN Zone Infiltration Sensible Heat Loss Energy and AFN Zone Mixing Sensible Heat Loss Energy. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.72 AFN Distribution Latent Heat Gain Rate [W]**

This is the average total latent heat gain rate, in Watts, in a specific zone caused by the forced air distribution system. The total latent gain rate is the sum of duct leakage latent gain rate and duct conduction latent gain rate. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.73 AFN Distribution Latent Heat Gain Energy [J]**

This is the total latent heat gain, in Joules, in a specific zone caused by the forced air distribution system. The total latent gain is the sum of duct leakage latent gain and duct diffusion latent gain. This value is summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.74 AFN Distribution Latent Heat Loss Rate [W]**

This is the average total latent heat loss rate, in Watts, in a specific zone caused by the forced air distribution system. The total latent loss rate is a sum of duct leakage latent loss rate and duct diffusion latent loss rate. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**1.28.35.2.75 AFN Distribution Latent Heat Loss Energy [J]**

This is the total latent heat loss, in Joules, in a specific zone caused by the forced air distribution system. The total latent loss is the sum of duct leakage latent loss and duct diffusion latent loss. This value is summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

**NOTE:** The following output variables should not be confused with similar output variables for the infiltration, mixing, and cross mixing objects (Ref. Infiltration Output, Mixing Output, or Cross Mixing Output). The output variables described below refer to infiltration, mixing, and cross-mixing when an Airflow Network Simulation is performed. The following output variables are always used to describe infiltration, mixing, and cross mixing when the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to “MultiZoneWithoutDistribution” or “MultiZoneWithDistribution”. In this case the output variables for the infiltration, mixing, and cross mixing objects will always be 0.

In contrast, the following output variables are only used to describe infiltration, mixing, and cross mixing when the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to “MultiZoneAirflowWithDistributionOnlyDuringFanOperation” and the fan is operating. When the fan is not operating, the output variables for the infiltration, mixing, and cross mixing objects are used.

In the case where the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to “NoMultiZoneOrDistribution”, the following output variables are not used and the output variables for the infiltration, mixing, and cross mixing objects are used instead.

#### **1.28.35.2.76 AFN Zone Infiltration Sensible Heat Gain Energy [J]**

The total convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature, otherwise the sensible gain is set to 0. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.77 AFN Zone Infiltration Sensible Heat Loss Energy [J]**

The total convective sensible heat loss, in Joules to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

#### **1.28.35.2.78 AFN Zone Infiltration Volume [m3]**

The volume of outdoor air flow into the zone from window/door openings and cracks in the exterior surfaces of the zone (i.e., the sum of ventilation and crack flows from the exterior into the zone). The zone air density is used to calculate the zone infiltration volume based on the mass flow rate. Note that AirflowNetwork Zone Infiltration Volume will be zero if all of the flows through the zone’s exterior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration volume calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.79 AFN Zone Infiltration Mass [kg]**

The mass of air corresponding to the AirflowNetwork Zone Infiltration Volume. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration mass calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.80 AFN Zone Infiltration Air Change Rate [ach]**

The number of air changes per hour produced by outdoor air flow into the zone from window/door openings and cracks in the exterior surfaces of the zone (i.e. the sum of ventilation and crack flows from the exterior into the zone). The target zone air density is used to calculate the zone infiltration air change rate based on the mass flow rate. Note that, like Zone Infiltration Volume, Zone Infiltration Air Change Rate will be zero if all flows through the zone’s exterior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration air change rate calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.81 AFN Zone Mixing Volume [m3]**

This is a measure of interzone air flow for each thermal zone. It is the volume of air flow into the zone from adjacent zones through window/door openings and cracks in the interior heat transfer surfaces of the zone. The target zone air density is used to calculate the zone mixing volume based on the mass flow rate. This variable does not include flows that are from the zone to adjacent zones. Note that Zone Mixing Volume will be zero if all flows through the zone’s interior surfaces are out of the zone. When a Fan:OnOff

object is used, the reported value is weighted by the system fan part-load ratio using the mixing volume calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.82 AFN Zone Mixing Mass [kg]**

The mass of air corresponding to the AFN Zone Mixing Volume. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing mass calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.83 AFN Zone Mixing Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from adjacent zones to the receiving zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing mass flow rate calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.84 AFN Zone Outdoor Air CO2 Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from outdoors multiplied by the outdoor carbon dioxide concentration level to the receiving zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the outdoor mass flow rate calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.85 AFN Zone Outdoor Air Generic Air Contaminant Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from outdoors multiplied by the outdoor generic air contaminant concentration level to the receiving zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the outdoor mass flow rate calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.86 AFN Zone Outdoor Air Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from outdoors to the receiving zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the outdoor mass flow rate calculated during the fan on and off periods for the simulation timestep.

#### **1.28.35.2.87 AFN Zone Total CO2 Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from adjacent zones or outdoors multiplied by the carbon dioxide concentration differences between the corresponding zone and the receiving zone.

#### **1.28.35.2.88 AFN Zone Total Generic Air Contaminant Mass Flow Rate [kg/s]**

This is a sum of mass flow rates from adjacent zones or outdoors multiplied by the generic contaminant concentration differences between the corresponding zone and the receiving zone.

The following output variables are reported only when an AirflowNetwork:OccupantVentilationControl object is used:

#### **1.28.35.2.89 AFN Surface Venting Window or Door Opening Factor at Previous Time Step []**

The value of the venting opening factor for a particular window or door at the previous time step. When the window or door is venting, this is the input value of the opening factor (see AirflowNetwork:MultiZone:Surface, Window/Door Opening Factor) times the multiplier for venting modulation (see description of next output variable, “Opening Factor Multiplier for AirflowNetwork Venting Modulation”).

For example, if the input Window/Door opening factor is 0.5 and the modulation multiplier is 0.7, then the value of this output variable will be  $0.5 \times 0.7 = 0.35$ .

#### **1.28.35.2.90 AFN Surface Opening Elapsed Time [min]**

This output is the opening elapsed time in the units of minutes since the window opened.

#### **1.28.35.2.91 AFN Surface Closing Elapsed Time [min]**

This output is the opening elapsed time in the units of minutes since the windows closed.

#### **1.28.35.2.92 AFN Surface Opening Status at Previous Time Step []**

This is the window or door opening factor control status at the previous time step using an AirflowNetwork:OccupantVentilationControl object, which can have three integer values: 0, 1, and 2. A 0 value indicates no occupant ventilation control. The opening factor is determined by the Ventilation Control Mode field. A value of 1 indicates that a window or door is allowed to open. The value of 1 is determined when the opening elapsed time is less than the minimum opening time. A value of 2 denotes that a window or door is forced to close. The value of 2 is determined when the closing elapsed time is less than the minimum closing time.

#### **1.28.35.2.93 AFN Surface Opening Status []**

This is the window or door opening factor control status at the current time step using an AirflowNetwork:OccupantVentilationControl object, which can have three integer values: 0, 1, and 2. A 0 value indicates no occupant ventilation control. The opening factor is determined by the Ventilation Control Mode field. A value of 1 indicates that a window or door is allowed to open. The value of 1 is determined when the opening elapsed time is less than the minimum opening time. A value of 2 denotes that a window or door is forced to close. The value of 2 is determined when the closing elapsed time is less than the minimum closing time.

#### **1.28.35.2.94 AFN Surface Opening Probability Status []**

This is the opening probability status at the current time step using an AirflowNetwork:OccupantVentilationControl object, which can have three integer values: 0, 1, and 2. A 0 value indicates no opening probability control action. A value of 1 indicates that a window or door is forced to open when the opening status is 0. A value of 2 denotes that the status at the previous time step will be kept.

#### **1.28.35.2.95 AFN Surface Closing Probability Status []**

This is the closing probability status at the current time step using an AirflowNetwork:OccupantVentilationControl object, which can have three integer values: 0, 1, and 2. A 0 value indicates no closing probability control action. A value of 1 indicates that a window or door is forced to close when the opening status is 0. A value of 2 denotes that the status at the previous time step will be kept.

#### **1.28.35.2.96 RoomAirflowNetwork Node Temperature [C]**

This is the RoomAirflowNetwork node temperature output in degrees C.

#### **1.28.35.2.97 RoomAirflowNetwork Node Humidity Ratio [kgWater/kgDryAir]**

This is the RoomAirflowNetwork node humidity ratio output in kgWater/kgDryAir.

**1.28.35.2.98 RoomAirflowNetwork Node Total Pressure [Pa]**

This is the RoomAirflowNetwork node total pressure in Pa with respect to outdoor barometric pressure. The total pressure is the sum of static pressure, dynamic pressure, and elevation impact at the node’s relative height.

**1.28.35.2.99 AFN Zone Exfiltration Heat Transfer Rate [W]**

**1.28.35.3 AFN Zone Exfiltration Sensible Heat Transfer Rate [W]**

**1.28.35.4 AFN Zone Exfiltration Latent Heat Transfer Rate [W]**

These output variables represent the heat emitted to ambient from exfiltration in Watts. The exfiltration rate is calculated by solving a mass flow balance on the zone airflow network including infiltration, ventilation, outdoor air mixing, zone-to-zone mixing, and all of the zone inlet, exhaust, and return nodes. The latent parts are determined by taking the difference between the total and the sensible rate. Positive values indicate the zone injects heat to the environment, while negative values indicate the building extracts heat from the environment.

**1.29 Group - Zone Equipment**

There are five main zone equipment statements that must be used to describe a block of zone equipment as shown in Figure 1.119 - “Zone Equipment Input Syntax Map” below:

Types of Zone equipment are listed below and shown below in figure “Zone Equipment”.

Table 1.47: Available Zone Equipment Types

Air Equipment	Distribution	AirTerminal:SingleDuct:ConstantVolume:Reheat		AirTer-
		terminal:SingleDuct:ConstantVolume:NoReheat		AirTermi-
		nal:SingleDuct:VAV:Reheat	AirTerminal:SingleDuct:VAV:NoReheat	
		AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan		AirTer-
		terminal:DualDuct:ConstantVolume	AirTerminal:DualDuct:VAV	
Powered Induction Units (Series and Parallel)				
Zone Forced Air Units		ZoneHVAC:IdealLoadsAirSystem		ZoneHVAC:FourPipeFanCoil
		ZoneHVAC:WindowAirConditioner		Zone-
		HVAC:RefrigerationChillerSet	Unit Ventilator/Heater	Air-to-Air
		Heat Pumps	Unitary Systems (heat only and heat/cool)	Furnaces
		(heat only and heat/cool)	Energy Recovery Ventilator:Stand Alone	
		CoilSystem:Cooling:DX		
Radiative/Convective Units		Baseboard Heaters Low Temp Radiant Systems High Temp Radiant		
		System		

The following Figure 1.121 “Air Loop/Zone Equipment Node Diagram” illustrates the connection between the zone equipment and the air loop systems.

Each zone served by an HVAC system must have three additional statements to complete the zone equipment specification. An **ZoneHVAC:AirDistributionUnit** allows equipment typically found within the zone inlet ductwork (such as dampers, reheat coils, etc.) to be attached to the supply air stream for a particular zone. A ZoneControl statement will allow the conditions in the zone to be managed. Finally,

Figure 1.119: Zone Equipment Input Syntax Map

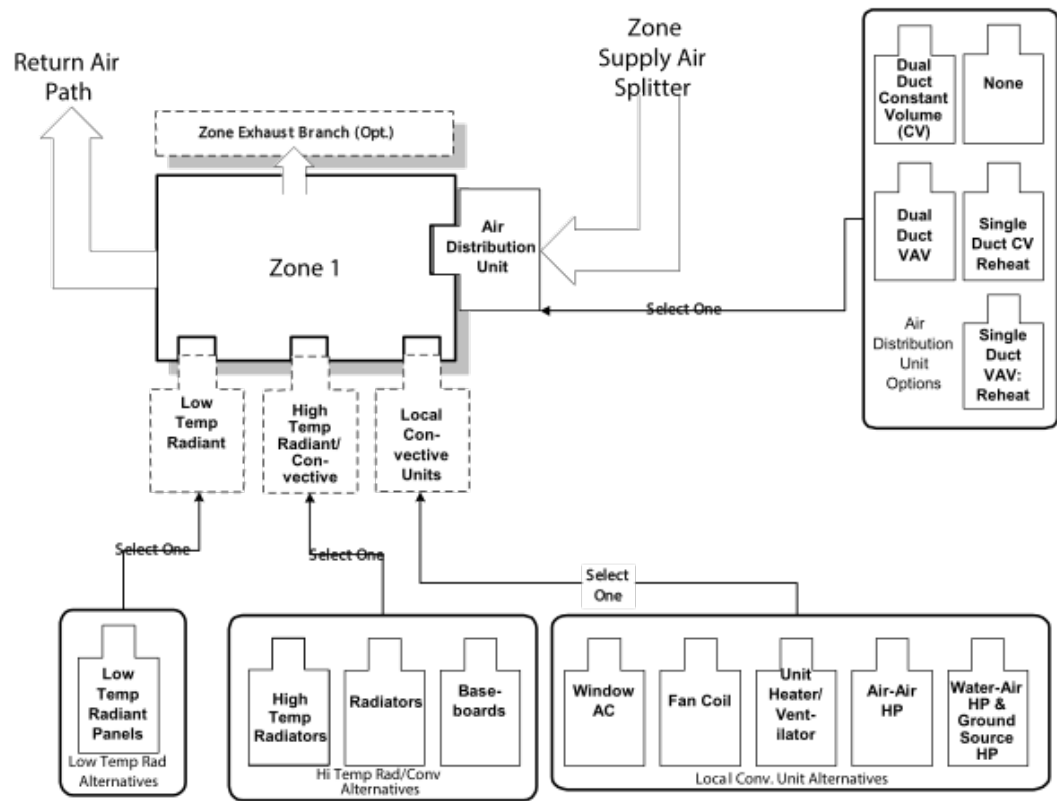

Figure 1.120: Representative Zone Equipment

Figure 1.121: Air Loop/Zone Equipment Node Diagram

a **ZoneHVAC:EquipmentConnections** statement describes all of the pertinent information about the zone from an HVAC perspective. Each of these statements is described in more detail below.

### 1.29.1 ZoneHVAC:AirDistributionUnit

The ZoneHVAC:AirDistributionUnit object gives further information on what air loop equipment (air terminal units) will be serving a particular zone. The ZoneHVAC:AirDistributionUnit is the part of the system that is supplied from a common main air handler simulated in the Air Loop Simulation and includes the equipment that controls or tempers the air going to each individual zone according to the desired thermostatic control. The current options for ZoneHVAC:AirDistributionUnit terminal unit types are:

- **AirTerminal:DualDuct:ConstantVolume**
- **AirTerminal:DualDuct:VAV**
- **AirTerminal:DualDuct:VAV:OutdoorAir**
- **AirTerminal:SingleDuct:ConstantVolume:Reheat**
- **AirTerminal:SingleDuct:VAV:Reheat**
- **AirTerminal:SingleDuct:VAV:NoReheat**
- **AirTerminal:SingleDuct:SeriesPIU:Reheat**
- **AirTerminal:SingleDuct:ParallelPIU:Reheat**
- **AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction**
- **AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan**
- **AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat**
- **AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat**
- **AirTerminal:SingleDuct:ConstantVolume:CooledBeam**
- **AirTerminal:SingleDuct:UserDefined**
- **AirTerminal:SingleDuct:Mixer**

Connections between the air distribution unit, the supply air duct, and the zone are specified in the input syntax for the air distribution unit and the **AirLoopHVAC:ZoneSplitter**. The input syntax also explicitly defines an outlet identifier. This implies a connection to a zone through a **NodeList** for zone inlets (see the **ZoneHVAC:EquipmentConnections** statement). The air distribution unit is limited to one combined component-controller unit; because controls are normally based on the zone thermostat and can work in parallel or series in complex fashion. Since the control and the flow resolution can be complex, each air distribution unit is unique in addressing these combinations and therefore only one is allowed per zone.

The Air Distribution unit also allows the user to specify leaks in the supply air duct system. These inputs are used in the EnergyPlus Simplified Duct Leakage Model (SDLM). This model simulates a specific configuration: supply leaks to a return plenum in a commercial VAV or CV system. The system must have a constant static pressure setpoint. Within these limitations SDLM allows the user to easily evaluate the energy penalty due to duct leakage.

### 1.29.1.1 Inputs

#### 1.29.1.1.1 Field: Name

Unique identifying name of the air distribution unit.

#### 1.29.1.1.2 Field: Air Distribution Unit Outlet Node Name

Outlet node name for the air distribution unit to the attached zone.

#### 1.29.1.1.3 Field: Air Terminal Object Type

Single combined component/controller unit for that attached zone. Selection of components as listed above.

#### 1.29.1.1.4 Field: Air Terminal Name

The unique identifying component name.

#### 1.29.1.1.5 Field: Nominal Upstream Leakage Fraction

This is the leakage upstream of the terminal unit as a fraction of the design flow rate through the unit. It is the leakage fraction at the design flow rate. It is used to calculate a leakage flow rate which is then held constant while the system air flow varies. This input is optional; the default is zero.

#### 1.29.1.1.6 Field: Constant Downstream Leakage Fraction

This is the leakage downstream of the terminal unit as a fraction of the current flow rate through the terminal unit. This fraction is held constant, so the leakage flow rate will vary proportionally with the supply air flow rate. This input is optional; the default is zero.

#### 1.29.1.1.7 Field: Design Specification Air Terminal Sizing Name

This optional input field is the name of a [DesignSpecification:AirTerminal:Sizing](#) object which specifies sizing adjustments to be made for the air terminal unit referenced by this object. The terminal unit is initially sized according to the inputs in the corresponding [Sizing:Zone](#) object. Then the adjustment factors in the [DesignSpecification:AirTerminal:Sizing](#) object are applied. See [DesignSpecification:AirTerminal:Sizing](#) for more details. If left blank, then no adjustments are made.

### 1.29.1.2 Outputs

- HVAC,Sum,Zone Air Terminal Sensible Heating Energy [J]
- HVAC,Sum,Zone Air Terminal Sensible Cooling Energy [J]
- HVAC,Average,Zone Air Terminal Sensible Heating Rate [W]
- HVAC,Average,Zone Air Terminal Sensible Cooling Rate [W]
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.29.1.2.1 Zone Air Terminal Sensible Heating Rate [W]

#### 1.29.1.2.2 Zone Air Terminal Sensible Heating Energy [J]

These outputs are the sensible heating rate and energy provided to the zone by the single duct constant volume no reheat air terminal unit.

### 1.29.1.2.3 Zone Air Terminal Sensible Cooling Rate [W]

### 1.29.1.2.4 Zone Air Terminal Sensible Cooling Energy [J]

These outputs are the sensible cooling rate and energy provided to the zone by the single duct constant volume no reheat air terminal unit.

### 1.29.1.2.5 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

Two example IDF excerpts (one with duct leakage, one without):

```
ZoneHVAC:AirDistributionUnit,
    SPACE1-1 ATU,           !- Air Distribution Unit Name
    SPACE1-1 In Node,       !- Air Dist Unit Outlet Node Name

## 1.29.2 ZoneHVAC:EquipmentConnections

Finally, the ZoneHVAC:EquipmentConnections statement defines the remaining details about each thermal zone from an HVAC perspective (besides the controls which were defined above). As with other statements, the first two items in this object are the keyword and an identifying name which links the zone back to its geometrical input, internal gains, etc. and other statements in the HVAC section of the input. The next three items are names of lists (equipment, air inlet nodes, and air exhaust nodes) that are described in more detail below. Note that if there are no air exhaust nodes from the zone that field is left blank. And if there are no air inlet nodes, that field is left blank. Finally, two node names are necessary to complete the zone-HVAC description. The first node is the main air node for the zone upon which the air heat balance is performed. The other node(s) begins the return air path(s) from the zone.

Note that all nodes mentioned in the ZoneHVAC:EquipmentConnections input must be unique. That is, all nodes in all the ZoneHVAC:EquipmentConnections statements referenced by the “Zone Air Inlet Nodes”, “Zone Air Exhaust Nodes”, “Zone Air Node Name” and “Zone Return Air Node Name” cannot have any node name appearing more than once.

### 1.29.2.1 Inputs

#### 1.29.2.1.1 Field: Zone Name

Name links this equipment list back to the heat balance for the zone.

#### 1.29.2.1.2 Field: Zone Conditioning Equipment List Name

List of zone equipment for this zone in a [ZoneHVAC:EquipmentList](#) object. This list will consist of air distribution units or other direct convection or radiant equipment, i.e. window air conditioner, baseboard, fan coils, etc.

### 1.29.2.1.3 Field: Zone Air Inlet Node or NodeList Name

There can be more than one air inlet node depending on how many pieces of equipment are in the `ZoneHVAC:EquipmentList`. Generally there will be one air inlet node for each piece of zone equipment that delivers conditioned air to the zone. Components such as electric or hot water baseboards and radiant systems do not require zone air inlet nodes. If there is only one node – its name can be put in this field. If there is more than one node, this must be the name of a node list object (a node list object can also contain only one node name). If this field is not required (as in the baseboard system), it should be blank.

### 1.29.2.1.4 Field: Zone Air Exhaust Node or NodeList Name

List of exhaust nodes leaving the zone for exhaust fans, zone energy recovery, etc. However these nodes are also used as sources of zone air for zone components such as fan coil units, unit heaters and ventilators, and window air conditioners. For each such component attached to a zone there should be a unique zone exhaust node acting as the inlet node to the component. If there is only one node – its name can be put in this field. If there is more than one node, this must be the name of a node list object (a node list object can also contain only one node name). If there are no air exhaust nodes, this field should be blank.

### 1.29.2.1.5 Field: Zone Air Node Name

The conditions at this node represent the average state of the air in the zone. For zones modeled as fully mixed the conditions at this node are assumed to represent the air in the entire zone. This field is required for all `ZoneHVAC:EquipmentConnections` statements.

### 1.29.2.1.6 Field: Zone Return Air Node or NodeList Name

The name of one or more return air nodes which attach the zone to an air loop return air path. Even if there is no return air or no return air path, a unique name must be entered in this field. The conditions at each return node represent the state of the air leaving the zone including any heat gain assigned to that return node from `Lights`, refrigeration equipment or airflow windows.

### 1.29.2.1.7 Field: Zone Return Air Node 1 Flow Rate Fraction Schedule Name

The name of a schedule to specify the return air flow rate for the first return air node as a fraction of the base return air. If the next field is blank, then the return air flow rate is the total supply inlet flow rate to the zone less the total exhaust node flow rate from the zone multiplied by this schedule name. If this field is left blank, the schedule defaults to 1.0 at all times.

### 1.29.2.1.8 Field: Zone Return Air Node 1 Flow Rate Basis Node or NodeList Name

The name of a node or list of nodes (`NodeList`) that is used to calculate the return air flow rate for the first return air node in this zone. The sum of the current flow rates for this node(s) multiplied by the Zone Return Air Node 1 Flow Rate Fraction Schedule determines the return air flow rate. If this field is blank, then the base return air flow rate is the total supply inlet flow rate to the zone less the total exhaust node flow rate from the zone in the case of a single air loop serving this zone. If there are multiple air loops serving this zone, the base return air flow rate is governed by the corresponding supply inlet flow rate and the `AirloopHVAC Design Return Air Flow Fraction of Supply Air Flow`.

An example of this statement in an IDF is:

```
ZoneHVAC:EquipmentConnections,
  SPACE3-1,                !- Zone Name
  SPACE3-1 Eq,              !- List Name: Zone Equipment
  SPACE3-1 In Nodes,        !- List Name: Zone Air Inlet Nodes
  ,                          !- List Name: Zone Air Exhaust Nodes
  SPACE3-1 Node,            !- Zone Air Node Name
```

SPACE3-1 Out Node;      !- Zone Return Air Node or NodeList Name

The following HVAC equipment types are allowed as zone equipment. The component matrix shows which coils and fans are allowed with which equipment models.

Parent Object	Zone Equipment	Child Object

Figure 1.122:

### 1.29.3 ZoneHVAC:EquipmentList

The first list encountered in the **ZoneHVAC:EquipmentConnections** statement is the **ZoneHVAC:EquipmentList**. This object lists all HVAC equipment serving the zone. Each item in the list has four fields associated with it: Object Type, Name, Cooling Sequence and Heating or No-Load Sequence. The Object Type and Name identify the specific equipment object. Cooling Sequence and Heating or No-Load Sequence specify the order of simulation for zones with more than one type of HVAC equipment.

Note that a **ZoneHVAC:AirDistributionUnit** must be listed in this statement if there is a forced air system serving the zone from an air loop.

#### 1.29.3.1 Inputs

##### 1.29.3.1.1 Field: Name

Unique identifying name.

### 1.29.3.1.2 Field: Load Distribution Scheme

The Load Distribution Scheme selects the algorithm used to allocate the current zone load across the zone equipment. There are four choices: SequentialLoad, UniformLoad, UniformPLR, and SequentialUniformPLR. The default is SequentialLoad. In all cases, the equipment operates in the order specified by the Zone Equipment Cooling Sequence and Heating or No-Load Sequence fields.

- SequentialLoad loads each piece of available equipment sequentially with the full remaining load.
- UniformLoad evenly distributes the total load equally among all available components on the equipment list for the current load type.
- UniformPLR evenly distributes the total load among all available components on the equipment list for the current load type at a uniform part load ratio (PLR).
- SequentialUniformPLR determines how many of the available components are required to meet the current load, then distributes the load at a uniform part load ratio (PLR).

### 1.29.3.1.3 Field Set (Zone Equipment: Object Type, Name, Cooling Sequence, Heating or No-Load Sequence, Sequential Cooling Fraction Schedule, Sequential Heating Fraction Schedule)

This set is used together in order to sequence the equipment for heating and cooling. The #1 sequence equipment will try to meet the entire demand with its capacity and then pass the results on to the #2 and so on for both heating and cooling. This field set is extensible by duplicating the last four fields.

Equipment is simulated in the order specified by Zone Equipment Cooling Sequence and Zone Equipment Heating or No-Load Sequence, depending on the current thermostat request. For equipment of similar type, assign sequence 1 to the first system intended to serve that type of load, assign sequence 2 to the next system, and so on. For situations where one or more equipment types has limited capacity or limited control capability, order the sequence so that the most controllable piece of equipment runs last. For example, with a dedicated outdoor air system (DOAS), the air terminal for the DOAS should be assigned Heating Sequence = 1 and Cooling Sequence = 1. Any other equipment should be assigned sequence 2 or higher so that it will see the net load after the DOAS air is added to the zone.

### 1.29.3.1.4 Field: Zone Equipment <x> Object Type

Type of zone equipment such as air distribution unit, baseboard, window air conditioner, etc. The current legal types are listed in the following table:

Table 1.48: Legal Zone Equipment Types (Zone-HVAC:EquipmentList)

Legal Zone Equipment Types
Fan:ZoneExhaust
WaterHeater:HeatPump:PumpedCondenser
WaterHeater:HeatPump:WrappedCondenser
ZoneHVAC:AirDistributionUnit
ZoneHVAC:Baseboard:Convective:Electric
ZoneHVAC:Baseboard:Convective:Water
ZoneHVAC:Baseboard:RadiantConvective:Electric
ZoneHVAC:Baseboard:RadiantConvective:Water

Table 1.48: Legal Zone Equipment Types (Zone-HVAC:EquipmentList)

**1.29.3.1.5 Field: Zone Equipment <x> Name**

Name of the zone equipment used in the object definition of its type.

**1.29.3.1.6 Field: Zone Equipment <x> Cooling Sequence**

Specifies the zone equipment simulation order when the zone thermostat requests cooling.

**1.29.3.1.7 Field: Zone Equipment <x> Heating or No-Load Sequence**

Specifies the zone equipment simulation order when the zone thermostat requests heating or no load.

**1.29.3.1.8 Field: Zone Equipment <x> Sequential Cooling Fraction Schedule Name**

References a schedule that specifies the fraction of the remaining cooling load this equipment will attempt to serve. Only applies if the load distribution scheme is SequentialLoad. Leaving this blank indicates a constant schedule of 1.0.

**1.29.3.1.9 Field: Zone Equipment <x> Sequential Heating Fraction Schedule Name**

References a schedule that specifies the fraction of the remaining heating load this equipment will attempt to serve. Only applies if the load distribution scheme is SequentialLoad. Leaving this blank indicates a constant schedule of 1.0.

Examples of this statement in an IDF are:

```

ZoneHVAC:EquipmentList,

## 1.30 Group – Zone HVAC Air Loop Terminal Units

The systems described in the Air Distribution Units (ADU's) are shown below. A variety of air terminal units are available for connecting air systems to thermal zones. These single description ADU's contain the reference to the components and the actual controls in one block of input. The idea is that the control volume is drawn tightly around the controls and loosely around the components. This allows complex interactions to take place between all of the components that respond to the Zone Thermostatic Control output. The coils that are referenced in the ADU's are explained fully in the "Coils" section of this manual.

### 1.30.1 AirTerminal:SingleDuct:ConstantVolume:Reheat

The AirTerminal:SingleDuct:ConstantVolume:Reheat or terminal reheat system is a constant volume reheat system. The systems cooling capabilities are provided by way of cooling coil that supplies cooling to the entire supply air volume. The cooling coil is controlled by a controller setpoint specified for the cooling coil. Zone control is accomplished by heating (reheating) the airflow into each zone as determined by the zone thermostat. Currently the reheat can be supplied by a electric, gas, or hot water coil that tries to meet the zone demand.

#### 1.30.1.1 Inputs

##### 1.30.1.1.1 Field: Name

Unique name for the terminal reheat Air Distribution Unit (ADU).

##### 1.30.1.1.2 Field: Availability Schedule Name

Schedule that this component will operate or is available to operate. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or

equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.30.1.1.3 Field: Air Outlet Node Name

The outlet node from the ADU to the zone. This is the same node as the reheat component air outlet node.

#### 1.30.1.1.4 Field: Air Inlet Node Name

The air-inlet node name that connects the air splitter to the individual zone ADU. This is the same node as the reheat component air inlet node.

#### 1.30.1.1.5 Field: Maximum Air Flow Rate

The design constant volume flow rate ( $\text{m}^3/\text{sec}$ ) specified for the terminal reheat ADU.

#### 1.30.1.1.6 Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

- Coil:Heating:Water
- Coil:Heating:Electric
- Coil:Heating:Fuel
- Coil:Heating:Steam

#### 1.30.1.1.7 Field: Reheat Coil Name

Reheat Coil Object name being simulated with this ADU. Applicable for all coils.

#### 1.30.1.1.8 Field: Maximum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the maximum design hot water or steam volumetric flow rate in  $\text{m}^3/\text{s}$  for the hot water or steam heating coil. The steam volumetric flow rate is calculated at 100C and 101325 Pa.

#### 1.30.1.1.9 Field: Minimum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the minimum design hot water or steam volumetric flow rate in  $\text{m}^3/\text{s}$  for the hot water or steam coil, normally set to be a shut off valve that is set to zero. The steam volumetric flow rate is calculated at 100C and 101325 Pa.

#### 1.30.1.1.10 Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved for by iteration. The iterative solution uses an interval halving routine and needs a termination criterion that is set with the Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand as the criteria, i.e. 0.001. The default for the field is 0.001.

### 1.30.1.1.11 Field: Maximum Reheat Air Temperature

This is the upper limit on the temperature in degrees C of the air leaving the terminal unit – reheat coil (and being delivered to the zone). If the user leaves this field blank, no maximum reheat air temperature is enforced.

### 1.30.1.2 Outputs

- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.30.1.2.1 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

An IDF example:

```
AirTerminal:SingleDuct:ConstantVolume:Reheat,
  Reheat Zone 1,  !- Name of System
  FanAndCoilAvailSched,  !- Availability schedule for VAV System
  Zone 1 Reheat Air Outlet Node,  !- Unit Air Outlet Node
  Zone 1 Reheat Air Inlet Node,  !- Unit Air Inlet Node
  0.59,  !- Maximum air flow rate {m3/s}
  COIL:Gas:Heating,  !- Reheat Component Object
  Reheat Coil Zone 1,  !- Name of Reheat Component
  0.0,  !- Max Reheat Water Flow {m3/s}
  0.0,  !- Min Reheat Water Flow {m3/s}
  0.001;  !- Convergence Tolerance
```

## 1.30.2 AirTerminal:SingleDuct:ConstantVolume:NoReheat

The AirTerminal:SingleDuct:ConstantVolume:NoReheat object creates the capability of supplying central system air directly to a zone without any zone level thermostat control. The supply air temperature is controlled by the central system controller. It is typically used with a unitary system and furnaces which controls the system supply temperature and flow rate with continuous or cycling fan. When used without the Design Specification Outdoor Air Object Name, the terminal unit is passive and accepts any flow rate supplied by the central system, but will never exceed the maximum air flow rate.

This object allows the program to know what zone this branch of the air system is attached to, and input fields for availability schedule, air inlet and outlet nodes, the maximum air flow rate, and other two optional input fields. The air inlet node should be the same as one of the *AirLoopHVAC:ZoneSplitter* or *AirLoopHVAC:SupplyPlenum* component outlet nodes. The air outlet node name should be same as zone air inlet node name and the air distribution unit air outlet node name. The last two optional input fields: *Design Specification Outdoor Air Object Name*, and *Per Person Ventilation Rate Mode* are used for modulating the outdoor air requirement of an air terminal unit depending on the method.

### 1.30.2.1 Inputs

#### 1.30.2.1.1 Field: Name

A unique user assigned name for the single duct constant volume no reheat air terminal unit.

#### 1.30.2.1.2 Field: Availability Schedule Name

Availability schedule name for this system. Schedule value > 0 means the system is available or else the system is off. If this field is blank, the system is always available.

**1.30.2.1.3 Field: Air Inlet Node Name**

The air inlet node name that connects the air splitter to the individual zone air distribution unit. This node should also be one of the outlet air node of an **AirLoopHVAC:ZoneSplitter** or **AirLoopHVAC:SupplyPlenum** component.

**1.30.2.1.4 Field: Air Outlet Node Name**

This is an air outlet node from the air distribution unit. This node name should be one of the supply air inlet node names of the zone served by this component.

**1.30.2.1.5 Field: Maximum Air Flow Rate**

The design maximum volume flow rate ( $\text{m}^3/\text{sec}$ ). This field is autosizable.

**1.30.2.1.6 Field: Design Specification Outdoor Air Object Name**

This field is used to modulate the terminal unit flow rate based on the specified outdoor air requirement. When the name of a **DesignSpecification:OutdoorAir** object is entered, the terminal unit will adjust flow to meet this outdoor air requirement and no more. Load is still "Uncontrolled." If Outdoor Air Flow per Person is non-zero, then the outdoor air requirement will be computed based on either the current or design occupancy as specified in the *Per Person Ventilation Rate Mode* input field below. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. The requested flow rate may not be fully met if the system is operating with cycling fan. The volume flow rate is converted to mass flow rate using the standard density of air at Pressure = 101325 Pa, Temperature = 20C, and Humidity Ratio = 0.0. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. This field is optional.

**1.30.2.1.7 Field: Per Person Ventilation Rate Mode**

This field specifies the occupancy level to use when calculating the ventilation rate per person when a Design Specification Outdoor Air Object Name has been specified. *CurrentOccupancy* uses the current number of people in the zone which may vary. *DesignOccupancy* uses the total Number of People specified for the zone which is constant.

**1.30.2.2 Outputs**

- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

**1.30.2.2.1 Zone Air Terminal Outdoor Air Volume Flow Rate [ $\text{m}^3/\text{s}$ ]**

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

An IDF example:

```
AirTerminal:SingleDuct:ConstantVolume:NoReheat,
  NoReheat Zone 1,           !- Name of System
  AlwaysOnFanAvailSched,     !- Availability Schedule Name
  Zone 1 Unit Air Inlet Node, !- Air Inlet Node Name
  Zone 1 Unit Air Outlet Node, !- Air Outlet Node Name
  0.60,                      !- Maximum Air Flow Rate {m3/s}
  ,                          !- Design Specification Outdoor Air Object Name
  ;                          !- Per Person Ventilation Rate Mode
```

---

### 1.30.3 AirTerminal:SingleDuct:VAV:Reheat

AirTerminal:SingleDuct:VAV:Reheat - Variable air volume (VAV) systems control the dry-bulb temperature inside a zone by varying the supply air volume instead of the air temperature. At full cooling the VAV damper is fully open supplying the specified maximum air flow rate. As the cooling load decreases, the damper closes until it reaches the minimum stop specified by the zone minimum air flow fraction. The zone minimum supply air flow can be further adjusted using scheduled fraction values specified in the field *Minimum Air Flow Turndown Schedule Name*.

VAV systems can be used for interior or perimeter zones with a common fan system, air temperature control, and reheating devices. The VAV concept may vary according to the VAV box locations, air temperature controls and types of heating elements. Heating can usually be provided by use of reheat coils or thermostatic baseboard.

#### 1.30.3.1 Inputs

##### 1.30.3.1.1 Field: Name

Unique name for the AirTerminal:SingleDuct:VAV:Reheat Air Distribution Unit (ADU).

##### 1.30.3.1.2 Field: Availability Schedule Name

Schedule that this component will operate or is available to operate. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.30.3.1.3 Field: Damper Air Outlet Node Name

The VAV damper outlet node. This is the outlet node of the damper and the inlet node of the reheat coil.

##### 1.30.3.1.4 Field: Air Inlet Node Name

The air inlet node name that connects the air splitter to the individual zone ADU. This is *not* the same as the air inlet node of the reheat component: it is upstream of that node. This is the inlet node to the terminal unit and the damper

##### 1.30.3.1.5 Field: Maximum Air Flow Rate

The design maximum volume flow rate ( $\text{m}^3/\text{sec}$ ) specified for VAV ADU.

##### 1.30.3.1.6 Field: Zone Minimum Air Flow Method

This field is used to select how the program will determine the minimum flow rate to the zone while the system is operating. The minimum flow rate is modeled as a fraction of the maximum flow rate. There are three choices for selecting how the minimum flow rate is specified: Constant, FixedFlowRate, and Scheduled. If Constant is entered, then the program will use the value for the constant minimum air flow fraction entered in the following field. If FixedFlowRate is entered, then the program will use the value for minimum flow rate entered in the field below called Fixed Minimum Air Flow Rate. If Scheduled is entered, then the program will obtain the value for minimum flow fraction from the schedule named in the field below called Minimum Air Flow Fraction Schedule Name. The default is Constant.

**1.30.3.1.7 Field: Constant Minimum Air Flow Fraction**

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal. This field is used if the previous field is set to Constant. If the previous field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils. If this field and the following field have values, the greater of the two is used for sizing.

This field is autosizable and defaulted to autosize. The autosized flow fraction is calculated using the maximum flow rate derived from the design outdoor air flow (including VRP adjustments) and the **Sizing:Zone** input fields "Cooling Minimum Air Flow per Zone Floor Area", "Cooling Minimum Air Flow", and "Cooling Minimum Air Flow Fraction". If there is no sizing calculation the defaults of 0.000762 cubic meters per second per square meter of zone floor area (0.15 cfm/ft<sup>2</sup>) and 0.2 are used.

**1.30.3.1.8 Field: Fixed Minimum Air Flow Rate**

The minimum flow rate to the zone while the system is operating, specified as a fixed minimum air flow rate in meters cubed per second. The minimum air flow rate is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the Zone Minimum Air Flow Method field is set to FixedFlowRate. If the Zone Minimum Air Flow Method field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils. Only one of these two minimum air flow fields (i.e., this field and the previous field) should be used at any time. If this field and the previous field have values, the greater of the two is used for sizing.

This field is autosizable and defaulted to autosize. The autosized flow rate is the maximum flow rate derived from the design outdoor air flow (including VRP adjustments) and the **Sizing:Zone** input fields "Cooling Minimum Air Flow per Zone Floor Area", "Cooling Minimum Air Flow", and "Cooling Minimum Air Flow Fraction". If there is no sizing calculation the defaults of 0.000762 cubic meters per second per square meter of zone floor area (0.15 cfm/ft<sup>2</sup>) and 0.2 flow fraction are used.

**1.30.3.1.9 Field: Minimum Air Flow Fraction Schedule Name**

The name of a schedule that determines the value of the minimum air flow fraction. The schedule should contain fractions from 0.0 to 1.0. These values will define the minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Scheduled. If the previous field is left blank (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then the air flow rate used for sizing normal-action reheat coils is the average of the minimum and maximum values in this schedule. The air flow rate used for reheat coil sizing is reported with other component sizing information as "Reheat Coil Sizing Air Volume Flow Rate."

**1.30.3.1.10 Field: Reheat Coil Object Type**

The valid reheat component objects currently available are:

- **Coil:Heating:Water**
- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**

- **Coil:Heating:Steam**

If there is no reheat coil, use **AirTerminal:SingleDuct:VAV:NoReheat** instead of this object.

#### 1.30.3.1.11 Field: Reheat Coil Name

Reheat Coil Object name being simulated with this ADU. Applicable for all coils. If there is no reheat coil, use object **AirTerminal:SingleDuct:VAV:NoReheat** instead of this object.

#### 1.30.3.1.12 Field: Maximum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the maximum design hot water or steam volumetric flow rate in  $\text{m}^3/\text{s}$  for the hot water or steam heating coil. The steam volumetric flow rate is calculated at 100C and 101325 Pa. This field is autosizable. If there is no reheat coil, this is left blank.

#### 1.30.3.1.13 Field: Minimum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the minimum design hot water or steam volumetric flow rate in  $\text{m}^3/\text{s}$  for the hot water or steam heating coil, normally set to be a shut off valve that is set to zero. The steam volumetric flow rate is calculated at 100C and 101325 Pa. If there is no reheat coil, this is left blank.

#### 1.30.3.1.14 Field: Air Outlet Node Name

The terminal unit outlet node. This is the outlet node of the reheat coil and the zone inlet node.

#### 1.30.3.1.15 Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved for by iteration. The iterative solution uses an interval halving routine and needs a termination criteria that is set with the Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand as the criteria, i.e. 0.001. The default for the field is 0.001.

#### 1.30.3.1.16 Field: Damper Heating Action

During heating operation, there are three control options for the damper controlling the air flow in the VAV terminal unit as the zone moves above or below the zone setpoint. With all three control options, the damper is at the minimum air flow rate whenever the zone temperature is between the cooling and heating setpoints (deadband condition).

With **Normal** action, the damper will remain at the minimum air flow rate during heating operation. As the heating load increases, the water flow rate in the reheat coil will be increased to maintain temperature in the zone until the maximum water flow rate is reached or the user-specified maximum reheat air temperature is reached. This is sometimes called the single maximum control logic as illustrated below.

With **Reverse** and **ReverseWithLimits** (the default) action, as the heating load increases, the unit starts at minimum air flow and minimum hot water flow. The hot water flow is increased until it reaches maximum flow or the user-specified maximum reheat air temperature is reached, then the air damper starts to open to meet the load. For **Reverse** the damper can open all the way. For **ReverseWithLimits** the damper can only partially open to a maximum flow rate given by the following two fields. These options are used if the minimum air flow rate is not adequate to serve the peak heating load. This is sometimes called the dual maximum control logic as illustrated in following figure. For heating coil types other than the hot-water coil, e.g. electric, steam, and gas, the reverse action works the same as the normal action – always keeping the air flow at the minimum during heating.

Figure 1.123: The Single Maximum Control Logic

The dual-max control currently applies to the AirTerminal:SingleDuct:VAV:Reheat objects with reverse acting dampers and hot-water coils.

#### 1.30.3.1.17 Control Fields for Maximum Flow During Reheat:

The following two fields are used only when Reheat Coil Object Type = **Coil:Heating:Water** and Damper Heating Action = ReverseWithLimits. Maximum Flow per Zone Floor Area During Reheat and Maximum Flow Fraction During Reheat are two optional methods to calculate the maximum allowable air flow rate during reheat operation. If both are entered, the greater resulting flow rate is used. If Design Specification Outdoor Air Object Name is also specified, it may increase this limit to meet the outdoor air flow rate requirement. At no time will the maximum flow rate calculated here exceed the value for Maximum Air Flow Rate.

This limit is active only when the zone thermostat requests heating and the VAV box damper is reverse acting (i.e., ReverseWithLimits).

#### 1.30.3.1.18 Field: Maximum Flow per Zone Floor Area During Reheat

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is multiplied by the zone area, to determine the maximum volume flow rate ( $\text{m}^3/\text{s}$ ) allowed during reheat operation (see detailed explanation above). This field is autosizable and its default is autosize. If autosize is selected or the field is blank, the value is filled from the similar inputs in **Sizing:Zone**. If there is no sizing calculation the value is set to  $0.002032 \text{ m}^3/\text{s}\cdot\text{m}^2$  ( $0.4 \text{ cfm}/\text{ft}^2$ ). If this field and the following field are entered, the greater of the two inputs is used. This field and the following field are only used if Damper Heating Action = ReverseWithLimits.

#### 1.30.3.1.19 Field: Maximum Flow Fraction During Reheat

This fraction is multiplied by the Maximum Air Flow Rate to determine the maximum volume flow

Figure 1.124: The Dual Maximum Control Logic

rate ( $\text{m}^3/\text{s}$ ) allowed during reheat operation (see detailed explanation above). This field is autosizeable and is defaulted to autosize. If autosizeable is selected or the field is blank, the value is set to  $0.002032 \text{ m}^3/\text{s}\cdot\text{m}^2$  ( $0.4 \text{ cfm}/\text{ft}^2$ ) multiplied by the zone floor area divided by the Maximum Air Flow Rate. If this field and the previous field are entered, the greater of the two inputs is used. This field and the following field are only used if Damper Heating Action = ReverseWithLimits.

#### 1.30.3.1.20 Field: Maximum Reheat Air Temperature

This field specifies a maximum supply air temperature ( $^{\circ}\text{C}$ ) leaving the reheat coil in a VAV terminal unit during heating operation. If leaving blank, the temperature of the supply air to the space in heating operation may get unrealistic high.

#### 1.30.3.1.21 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person is non-zero, then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref **DesignSpecification:OutdoorAir**).

#### 1.30.3.1.22 Field: Minimum Air Flow Turndown Schedule Name

This field adjusts the *Constant Minimum Air Flow Fraction*, *Fixed Minimum Air Flow Rate*, or *Minimum Air Flow Fraction Schedule* value by multiplying it using this schedule. Schedule values are fractions, 0.0 to 1.0. This field adjusts the minimum airflow turndown value below the zone design minimum air flow and is intended for use with ASHRAE Standard 170. This field can also be used to adjust the design

minimum air flow sizing calculation by applying a desired fraction values to summer and winter design days turndown schedule. If this field is left blank, then the turndown minimum air flow fraction value is set to 1.

An IDF example:

```
AirTerminal:SingleDuct:VAV:Reheat,
SPACE2-1 VAV Reheat, !- Name of System

### 1.30.3.2 Outputs

- HVAC,Average,Zone Air Terminal VAV Damper Position []
- HVAC,Average,Zone Air Terminal Minimum Air Flow Fraction []
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.30.3.2.1 Zone Air Terminal VAV Damper Position []

This output is the variable air volume damper position required to meet the zone load. This is the average value over the frequency being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

#### 1.30.3.2.2 Zone Air Terminal Minimum Air Flow Fraction []

This output is the value for the minimum air flow fraction setting on a VAV terminal. This is the average value over the frequency being reported. The minimum air flow fraction is defined as the lower limit on the terminal unit air mass flow rate divided by the terminal units maximum air mass flow rate.

#### 1.30.3.2.3 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

## 1.30.4 AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan

The VAV terminal unit with variable-speed fan and reheat coil is an air system terminal unit consisting of a variable speed fan in series with a heating coil. These units are usually employed in underfloor air distribution (UFAD) systems where the air is supplied at low static pressure through an underfloor plenum. The fan is used to control the flow of conditioned air that enters the space. When the fan is off the plenum pressure drives the minimum air flow through the terminal unit. At maximum cooling the fan runs at its maximum speed. At full heating the fan runs at its heating maximum – usually less than the cooling maximum flow rate. Thus this unit has two separate maximum flow rates – one for heating and one for cooling.

For cooling, control is maintained simply by varying the fan speed. For heating, the unit first tries to meet the heating load by varying the heating coil output while keeping the air flow at minimum (fan off). If this is not adequate the fan turns on and operates in variable flow mode up to the heating maximum flow rate. The zone fan-off minimum supply air flow can be further adjusted using scheduled fraction values specified in the field *Minimum Air Flow Turndown Schedule Name*.

This unit is modeled in EnergyPlus as a compound component – a variable speed fan and a heating coil in series in the air stream. The unit is blow through – the fan is upstream of the heating coil.

### 1.30.4.1 Inputs

#### 1.30.4.1.1 Field: Name

A unique user assigned name for a particular VS fan VAV reheat terminal unit. Any reference to this unit by another object will use this name.

**1.30.4.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.30.4.1.3 Field: Maximum Cooling Air Flow Rate**

The maximum volumetric air flow rate through the unit in cubic meters per second when the thermostat is calling for cooling. Normally this is the same as the unit's fan maximum volumetric flow rate.

**1.30.4.1.4 Field: Maximum Heating Air Flow Rate**

The maximum volumetric air flow rate through the unit in cubic meters per second when the thermostat is calling for heating.

**1.30.4.1.5 Field: Zone Minimum Air Flow Fraction**

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. For this unit this is the flow rate when the fan is off.

**1.30.4.1.6 Field: Air Inlet Node Name**

The name of the HVAC system node that is the air inlet node for the terminal unit. This is also the air inlet node for the unit's fan.

**1.30.4.1.7 Field: Air Outlet Node Name**

The name of the HVAC system node that is the air outlet node of the unit. This same node will be the unit heating coil's air outlet node. This node is also a zone inlet node.

**1.30.4.1.8 Field: Fan Object Type**

The type of fan in the terminal unit. At this time the only type of fan allowed is *Fan:SystemModel* or *Fan:VariableVolume*.

**1.30.4.1.9 Field: Fan Name**

The name of the particular fan object in this terminal unit.

**1.30.4.1.10 Field: Heating Coil Object Type**

The type of heating coil in the terminal unit. The valid choices are:

- *Coil:Heating:Water*
- *Coil:Heating:Electric*
- *Coil:Heating:Fuel*
- *Coil:Heating:Steam*

**1.30.4.1.11 Field: Heating Coil Name**

The name of the heating coil object contained in this terminal unit.

#### 1.30.4.1.12 Field: Maximum Hot Water or Steam Flow Rate

The maximum hot water or steam volumetric flow rate in m<sup>3</sup>/s through the unit's heating coil. The steam volumetric flow rate is calculated at 100C and 101325 Pa. If the heating coil is not a hot water or steam coil this field should be left blank.

#### 1.30.4.1.13 Field: Minimum Hot Water or Steam Flow Rate

The minimum hot water or steam volumetric flow rate in m<sup>3</sup>/s through the unit's heating coil. The steam volumetric flow rate is calculated at 100C and 101325 Pa. If the heating coil is not a hot water or steam coil this field should be left blank.

#### 1.30.4.1.14 Field: Heating Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically, this is the fraction:

$$\frac{|Q_{\text{unit,out}} - Q_{\text{zoneload}}|}{Q_{\text{zoneload}}} \leq \text{ConvergenceTolerance} \quad (1.121)$$

The default is 0.001.

#### 1.30.4.1.15 Field: Minimum Air Flow Turndown Schedule Name

This field adjusts *Zone Minimum Air Flow Fraction* by multiplying it using this schedule. Schedule values are fractions, 0.0 to 1.0. This field adjusts the minimum airflow turndown value below the zone design minimum air flow and is intended for use with ASHRAE Standard 170. This field can also be used to adjust the design minimum air flow sizing calculation by applying a desired fraction values to summer and winter design days turndown schedule. If this field is left blank, then the turndown minimum air flow fraction value is set to 1 and the VAV air terminal uses the fixed fraction specified in in the field *Zone Minimum Air Flow Fraction*.

### 1.30.4.2 Outputs

- HVAC,Average,Zone Air Terminal VAV Damper Position []
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.30.4.2.1 Zone Air Terminal VAV Damper Position

This output is the variable air volume flow fraction required to meet the zone load. This is the average value over the frequency being reported. The flow fraction is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

#### 1.30.4.2.2 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

### 1.30.5 AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat

Variable air volume (VAV) systems typically control the dry-bulb temperature inside a zone by varying the supply air volume instead of the supply air temperature (ref: [AirTerminal:SingleDuct:VAV:NoReheat](#)). Reheat coils may be required to avoid overcooling (ref: [AirTerminal:SingleDuct:VAV:Reheat](#)).

This terminal unit is slightly different from the [AirTerminal:SingleDuct:VAV:Reheat](#) terminal unit. Both operate the same in cooling mode: the damper opens as needed to provide additional sensible cooling to the zone. The difference between the two is in heating mode. For the Single Duct VAV Reheat terminal unit, the air flow rate is reduced to the minimum value (max air flow rate x zone minimum air flow fraction) when zone heating is required and the reheat coil output is modulated to meet the zone heating load. The zone minimum supply air flow can be further adjusted using scheduled fraction values specified in the field

*Minimum Air Flow Turndown Schedule Name.* For the AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat terminal unit, the air flow rate in heating mode is increased to meet higher zone heating loads (similar to what is done in cooling mode). If additional heat is required (beyond what the terminal unit can provide with its damper fully open), then the reheat coil is modulated as needed to meet the additional heating load.

This terminal unit model was originally developed and tested for use with the changeover-bypass VAV unitary system.

Figure 1.125: Single Duct VAV Heat and Cool Reheat Schematic

### 1.30.5.1 Inputs

#### 1.30.5.1.1 Field: Name

Unique user-defined name for this Air Distribution Unit (ADU).

#### 1.30.5.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether or not this component is available to operate during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.30.5.1.3 Field: Damper Air Outlet Node Name

This alpha field defines the name of the VAV damper air outlet node. This is the outlet node of the damper and the inlet node of the reheat coil.

#### 1.30.5.1.4 Field: Air Inlet Node Name

This alpha field defines the name of the air inlet node that connects the air splitter to the individual zone ADU. This is *not* the same as the air inlet node of the reheat component: it is upstream of that node. This is the inlet node to the terminal unit and the damper.

#### 1.30.5.1.5 Field: Maximum Air Flow Rate

This numeric field defines the design maximum volumetric flow rate ( $\text{m}^3/\text{sec}$ ) specified for this VAV ADU. This flow rate must be greater than 0 or can be autosized.

#### 1.30.5.1.6 Field: Zone Minimum Air Flow Fraction

This numeric field defines the minimum air volumetric flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates as needed to maintain the heating set point specified in the Zone Control:Thermostatic object. This value must be between 0 and 1.

#### 1.30.5.1.7 Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

- `Coil:Heating:Water`
- `Coil:Heating:Electric`
- `Coil:Heating:Fuel`
- `Coil:Heating:Steam`

If no reheat coil is required, use `AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat` instead of this object.

#### 1.30.5.1.8 Field: Reheat Coil Name

Unique coil name being simulated with this ADU. Applicable for all coils. If there is no reheat coil, use `AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat` instead of this object.

#### 1.30.5.1.9 Field: Maximum Hot Water or Steam Flow Rate

This field is ignored for gas or electric reheat coils. If using a hot water or steam reheat coil, set to the maximum design water or steam volumetric flow rate in  $\text{m}^3/\text{s}$  for the hot water or steam heating coil. The steam volume flow rate is calculated at 100C and 101325 Pa. This volumetric flow rate can be autosized.

#### 1.30.5.1.10 Field: Minimum Hot Water or Steam Flow Rate

This field is ignored for gas and electric coils. Set to the minimum design water or steam volumetric flow rate in  $\text{m}^3/\text{s}$  for the hot water or steam heating coil, normally set to be a shut-off valve that is set to zero. The steam volume flow rate is calculated at 100C and 101325 Pa.

#### 1.30.5.1.11 Field: Air Outlet Node Name

This is the air outlet node for the ADU and is then connected to the zone. This is the same node as the air outlet node of the reheat component.

#### 1.30.5.1.12 Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted and this field is not used. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved by iteration. The iterative solution uses an interval-halving routine and needs a termination criterion that is set with this Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand. The default value for this field is 0.001.

### 1.30.5.1.13 Field: Maximum Reheat Air Temperature

This is the upper limit on the temperature in degrees C of the air leaving the terminal unit – reheat coil (and being delivered to the zone). If the user leaves this field blank, no maximum reheat air temperature is enforced.

### 1.30.5.1.14 Field: Minimum Air Flow Turndown Schedule Name

This field adjusts the *Zone Minimum Air Flow Fraction* by multiplying it using this schedule. Schedule values are fractions, 0.0 to 1.0. This field adjusts the minimum airflow turndown value below the zone design minimum air flow and is intended for use with ASHRAE Standard 170. This field can also be used to adjust the design minimum air flow sizing calculation by applying a desired fraction values to summer and winter design days turndown schedule. If this field is left blank, then the turndown minimum air flow fraction value is set to 1 and uses the fixed fraction specified in the field *Zone Minimum Air Flow Fraction*.

An IDF example is provided below:

```

## 1.30.5.2 Outputs

- HVAC,Average,Zone Air Terminal VAV Damper Position []
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

### 1.30.5.2.1 Zone Air Terminal VAV Damper Position []

This output is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

### 1.30.5.2.2 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

### 1.30.6 AirTerminal:SingleDuct:VAV:NoReheat

Variable air volume (VAV) systems control the dry-bulb temperature inside a zone by varying the supply air volume instead of the air temperature. At full cooling the VAV damper is fully open supplying the specified maximum air flow rate. As the cooling load decreases, the damper closes until it reaches the minimum stop specified by the zone minimum air flow fraction. The zone minimum supply air flow can be adjusted using scheduled fraction values specified in the field *Minimum Air Flow Turndown Schedule Name*.

VAV systems can be used for interior or perimeter zones with a common fan system and air temperature control. The VAV concept may vary according to the VAV box locations and air temperature controls. Heating can be provided if necessary by use of baseboard.

#### 1.30.6.1 Inputs

##### 1.30.6.1.1 Field: Name

Unique name for the VAV Air Distribution Unit (ADU).

##### 1.30.6.1.2 Field: Availability Schedule Name

Schedule that this component will operate or is available to operate. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.30.6.1.3 Field: Air Outlet Node Name

The VAV damper and Unit outlet node.

##### 1.30.6.1.4 Field: Air Inlet Node Name

The air inlet node name that connects the air splitter to the individual zone ADU.

##### 1.30.6.1.5 Field: Maximum Air Flow Rate

The design maximum volume flow rate ( $\text{m}^3/\text{sec}$ ) specified for VAV ADU. This is autosizable.

##### 1.30.6.1.6 Field: Zone Minimum Air Flow Method

This field is used to select how the program will determine the minimum flow rate to the zone while the system is operating. The minimum flow rate is modeled as a fraction of the maximum flow rate. There are three choices for selecting how the minimum flow rate is specified: Constant, FixedFlowRate, and Scheduled. If Constant is entered, then the program will use the value for the constant minimum air flow fraction entered in the following field. If FixedFlowRate is entered, then the program will use the value for minimum flow rate entered in the field below called Fixed Minimum Air Flow Rate. If Scheduled is entered, then the program will obtain the value for minimum flow fraction from the schedule named in the field below called Minimum Air Flow Fraction Schedule Name. The default is Constant.

##### 1.30.6.1.7 Field: Constant Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. This field is only used if the Zone Minimum Air Flow Method field is set to Constant.

This field is autosizable and defaulted to autosize. The autosized flow fraction is calculated using the maximum flow rate derived from the design outdoor air flow (including VRP adjustments) and the

**Sizing:Zone** input fields "Cooling Minimum Air Flow per Zone Floor Area", "Cooling Minimum Air Flow", and "Cooling Minimum Air Flow Fraction". If there is no sizing calculation the defaults of 0.000762 cubic meters per second per square meter of zone floor area (0.15 cfm/ft<sup>2</sup>) and 0.2 are used.

#### 1.30.6.1.8 Field: Fixed Minimum Air Flow Rate

The minimum flow rate to the zone while the system is operating, specified as a fixed minimum air flow rate in meters cubed per second. The minimum air flow rate is normally specified to meet the minimum ventilation requirement for the occupants. This field is only used if the Zone Minimum Air Flow Method field is set to FixedFlowRate.

This field is autosizable and defaulted to autosize. The autosized flow rate is the maximum flow rate derived from the design outdoor air flow (including VRP adjustments) and the **Sizing:Zone** input fields "Cooling Minimum Air Flow per Zone Floor Area", "Cooling Minimum Air Flow", and "Cooling Minimum Air Flow Fraction". If there is no sizing calculation the defaults of 0.000762 cubic meters per second per square meter of zone floor area (0.15 cfm/ft<sup>2</sup>) and 0.2 flow fraction are used.

#### 1.30.6.1.9 Field: Minimum Air Flow Fraction Schedule Name

The name of a schedule that determines the value of the minimum air flow fraction. The schedule should contain fractions from 0.0 to 1.0. These values will define the minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. This field is only used if the Zone Minimum Air Flow Method field is set to Scheduled.

#### 1.30.6.1.10 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person is non-zero, then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref **DesignSpecification:OutdoorAir**).

#### 1.30.6.1.11 Field: Minimum Air Flow Turndown Schedule Name

This field adjusts the *Constant Minimum Air Flow Fraction*, *Fixed Minimum Air Flow Rate*, or *Minimum Air Flow Fraction Schedule* value by multiplying it using this schedule. Schedule values are fractions, 0.0 to 1.0. This field adjusts the minimum airflow turndown value below the zone design minimum air flow and is intended for use with ASHRAE Standard 170. This field can also be used to adjust the design minimum air flow sizing calculation by applying a desired fraction values to summer and winter design days turndown schedule. If this field is left blank, then the turndown minimum air flow fraction value is set to 1.

### 1.30.6.2 Outputs

- HVAC,Average,Zone Air Terminal VAV Damper Position []
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.30.6.2.1 Zone Air Terminal VAV Damper Position []

This output is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

#### 1.30.6.2.2 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

### 1.30.7 AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat

Variable air volume (VAV) systems typically control the dry-bulb temperature inside a zone by varying the supply air volume instead of the supply air temperature (ref: [AirTerminal:SingleDuct:VAV:NoReheat](#)). Reheat coils may be required to avoid overcooling (ref: [AirTerminal:SingleDuct:VAV:Reheat](#)).

This terminal unit is slightly different from the [AirTerminal:SingleDuct:VAV:NoReheat](#) terminal unit. Both operate the same in cooling mode: the damper opens as needed to provide additional sensible cooling to the zone. The difference between the two is in heating mode. For the Single Duct VAV NoReheat terminal unit, the air flow rate is reduced to the minimum value (max air flow rate x zone minimum air flow fraction) when zone heating is required. The zone minimum supply air flow can be further adjusted

using scheduled fraction values specified in the field *Minimum Air Flow Turndown Schedule Name*. For the `AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat` terminal unit, the air flow rate in heating mode is increased to meet higher zone heating loads (similar to what is done in cooling mode).

This terminal unit model was originally developed and tested for use with the changeover-bypass VAV unitary system. This object may be used when the central heating coil is sufficient to maintain the heating set point temperature. Additional heating may be provided, if necessary, by use of `AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat` or `ZoneHVAC:Baseboard:*` objects.

Figure 1.126: Single Duct VAV Heat and Cool NoReheat Schematic

### 1.30.7.1 Inputs

#### 1.30.7.1.1 Field: Name

Unique user-defined name for this Air Distribution Unit (ADU).

#### 1.30.7.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether or not this component is available to operate during a given time period. If a schedule value is greater than zero then the system is available to operate; otherwise, the system is unavailable for that time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.30.7.1.3 Field: Air Outlet Node Name

This alpha field defines the name of the VAV damper air outlet node.

#### 1.30.7.1.4 Field: Air Inlet Node Name

This alpha field defines the name of the air inlet node that connects the air splitter to the individual zone ADU.

#### 1.30.7.1.5 Field: Maximum Air Flow Rate

This numeric field defines the design maximum volume flow rate ( $\text{m}^3/\text{sec}$ ) specified for this VAV ADU. This flow rate must be greater than 0 or can be autosized.

#### 1.30.7.1.6 Field: Zone Minimum Air Flow Fraction

This numeric field defines the minimum air volume flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. This value must be between 0 and 1.

### 1.30.7.1.7 Field: Minimum Air Flow Turndown Schedule Name

This field adjusts the *Zone Minimum Air Flow Fraction* by multiplying it using this schedule. Schedule values are fractions, 0.0 to 1.0. This field adjusts the minimum airflow turndown value below the zone design minimum air flow and is intended for use with ASHRAE Standard 170. This field can also be used to adjust the design minimum air flow sizing calculation by applying a desired fraction values to summer and winter design days turndown schedule. If this field is left blank, then the turndown minimum air flow fraction value is set to 1 and uses the fixed fraction specified in the field *Zone Minimum Air Flow Fraction*.

An IDF example is provided below:

```
AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat,
  Zone 3 VAV System,           !- Name of System
  FanAndCoilAvailSched,       !- System Availability schedule
  Zone 3 Reheat Air Outlet Node, !- UNIT Air Outlet Node
  Zone 3 VAV Inlet Node,       !- UNIT Air Inlet Node
  0.584,                       !- Maximum air flow rate {m3/s}
  0.25;                         !- Zone Minimum Air Flow Fraction
```

## 1.30.7.2 Outputs

- HVAC,Average,Zone Air Terminal VAV Damper Position []
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

### 1.30.7.2.1 Zone Air Terminal VAV Damper Position []

This output is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

### 1.30.7.2.2 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

## 1.30.8 AirTerminal:SingleDuct:SeriesPIU:Reheat

The series powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a fixed flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The fan runs at a constant volume flow rate whenever the unit is on (and the fan's availability schedule is on or it is activated by an availability manager). The fan is downstream of the primary and secondary air inlets. The variable mixing is accomplished by a damper in the unit's primary air supply inlet duct. This damper can move from fully open (100% primary air. 0% secondary air) to a minimum stop that is specified in the input description. At full cooling the damper will be fully open. At minimum cooling and for heating the damper will be at the minimum stop and the secondary air flow will be at its maximum. During night cycle operation, if the availability manager status is CycleOnZoneFansOnly, then the fan will run only if there is a heating load. If the status is CycleOn, then the fan will run according to the normal controls.

The EnergyPlus model of the series PIU terminal unit is composed of three components: a zone mixer, a constant volume fan, and a heating coil (hot water, electric, or gas).

Figure 1.127: Series PIU Terminal Unit

### 1.30.8.1 Inputs

#### 1.30.8.1.1 Field: Name

A unique user assigned name for a particular series powered induction terminal unit. Any reference to this unit by another object will use this name.

#### 1.30.8.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.30.8.1.3 Field: Maximum Air Flow Rate

The maximum volumetric air flow rate through the unit in cubic meters per second. Since this is a constant air volume unit, this is also the design, rated air flow rate of the unit.

#### 1.30.8.1.4 Field: Maximum Primary Air Flow Rate

The maximum volumetric air flow rate of primary air through the unit in cubic meters per second. This is the primary air flow rate at full cooling load when the primary air damper is fully open. Usually this quantity is the same as the total unit flow rate, but it can be less.

#### 1.30.8.1.5 Field: Minimum Primary Air Flow Fraction

The minimum volumetric air flow rate of primary air through the unit expressed as a fraction of the maximum volumetric air flow rate of primary air. This input can be 0.0.

#### 1.30.8.1.6 Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

#### 1.30.8.1.7 Field: Secondary Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air. The unit can draw secondary air from its conditioned zone directly or from a return air plenum. Thus this node should be one of the zones exhaust air nodes (see *Zone Air Exhaust Node* in **Zone-HVAC:EquipmentConnections**) or an induced air node outlet of a return plenum (see *Induced Air Outlet Node* in **AirLoopHVAC:ReturnPlenum**).

**1.30.8.1.8 Field: Outlet Node Name**

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

**1.30.8.1.9 Field: Reheat Coil Air Inlet Node Name**

The name of the HVAC system node which is the inlet node of the unit's heating coil. This is also the outlet node of the unit's fan.

**1.30.8.1.10 Field: Zone Mixer Name**

The name of a zone mixer component (object: `AirLoopHVAC:ZoneMixer`) which composes part of the unit. Note that some of the input for the mixer will duplicate input fields of the powered induction unit. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the PIU; the other inlet node of the zone mixer should be the same as the secondary air inlet node of the PIU. The outlet node of the zone mixer should be the same as the inlet node of the PIU fan.

**1.30.8.1.11 Field: Fan Name**

The name of a fan component which composes part of the unit. Note that the fan's maximum flow rate should be the same as the maximum air flow rate of the PIU and the type of fan object must be `Fan:SystemModel` or `Fan:ConstantVolume`. The fan's inlet node should be the same as the zone mixer's outlet node. The fan's outlet node should be the same as the heating coil's air inlet node. The secondary fan will run only when the Availability Schedule specified in the fan object is  $>0$  or when it is overridden by an availability manager (ref. `AvailabilityManager:NightCycle` and others).

**1.30.8.1.12 Field: Reheat Coil Object Type**

The type of coil in the PIU. The valid choices are:

- `Coil:Heating:Water`
- `Coil:Heating:Electric`
- `Coil:Heating:Fuel`
- `Coil:Heating:Steam`

In other words, the PIU may have a hot water, gas, electric or steam reheat coil.

**1.30.8.1.13 Field: Reheat Coil Name**

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the fan outlet node and the heating coil's air outlet node is the same as the PIU outlet node.

**1.30.8.1.14 Field: Maximum Hot Water or Steam Flow Rate**

The maximum hot water volumetric flow rate in  $\text{m}^3/\text{sec}$  through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

**1.30.8.1.15 Field: Minimum Hot Water or Steam Flow Rate**

The minimum hot water volumetric flow rate in  $\text{m}^3/\text{sec}$  through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

### 1.30.8.1.16 Field: Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically, this is the fraction:

$$\frac{|Q_{PIU,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq ConvergenceTolerance \quad (1.122)$$

For gas or electric heating coils, this input should be left blank. The default is 0.001.

An IDF example:

```
AirTerminal:SingleDuct:SeriesPIU:Reheat,
Zone 1 SPIU ATU,           ! Name of air terminal unit
FanAndCoilAvailSched,      ! Availability schedule for series PIU ATU
0.47,                      ! Total volume flow rate through ATU
0.47,                      ! Maximum primary air flow rate through terminal unit
0.3,                      ! Minimum primary air flow rate (fraction of max)
Zone 1 PIU Pri Air Inlet Node, ! Air Terminal unit supply air inlet node
Zone 1 PIU Sec Air Inlet Node, ! Air Terminal unit secondary air inlet node

Zone 1 PIU Fan,              ! Air terminal unit fan name
COIL:Heating:Water,         ! type of air terminal unit reheat coil
Reheat Coil Zone 1,         ! name of air terminal unit reheat coil
0.0013,                    ! Max Reheat Water Flow {Flow: m3/sec}
0.0,                       ! Min Reheat Water Flow {Flow: m3/sec}
0.001;                     ! Convergence tolerance
```

## 1.30.8.2 Outputs

- HVAC,Average,Zone Air Terminal Primary Damper Position []
- HVAC,Average,Zone Air Terminal Heating Rate [W]
- HVAC,Sum,Zone Air Terminal Heating Energy [J]
- HVAC,Average,Zone Air Terminal Sensible Cooling Rate [W]
- HVAC,Sum,Zone Air Terminal Sensible Cooling Energy [J]
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

### 1.30.8.2.1 Zone Air Terminal Primary Damper Position []

This output is the variable air volume primary damper position required to meet the zone load. This is the average value over the frequency being reported. The damper position is defined as the terminal unit primary air mass flow rate divided by the terminal unit's maximum primary air mass flow rate.

### 1.30.8.2.2 Zone Air Terminal Heating Rate [W]

This field reports the dry air heating addition rate of the series PIU terminal unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the terminal unit.

**1.30.8.2.3 Zone Air Terminal Heating Energy [J]**

This field reports the dry air heat addition of the series PIU terminal unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

**1.30.8.2.4 Zone Air Terminal Sensible Cooling Rate [W]**

This field reports the dry air sensible heat extraction rate of the series PIU terminal unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the terminal unit.

**1.30.8.2.5 Zone Air Terminal Sensible Cooling Energy [J]**

This field reports the dry air sensible heat extraction of the series PIU terminal unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

**1.30.8.2.6 Zone Air Terminal Outdoor Air Volume Flow Rate [m<sup>3</sup>/s]**

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

**1.30.9 AirTerminal:SingleDuct:ParallelPIU:Reheat**

The parallel powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a variable total flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The secondary and primary air streams enter the unit in parallel. The fan sits in the secondary air stream and runs only when the primary air flow is below the Fan On Flow Fraction and the fan's availability schedule is on or it is activated by an availability manager. The primary air inlet contains a damper that can move from fully open (maximum primary air) to a minimum stop (minimum primary air).

At full cooling load the primary air damper is fully open and the fan is off. The primary air flow is at maximum and there is little or no secondary air flow. As the cooling load decreases, the primary air damper gradually closes and the secondary air flow remains close to zero. At some point, usually when the primary air flow has reached the minimum, the fan switches on and secondary air is induced. The heating coil will switch on as needed to meet any heating demand. The Fan On Flow Fraction field controls the fan operation; see this field description for more details.

The EnergyPlus model of the parallel PIU terminal unit is composed of three components: a constant volume fan, a zone mixer, and a heating coil (hot water, electric, or gas).

**1.30.9.1 Inputs****1.30.9.1.1 Field: Name**

A unique user assigned name for a particular parallel powered induction terminal unit. Any reference to this unit by another object will use this name.

**1.30.9.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the

Figure 1.128: Parallel PIU Terminal Unit

time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.30.9.1.3 Field: Maximum Primary Air Flow Rate

The maximum volumetric air flow rate of primary air through the unit in cubic meters per second. This is the primary air flow rate at full cooling load when the primary air damper is fully open.

#### 1.30.9.1.4 Field: Maximum Secondary Air Flow Rate

The maximum volumetric air flow rate of secondary air through the unit in cubic meters per second. This flow rate can be any amount but is commonly less than the maximum primary air flow rate.

#### 1.30.9.1.5 Field: Minimum Primary Air Flow Fraction

The minimum volumetric air flow rate of primary air through the unit expressed as a fraction of the maximum volumetric air flow rate of primary air. This input can be 0.0.

#### 1.30.9.1.6 Field: Fan On Flow Fraction

This is the fraction of the primary air flow at or below which the secondary fan turns on. In the parallel PIU the fan operation is intermittent. If the primary air flow is above this fraction of the maximum, the fan is off unless reheat is required. The fan will only operate if the Availability Schedule specified in the **Fan:ConstantVolume** object (see Fan Name below) is >0 or when it is overridden by an availability manager (ref. **AvailabilityManager:NightCycle** and others). If the availability manager status is **CycleOn-ZoneFansOnly**, then the fan will run only if there is a heating load. If the status is **CycleOn**, then the fan will run according to the normal controls (low flow or reheat required).

#### 1.30.9.1.7 Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

#### 1.30.9.1.8 Field: Secondary Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air. The unit can draw secondary air from its conditioned zone directly or from a return air plenum. Thus this node should be one of the zones exhaust air nodes (see *Zone Air Exhaust Node* in **Zone-HVAC:EquipmentConnections**) or an induced air node outlet of a return plenum (see *Induced Air Outlet Node* in **AirLoopHVAC:ReturnPlenum**).

**1.30.9.1.9 Field: Outlet Node Name**

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

**1.30.9.1.10 Field: Reheat Coil Air Inlet Node Name**

The name of the HVAC system node which is the inlet node of the unit's heating coil. This is also the outlet node of the unit's zone mixer.

**1.30.9.1.11 Field: Zone Mixer Name**

The name of an zone mixer component (object: [AirLoopHVAC:ZoneMixer](#)) which composes part of the unit. Note that some of the input for the mixer will duplicate input fields of the powered induction unit. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the PIU; the other inlet node of the zone mixer should be the same as the air outlet node of the fan. The outlet node of the zone mixer should be the same as the inlet node of the heating coil.

**1.30.9.1.12 Field: Fan Name**

The name of a fan component which composes part of the unit. Note that the fan's maximum flow rate should be the same as the maximum secondary air flow rate of the PIU and the type of fan object must be [Fan:SystemModel](#) or [Fan:ConstantVolume](#). The fan's inlet node should be the same as the PIU secondary air inlet node. The fan's outlet node should be the same as one of the zone mixer's inlet nodes. The secondary fan will run only when the Availability Schedule specified in the [Fan:ConstantVolume](#) object is >0 or when it is overridden by an availability manager (ref. [AvailabilityManager:NightCycle](#) and others). See description of fan controls under Fan On Flow Fraction above.

**1.30.9.1.13 Field: Reheat Coil Object Type**

The type of coil in the PIU. The valid choices are:

- [Coil:Heating:Water](#)
- [Coil:Heating:Electric](#)
- [Coil:Heating:Fuel](#)
- [Coil:Heating:Steam](#)

In other words, the PIU may have a hot water, gas, electric or steam reheat coil.

**1.30.9.1.14 Field: Reheat Coil Name**

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the zone mixer's outlet node and the heating coil's air outlet node is the same as the PIU outlet node.

**1.30.9.1.15 Field: Maximum Hot Water or Steam Flow Rate**

The maximum hot water or steam volumetric flow rate in m<sup>3</sup>/s through the unit's heating coil. The steam volumetric flow rate is calculated at 100C and 101325 Pa. If the heating coil is gas or electric this field should be blank.

**1.30.9.1.16 Field: Minimum Hot Water or Steam Flow Rate**

The minimum hot water or steam volumetric flow rate in m<sup>3</sup>/s through the unit's heating coil. The steam volumetric flow rate is calculated at 100C and 101325 Pa. If the heating coil is gas or electric this field should be blank.

### 1.30.9.1.17 Field: Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically, this is the fraction:

$$\frac{|Q_{PIU,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq ConvergenceTolerance \quad (1.123)$$

For gas or electric heating coils, this input should be left blank. The default is 0.001.

An IDF example:

```
AirTerminal:SingleDuct:ParallelPIU:Reheat,

- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

### 1.30.9.2.1 Zone Air Terminal Primary Damper Position []

This output is the variable air volume primary damper position required to meet the zone load. This is the average value over the frequency being reported. The damper position is defined as the terminal unit primary air mass flow rate divided by the terminal unit's maximum primary air mass flow rate.

### 1.30.9.2.2 Zone Air Terminal Heating Rate [W]

This field reports the dry air heating addition rate of the parallel PIU terminal unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the terminal unit.

**1.30.9.2.3 Zone Air Terminal Heating Energy [J]**

This field reports the dry air heat addition of the parallel PIU terminal unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

**1.30.9.2.4 Zone Air Terminal Sensible Cooling Rate [W]**

This field reports the sensible heat extraction rate of the parallel PIU terminal unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the terminal unit.

**1.30.9.2.5 Zone Air Terminal Sensible Cooling Energy [J]**

This field reports the dry air sensible heat extraction of the parallel PIU terminal unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

**1.30.9.2.6 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]**

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

**1.30.10 AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction**

The four pipe induction terminal unit provides local hot water heating or chilled water cooling of induced zone air which then mixes with centrally conditioned supply air. An air conditioning system consisting of these terminal units is effectively a mixed central air / local hydronic system. The centrally conditioned air supplied to the induction terminal units is constant volume at quite high pressure. The central air is discharged through a nozzle in the terminal unit, inducing a flow of room air over a hydronic heating/cooling coil. The coil is connected either to a single inlet and outlet pipe (2 pipe unit) or to 2 inlets and 2 outlets (4 pipe unit). The heated or cooled induced air mixes with the centrally conditioned air before being discharged into the zone. The terminal units are usually expected to do only sensible cooling – any dehumidification is done by the central air conditioning system.

The EnergyPlus model of the four pipe induction terminal unit is a compound component consisting of a hot water heating coil, a chilled water cooling coil, and an air mixer. The unit has two inlet air streams: the centrally conditioned supply air and the induced air from the zone. The induced air passes first through the heating coil, then through the cooling coil and finally through the mixer. The central supply air goes directly into the mixer. The water flow through the hot or cold water coil is varied to meet the zone air conditioning requirement. Note that EnergyPlus models the four pipe induction terminal unit as having separate heating and cooling coils whereas real units have only a single coil used for both heating and cooling. Note also that the four pipe induction unit model can be used to model a two pipe unit by simply adjusting the heating and cooling coil schedules so that the heating coil is off when the cooling coil is on and vice versa.

**1.30.10.1 Inputs****1.30.10.1.1 Field: Name**

A unique user assigned name for a particular four pipe induction terminal unit. Any reference to this unit by another object will use this name.

**1.30.10.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.30.10.1.3 Field: Maximum Total Air Flow Rate**

The maximum volumetric air flow rate discharged from the unit in cubic meters per second. Since this is a constant air volume unit, this is also the design, rated air flow rate of the unit. Note that this is the total discharge flow rate – including both central supply and induced air.

**1.30.10.1.4 Field: Induction Ratio**

The ratio of induced air flow rate to primary supply air flow rate. The default is 2.5 the supply air induces zone air flow at 2.5 times the primary supply air flow rate.

**1.30.10.1.5 Field: Supply Air Inlet Node Name**

The name of the HVAC system node from which the unit draws its primary or supply air

**1.30.10.1.6 Field: Induced Air Inlet Node Name**

The name of the HVAC system node from which the unit draws its secondary or recirculated air. This should be the same node as one of the zone exhaust nodes.

**1.30.10.1.7 Field: Air Outlet Node Name**

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

**1.30.10.1.8 Field: Heating Coil Object Type**

The type of heating coil in the terminal unit. The choices are:

- **Coil:Heating:Water**

In other words, the unit may have a hot water coil only.

**1.30.10.1.9 Field: Heating Coil Name**

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the terminal unit's induced air inlet node. The heating coil's air outlet node is the same as the cooling coil's air inlet node.

**1.30.10.1.10 Field: Maximum Hot Water Flow Rate**

The maximum hot water volumetric flow rate in m<sup>3</sup>/sec through the unit's heating coil.

**1.30.10.1.11 Field: Minimum Hot Water Flow Rate**

The minimum hot water volumetric flow rate in m<sup>3</sup>/sec through the unit's heating coil.

**1.30.10.1.12 Field: Heating Convergence Tolerance**

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically, this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq ConvergenceTolerance \quad (1.124)$$

The default is 0.001.

**1.30.10.1.13 Field: Cooling Coil Object Type**

The type of cooling coil in the terminal unit. The choices are:

- **Coil:Cooling:Water**
- **Coil:Cooling:Water:DetailedGeometry**

In other words, the unit must use only the water cooling coils.

**1.30.10.1.14 Field: Cooling Coil Name**

The name of the cooling coil component which composes part of the unit. Note that the cooling coil's air inlet node is the same as the heating coil's air outlet node. The cooling coil's air outlet node is the same as one of the zone mixer's inlets.

**1.30.10.1.15 Field: Maximum Cold Water Flow Rate**

The maximum cold water volumetric flow rate in m<sup>3</sup>/sec through the unit's cooling coil.

**1.30.10.1.16 Field: Minimum Cold Water Flow Rate**

The minimum cold water volumetric flow rate in m<sup>3</sup>/sec through the unit's cooling coil.

**1.30.10.1.17 Field: Cooling Convergence Tolerance**

The control tolerance for the unit cooling output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically, this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq ConvergenceTolerance \quad (1.125)$$

The default is 0.001.

**1.30.10.1.18 Field: Zone Mixer Name**

The name of an zone mixer component (object: **AirLoopHVAC:ZoneMixer**) which composes part of the terminal unit. Note that some of the zone mixer's inputs will duplicate some of the terminal unit's inputs. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the terminal unit; the other inlet node of the zone mixer should be the same as the cooling coil air outlet node. The outlet node of the zone mixer should be the same as the outlet node of the terminal unit.

### 1.30.10.2 Outputs

- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.30.10.2.1 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

### 1.30.11 AirTerminal:SingleDuct:ConstantVolume:FourPipeBeam

The four-pipe beam air terminal system is a mixed air-hydronic system. A central, single-duct forced-air system that supplies conditioned air to the zones. Chilled water circulates through ceiling-mounted fin-tube convector units to provide sensible cooling. Hot water circulates through

the same convectors to provide heating. Water flow rate through the beam unit is varied to meet the zone sensible cooling or heating load. Any dehumidification is done by the central forced-air system. Thermodynamically, the cooled beam system resembles the four-pipe induction unit (**AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction**).

To model a typical four-pipe beam system the user will need to define a conventional central constant volume forced air system in order to deliver primary air to the beam. This central system (usually) provides outside air for ventilation. Primary air is normally delivered at a fixed temperature but could be reset by a schedule or using an outdoor air reset setpoint manager. On the supply side of this air loop there will be the usual central conditioning equipment: outside air mixer, fan, heating and cooling coil. On the zone equipment (demand) side of the loop, the four-pipe beams will be represented as air terminal units. Because the four-pipe beam can provide heating the system can avoid over-cooling zones during times of low load with cool primary air temperatures, similar to the action of a reheat coil in a VAV terminal. Therefore, it is not necessary to have additional zone equipment (such as baseboard heaters) to handle heating (or reheating) loads.

Although the four-pipe beam equipment in a zone is treated by the program as a single terminal unit, the actual installation will often have multiple beam units in each zone. In this model, it is only the total length of all the beams and the total air flow of all the units that are described, not the number of individual beam units.

If needed, the program (in its sizing calculation for the system) determines the total length of beams and primary supply air flow that is needed to meet the zone design loads. The four pipe beam air terminal sizing differs from other air terminals in that the primary supply air flow rate is sized using the entire performance model and the flow rate is not the direct result from the **Sizing:Zone** and **Sizing:System** calculations. The flow rates will be somewhere between what an air terminal would size out using *VentilationRequirement* or *Sensible* in the **Sizing:System** object (either setting can be used).

The model includes two different types of inputs for flow rates, “design” and “rated ... per-meter.” The design values are the actual sizes of the flow rates as viewed from the zone and central air handler (but before zone multipliers). The design values include all the individual beam units and their lengths. The rated per-meter values are used to characterize product performance at nominal rating conditions in such a way that it can be scaled to match the size of a zone. The performance characteristics at the rating point are not fixed in the program and can be entered by the user when they differ from default values. The rated per meter values are normalized by the linear dimensions of the beam and are generally obtained from product catalog data by dividing by the length of the beam. The rated primary air flow rate is assumed to be for sea level conditions while the design primary air flow rate is modeled for the location elevation above sea level.

### 1.30.11.1 Inputs

#### 1.30.11.1.1 Field: Name

A unique user-assigned name for a particular beam unit. Any reference to this unit by another object will use this name.

#### 1.30.11.1.2 Field: Primary Air Availability Schedule Name

The name of the schedule that denotes whether the terminal unit is operating to provide primary air during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit is on and requesting primary air flow during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.30.11.1.3 Field: Cooling Availability Schedule Name

The name of the schedule that denotes whether the terminal unit is operating to provide cooling during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit is on and available for beam cooling during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods. The primary air availability schedule named in the previous input field must have a value that is “on” during times that cooling is available.

#### **1.30.11.1.4 Field: Heating Availability Schedule Name**

The name of the schedule that denotes whether the terminal unit can operate to provide heating during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit is on and available for beam heating during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods. The primary air availability schedule named in the input field above must have a value that is “on” during times that heating is available.

#### **1.30.11.1.5 Field: Primary Air Inlet Node Name**

The name of the HVAC system air node from which the unit draws its primary air.

#### **1.30.11.1.6 Field: Primary Air Outlet Node Name**

The name of the HVAC system air node that connects this terminal unit to the zone. There will be the same as one of the zone inlet nodes.

#### **1.30.11.1.7 Field: Chilled Water Inlet Node Name**

The name of the chilled water inlet node. If desired, the chilled water node connections can be omitted and the model will assume the intent is to model a two-pipe heating only beam.

#### **1.30.11.1.8 Field: Chilled Water Outlet Node Name**

The name of the chilled water outlet node.

#### **1.30.11.1.9 Field: Design Primary Air Volume Flow Rate**

This is the air flow rate (m<sup>3</sup>/s) of the primary air entering the air terminal unit from the central air handling unit. This input can be autosized.

#### **1.30.11.1.10 Field: Design Chilled Water Volume Flow Rate**

The maximum chilled water flow rate (m<sup>3</sup>/s) for the unit(s) serving the entire zone. This input can be autosized based on the zone design load.

#### **1.30.11.1.11 Field: Design Hot Water Volume Flow Rate**

The maximum hot water flow rate (m<sup>3</sup>/s) for the unit(s) serving the entire zone. This input can be autosized based on the zone design load.

#### **1.30.11.1.12 Field: Zone Total Beam Length (m)**

The total length of all the beams in the zone (m). The real spaces may actually have a number of individual beam units of a specific length and this is the length of individual beams times the total number of beams in the thermal zone. It need not be an even multiple of actual unit's beam length but it can be if desired. This field is autosizable.

**1.30.11.1.13 Field: Rated Primary Air Flow Rate per Beam Length (m<sup>3</sup>/s-m)**

This is the primary air volume flow rate at rating conditions divided by the length of the beam, in m<sup>3</sup>/s-m. This “catalog” value for volume flow rate input is converted to a mass flow rate using standard air density at sea level. This value will be used for sizing the design primary air volume flow rate if the total beam length is not also autosized. The default is 0.035 m<sup>3</sup>/s-m.

**1.30.11.1.14 Field: Beam Rated Cooling Capacity per Beam Length (W/m)**

This is the beam cooling capacity at rating conditions divided by the length of the beam, in W/m. This is only the cooling contributed by the chilled water circulating through the convector and is separate from any cooling (or heating) that may also be provided by the primary air. The default is 600 W/m.

**1.30.11.1.15 Field: Beam Rated Cooling Room Air Chilled Water Temperature Difference (Delta C)**

This input defines the value of the temperature difference between the room air and entering chilled water at the rating point, in delta Celsius. This “catalog” input helps to define the operating conditions that correspond with Rated Beam Cooling Capacity per Meter. It is used to normalize the independent variable in the input field called Beam Cooling Capacity Temperature Difference Modification Factor Curve or Table Name. The default is 10.0 delta C.

**1.30.11.1.16 Field: Beam Rated Chilled Water Volume Flow Rate per Beam Length (m<sup>3</sup>/s-m)**

This input defines the value of the chilled water flow rate per meter length of beam at the rating point, in m<sup>3</sup>/s-m. This input helps to define the operating conditions that correspond with Rated Beam Cooling Capacity per Meter. It is used to normalize the independent variable in the input field called Beam Cooling Capacity Chilled Water Flow Modification Factor Curve or Table Name. The default is 0.00005 m<sup>3</sup>/s-m.

**1.30.11.1.17 Field: Beam Cooling Capacity Temperature Difference Modification Factor Curve Name**

This field is the name of a curve or table object that describes how the beam convector’s cooling capacity varies as a function of the temperature difference between the zone air and the entering chilled water. The single independent variable is the ratio of the current simulation results for the difference between the air and entering water and the difference at the rating point. The result of the curve or table is multiplied by the rated capacity to adjust the cooling capacity.

**1.30.11.1.18 Field: Beam Cooling Capacity Air Flow Modification Factor Curve Name**

This field is the name of a curve or table object that describes how the beam convector’s cooling capacity varies as a function of the primary air flow rate. The single independent variable is the ratio of the current primary air flow rate and the primary air flow rate at the rating point. The result of the curve or table is multiplied by the rated capacity to adjust the cooling capacity. The factor is useful to adjust for a range of primary air flow rates that a given product can accommodate. However, since this is a constant volume air terminal, the modification does not typically vary during the simulation and the range of independent variable does not need to be all that broad in practice.

**1.30.11.1.19 Field: Beam Cooling Capacity Chilled Water Flow Modification Factor Curve Name**

This field is the name of a curve or table object that describes how the beam convector’s cooling capacity varies as a function of the water flow rate. The single independent variable is the ratio of the

current fluid flow rate to the fluid flow rate at the rating point. The result of the curve or table is multiplied by the rated capacity to adjust the cooling capacity. The model will adjust the chilled water flow rate to vary cooling power to meet the zone load, so for control purposes, the range of the independent variable must include all the way down to zero flow, with zero capacity at zero flow.

#### **1.30.11.1.20 Field: Beam Rated Heating Capacity per Beam Length (W/m)**

This is the beam heating capacity at rating conditions divided by the length of the beam, in W/m. This is only the heating contributed by the hot water circulating through the convector and is separate from any heating (or cooling) that may also be provided by the primary air. The default is 1.200 W/m.

#### **1.30.11.1.21 Field: Beam Rated Heating Room Air Hot Water Temperature Difference (Delta C)**

This input defines the value of the temperature difference between the entering hot water and the room air at the rating point, in delta Celsius. This input helps to define the operating conditions that correspond with Rated Beam Heating Capacity per Meter. It is used to normalize the independent variable in the input field called Beam Heating Capacity Temperature Difference Modification Factor Curve or Table Name. The default is 27.8 delta C.

#### **1.30.11.1.22 Field: Beam Rated Hot Water Volume Flow Rate per Beam Length (m3/s-m)**

This input defines the value of the hot water flow rate per meter length of beam at the rating point, in m3/s/m, or more strictly m3/s-m. This input helps to define the operating conditions that correspond with Rated Beam Heating Capacity per Meter. It is used to normalize the independent variable in the input field called Beam Heating Capacity Hot Water Flow Modification Factor Curve or Table Name. The default is 0.00005 m3/s-m.

#### **1.30.11.1.23 Field: Beam Heating Capacity Temperature Difference Modification Factor Curve Name**

This field is the name of a curve or table object that describes how the beam convector's heating capacity varies as a function of the temperature difference between the entering hot water and the zone air. The single independent variable is the ratio of the current simulation results for the difference between the water and air and the difference at the rating point. The result of the curve or table is multiplied by the rated capacity to adjust the heating capacity.

#### **1.30.11.1.24 Field: Beam Heating Capacity Air Flow Modification Factor Curve Name**

This field is the name of a curve or table object that describes how the beam convectors heating capacity varies as a function of the primary air flow rate. The single independent variable is the ratio of the current primary air flow rate and the primary air flow rate at the rating point. The result of the curve or table is multiplied by the rated capacity to adjust the heating capacity. The factor is useful to adjust for a range of primary air rates that a given product can accommodate. However, since this is a constant volume air terminal, the modification does not typically vary during the simulation and the range of independent variable does not need to be all that broad in practice.

#### **1.30.11.1.25 Field: Beam Heating Capacity Hot Water Flow Modification Factor Curve Name**

This field is the name of a curve or table object that describes how the beam convector's heating capacity varies as a function of the water flow rate. The single independent variable is the ratio of the

current fluid flow rate to the fluid flow rate at the rating point. The result of the curve or table is multiplied by the rated capacity to adjust the heating capacity. The model will adjust the hot water flow rate to vary heating power to meet the zone load, so for control purposes, the range of the independent variable must include all the way down to zero flow, with zero capacity at zero flow.

## 1.30.11.2 Outputs

### 1.30.11.2.1 Zone Air Terminal Beam Sensible Cooling Rate [W]

### 1.30.11.2.2 Zone Air Terminal Beam Sensible Cooling Energy [J]

These are the sensible cooling power and energy delivered by the beams to the zone, exclusive of any cooling or heating done by the primary air.

### 1.30.11.2.3 Zone Air Terminal Beam Sensible Heating Rate [W]

### 1.30.11.2.4 Zone Air Terminal Beam Sensible Heating Energy [J]

These are the sensible heating power and energy delivered by the beams to the zone, exclusive of any cooling or heating done by the primary air.

### 1.30.11.2.5 Zone Air Terminal Primary Air Sensible Cooling Rate [W]

Sensible cooling by the primary air to the zone, exclusive of any cooling or heating done by the beams.

### 1.30.11.2.6 Zone Air Terminal Primary Air Sensible Cooling Energy [J]

Sensible cooling by the primary air to the zone, exclusive of any cooling or heating done by the beams.

**1.30.11.2.7 Zone Air Terminal Primary Air Sensible Heating Rate [W]**

Heating by the primary air to the zone, exclusive of any cooling or heating done by the beams.

**1.30.11.2.8 Zone Air Terminal Primary Air Sensible Heating Energy [J]**

Heating by the primary air to the zone, exclusive of any cooling or heating done by the beams.

**1.30.11.2.9 Zone Air Terminal Primary Air Flow Rate [m<sup>3</sup>/s]**

Air flow rate from the central air handler into the zone in m<sup>3</sup>/s. Note that this does not include any of the secondary air flow that is induced by the convector and nozzle action (the model does not resolve secondary air flow rate and the result are not available).

**1.30.11.2.10 Zone Air Terminal Outdoor Air Volume Flow Rate [m<sup>3</sup>/s]**

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

**1.30.12 AirTerminal:SingleDuct:ConstantVolume:CooledBeam**

The Cooled Beam system is a mixed air-hydronic system. A central, single-duct forced-air system supplies conditioned ventilation air to the zones. Sensible cooling is done by chilled water circulating through ceiling mounted cooled beam units. Chilled water flow rate through the cooled beam units is varied to meet the zone sensible cooling load. Any dehumidification is done by the central ventilation air system. Heating is usually accomplished with hot water radiators. Thermodynamically, the cooled beam system resembles the four-pipe induction unit.

To model a typical cooled beam system the user will need to define a conventional central constant volume forced air system. This system will normally be 100% outside air delivered at a fixed supply temperature (which could be reset by schedule or by outside air temperature). On the supply side of this air loop there will be the usual central AC equipment: outside air mixer, fan, heating and cooling coil. On the zone equipment (demand) side of the loop, the chilled beams will be represented as terminal units. Additional zone equipment (such as baseboard heaters) will be needed to handle heating loads.

Although the cooled beam equipment in a zone is treated by the program as a single terminal unit, the actual installation will have multiple beams in each zone. The program (in its sizing calculation for the system) figures out how many beams of what length are needed to meet the zone design load.

**1.30.12.1 Inputs****1.30.12.1.1 Field: Name**

A unique user assigned name for a particular chilled beam unit. Any reference to this unit by another object will use this name.

**1.30.12.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.30.12.1.3 Field: Cooled Beam Type**

Two types of units are modeled: *Active* or *Passive*. In the active unit, primary air is supplied through the beam, inducing some secondary zone air into contact with the coil. This unit acts as an active convector. The passive unit is simply a passive, finned convector. Primary air is supplied through a normal diffuser.

**1.30.12.1.4 Field: Supply Air Inlet Node Name**

The name of the HVAC system node from which the unit draws its primary or supply air. Note that this field should be specified for both types of unit, even though supply air does not pass through the passive unit.

**1.30.12.1.5 Field: Supply Air Outlet Node Name**

The name of the air node that connects this terminal unit to the zone. There will be the same as one of the zone inlet nodes. The name of this node must be entered even if the actual beams are passive and is not actually supplying air to the zone.

**1.30.12.1.6 Field: Chilled Water Inlet Node Name**

The name of the chilled water inlet node.

**1.30.12.1.7 Field: Chilled Water Outlet Node Name**

The name of the chilled water outlet node.

**1.30.12.1.8 Field: Supply Air Volumetric Flow Rate**

This is the air flow rate in cubic meters per second of the supply air entering the zone. This input would normally be autosized based on the ventilation requirement (see Zone Sizing).

**1.30.12.1.9 Field: Maximum Total Chilled Water Volumetric Flow Rate**

The maximum chilled water flow rate (in cubic meters per second) for the unit. This input would normally be autosized based on the zone design load.

**1.30.12.1.10 Field: Number of Beams**

The number of individual cooled beam units in the zone. Normally this unit would be autocalculated by the program based upon the previous field and the nominal flow rate for a single beam unit (set by the program to 0.07 kg/s).

**1.30.12.1.11 Field: Beam Length**

The length of an individual beam in meters. Normally this will be autocalculated by the program based upon the number of beam units and the zone design sensible cooling load. 1 to 4 meters is a typical length range.

**1.30.12.1.12 Field: Design Inlet Water Temperature**

The nominal or design inlet water temperature in degrees Celsius. The default is 15°C.

**1.30.12.1.13 Field: Design Outlet Water Temperature**

The nominal or design outlet water temperature in degrees Celsius. The default is 17°C.

*The following inputs are parameters used to characterize the performance of the chilled beam units. Values for a given unit can be obtained from the manufacturer. The parameters are used in the following equations.*

$$P_{beam} = A \cdot K \cdot DT \quad \text{beam cooling output per unit length W/m}$$

$$K = a \cdot DT^{n1} \cdot vr^{n2} \cdot w^{n3}$$

coil heat transfer coefficient W/(m<sup>2</sup>K)

$$vr = (q_{in}/a_0) \cdot r_{air}$$

room air mass flow rate across coil kg/(m<sup>2</sup>s)

$$q_{in} = K_1 \cdot DT^n + K_{in} \cdot q_{pr}$$

room air volumetric flow rate across coil per

$$\text{unit length m}^3/(\text{s-m})$$

DT is the room air –water temperature difference (average water temperature is used) in degrees C.

w is the water velocity in m/s.

q<sub>pr</sub> is the supply air flow rate per unit length m<sup>3</sup>/(s-m)

#### 1.30.12.1.14 Field: Coil Surface Area per Coil Length

Surface area on the air side of the beam per unit beam length. The units are square meters per meter. The default is 5.422. This is *A* in the above equations.

#### 1.30.12.1.15 Field: Model Parameter a (a)

This is *a* in the above equations. The default is 15.3

#### 1.30.12.1.16 Field: Model Parameter n1

This is *n1* in the above equations. The default is 0.

#### 1.30.12.1.17 Field: Model Parameter n2

This is *n2* in the above equations. The default is 0.84.

#### 1.30.12.1.18 Field: Model Parameter n3

This is *n3* in the above equations. The default is 0.12.

#### 1.30.12.1.19 Field: Model Parameter a<sub>0</sub> (a)

This is *a<sub>0</sub>* in the above equations. It is the free area of the coil in plan view (for the air flow) per unit beam length. The units are square meters per meter. The default is 0.171.

#### 1.30.12.1.20 Field: Model Parameter K<sub>1</sub> (K1)

This is *K<sub>1</sub>* in the above equations. The default is 0.005.

#### 1.30.12.1.21 Field: Model Parameter n

This is *n* in the above equations. The default is 0.4.

#### 1.30.12.1.22 Field: Coefficient of Induction K<sub>in</sub> (Kin)

The coefficient of induction *K<sub>in</sub>* in the above equations. The default is 2.0 for active beams and 0.0 for passive beams.

#### 1.30.12.1.23 Field: Pipe Inside Diameter

The water pipe inside diameter in meters. The default is 0.0145.

### 1.30.12.2 Outputs

- HVAC,Sum,Zone Air Terminal Beam Sensible Cooling Energy [J]
- HVAC,Average,Zone Air Terminal Beam Sensible Cooling Rate [W]
- HVAC,Sum, Zone Air Terminal Supply Air Sensible Cooling Energy [J]
- HVAC,Average,Zone Air Terminal Supply Air Sensible Cooling Rate [W]
- HVAC,Sum,Zone Air Terminal Supply Air Sensible Heating Energy [J]
- HVAC,Average,Zone Air Terminal Supply Air Sensible Heating Rate [W]
- HVAC,Sum,Zone Air Terminal Beam Chilled Water Energy [J]
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.30.12.2.1 Zone Air Terminal Beam Sensible Cooling Rate [W]

Sensible cooling by the beams in the zone, exclusive of any cooling or heating done by the supply air.

#### 1.30.12.2.2 Zone Air Terminal Beam Sensible Cooling Energy [J]

Sensible cooling by the beams in the zone, exclusive of any cooling or heating done by the supply air.

#### 1.30.12.2.3 Zone Air Terminal Supply Air Sensible Cooling Rate [W]

Sensible cooling by the supply air to the zone, exclusive of any cooling done by the beams.

#### 1.30.12.2.4 Zone Air Terminal Supply Air Sensible Cooling Energy [J]

Sensible cooling by the supply air to the zone, exclusive of any cooling done by the beams.

#### 1.30.12.2.5 Zone Air Terminal Supply Air Sensible Heating Rate [W]

Heating by the supply air to the zone, exclusive of any cooling done by the beams.

#### 1.30.12.2.6 Zone Air Terminal Supply Air Sensible Heating Energy [J]

Heating by the supply air to the zone, exclusive of any cooling done by the beams.

#### 1.30.12.2.7 Zone Air Terminal Beam Chilled Water Energy [J]

The heat transfer energy for the chilled water serving the beams, in Joules.

### 1.30.12.2.8 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

## 1.30.13 AirTerminal:SingleDuct:Mixer

The air terminal mixer provides a means of supplying central system air either to air inlet or supply side of a ZoneHVAC equipment such as a four pipe fan coil. Normally the central air would be ventilation air from a dedicated outside air system (DOAS).

This terminal mixer object mixes conditioned outdoor air (primary air) from DOAS air loop and recirculating (secondary air) and deliver it either to inlet or supply side of a local ZoneHVAC equipment. The terminal mixer can be connected either to the inlet or supply side of the local ZoneHVAC equipment and the connection type is specified in the input field *Mixer Connection Type*. If the AirTerminal:SingleDuct:Mixer object is connected to the supply side, a mix of conditioned outdoor air from a central dedicated outdoor air system (DOAS) with conditioned recirculation air from the local ZoneHVAC equipment is supplied as a single stream to the conditioned zone at its inlet node. If the AirTerminal:SingleDuct:Mixer object is connected to the inlet side, a mix of outdoor air from the a central dedicated outdoor air system (DOAS) with un-conditioned recirculation air from a zone exhaust node is supplied to the ZoneHVAC equipment inlet node. The mixer model will sum the two air streams and average the air properties. The AirTerminal:SingleDuct:Mixer is used with:

- ZoneHVAC:FourPipeFanCoil
- ZoneHVAC:WaterToAirHeatPump
- ZoneHVAC:PackagedTerminalAirConditioner
- ZoneHVAC:PackagedTerminalHeatPump
- ZoneHVAC:TerminalUnit:VariableRefrigerantFlow
- ZoneHVAC:UnitVentilator
- AirLoopHVAC:UnitarySystem

The AirLoopHVAC:UnitarySystem object must be specified as a ZoneHVAC equipment. Since the ZoneHVAC equipment gets the outdoor air or ventilation air from central dedicated OA system, the design outdoor air flow rate input fields in the ZoneHVAC equipment are set to zero and the OutdoorAir:Mixer object type and object name input fields are left blank.

### 1.30.13.1 Inputs

#### 1.30.13.1.1 Field: Name

A unique user assigned name for a particular terminal mixer unit. Any reference to this unit by another object will use this name.

#### 1.30.13.1.2 Field: ZoneHVAC Unit Object Type

The type of ZoneHVAC equipment to which this terminal mixer will be connected. This is a choice input field. Valid ZoneHVAC choices are:

- ZoneHVAC:FourPipeFanCoil
- ZoneHVAC:WaterToAirHeatPump
- ZoneHVAC:PackagedTerminalAirConditioner
- ZoneHVAC:PackagedTerminalHeatPump
- ZoneHVAC:TerminalUnit:VariableRefrigerantFlow

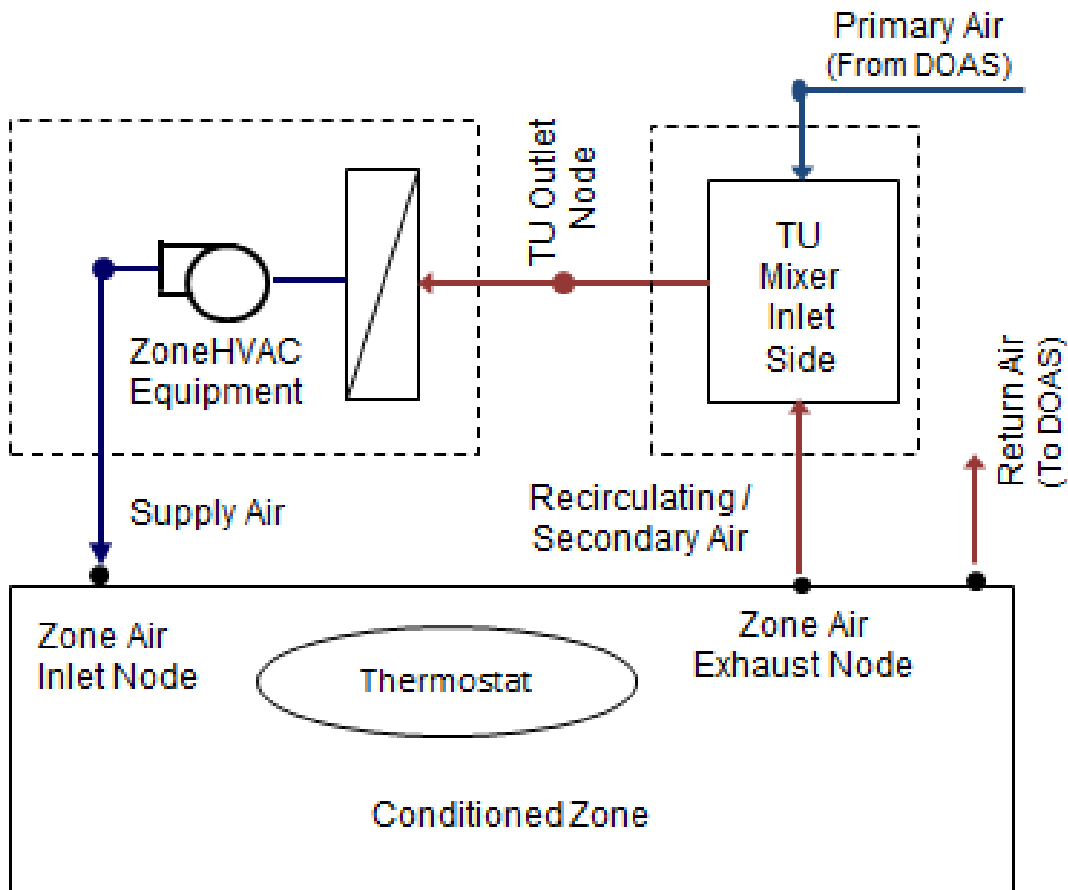

Figure 1.129: Inlet Side Mixer Air Terminal Unit with ZoneHVAC Equipment

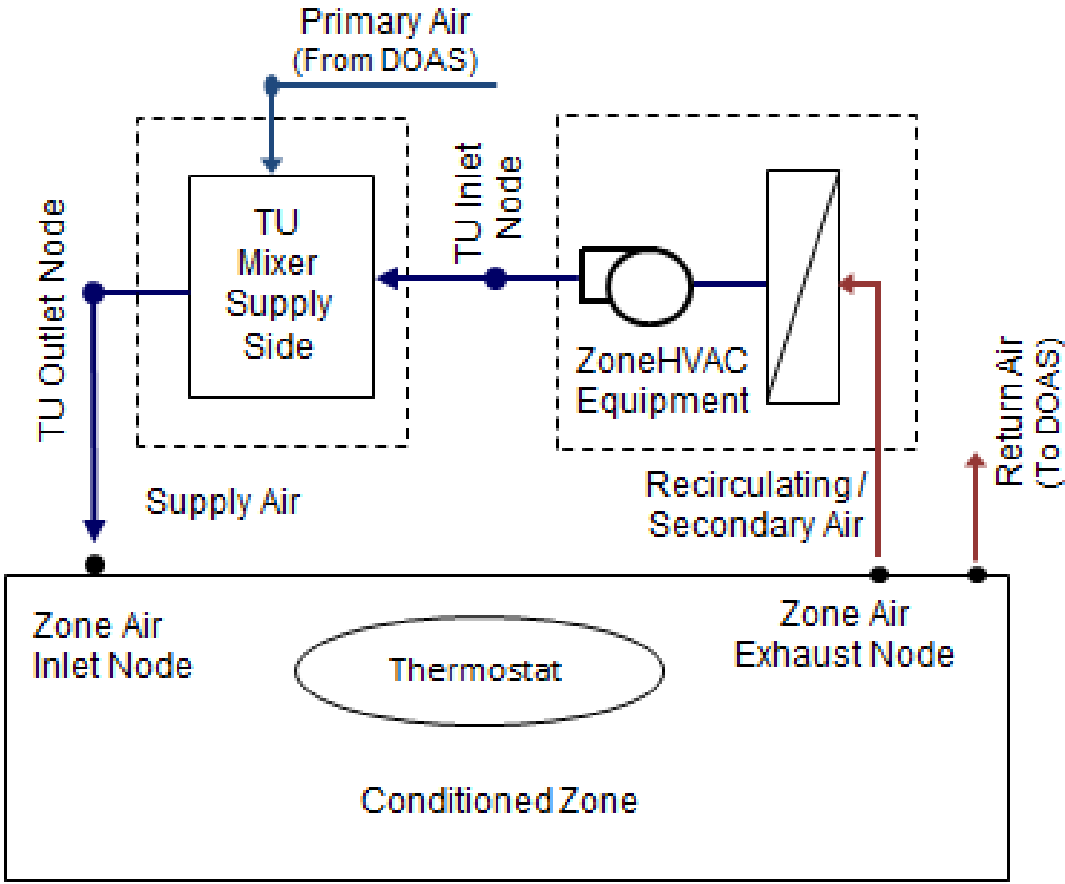

Figure 1.130: Supply Side Mixer Air Terminal Unit with ZoneHVAC equipment

- **ZoneHVAC:UnitVentilator**
- **AirLoopHVAC:UnitarySystem**

#### 1.30.13.1.3 Field: ZoneHVAC Unit Object Name

The name of ZoneHVAC equipment to which this mixer will be connected.

#### 1.30.13.1.4 Field: Mixer Outlet Node Name

The outlet air node name of the mixer. This will be an inlet air node name of the conditioned zone if the connection type specified in the input field *Mixer Connection Type* below is **SupplySide**, or else this will be the inlet air node name of the ZoneHVAC equipment if the connection type in the input field *Mixer Connection Type* below is **InletSide**.

#### 1.30.13.1.5 Field: Mixer Primary Air Inlet Node Name

The primary air (treated outdoor air) inlet node name of the mixer. This will be the outlet air node name of an **AirLoopHVAC:ZoneSplitter** or **AirLoopHVAC:SupplyPlenum**, providing the connection to the DOAS system.

#### 1.30.13.1.6 Field: Mixer Secondary Air Inlet Node Name

The secondary air (recirculating air) inlet node name of the mixer. This will be the outlet air node name of the ZoneHVAC equipment if the connection type in the input field *Mixer Connection Type* below is **SupplySide**, or else this will be an exhaust air node name of the conditioned zone if the connection type in the input field *Mixer Connection Type* below is **InletSide**.

#### 1.30.13.1.7 Field: Mixer Connection Type

This input field allows user to specify the mixer connection type. Valid choices are **InletSide** or **SupplySide**. This is a required input field. If the mixer connection type selected is **InletSide**, then the mixer is connected on the inlet side of the ZoneHVAC equipment, or else if the mixer connection type selected is **SupplySide**, then the mixer is connected at the outlet side of the ZoneHVAC equipment.

#### 1.30.13.1.8 Field: Design Specification Outdoor Air Object Name

This field allows modifying the behavior of this air terminal so that it is modulated to supply the required outdoor air to the zone. This field is optional. When the name of an **DesignSpecification:OutdoorAir** object is entered, the model is changed to adjust the flow rate to provide the volume of outdoor air described by that object. This feature allows modeling demand controlled ventilation on a zone-by-zone basis using the Outdoor Air Flow per Person rate (specified in the **DesignSpecification:OutdoorAir** object) and the number of occupants (specified in the **People** object schedules). If the outdoor air fraction of the supply air is 1.0, as for a dedicated outdoor air system, the air flow rate will match the outdoor air requirement. When the outdoor air fraction is less than 1.0, as for a recirculating air system, the terminal air flow will be modulated upward to account for the increased total air flow needed to provide the required flow rate of outdoor air. The total air flow rate will not exceed the Maximum Air Flow Rate specified above. The volume flow rate is converted to mass flow rate using the standard density of air at Pressure = 101325 Pa, Temperature = 20C, and Humidity Ratio = 0.0.

#### 1.30.13.1.9 Field: Per Person Ventilation Rate Mode

This field specifies how the outdoor air ventilation rates are calculated when based on a rate per person. It can be either based on the current number of people as affected by time-varying occupancy

schedules, or on the constant value for the maximum number of people. Enter the key CurrentOccupancy for the former and DesignOccupancy for the later.

---

### 1.30.14 AirTerminal:DualDuct:ConstantVolume

The AirTerminal:DualDuct:ConstantVolume simulation or the typical Multizone is described by this Air Distribution Unit (ADU). Multizone systems condition all the air in a central apparatus and distribute it to the conditioned zones through two parallel ducts. One duct carries cold air and the other warm air, providing air sources for both heating and cooling at all times. In each conditioned zone, a mixing valve responsive to a room thermostat mixes the warm and cold air in proper proportions to satisfy the prevailing heating or cooling load of the space. The Multizone ADU is the specific component that leads to the zone containing the mixer and the mixing damper and then connecting to the zone. The total airflow to each room is kept constant while the proportion of hot air to cold air is adjusted to maintain the temperature in each zone at the desired level.

#### 1.30.14.1 Inputs

##### 1.30.14.1.1 Field: Name

Unique name for the Multizone ADU.

##### 1.30.14.1.2 Field: Availability Schedule Name

Schedule that this component will operate or is available to operate for a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.30.14.1.3 Field: Air Outlet Node Name

The outlet node from the ADU to the zone.

##### 1.30.14.1.4 Field: Hot Air Inlet Node Name

The air-inlet node name that connects the hot air splitter to the individual zone ADU.

**1.30.14.1.5 Field: Cold Air Inlet Node Name**

The air-inlet node name that connects the cold air splitter to the individual zone ADU.

**1.30.14.1.6 Field: Maximum Air Flow Rate**

The design constant volume flow rate ( $\text{m}^3/\text{sec}$ ) specified for that Multizone ADU.

An IDF example:

```
AirTerminal:DualDuct:ConstantVolume,
  Zone2MixDamp,    !- Name
  FanAndCoilAvailSched, !- Availability Schedule
  Zone 2 Dual Duct Outlet, !- Unit Air Outlet Node
  Zone 2 Dual Duct Hot Inlet, !- Unit Hot Air Inlet Node
  Zone 2 Dual Duct Cold Inlet, !- Unit Cold Air Inlet Node
  0.36; !- Max Air Flow Rate {m3/s}
```

**1.30.14.2 Outputs**

- HVAC,Average,Zone Air Terminal Cold Supply Duct Damper Position []
- HVAC,Average,Zone Air Terminal Hot Supply Duct Damper Position []

**1.30.14.2.1 Zone Air Terminal Cold Supply Duct Damper Position**

This output is the damper position of the cold air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit cold air mass flow rate divided by the terminal unit's maximum cold air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

**1.30.14.2.2 Zone Air Terminal Hot Supply Duct Damper Position**

This output is the damper position of the hot air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit hot air mass flow rate divided by the terminal unit's maximum hot air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

**1.30.15 AirTerminal:DualDuct:VAV**

AirTerminal:DualDuct:VAV (i.e., Dual duct variable air volume (DDVAV)) systems are used to obtain zone temperature control by mixing the cold and warm air in various volume combinations. The fan is sized for the anticipated maximum coincident hot or cold volume, not the sum of the instantaneous peaks. This system has an advantage of a true single path VAV system, except for warm port leakage. When cold air is modulated for control before mixing, it operates similar to the VAV induction when mixing occurs without hot deck reheat. It is similar to a reheat system when mixing occurs while the hot deck is using the reheat coil. It uses more energy than a true VAV system, but less than a constant volume dual duct system.

The zone minimum supply air flow can be further adjusted using scheduled fraction values specified in the field *Minimum Air Flow Turndown Schedule Name*.

**1.30.15.1 Inputs****1.30.15.1.1 Field: Name**

Unique name for the AirTerminal:DualDuct:VAV Air Distribution Unit (ADU).

**1.30.15.1.2 Field: Availability Schedule Name**

Schedule that this component will operate or is available to operate for a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

**1.30.15.1.3 Field: Air Outlet Node Name**

The outlet node from the ADU to the zone.

**1.30.15.1.4 Field: Hot Air Inlet Node Name**

The air-inlet node name that connects the hot air splitter to the individual zone ADU.

**1.30.15.1.5 Field: Cold Air Inlet Node Name**

The air-inlet node name that connects the cold air splitter to the individual zone ADU.

**1.30.15.1.6 Field: Maximum Damper Air Flow Rate**

The design maximum volume flow rate ( $\text{m}^3/\text{sec}$ ) specified for DDVAV ADU.

**1.30.15.1.7 Field: Zone Minimum Air Flow Fraction**

The minimum flow rate to the zone while the system is operating, specified as a fraction of the Max Damper Air Flow Rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants.

**1.30.15.1.8 Field: Design Specification Outdoor Air Object Name**

This alpha field specifies the name of a [DesignSpecification:OutdoorAir](#) object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person is non-zero, then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref [DesignSpecification:OutdoorAir](#)).

**1.30.15.1.9 Field: Minimum Air Flow Turndown Schedule Name**

This field adjusts *Zone Minimum Air Flow Fraction* by multiplying it using this schedule. Schedule values are fractions, 0.0 to 1.0. This field adjusts the minimum airflow turndown value below the zone design minimum air flow and is intended for use with ASHRAE Standard 170. This field can also be used to adjust the design minimum air flow sizing calculation by applying a desired fraction values to summer and winter design days turndown schedule. If this field is left blank, then the turndown minimum air flow fraction value is set to 1 and the VAV air terminal uses the fixed fraction specified in in the field *Zone Minimum Air Flow Fraction*.

### 1.30.15.2 Outputs

- HVAC,Average,Zone Air Terminal Cold Supply Duct Damper Position []
- HVAC,Average,Zone Air Terminal Hot Supply Duct Damper Position []
- HVAC,Average,Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

#### 1.30.15.2.1 Zone Air Terminal Cold Supply Duct Damper Position []

This output is the damper position of the cold air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit cold air mass flow rate divided by the terminal unit's maximum cold air mass flow rate.

#### 1.30.15.2.2 Zone Air Terminal Hot Supply Duct Damper Position []

This output is the damper position of the hot air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit hot air mass flow rate divided by the terminal unit's maximum hot air mass flow rate.

#### 1.30.15.2.3 Zone Air Terminal Outdoor Air Volume Flow Rate [m3/s]

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outdoor air system.

### 1.30.16 AirTerminal:DualDuct:VAV:OutdoorAir

AirTerminal:DualDuct:VAV:OutdoorAir provides a model for a type of dual duct air system in which one duct provides outdoor air ventilation and the other provides VAV cooling. The Outdoor Air stream and the Recirculated Air stream are conditioned and supplied through separate air streams as part of a centralized dedicated outdoor air (DOAS) distribution system. The dual duct arrangement allows the ventilation air to be controlled separately using schedules or occupancy demand while the recirculated air is controlled to meet the dry-bulb zone temperature setpoint. The two airstreams remain decoupled until the terminal box where they are mixed. The terminal unit is meant for systems regulating outdoor air based only on demand control or code minimum settings and not on economizer operation.

This air terminal does not have heating coils and is not configured for conditions zones that need heat. Additional ZoneHVAC equipment, such as baseboards or fan coil units, are needed to provide heating to the zone when using this air terminal.

Although this air terminal is primarily for dual duct system, it is allowed to use just the outdoor air side in a single duct system. This can be useful for modeling single duct DOAS when the required volume of outdoor air varies over time.

#### 1.30.16.1 Inputs

##### 1.30.16.1.1 Field: Name

Unique name for the AirTerminal:DualDuct:VAV:OutdoorAir Air Distribution Unit (ADU).

##### 1.30.16.1.2 Field: Availability Schedule Name

Schedule that this component will operate or is available to operate for a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.30.16.1.3 Field: Air Outlet Node Name

The outlet node of the terminal unit. This is the node leaving the unit and serving as the inlet to the zone. It is for the mixed flow leaving from both of the inlet node.

##### 1.30.16.1.4 Field: Outdoor Air Inlet Node Name

The inlet node of the Outdoor Air (OA) stream deck of the Dual Duct system.

##### 1.30.16.1.5 Field: Recirculated Air Inlet Node Name

The inlet node of the Recirculated Air (RA) stream deck of the Dual Duct system. This input is optional. If no node name is entered here, then the recirculation duct is disabled and the model functions as a single duct terminal and no second cooling deck is needed.

##### 1.30.16.1.6 Field: Maximum Zone Total Airflow Rate

Max total airflow rate (in m3/s) at the terminal unit outlet including both the Outdoor Air stream and the Recirculated stream. Can be autosized based on the Design Outdoor Airflow Rate and the zone thermal cooling load. The autosized flow rate will be the sum of the maximum outdoor air requirement and the flow for cooling. When autosizing, this maximum and the individual inlet flow rate sizes are reported to the eio file.

### 1.30.16.1.7 Field: Design Specification Outdoor Air Object Name

This field specifies the name of a **DesignSpecification:OutdoorAir** object. This field is required for this object. The terminal unit will modulate the Outdoor Air stream to meet this outdoor air requirement. If Outdoor Air Flow per Person is applied, then the outdoor air required will be based on either the current number of occupants in the zone, as for demand controlled ventilation, or the design level of occupants depending on the setting in the next field.

### 1.30.16.1.8 Field: Per Person Ventilation Rate Mode

This field specifies how the outdoor air ventilation rates are calculated when based on a rate per person. It can be either based on the current number of people as affected by time-varying occupancy schedules, or on the constant value for the maximum number of people. Enter the key CurrentOccupancy for the former and DesignOccupancy for the later.

An example input object follows.

```

## 1.30.16.2 Outputs

- Output:Variable,\*,Zone Air Terminal Outdoor Air Duct Damper Position,hourly; !- HVAC Average  $\square$
- Output:Variable,\*,Zone Air Terminal Recirculated Air Duct Damper Position,hourly; !- HVAC Average  $\square$
- Output:Variable,\*,Zone Air Terminal Outdoor Air Fraction,hourly; !- HVAC Average  $\square$

### 1.30.16.2.1 Zone Air Terminal Outdoor Air Duct Damper Position $\square$

This output is the damper position of the outdoor air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit outdoor air mass flow rate divided by the terminal unit's maximum outdoor air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

### 1.30.16.2.2 Zone Air Terminal Recirculated Air Duct Damper Position $\square$

This output is the damper position of the recirculated cool air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit cool air mass flow rate divided by the terminal unit's maximum cool air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

### 1.30.16.2.3 Zone Air Terminal Outdoor Air Fraction []

This output is the current fraction of outdoor air contained in the combined flow of air entering the zone from the terminal unit. This is the average value over the frequency being reported. The outdoor air fraction is defined as the terminal unit outdoor air mass flow rate divided by the total air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

## 1.31 Group – Zone Forced Air Units

**1.31.0.0.1 Schedules And Availability Manager** Regarding component schedules, the general rule is don't schedule any components except the supply fan and the corresponding availability manager(s). Beyond that, every component should always be available and let the controls determine what runs or doesn't run. If a component other than the supply fan is scheduled off, then it will remain off even if the night cycle manager turns on the system.

### 1.31.1 ZoneHVAC:IdealLoadsAirSystem

The simplest piece of zone equipment is the ZoneHVAC:IdealLoadsAirSystem component. ZoneHVAC:IdealLoadsAirSystem is used in situations where the user wishes to study the performance of a building without modeling a full HVAC system. In such a case, the Ideal Loads Air System is usually the sole conditioning component: the user does not need to specify air loops, water loops, etc. All that is needed for the ideal system are zone controls, zone equipment configurations, and the ideal loads system component. The use of a return plenum is optional and will require use of the AirloopHVAC:ReturnPlenum object.

This component can be operated with infinite or finite heating and cooling capacity. For either mode – infinite or limited capacity – the user can also specify on/off schedules for heating and cooling and outdoor air controls. There are also optional controls for dehumidification, humidification, economizer, and heat recovery. This component may be used in combination with other HVAC equipment serving the same zone.

This component can be thought of as an ideal unit that mixes air at the zone exhaust condition (or plenum outlet condition when a plenum is attached) with the specified amount of outdoor air and then adds or removes heat and moisture at 100% efficiency in order to produce a supply air stream at the specified conditions. The energy required to condition the supply air is metered and reported as **DistrictHeating** and **DistrictCooling**.

**Notes:** The ideal loads system uses the zone return node or an optional zone exhaust node to extract air from the zone. When the AirloopHVAC:ReturnPlenum is used the inlet of the ideal loads system is connected to the plenum outlet air node while the outlet of the ideal loads system is connected to a zone inlet node. The node name connected between the zone exhaust air node and plenum inlet air node must match in the **ZoneHVAC:EquipmentConnections** and AirloopHVAC:ReturnPlenum objects. Every zone served by an HVAC component must have a return air node, even though this node may not be connected to anything. If more than one ideal loads air systems are connected to the same AirloopHVAC:ReturnPlenum then one of the ideal loads air systems will connect to the ZoneHVAC:ReturnPlenum outlet air node and the remaining ideal loads air systems connected to the same return plenum will connect to the ZoneHVAC:ReturnPlenum induced air outlet nodes.

The ideal loads system was significantly expanded in version 7.0 (October 2011). As part of this upgrade, any change in the moisture content of the supply air stream results in a latent cooling (dehumidification) or latent heating (humidification) load which is metered as **DistrictCooling** and **DistrictHeating** energy consumption. Prior to version 7.0, when the ideal loads system was in heating mode, only the energy for sensible heating was metered. This results in significant changes in reported energy use compared

to earlier versions, especially when using the *ConstantSupplyHumidityRatio* option for Humidification Control Type.

Older idf files which are transitioned to version 7.0 will automatically be set to use the *ConstantSupplyHumidityRatio* option for both dehumidification and humidification controls, because this is equivalent to the controls used in the older version of this system. However, the user should review all of the humidity control options and select the one which best reflects the goal of the simulation.

### 1.31.1.1 Inputs

#### 1.31.1.1.1 Field: Name

A unique user assigned name for each ideal loads air system component. This name is referenced in a *ZoneHVAC:EquipmentList* object.

#### 1.31.1.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether or not this component is available to operate during a given time period. If the schedule value is greater than zero then the system is available to operate; otherwise, the system is unavailable for that time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.31.1.1.3 Field: Zone Supply Air Node Name

The name of the outlet air node of the ideal loads object. This should be the same as one of the zone air inlet nodes for the zone the ideal loads component is serving.

#### 1.31.1.1.4 Field: Zone Exhaust Air Node Name

The name of the zone exhaust air node of the ideal loads object. This should be the same as one of the zone air exhaust nodes for the zone this component is serving. This node name is required if *ZoneHVAC:IdealLoadsAirSystem* is used in a zone which also has other forced air HVAC equipment. Otherwise this node name is optional but recommended.

#### 1.31.1.1.5 Field: System Inlet Air Node Name

The optional name of the return plenum outlet node (or induced air outlet node) connected to the ideal loads object. When a return plenum is used, the previous fields for Zone Supply Air Node Name and Zone Exhaust Air Node Name are also required. When an *AirloopHVAC:ReturnPlenum* is connected to the Ideal Loads Air System the Zone Supply Air Node Name must match a zone air inlet node name and the Zone Exhaust Air Node Name must match a zone air exhaust node (see *ZoneHAVC:EquipmentConnections* object). The Zone Exhaust Air Node Name must also match an *AirloopHVAC:ReturnPlenum* inlet node name. In the *AirloopHVAC:ReturnPlenum* object, when more than one ideal loads air systems are connected to the same return plenum, the System Inlet Air Node Name for one of the ideal loads air systems must match the return plenum Outlet Node Name while all remaining ideal loads air systems, if more than one are connected, would enter the System Inlet Air Node Name in the return plenum Induced Air Outlet Node or *NodeList* Name field (see Engineering Reference for schematic).

#### 1.31.1.1.6 Field: Maximum Heating Supply Air Temperature

The maximum air temperature (°C) of the air used for heating the zone. The default is 50°C (122F).

#### 1.31.1.1.7 Field: Minimum Cooling Supply Air Temperature

The minimum air temperature (°C) of the air used for cooling the zone. The default is 13°C (55.4F).

#### 1.31.1.1.8 Field: Maximum Heating Supply Air Humidity Ratio

The maximum humidity ratio (kg of water per kg of dry air) of the hot supply air. The default is 0.0156 kgWater/kgDryAir which corresponds to a 20%RH at 50°C (122F) dry bulb.

#### 1.31.1.1.9 Field: Minimum Cooling Supply Air Humidity Ratio

The minimum humidity ratio (kg of water per kg of dry air) of the cool supply air. The default is 0.0077 kgWater/kgDryAir which corresponds to a 10°C (50F) dew point.

#### 1.31.1.1.10 Field: Heating Limit

The input must be either *LimitFlowRate*, *LimitCapacity*, *LimitFlowRateAndCapacity* or *NoLimit*. *LimitFlowRate* means that the heating supply air flow rate will be limited to the value specified in the next input field. *LimitCapacity* means that the sensible heating capacity will be limited to the value specified in the Maximum Sensible Heating Capacity field. *LimitFlowRateAndCapacity* means that both flow rate and capacity will be limited. *NoLimit* (the default) means that there will not be any limit on the heating supply air flow rate or capacity and the subsequent two fields will be ignored.

#### 1.31.1.1.11 Field: Maximum Heating Air Flow Rate

The maximum heating supply air flow rate in cubic meters per second if heating limit is set to *LimitFlowRate* or *LimitFlowRateAndCapacity*. This field may be autosized. This field is ignored if heating limit is set to *NoLimit* or *LimitCapacity*. If blank, there is no limit.

#### 1.31.1.1.12 Field: Maximum Sensible Heating Capacity

The maximum allowed sensible heating capacity in Watts if Heating Limit is set to *LimitCapacity* or *LimitFlowRateAndCapacity*. This field may be autosized. If blank, there is no limit. If Heating Limit is set to *NoLimit* or *LimitFlowRate*, this field is ignored.

#### 1.31.1.1.13 Field: Cooling Limit

The input must be either *LimitFlowRate*, *LimitCapacity*, *LimitFlowRateAndCapacity* or *NoLimit*. *LimitFlowrate* means that the cooling supply air flow rate will be limited to the value specified in the next input field. *LimitCapacity* means that the total cooling capacity will be limited to the value specified in the Maximum Total Cooling Capacity field. *LimitFlowRateAndCapacity* means that both flow rate and capacity will be limited. *NoLimit* (the default) means that there will not be any limit on the cooling supply air flow rate or capacity and the subsequent two fields will be ignored.

#### 1.31.1.1.14 Field: Maximum Cooling Air Flow Rate

The maximum cooling supply air flow rate in cubic meters per second if Cooling Limit is set to *LimitFlowRate* or *LimitFlowRateAndCapacity*. This field may be autosized. This field is ignored if cooling limit is set to *NoLimit* or *LimitCapacity*. If blank, there is no limit. If *Cooling Limit* is set to *NoLimit*, this field is ignored. This field is required if Outdoor Air Control Type is *TemperatureEconomizer* in order to establish an upper limit on outdoor air flow when the economizer is active.

#### 1.31.1.1.15 Field: Maximum Total Cooling Capacity

The maximum allowed total (sensible plus latent) cooling capacity in Watts if Cooling Limit is set to *LimitCapacity* or *LimitFlowRateAndCapacity*. This field may be autosized. If blank, there is no limit. If Cooling Limit is set to *NoLimit* or *LimitFlowRate*, this field is ignored.

**1.31.1.1.16 Field: Heating Availability Schedule Name**

The name of a schedule (ref: Schedule) that denotes whether heating is available. A schedule value greater than 0 (usually 1 is used) indicates that heating and humidification are available. A value less than or equal to 0 (usually 0 is used) denotes that heating and humidification are not available. If blank, heating and humidification are always available.

**1.31.1.1.17 Field: Cooling Availability Schedule Name**

The name of a schedule (ref: Schedule) that denotes whether cooling is available. A schedule value greater than 0 (usually 1 is used) indicates that cooling and dehumidification are available. A value less than or equal to 0 (usually 0 is used) denotes that cooling and dehumidification is not available. If blank, cooling and dehumidification are always available.

**1.31.1.1.18 Field: Dehumidification Control Type**

Select from *ConstantSensibleHeatRatio*, *Humidistat*, *None*, or *ConstantSupplyHumidityRatio*. *ConstantSensibleHeatRatio* (the default) means that the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using a constant sensible heat ratio (SHR) (see next field). *Humidistat* means that there is a **ZoneControl:Humidistat** for this zone and the ideal loads system will attempt to meet the humidistat request (i.e. will dehumidify according to the Dehumidifying Relative Humidity Schedule in the **ZoneControl:Humidistat** object). *None* means that there is no dehumidification. *ConstantSupplyHumidityRatio* means that during cooling the supply air will always be at the Minimum Cooling Supply Humidity Ratio. For *ConstantSensibleHeatRatio* and *Humidistat*, if the mixed air humidity ratio is less than the target humidity ratio, then the mixed air humidity ratio will be used. For all options, the supply air humidity ratio will never be allowed to exceed saturation at the supply dry bulb temperature.

The selected dehumidification control type is always applied when the unit is in cooling mode. If the unit is in deadband mode (not actively heating the supply air) control type *Humidistat* will be active. If the unit is in heating mode, control type *Humidistat* will be active if the Humidification Control Type field below is set to *Humidistat* or *None*.

This allows the ideal loads system to heat and dehumidify at the same time.

**1.31.1.1.19 Field: Cooling Sensible Heat Ratio**

When the Dehumidification Control Type is set to *ConstantSensibleHeatRatio* the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using the value of Cooling Sensible Heat Ratio (SHR), where  $SHR = \text{Sensible Cooling} / \text{Total Cooling (sensible plus latent)}$ . The default is 0.7. If Dehumidification Control Type is set to something other than *ConstantSensibleHeatRatio* then this field will be ignored.

**1.31.1.1.20 Field: Humidification Control Type**

Select from *None*, *Humidistat*, or *ConstantSupplyHumidityRatio*. *None* means that there is no humidification. *Humidistat* means that there is a **ZoneControl:Humidistat** for this zone and the ideal loads system will attempt to meet the humidistat request (i.e., humidify according to the Humidifying Relative Humidity Setpoint Schedule in the **ZoneControl:Humidistat** object). *ConstantSupplyHumidityRatio* means that during heating the supply air will always be at the Maximum Heating Supply Humidity Ratio. The default is *None*. For *Humidistat*, if the mixed air humidity ratio is greater than the target humidity ratio, then the mixed air humidity ratio will be used. For all options, the supply air humidity ratio will never be allowed to exceed saturation at the supply dry bulb temperature.

The selected humidification control type is always applied when the unit is in heating mode. If the unit is in deadband mode (not actively heating the supply air) control type *Humidistat* will be active. If

the unit is in cooling mode, control type ***Humidistat*** will be active if the Dehumidification Control Type field above is set to *Humidistat* or *None*.

This allows the ideal loads system to cool and humidify at the same time.

#### 1.31.1.1.21 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the outdoor air requirements and schedule for this system. The outdoor air flow rate may also be affected by the next two fields, Demand Controlled Ventilation Type and Outdoor Air Economizer Type. If this field is blank, this system will have no outdoor air, and all outdoor air control and heat recovery options will be ignored..

#### 1.31.1.1.22 Field: Outdoor Air Inlet Node Name

This alpha field specifies the node name of the outdoor air inlet node. This node name is also specified in an **OutdoorAir:Node** or **OutdoorAir:NodeList** object. If this field is blank, a node name will be created internally.

#### 1.31.1.1.23 Field: Demand Controlled Ventilation Type

This field, along with the Design Specification Outdoor Air Object (if used) specifies how the minimum outdoor air flow rate is calculated. The choices are: ***None***, ***OccupancySchedule*** or ***CO2Setpoint***. The default is ***None***.

- ***None*** means that the design occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field).
- ***OccupancySchedule*** means that the current occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field).
- ***CO2Setpoint*** means that the design occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field). In addition, the minimum outdoor air flow rate may be increased if necessary to maintain the level of indoor air carbon dioxide at or below the setpoint defined in a **ZoneControl:ContaminantController** object.

#### 1.31.1.1.24 Field: Outdoor Air Economizer Type

This field specifies if there is an outdoor air economizer. The choices are: ***NoEconomizer***, ***DifferentialDryBulb***, or ***DifferentialEnthalpy***. The default is ***NoEconomizer***. ***DifferentialDryBulb*** and ***DifferentialEnthalpy*** mean that the economizer will increase the outdoor air flow rate above the minimum outdoor air flow (see fields Design Specification Outdoor Air Object Name and Demand Controlled Ventilation Type) when there is a cooling load and the outdoor air temperature or enthalpy is below the zone exhaust air temperature or enthalpy. The ***DifferentialDryBulb*** and ***DifferentialEnthalpy*** options require that the Maximum Cooling Air Flow Rate be specified which will be used as the limit for maximum outdoor air flow rate.

#### 1.31.1.1.25 Field: Heat Recovery Type

Select from ***None***, ***Sensible***, or ***Enthalpy***. ***None*** means that there is no heat recovery. ***Sensible*** means that there is sensible heat recovery whenever the zone exhaust air temperature is more favorable than the outdoor air temperature. ***Enthalpy*** means that there is latent and sensible heat recovery whenever the zone exhaust air enthalpy is more favorable than the outdoor air enthalpy. The default is ***None***.

**1.31.1.1.26 Field: Sensible Heat Recovery Effectiveness**

The sensible heat recovery effectiveness, where effectiveness is defined as the change in supply temperature divided by the difference in entering supply and relief air temperatures. The default is 0.70.

**1.31.1.1.27 Field: Latent Heat Recovery Effectiveness**

The latent heat recovery effectiveness, where effectiveness is defined as the change in supply humidity ratio divided by the difference in entering supply and relief air humidity ratios. The default is 0.65.

**1.31.1.1.28 Field: Design Specification ZoneHVAC Sizing Object Name**

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Specification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Maximum Heating Air Flow Rate and Maximum Cooling Air Flow Rate in a Ideal Load Air System zone HVAC object. The scaled maximum heating and cooling air flow rates are used to size the heating and cooling capacities.

An example of this object in an IDF is:

```
ZoneHVAC:IdealLoadsAirSystem,
  Zone1 Ideal Loads System, !- Name
  AlwaysOn, !- Availability Schedule Name

#### 1.31.1.2.1 Ideal Loads Output Variable Overview

All of the ZoneHVAC:IdealLoadsAirSystem loads and energy use are reported for Sensible Heating, Latent Heating, Total Heating, Sensible Cooling, Latent Cooling, and Total Cooling. To explain the relationship between the various outputs, Total Cooling Energy will be used. Note that the outdoor air load variables are only calculated when there is active heating or cooling (or humidification/dehumidification).

*Zone Ideal Loads Supply Air Total Cooling Energy* is the district cooling energy consumed by the ideal loads system “cooling coil” to cool and dehumidify the supply air.

*Zone Ideal Loads Zone Total Cooling Energy* is the total (sensible plus latent) cooling energy delivered to the zone. If there is no outdoor air, then *Zone Ideal Loads Supply Air Total Cooling Energy = Zone Ideal Loads Zone Total Cooling Energy*.

*Zone Ideal Loads Outdoor Air Total Cooling Energy* is the total (sensible plus latent) cooling energy required to cool the outdoor air to the zone exhaust air temperature and humidity ratio.

*Zone Ideal Loads Heat Recovery Total Cooling Energy* is the total (sensible plus latent) cooling energy supplied by heat recovery. This offsets a portion of the *Zone Ideal Loads Outdoor Air Total Cooling Energy*.

When the economizer is not active, these values are related by the following equation:

*Zone Ideal Loads Supply Air Total Cooling Energy + Zone Ideal Loads Heat Recovery Total Cooling Energy = Zone Ideal Loads Zone Total Cooling Energy + Zone Ideal Loads Outdoor Air Total Cooling Energy*

#### 1.31.1.2.2 Zone Ideal Loads Supply Air Sensible Heating Energy [J]

#### 1.31.1.2.3 Zone Ideal Loads Supply Air Sensible Heating Rate [W]

The sensible heating energy (or rate) added to raise the temperature of the mixed air stream to the temperature of the supply air stream. This is the ideal “heating coil” load.

#### 1.31.1.2.4 Zone Ideal Loads Supply Air Latent Heating Energy [J]

#### 1.31.1.2.5 Zone Ideal Loads Supply Air Latent Heating Rate [W]

The latent heating energy (or rate) added to raise the humidity ratio of the mixed air stream to the temperature of the supply air stream. This is the ideal “humidifier” load.

#### 1.31.1.2.6 Zone Ideal Loads Supply Air Total Heating Energy [J]

#### 1.31.1.2.7 Zone Ideal Loads Supply Air Total Heating Rate [W]

The total (sensible and latent) heating energy (or rate) added to raise the mixed air stream to the temperature and humidity ratio of the supply air stream. *Zone Ideal Loads Supply Air Total Heating Energy* is metered as DistrictHeating energy.

#### 1.31.1.2.8 Zone Ideal Loads Supply Air Sensible Cooling Energy [J]

#### 1.31.1.2.9 Zone Ideal Loads Supply Air Sensible Cooling Rate [W]

The sensible cooling energy (or rate) removed to lower the temperature of the mixed air stream to the temperature of the supply air stream. This is the ideal “cooling coil” sensible load.

#### 1.31.1.2.10 Zone Ideal Loads Supply Air Latent Cooling Energy [J]

#### 1.31.1.2.11 Zone Ideal Loads Supply Air Latent Cooling Rate [W]

The latent cooling energy (or rate) removed to lower the humidity ratio of the mixed air stream to the temperature of the supply air stream. This is the ideal “cooling coil” latent load.

#### 1.31.1.2.12 Zone Ideal Loads Supply Air Total Cooling Energy [J]

**1.31.1.2.13 Zone Ideal Loads Supply Air Total Cooling Rate [W]**

The total (sensible and latent) cooling energy (or rate) removed to lower the mixed air stream to the temperature and humidity ratio of the supply air stream. *Zone Ideal Loads Supply Air Total Cooling Energy* is metered as DistrictCooling energy. This is the ideal “cooling coil” total load.

**1.31.1.2.14 Zone Ideal Loads Zone Sensible Heating Energy [J]****1.31.1.2.15 Zone Ideal Loads Zone Sensible Heating Rate [W]**

The sensible heating energy (or rate) added to the zone.

**1.31.1.2.16 Zone Ideal Loads Zone Latent Heating Energy [J]****1.31.1.2.17 Zone Ideal Loads Zone Latent Heating Rate [W]**

The latent heating energy (or rate) added to the zone.

**1.31.1.2.18 Zone Ideal Loads Zone Total Heating Energy [J]****1.31.1.2.19 Zone Ideal Loads Zone Total Heating Rate [W]**

The total (sensible and latent) heating energy (or rate) added to the zone.

**1.31.1.2.20 Zone Ideal Loads Zone Sensible Cooling Energy [J]****1.31.1.2.21 Zone Ideal Loads Zone Sensible Cooling Rate [W]**

The sensible cooling energy (or rate) removed from the zone.

**1.31.1.2.22 Zone Ideal Loads Zone Latent Cooling Energy [J]****1.31.1.2.23 Zone Ideal Loads Zone Latent Cooling Rate [W]**

The latent cooling energy (or rate) removed from the zone.

**1.31.1.2.24 Zone Ideal Loads Zone Total Cooling Energy [J]****1.31.1.2.25 Zone Ideal Loads Zone Total Cooling Rate [W]**

The total (sensible and latent) cooling energy (or rate) removed from the zone.

**1.31.1.2.26 Zone Ideal Loads Outdoor Air Sensible Heating Energy [J]****1.31.1.2.27 Zone Ideal Loads Outdoor Air Sensible Heating Rate [W]**

The sensible heating energy (or rate) required to raise the temperature of the outdoor air to the zone exhaust air temperature. This value will be calculated only when heating is active.

**1.31.1.2.28 Zone Ideal Loads Outdoor Air Latent Heating Energy [J]****1.31.1.2.29 Zone Ideal Loads Outdoor Air Latent Heating Rate [W]**

The latent heating energy (or rate) required to raise the humidity ratio of the outdoor air to the zone exhaust air humidity ratio. This value will be calculated only when humidification is active.

**1.31.1.2.30 Zone Ideal Loads Outdoor Air Total Heating Energy [J]****1.31.1.2.31 Zone Ideal Loads Outdoor Air Total Heating Rate [W]**

The total (sensible and latent) heating energy (or rate) required to raise the temperature and humidity ratio of the outdoor air to the zone exhaust air humidity ratio. This value will be calculated only when heating or humidification is active.

**1.31.1.2.32 Zone Ideal Loads Outdoor Air Sensible Cooling Energy [J]****1.31.1.2.33 Zone Ideal Loads Outdoor Air Sensible Cooling Rate [W]**

The sensible cooling energy (or rate) required to lower (or raise) the temperature of the outdoor air to the zone exhaust air temperature. This value will be calculated only when cooling is active.

**1.31.1.2.34 Zone Ideal Loads Outdoor Air Latent Cooling Energy [J]****1.31.1.2.35 Zone Ideal Loads Outdoor Air Latent Cooling Rate [W]**

The latent cooling energy (or rate) required to lower (or raise) the humidity ratio of the outdoor air to the zone exhaust air humidity ratio. This will be calculated only when dehumidification is active.

**1.31.1.2.36 Zone Ideal Loads Outdoor Air Total Cooling Energy [J]****1.31.1.2.37 Zone Ideal Loads Outdoor Air Total Cooling Rate [W]**

The total (sensible and latent) cooling energy (or rate) required to lower the temperature and humidity ratio of the outdoor air to the zone exhaust air temperature and humidity ratio. This value will be calculated only when cooling or dehumidification is active.

**1.31.1.2.38 Zone Ideal Loads Heat Recovery Sensible Heating Energy [J]****1.31.1.2.39 Zone Ideal Loads Heat Recovery Sensible Heating Rate [W]**

The sensible heating energy (or rate) added to the outdoor air stream from heat recovery.

**1.31.1.2.40 Zone Ideal Loads Heat Recovery Latent Heating Energy [J]****1.31.1.2.41 Zone Ideal Loads Heat Recovery Latent Heating Rate [W]**

The latent heating energy (or rate) added to the outdoor air stream from heat recovery.

**1.31.1.2.42 Zone Ideal Loads Heat Recovery Total Heating Energy [J]****1.31.1.2.43 Zone Ideal Loads Heat Recovery Total Heating Rate [W]**

The total (sensible and latent) heating energy (or rate) added to the outdoor air stream from heat recovery.

**1.31.1.2.44 Zone Ideal Loads Heat Recovery Sensible Cooling Energy [J]****1.31.1.2.45 Zone Ideal Loads Heat Recovery Sensible Cooling Rate [W]**

The sensible cooling energy (or rate) removed from the outdoor air stream from heat recovery.

**1.31.1.2.46 Zone Ideal Loads Heat Recovery Latent Cooling Energy [J]****1.31.1.2.47 Zone Ideal Loads Heat Recovery Latent Cooling Rate [W]**

The latent cooling energy (or rate) removed from the outdoor air stream from heat recovery.

**1.31.1.2.48 Zone Ideal Loads Heat Recovery Total Cooling Energy [J]****1.31.1.2.49 Zone Ideal Loads Heat Recovery Total Cooling Rate [W]**

The total (sensible and latent) cooling energy (or rate) removed from the outdoor air stream from heat recovery.

**1.31.1.2.50 Zone Ideal Loads Economizer Active Time [hr]**

Hours when the Ideal Loads economizer increased the outdoor air flow rate above the minimum.

**1.31.1.2.51 Zone Ideal Loads Heat Recovery Active Time [hr]**

Hours when the Ideal Loads heat recovery was actively heating or cooling the outdoor air stream.

**1.31.1.2.52 Zone Ideal Loads Hybrid Ventilation Available Status []**

This is the availability status of the ideal loads object as set by the hybrid ventilation manager. Rules to determine the availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 and 1. These integers represent NoAction (0) and ForceOff (1). When the availability status is ForceOff, the unit is turned off regardless of its availability schedule. The other status flag i.e. NoAction does not control the unit and the controls of the unit turn it back on. Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

**1.31.1.2.53 Zone Ideal Loads Outdoor Air Mass Flow Rate [kg/s]**

The mass flow rate of the outdoor air stream in kg/s.

**1.31.1.2.54 Zone Ideal Loads Outdoor Air Standard Density Volume Flow Rate [m3/s]**

The volume flow rate of the outdoor air stream in m3/s using the standard density. The standard density is determined for dry air at the standard barometric pressure for the location’s elevation and a temperature of 20.0°C. The standard density does not vary over time.

**1.31.1.2.55 Zone Ideal Loads Supply Air Mass Flow Rate [kg/s]**

The mass flow rate of the supply air stream in kg/s.

**1.31.1.2.56 Zone Ideal Loads Supply Air Standard Density Volume Flow Rate [m3/s]**

The volume flow rate of the supply air stream in m3/s using the standard density. The standard density is determined for dry air at the standard barometric pressure for the location’s elevation and a temperature of 20.0°C. The standard density does not vary over time.

**1.31.1.2.57 Zone Ideal Loads Supply Air Temperature [°C]**

The dry bulb temperature of the supply air stream in °C.

**1.31.1.2.58 Zone Ideal Loads Supply Air Humidity Ratio [kgWater/kgDryAir]**

The humidity ratio of the supply air stream in kgWater/kgDryAir.

**1.31.1.2.59 Zone Ideal Loads Mixed Air Temperature [°C]**

The dry bulb temperature of the mixed air stream after mixing the recirculation air stream and outdoor air stream (if present), in °C.

**1.31.1.2.60 Zone Ideal Loads Mixed Air Humidity Ratio [kgWater/kgDryAir]**

The humidity ratio of the mixed air stream after mixing the recirculation air stream and outdoor air stream (if present) in kgWater/kgDryAir.

**1.31.2 ZoneHVAC:FourPipeFanCoil**

What is a fan coil unit? Like many HVAC terms, “fan coil unit” is used rather loosely. Sometimes it is used for terminal units that would be better described as powered induction units. Carrier and others use the term for the room side of refrigerant-based split systems. Here we are modeling in-room forced-convection hydronic units. The hydronic heating coil may be replaced with an electric heating coil. Typically these units are small (200 – 1200 cfm) and self-contained. They are mostly used in exterior zones, usually in hotels, apartments, or offices. They may be connected to ducted outside air, or have a direct outside air vent, but they do not have outside air economizers. Units with outside air economizers are marketed (in the United States) as unit ventilators. Unit ventilators are typically bigger than fan coils and are widely used in classrooms or other applications where ventilation is a priority. If a zonal unit with an outside economizer is desired, *ZoneHVAC:UnitVentilator* should be used.

The heating or cooling output of the fan coil unit is controlled by varying the air flow rate, the water flow rate, or both. Air flow rate can be controlled by cycling the fan on/off or with a variable speed fan drive. The most common setup is a two or three speed fan with the speed selected by hand. The fan then cycles on/off to control heating / cooling output. The controls are often a wall mounted thermostat with hand selection of heating/cooling and fan speed (off/low/medium/high). These controls may also be mounted on the unit.

Carrier offers a retrofit VSD motor for fan coil units. It claims up to 45% energy savings from such a retrofit, as well as increased comfort and less noise compared to a cycling fan (fan coil fans are typically noisy and inefficient). Some other manufacturers are also offering units with VSD fans. Variable speed fans appear to offer an easy way to significantly increase the efficiency of what have typically been very inefficient units.

EnergyPlus provides 6 capacity control methods for this unit:

1. multi-speed cycling fan with constant water flow rate
2. constant speed continuous fan with variable water flow rate
3. variable-speed fan with constant water flow rate
4. variable-speed fan with variable water flow rate
5. multi-speed fan with cycling between speeds and constant water flow.
6. fan speed control based on ASHRAE 90.1

In EnergyPlus the fan coil units are modeled as compound components. That is, they are assembled from other components. Fan coils contain an outdoor air mixer, a fan, a heating coil and a cooling coil. These components are described elsewhere in this document. The fan coil input simply requires the names

of these four components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, outdoor airflow rate, and maximum and minimum hot (for hydronic heating coil only) and cold water volumetric flow rates. The unit is connected to the zone inlet and exhaust nodes and the outdoor air by specifying unit inlet, and outlet air node names and the outdoor air mixer object name. The outdoor air mixer child object provides the outdoor air and relief air nodes names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node. The fan coil unit is connected to a hot water loop through its hot water coil or with no hot water loop when using an electric coil (demand side) and to a chilled water loop (demand side) through its cooling coil.

Note that the type of fan component associated with the fan coil unit depends on the type of capacity control method chosen. For *ConstantFanVariableFlow* a *Fan:OnOff* or *Fan:ConstantVolume* should be used. For *CyclingFan*, a *Fan:OnOff* should be used, for *VariableFanVariableFlow* or *VariableFanConstantFlow* a *Fan:VariableVolume*, for *MultiSpeedFan* a *Fan:OnOff* should be used, and for *ASHRAE90VariableFan*, a *Fan:OnOff* or *Fan:VariableVolume* should be chosen.

Fan coil units can be 4-pipe or 2-pipe. For 4-pipe units there are 2 supply pipes and 2 return pipes. For 2-pipe units there is a single supply pipe and a single return pipe and the supply is switched between hot and chilled water depending on the season. EnergyPlus models 4-pipe units, but the 4-pipe model can be used to model 2-pipe units by using the coil availability schedules to make sure that either hot or chilled water is exclusively available. Fan coil units with hydronic heat can instead be modeled using an electric heating coil if desired (i.e., replace the hydronic heating coil with an electric heating coil).

### 1.31.2.1 Inputs

#### 1.31.2.1.1 Field: Name

A unique user assigned name for an instance of a Fan Coil unit. Any reference to this Fan Coil unit by another object will use this name.

#### 1.31.2.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan coil unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.31.2.1.3 Field: Capacity Control Method

This input denotes how the unit's output is controlled in order to meet zone heating or cooling requirement. The choices are *ConstantFanVariableFlow*, *CyclingFan*, *VariableFanVariableFlow*, *VariableFanConstantFlow*, *MultiSpeedFan*, or *ASHRAE90VariableFan*. For *ConstantFanVariableFlow*, the fan speed is held constant to produce a fixed air flow rate whenever the unit is scheduled on. The hot water or chilled flow rate is varied so that the unit output matches the zone heating or cooling requirement. For *CyclingFan*, the fan speed is chosen so that the unit capacity is greater than or equal to the heating / cooling load and the fan is cycled to match unit output with the load. For *VariableFanVariableFlow* both air and water flow rates are varied to match the load. For *VariableFanConstantFlow*, the water flow rate is at full flow and the fan speed varies to meet the load. For *MultiSpeedFan* the water flow rate is at full flow when there is load or fully closed when there is no load and the supply air flow rate is varied by varying the fan speed in order to match the load. For *ASHRAE90VariableFan*, the fan air flow rate is reduced according to the low speed supply air flow ratio when the zone sensible load is less than the zone sensible load multiplied by the low speed supply air flow ratio. The water coil water flow rate, or the electric heating coil part-load ratio, is modulated to meet the zone load. If the zone sensible load is greater than the zone sensible load multiplied by the low speed supply air flow ratio, then the air and

water flow rate is increased to meet the load. If the zone load is greater than the design sensible load, the fan air flow rate is maintained at the maximum value while the water flow rate is further increased to the maximum available while electric heating coils are maintained at the maximum output.

**Note:** *when ASHRAE90VariableFan is selected, if the the Minimum Supply Air Temperature in Cooling/Heating Mode inputs are not specified, the simulation must include zone sizing to calculate the zone design sensible cooling and heating load used to modulate the fan speed and, for water coils, the water flow rate or for electric heating coils, the part load ratio.*

**MultiSpeedFan:** for a given load, the fan cycles between speeds when fan speed selected is higher than the minimum speed or the fan cycles on-off when the fan speed selected is the minimum and the fan operating schedule is cycling fan. When the fan is operating as a continuous fan, then the fan runs at minimum speed even when there is no load to meet. When the speed selected is higher than the minimum speed, then the fan cycles between consecutive speed regardless of the fan operating schedule type. The model selects at what fan speed to run depending on cooling or heating load.

#### 1.31.2.1.4 Field: Maximum Supply Air Flow Rate

The maximum volumetric airflow rate ( $\text{m}^3/\text{sec}$ ) through the fan coil unit. This is also the design, rated airflow rate of the unit.

#### 1.31.2.1.5 Field: Low Speed Supply Air Flow Ratio

This numerical field specifies the ratio of the low speed flow rate to the maximum supply air flow rate. This value should be less than the *Medium Speed Supply Air Flow Ratio*. If left blank, the default value is 0.33. Leave this field blank if the capacity control method selected is not *CyclingFan* or *ASHRAE90VariableFan*. The suggested value is 0.5 when using the ASHRAE90VariableFan capacity control method.

#### 1.31.2.1.6 Field: Medium Speed Supply Air Flow Ratio

This numerical field specifies the ratio of the medium speed flow rate to the maximum supply air flow rate. Its value should be greater than the *Low Speed Supply Air Flow Ratio* but less than 1. If left blank, the default value is 0.66. Leave this field blank if the capacity control method selected is not *CyclingFan* or *MultiSpeedFan*.

#### 1.31.2.1.7 Field: Maximum Outdoor Air Flow Rate

If the fan coil unit uses outdoor air, this field specifies the outdoor air volumetric flow rate ( $\text{m}^3/\text{sec}$ ). This flow rate should be less than or equal to the maximum airflow rate. A value of zero specifies no outdoor air. This field is set to zero flow when the FanCoil is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.2.1.8 Field: Outdoor Air Schedule Name

The name of a schedule whose values (0.0 to 1.0) are used as multipliers to alter the outdoor air flow rate. If this field is left blank, the values will default to 1.0.

#### 1.31.2.1.9 Field: Air Inlet Node Name

The name of the HVAC system node from which the fan coil unit draws its indoor air. This should be one of zone exhaust nodes for the zone which the fan coil unit is serving.

#### 1.31.2.1.10 Field: Air Outlet Node Name

The name of the HVAC system node to which the fan coil unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

**1.31.2.1.11 Field: Outdoor Air Mixer Object Type**

This field specifies the type of outdoor air mixer used by this fan coil unit. The outdoor air mixer component is part of the fan coil compound object. The only available outdoor air mixer type is:

- **OutdoorAir:Mixer**

This input field should be left blank when the FanCoil is connected to an *AirTerminal:SingleDuct:Mixer* object. If this field is left blank, an outdoor air mixer object is not simulated.

**1.31.2.1.12 Field: Outdoor Air Mixer Name**

The name of an outdoor air mixer component (object:**OutdoorAir:Mixer**) which composes part of the fan coil unit. Note that the return air node of the outdoor air mixer should be the same node as the air inlet node of the fan coil unit. In addition, the outdoor air mixer's mixed air node should be the same as the inlet air node of the fan coil unit's fan. This field should be left blank when the FanCoil is connected to an *AirTerminal:SingleDuct:Mixer* object.

**1.31.2.1.13 Field: Supply Air Fan Object Type**

This field specifies the type of supply air fan object used by this fan coil. The supply air fan is part of the fan coil compound object. The only valid supply air fan types are:

- **Fan:SystemModel**
- **Fan:OnOff**
- **Fan:ConstantVolume**
- **Fan:VariableVolume**

Note that **Fan:SystemModel** was added as of version 8.6 and is recommended for use in new models. **Fan:OnOff**, **Fan:ConstantVolume**, and **Fan:VariableVolume** may be deprecated in a future version.

**1.31.2.1.14 Field: Supply Air Fan Name**

The name of a fan component that composes part of the fan coil unit. Note that the fan's maximum flow rate should be the same as the maximum airflow rate of the fan coil unit and the type of fan object should correspond to the capacity control method. Namely, for *ConstantFanVariableFlow* a *Fan:SystemModel*, *Fan:OnOff*, or *Fan:ConstantVolume* should be used. For *CyclingFan*, a *Fan:OnOff* or *Fan:SystemModel* should be used. For *VariableFanVariableFlow* or *VariableFanConstantFlow* a *Fan:SystemModel* or *Fan:VariableVolume* should be chosen. For *MultiSpeedFan* a *Fan:SystemModel* or *Fan:OnOff* should be used. And for *ASHRAE90VariableFan*, a *Fan:SystemModel*, *Fan:OnOff*, or *Fan:VariableVolume* should be chosen.

The fan's inlet node should be the same as the outdoor air mixer's mixed air node.  
The fan's outlet node should be the same as the cooling coil's air inlet node.

**1.31.2.1.15 Field: Cooling Coil Object Type**

This field specifies the type of chilled water cooling coil to be modeled for this fan coil unit. Only the following coil types can be used:

- **Coil:Cooling:Water**
- **Coil:Cooling:Water:DetailedGeometry**
- **CoilSystem:Cooling:Water:HeatExchangerAssisted**

The input requirements for these chilled water coil objects are described elsewhere in this document.

**1.31.2.1.16 Field: Cooling Coil Name**

The name of the cooling coil component that composes part of the fan coil unit. The cooling coil air inlet node should be the same as the fan outlet node. The cooling coil air outlet node should be the same as the heating coil air inlet node.

Only the following coil types can be used:

- `Coil:Cooling:Water`
- `Coil:Cooling:Water:DetailedGeometry`
- `CoilSystem:Cooling:Water:HeatExchangerAssisted`

**1.31.2.1.17 Field: Maximum Cold Water Flow Rate**

The maximum cold water volumetric flow rate (m<sup>3</sup>/sec) through the fan coil unit's cooling coil.

**1.31.2.1.18 Field: Minimum Cold Water Flow Rate**

The minimum cold water volumetric flow rate (m<sup>3</sup>/sec) through the fan coil unit's cooling coil.

**1.31.2.1.19 Field: Cooling Convergence Tolerance**

The convergence tolerance for the control of the unit cooling output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The cooling convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{fancoil,out} - Q_{zoneload}|}{Q_{zoneload}} \leq CoolingConvergenceTolerance \quad (1.126)$$

**1.31.2.1.20 Field: Heating Coil Object Type**

This field is the type of coil that is used for heating in the fan coil system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. The only allowable heating coil types are:

- `Coil:Heating:Water`
- `Coil:Heating:Electric`

**1.31.2.1.21 Field: Heating Coil Name**

The name of the heating coil component that composes part of the fan coil unit. The heating coil air inlet node should be the same as the cooling coil outlet node. The heating coil air outlet node should be the same as the fan coil air outlet node.

Only the following coil types can be used:

- `Coil:Heating:Water`
- `Coil:Heating:Electric`

**1.31.2.1.22 Field: Maximum Hot Water Flow Rate**

The maximum hot water volumetric flow rate (m<sup>3</sup>/sec) through the fan coil unit's heating coil. This field is not used with an electric heating coil.

**1.31.2.1.23 Field: Minimum Hot Water Flow Rate**

The minimum hot water volumetric flow rate (m<sup>3</sup>/sec) through the fan coil unit's heating coil. This field is not used with an electric heating coil.

**1.31.2.1.24 Field: Heating Convergence Tolerance**

The convergence tolerance for the control of the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{fancoil,out} - Q_{zoneload}|}{Q_{zoneload}} \leq HeatingConvergenceTolerance \quad (1.127)$$

**1.31.2.1.25 Field: Availability Manager List Name**

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this object's fan. If the fan coil is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this object should be on or off.

**1.31.2.1.26 Field: Design Specification ZoneHVAC Sizing Object Name**

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Maximum Air Flow Rate in this Four Pipe FanCoil zone HVAC object. The scaled Maximum Air Flow Rate in turn is used to size cooling and heating capacity of the unit.

**1.31.2.1.27 Field: Supply Air Fan Operating Mode Schedule Name**

This input field is the name of a schedule that controls fan operation. Schedule Name values of 0 denote cycling fan operation (fan cycles with heating or cooling coil). Schedule values greater than 0 denote constant fan operation (fan runs continually regardless of coil operation). The fan operating mode defaults to cycling fan operation if this field is left blank. This input field is currently used with *MultiSpeedFan* capacity control method only.

**1.31.2.1.28 Field: Minimum Supply Air Temperature in Cooling Mode**

This optional input is used only when *Capacity Control Method = ASHRAE90VariableFan*. Specify the minimum supply air temperature in cooling mode. When the fan coil capacity is greater than the zone load, the fan speed will modulate down to the minimum fan speed, based on the Low Speed Supply Air Flow Ratio input field, and the water flow rate will also be reduced to maintain the zone thermostat set point temperature. When the zone load is one-half the fan coil capacity, the fan will operate at the minimum speed. When these fields are not entered, a zone sizing simulation must be performed. Both the cooling and heating supply air temperature must be entered or blank in unison. Values must be greater than 0 or this field is autosizable. A value of 0 (in both fields) will disregard these fields.

**1.31.2.1.29 Field: Maximum Supply Air Temperature in Heating Mode**

This optional input is used only when *Capacity Control Method = ASHRAE90VariableFan*. Specify the maximum supply air temperature in heating mode. When the fan coil capacity is greater than the

zone load, the fan speed will modulate down to the minimum fan speed, based on the Low Speed Supply Air Flow Ratio input field, and the water flow rate will also be reduced to maintain the zone thermostat set point temperature. When the zone load is one-half the fan coil capacity, the fan will operate at the minimum speed. When these fields are not entered, a zone sizing simulation must be performed. Both the cooling and heating supply air temperature must be entered or blank in unison. Values must be greater than 0 or this field is autosizable. A value of 0 (in both fields) will disregard these fields.

An example input for a fan coil unit, including its constituent components, is shown below.

- HVAC,Average, Fan Coil Part Load Ratio []
- HVAC,Average, Fan Coil Speed Ratio []

#### 1.31.2.2.1 Fan Coil Heating Rate [W]

This field reports the dry air heating addition rate of the fan coil unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit.

#### 1.31.2.2.2 Fan Coil Heating Energy [J]

This field is the dry air heat addition of the fan coil unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

#### 1.31.2.2.3 Fan Coil Total Cooling Rate [W]

This field is the total (sensible and latent) heat extraction rate of the fan coil unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

#### 1.31.2.2.4 Fan Coil Total Cooling Energy [J]

This field is the total (sensible and latent) heat extraction of the fan coil unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

#### 1.31.2.2.5 Fan Coil Sensible Cooling Rate [W]

This field reports the dry air sensible heat extraction rate of the fan coil unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

#### 1.31.2.2.6 Fan Coil Sensible Cooling Energy [J]

This field is the dry air sensible heat extraction of the fan coil unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions, the mass flow rate through the unit, and the timestep.

#### 1.31.2.2.7 Fan Coil Fan Electricity Rate [W]

This field reports the electricity consumption rate of the fan coil unit in Watts.

#### 1.31.2.2.8 Fan Coil Fan Electricity Energy [J]

This field is the electricity consumption of the fan coil unit in Joules over the timestep being reported.

#### 1.31.2.2.9 Fan Coil Runtime Fraction[]

This field is the fraction of the system timestep the fan coil unit is running for the *CyclingFan* capacity control method. This variable is defined only for the *CyclingFan* capacity control method.

#### 1.31.2.2.10 Fan Coil Fan Speed Level []

This field indicates the speed chosen for the fan in the *CyclingFan* and *MultiSpeedFan* capacity control methods. A value of '0' means that the unit is off, '1' the fan is running at its low speed, '2' medium speed, and '3' high speed (maximum). This variable is defined only for the *CyclingFan* and *MultiSpeedFan* capacity control methods.

**1.31.2.2.11 Fan Coil Part Load Ratio []**

When the capacity control method is *VariableFanVariableFlow* or *VariableFanConstantFlow*, this output variable reports the unit part load ratio (ratio of unit heating / cooling output to the maximum heating / cooling output). This variable is defined only for *VariableFanVariableFlow*, *VariableFanConstantFlow* or *MultiSpeedFan* capacity control methods. The unit part load ratio is applicable to *MultiSpeedFan* only when the fan speed level selected is the minimum (Speed 1).

**1.31.2.2.12 Fan Coil Availability Status []**

This is the availability status of the fan coil unit fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the fan coil unit object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZone-FansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

**1.31.2.2.13 Fan Coil Speed Ratio []**

This output variable is the ratio of time in a system timestep that the fan coil unit is at rated speed between two consecutive speed levels ( $[\text{load} - \text{Capacity at Fan Speed } i-1] / [\text{Capacity at Fan Speed } i - \text{Capacity at Fan Speed } i-1]$ ). The fan speed ratio has minimum value of 0.0, and a maximum value of 1.0 and any value in between as it is averaged over the timestep. The value is 0.0 during Speed Level 1 operation. Hydronic FanCoil units speed ratio depends on the fan speed and current load. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep.

**1.31.3 ZoneHVAC:UnitVentilator**

Unit ventilators are zone equipment units which are assembled from other components. They contain a built-in outdoor air mixer, a fan, a heating coil, and a cooling coil. These components are described elsewhere in this document, except the built-in outdoor air mixer which is contained within the unit ventilator statement. The unit ventilator input simply requires the names of these other three components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, outdoor air control information (control type and schedules), an outdoor airflow rate, and maximum and minimum hot and cold water mass flow rates. The unit is connected to the zone inlet and exhaust nodes and the outdoor air by specifying unit inlet, outlet, outdoor air and exhaust (relief) air node names. Note that if the Unit Ventilator is not connected to central dedicated outdoor air (DOA), then the unit air inlet node should be the same as a zone exhaust air node and the unit air outlet node should be the same as a zone air inlet node. The three node name input fields: *Outdoor Air Node Name*, *Exhaust Air Node Name*, and *Mixed Air Node Name* are required fields only when the built-in outdoor air mixer is used to provide outdoor air. If the Unit Ventilator is connected to a central dedicated outdoor air (DOA) via *AirTerminal:SingleDuct:Mixer*, then the above three node name input fields are not required and must be left blank. In the later case the Unit Ventilator node connection to the zone air exhaust node and the zone air inlet node are described in *AirTerminal:SingleDuct:Mixer* object. In general, the unit ventilator input is very similar to the fan coil unit input, and the unit is connected to a

hot water loop (demand side) through its hot water coil and to a chilled water loop (demand side) through its cooling coil.

The main difference between the fan coil and unit ventilator input is that the unit ventilator has a built-in outdoor air mixer with its own specialized controls. The outdoor air control type can be selected from one of the following options: “variable percent”, “fixed temperature” or “fixed amount”. In fixed temperature control, the amount of outdoor air is varied between the minimum outdoor air fraction (specified by a schedule) and 100% outdoor air to obtain a mixed air temperature as close as possible to the temperature schedule defined in the input. Variable percent control will also vary the amount of outdoor air between the minimum and maximum fractions (both specified in input by the user) to meet the load without the use of a coil if possible. In fixed amount control, the outdoor air flow rate is fixed to the specified value by the user. In this control strategy, the maximum outdoor air flow rate and schedule are automatically set to be equal to the minimum outdoor air flow rate and schedule. These control types are based on the 2004 ASHRAE Systems and Equipment Handbook (pp. 31.1-31.3) description of unit ventilator systems. The three outdoor air control strategies are also valid and available when the Unit Ventilator is connected to central DOA.

The unit is controlled to meet the zone (remaining) heating or cooling demand. If there is a heating demand, the cooling coil is off and the hot water flow through the heating coil is throttled to meet the demand. The hot water control node must be specified (same as the hot water coil inlet node). If there is a cooling demand from the zone, the hot water coil is off and the chilled water flow through the cooling coil is throttled to meet the load. The cooling coil control node must be specified (same as the cooling coil inlet node). Finally both heating and cooling require a convergence tolerance, which is the tolerance denoting how closely the fan coil unit will meet the heating or cooling load. The tolerance is always relative to the zone load.

Overall, control of the unit must consider the outdoor air. Here is a more detailed description of the overall unit control:

**Off:** Unit is schedule off or there is no load on it. All flow rates are set to zero and the temperatures are set to zone conditions (except for the outdoor air inlet). Outdoor air requirements will not override this condition.

**Heating/No Coil/VariablePercent:** The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and variable percent outdoor air control type has been specified. In this case, the variable percent outdoor air controls what happens with the outdoor air. If the outside temperature is greater than the return temperature, then the outdoor air is set to the maximum as defined by the user input. If the outdoor air temperature is less than the return temperature from the zone, then the outdoor air is set to the minimum outdoor air flow rate as defined by the user. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

**Heating/No Coil/FixedTemperature:** The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate.

**Heating/No Coil/FixedAmount:** The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

**Heating /With Coil/VariablePercent:** The unit is on, there is a heating load, and variable percent control is specified. The outdoor air fraction is set to the minimum outdoor air fraction (schedule based),

and the heating coil is activated. The heating coil attempts to meet the remaining load on the zone being served by the unit ventilator.

**Heating /With Coil/FixedAmount:** The unit is on, there is a heating load, a heating coil is present and is scheduled on, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. The heating coil then attempts to meet any remaining zone heating load.

**Cooling/No Coil/VariablePercent:** The unit is on, there is a cooling load, no coil is present or it has been scheduled off, and variable percent outdoor air control type has been specified. In this case, the variable percent outdoor air controls what happens with the outdoor air. If the outside temperature is greater than the return temperature, then the outdoor air is set to the minimum as defined by the user input. If the outdoor air temperature is less than the return temperature from the zone, then the outdoor air is varied up to the maximum flow rate to try to meet whatever cooling load is present. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

**Cooling/No Coil/FixedTemperature:** The unit is on, there is a cooling load, no cooling coil is present or it has been scheduled off, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate in the same fashion as the variable percent outdoor air control.

**Cooling/No Coil/FixedAmount:** The unit is on, there is a cooling load, no cooling coil is present or it has been scheduled off, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outside air controls.

**Cooling/With Coil/VariablePercent:** The unit is on, there is a cooling load, a coil is present and is scheduled on, and variable percent outdoor air control type has been specified. In this case, the variable percent outdoor air controls what happens with the outdoor air. If the outside temperature is greater than the return temperature, then the outdoor air is set to the minimum as defined by the user input. If the outdoor air temperature is less than the return temperature from the zone, then the outdoor air is varied up to the maximum flow rate to try to meet whatever cooling load is present. The coil then attempts to meet any remaining zone load.

**Cooling/With Coil/FixedTemperature:** The unit is on, there is a cooling load, a cooling coil is present and is scheduled on, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate in the same fashion as the fixed temperature outdoor air control for the “no coil” conditions. The cooling coil then attempts to meet any remaining zone load.

**Cooling/With Coil/FixedAmount:** The unit is on, there is a cooling load, a cooling coil is present and is scheduled on, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. The cooling coil then attempts to meet any remaining zone cooling load.

Note: the unit ventilator controls are strictly temperature based and do not factor humidity into the equation (not an enthalpy economy cycle but rather a simple return air economy cycle). In addition, temperature predictions are not strict energy balances here in the control routine though in the mixing

routine an energy balance is preserved.

### 1.31.3.1 Inputs

#### 1.31.3.1.1 Field: Name

This field is simply the identifying name that distinguishes one particular unit ventilator from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other unit ventilators use this same name.

#### 1.31.3.1.2 Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the unit ventilator is available to operate. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.31.3.1.3 Field: Maximum Supply Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the unit ventilator system in  $\text{m}^3/\text{sec}$ . This parameter should be some real number greater than zero.

#### 1.31.3.1.4 Field: Outdoor Air Control Type

This field allows the user to control how outdoor air is used in the unit ventilator system. The unit ventilator system described by this syntax has its own outdoor air handler. The three options for outdoor air control are “**VariablePercent**”, “**FixedTemperature**” and “**FixedAmount**”. Those keys are the only allowed choices for this parameter. In general, the variable percent control will attempt to vary the amount of outdoor air between some minimum and maximum schedules of fractions (see next two fields) to best meet the current heating or cooling load. The fixed temperature control will vary the amount of outdoor air between the minimum schedule (fraction of maximum, see next field) and 100% available outdoor air to come as close as possible to a desired mixed air temperature (see 2 fields down) that can be scheduled. The fixed amount control will fix the outdoor air flow rate as minimum outdoor air flow rate and schedule specified by the user and automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate. More information on the controls and operation of the unit ventilator are given in the introductory section above. For cycling fan operating mode, the outdoor air mass rate is capped by the actual supply air flow rate if the former is greater than the latter; otherwise, uses the amount calculated by the outdoor air control.

#### 1.31.3.1.5 Field: Minimum Outdoor Air Flow Rate

This field allows the user to enter the minimum volumetric flow rate of outdoor air (in  $\text{m}^3/\text{sec}$ ) that will be brought in to the unit ventilator. The actual minimum outdoor air flow rate will be this number multiplied by the schedule value from the minimum outdoor air schedule. If “**FixedAmount**” type is selected as the outdoor air control strategy, the outdoor air flow rate will be fixed as this field and the unit ventilator will automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate.

#### 1.31.3.1.6 Field: Minimum Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that should contain values for the minimum outdoor air used by the unit ventilator system for IAQ or other reasons. Note that if the unit ventilator is scheduled off or if there is no load sensed in the zone that the system will not operate even to achieve the minimum air fraction. However, if the system is operating, it will always bring in this fraction of the minimum air flow rate (see minimum air flow rate field above). If “**FixedAmount**” type is selected as the outdoor air

control strategy, the actual outdoor air flow rate will be this number multiplied by the minimum outdoor air flow rate in the field above. The unit ventilator will automatically set the maximum and minimum outdoor air schedule to be equal by ignoring the maximum outdoor air schedule.

#### 1.31.3.1.7 Field: Maximum Outdoor Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of outdoor air that can be brought into the unit ventilator system in m<sup>3</sup>/sec. This parameter should be some real number greater than zero. Note that the value for this parameter may be less than the maximum air flow rate of the unit ventilator and this may affect the maximum fraction of outdoor air within the control strategy defined above. This parameter is an absolute maximum and will supercede any scheduled fraction of the unit ventilator maximum airflow rate. If “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air flow rate specified in the field above.

#### 1.31.3.1.8 Field: Maximum Outdoor Air Fraction or Temperature Schedule Name

This field can have one of two meanings depending the type of control selected in the outdoor air control type parameter above. If “VariablePercent” or “FixedAmount” was selected, then this field is a schedule name (ref: Schedule) corresponding to a maximum air fraction schedule. Furthermore, if “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air fraction specified in the field below. Note that this is a fraction of the maximum airflow rate field (see parameter above) for the unit ventilator. If “FixedTemperature” control was selected, then this field is still a schedule name (ref: Schedule), but it corresponds to a schedule of mixed air temperatures that the outdoor air control will try to attain.

#### 1.31.3.1.9 Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the unit ventilator. In a unit ventilator, the air inlet node name must be zone exhaust node name if there is no DOA Mixer, or if the unit ventilator is connected to DOA, then the air inlet node name must be the DOA mixer outlet node name for InletSide mixer connection. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

#### 1.31.3.1.10 Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) to the unit ventilator. In a unit ventilator, the air outlet node name must be zone inlet node name if there is no DOA Mixer, or if the unit ventilator is connected to DOA, then the air outlet node name must be the DOA mixer secondary air inlet node name for SupplySide mixer connection. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

#### 1.31.3.1.11 Field: Outdoor Air Node Name

This field is a node name used to identify the node associated with fresh air brought into the unit ventilator from the outdoor environment. You should also have defined an **OutdoorAir:Node** object with the same name and assign it an optional height (above ground). This input field must be left blank if the Unit ventilator is connected to a central dedicated outdoor air (DOA) via *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.3.1.12 Field: Exhaust Air Node Name

This field is a node name used to identify the node associated with air exhausted out of the unit ventilator to the outdoor environment. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the unit ventilator. This input field must be left blank if the Unit ventilator is connected to a central dedicated outdoor air (DOA) via *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.3.1.13 Field: Mixed Air Node Name

This field is a node name used to identify the node associated with the “mixed” air of the unit ventilator. These conditions are post-“mixing box” since they are the conditions of the fraction of return air combined with the outdoor air. Since this is a simple system, this can also be viewed as the conditions of the air being sent to the coils. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the unit ventilator. This input field must be left blank if the Unit ventilator is connected to a central dedicated outdoor air (DOA) via *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.3.1.14 Field: Supply Air Fan Object Type

This field specifies the type of supply air fan used by this unit ventilator. The supply air fan is part of the unit ventilator compound object. The only valid supply air fan types are:

- *Fan:SystemModel*
- *Fan:OnOff*
- *Fan:ConstantVolume*
- *Fan:VariableVolume*

Note that *Fan:SystemModel* was added as of version 8.7 and is recommended for use in new models. *Fan:OnOff*, *Fan:ConstantVolume*, and *Fan:VariableVolume* may be deprecated in a future version.

#### 1.31.3.1.15 Field: Supply Air Fan Name

This field is the name of a fan (ref: *Fan:SystemModel*, *Fan:OnOff*, *Fan:ConstantVolume*, *Fan:VariableVolume*) that is part of the unit ventilator system. This name links the unit ventilator to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the unit ventilator system.

#### 1.31.3.1.16 Field: Coil Option

This field allows the user to specify the coil operating options as one of the following options: **None**, **Heating**, **Cooling** or **HeatingAndCooling**. If **None** is selected, the unit ventilator does not have any coils, and any other input will be ignored. If either **Heating** or **Cooling** is selected, only a heating or cooling coil, respectively, is present. Thus, only four more inputs will be expected. If **HeatingAndCooling** is selected, both heating and cooling coil input must be entered, and the unit ventilator will have both a heating and a cooling coil.

#### 1.31.3.1.17 Field: Supply Air Fan Operating Mode Schedule Name

This field is a schedule name (ref: Schedule) that determines the operating modes of the unit ventilator’s On:Off fan. A schedule value of 0 indicates cycling fan operation (fan cycles with cooling/heating coil). A schedule value greater than 0 (usually 1 is used) indicates constant fan operation (fan runs continually regardless of the coils operation). If this input field is left blank, then the operating mode of the On:Off fan type defaults to cycling operation.

**1.31.3.1.18 Field: Heating Coil Object Type**

This field is the type of coil that is used for heating in the unit ventilator system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. Allowable heating coil types are:

- Coil:Heating:Water
- Coil:Heating:Electric
- Coil:Heating:Fuel
- Coil:Heating:Steam

**1.31.3.1.19 Field: Heating Coil Name**

This field is the name of the heating coil that is part of the unit ventilator system. It is assumed that there is always some sort of heating coil associated with a unit ventilator system. This name links the unit ventilator to particular heating coil data entered elsewhere in the input data file.

**1.31.3.1.20 Field: Heating Convergence Tolerance**

The control tolerance for the unit heating output. This field allows the user some control over how closely the heating coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point. This field is ignored for gas and electric heating coils.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{UnitVentilator,Out} - Q_{ZoneLoad}|}{Q_{ZoneLoad}} \leq HeatingConvergenceTolerance \quad (1.128)$$

**1.31.3.1.21 Field: Cooling Coil Object Type**

This field is the type of coil that is used for cooling in the unit ventilator system. It is used in conjunction with the cooling coil name (see next field) to specify the cooling coil present within the system.

Only the following coil types can be used:

- Coil:Cooling:Water
- Coil:Cooling:Water:DetailedGeometry
- CoilSystem:Cooling:Water:HeatExchangerAssisted

**1.31.3.1.22 Field: Cooling Coil Name**

This field is the name of the cooling coil that is part of the unit ventilator system. This name links the unit ventilator to particular cooling coil data entered elsewhere in the input data file. Note that a cooling coil is not a required part of a unit ventilator system. If no cooling coil is present, the previous field may be followed by a semi-colon and the remaining parameters in this statement may be ignored.

### 1.31.3.1.23 Field: Cooling Convergence Tolerance

The convergence tolerance for the unit cooling output. This field allows the user some control over how closely the cooling coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The cooling convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{UnitVentilator,Out} - Q_{ZoneLoad}|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance \quad (1.129)$$

### 1.31.3.1.24 Field: Availability Manager List Name

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this unit ventilator object's fan. If the unit ventilator is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this unit ventilator object should be on or off.

### 1.31.3.1.25 Field: Design Specification ZoneHVAC Sizing Object Name

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Maximum Air Flow Rate in this Unit Ventilator zone HVAC object. The scaled Maximum Air Flow Rate in turn is used to size cooling and heating capacity of the unit.

An example input for a unit ventilator, including its constituent components, is shown below.

```
ZoneHVAC:UnitVentilator,

### 1.31.3.2 Outputs

- HVAC,Average,Zone Unit Ventilator Heating Rate [W]
- HVAC,Sum,Zone Unit Ventilator Heating Energy [J]
- HVAC,Average,Zone Unit Ventilator Total Cooling Rate [W]
- HVAC,Sum,Zone Unit Ventilator Total Cooling Energy [J]
- HVAC,Average,Zone Unit Ventilator Sensible Cooling Rate [W]
- HVAC,Sum,Zone Unit Ventilator Sensible Cooling Energy [J]
- HVAC,Average,Zone Unit Ventilator Fan Electricity Rate [W]
- HVAC,Sum,Zone Unit Ventilator Fan Electricity Energy [J]
- HVAC,Average,Zone Unit Ventilator Fan Availability Status []

- HVAC,Average, Zone Unit Ventilator Fan Part Load Ratio []

#### 1.31.3.2.1 Zone Unit Ventilator Heating Rate [W]

This field reports the heating output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

#### 1.31.3.2.2 Zone Unit Ventilator Heating Energy [J]

This field is the heating output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

#### 1.31.3.2.3 Zone Unit Ventilator Total Cooling Rate [W]

This field reports the total cooling (sensible plus latent) output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

#### 1.31.3.2.4 Zone Unit Ventilator Total Cooling Energy [J]

This field is the total cooling (sensible plus latent) output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

#### 1.31.3.2.5 Zone Unit Ventilator Sensible Cooling Rate [W]

This field reports the sensible cooling output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

#### 1.31.3.2.6 Zone Unit Ventilator Sensible Cooling Energy [J]

This field is the sensible cooling output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

#### 1.31.3.2.7 Zone Unit Ventilator Fan Electricity Rate [W]

This field reports the electric power consumption rate of the fan of the unit ventilator in Watts.

#### 1.31.3.2.8 Zone Unit Ventilator Fan Electricity Energy [J]

This field reports the electric power consumed by the fan of the unit ventilator over the timestep in Joules.

#### 1.31.3.2.9 Zone Unit Ventilator Fan Availability Status []

This is the availability status of the unit ventilator fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the unit ventilator object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and

CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

#### 1.31.3.2.10 Zone Unit Ventilator Fan Part Load Ratio []

This is the fan’s part load ratio for the report timestep during which the fan had operated. This variable is available for OnOff supply air fan type only.

### 1.31.4 ZoneHVAC:UnitHeater

Unit heaters are zone equipment units which are assembled from other components and are a simplification of unit ventilators. They contain only a fan and a heating coil. These components are described elsewhere in this document. The unit heater input simply requires the names of these components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, and maximum and minimum hot water volumetric flow rates. The unit is connected to the zone inlet and exhaust nodes by specifying unit inlet and outlet node names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node.

While the control of the heating coil is similar to the fan coil units and the unit ventilator, the overall control of the unit heater is much different. There are four different modes in which a unit heat can operate based on the user input:

**Off:** Unit is schedule off. All flow rates are set to zero and the temperatures are set to zone conditions.

**NoLoad OR Cooling/”No”** is specified in input field “Supply Air Fan Operation During No Heating”: Unit is available, but there is no heating load. With “No” specified for “Supply Air Fan Operation During No Heating” and the supply fan operating mode set to 0, the fan will be off since there is no heating load. All flow rates are set to zero and the temperatures are set to zone conditions.

**NoLoad OR Cooling/”Yes”** is specified in input field “Supply Air Fan Operation During No Heating”: Unit is available, the supply fan operating mode schedule value is greater than 0 (for OnOff Fan) and the fan is running (if it is scheduled to be available also). No heating is provided, only air circulation via the fan running. However, any heat added by the fan is introduced into the space with the circulation of the air.

**Heating:** The unit is on/available and there is a heating load. The heating coil is modulated (constant fan speed) to meet the heating load. When the fan type is not an OnOff fan then the control of the heating coil and its flow rate is identical to the fan coil unit. In the case of OnOff fan, the fan cycles with heating coil if the current timestep supply fan operating mode is schedule value is 0, or else if the current timestep supply fan operating mode schedule value is greater than 0, then the supply fan runs continuously for the entire timestep.

#### 1.31.4.1 Inputs

##### 1.31.4.1.1 Field: Name

This field is simply the identifying name that distinguishes one particular unit heater from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other unit heaters use this same name.

##### 1.31.4.1.2 Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the unit heater is available to operate. A schedule value greater than 0 (usually 1 is used) indicates that the component can be on during

the time period. A value less than or equal to 0 (usually 0 is used) denotes that the component must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.31.4.1.3 Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the unit heater. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit heater, the air inlet node to the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

#### 1.31.4.1.4 Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) to the unit heater. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit heater, the air outlet node from the system will typically be the same node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

#### 1.31.4.1.5 Field: Supply Air Fan Object Type

This field specifies the type of supply air fan used by this unit heater. The supply air fan is part of the unit heater compound object. The only valid supply air fan types are:

- `Fan:SystemModel`
- `Fan:OnOff`
- `Fan:ConstantVolume`
- `Fan:VariableVolume`

Note that `Fan:SystemModel` was added as of version 8.7 and is recommended for use in new models. `Fan:OnOff`, `Fan:ConstantVolume`, and `Fan:VariableVolume` may be deprecated in a future version.

#### 1.31.4.1.6 Field: Supply Air Fan Name

This field is the name of a fan (ref: `FanSystemModel`, `Fan:ConstantVolume`, `Fan:VariableVolume`) that is part of the unit heater system. This name links the unit heater to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the unit heater system.

#### 1.31.4.1.7 Field: Maximum Supply Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the unit heater system in  $\text{m}^3/\text{s}$ . This parameter should be some real number greater than zero.

#### 1.31.4.1.8 Field: Heating Coil Object Type

This field is the type of coil that is used for heating in the unit heater system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. Allowable heating coil types are:

- `Coil:Heating:Water`
- `Coil:Heating:Electric`
- `Coil:Heating:Fuel`
- `Coil:Heating:Steam`

**1.31.4.1.9 Field: Heating Coil Name**

This field is the name of the heating coil that is part of the unit heater system. It is assumed that there is always some sort of heating coil associated with a unit heater system. This name links the unit ventilator to particular heating coil data entered elsewhere in the input data file.

**1.31.4.1.10 Field: Supply Air Fan Operating Mode Schedule Name**

This field is a schedule name (ref: Schedule) that determines the operating modes of the unit heater's On:Off fan. A schedule value of 0 indicates cycling fan operation (fan cycles with cooling/heating coil). A schedule value greater than 0 (usually 1 is used) indicates constant fan operation (fan runs continually regardless of the coils operation). If this input field is left blank, then the operating mode of the On:Off fan type defaults to cycling operation.

**1.31.4.1.11 Field: Supply Air Fan Operation During No Heating**

This choice field allows the user to define how the unit heater will operate under “no heating load” or cooling conditions. The user may select from two options (“Yes”, “No”). If the “**No**” control is selected, then the fan will not run unless there is a heating load. If the fan does not run, this effectively shuts the unit heater system off. If the “**Yes**” control is selected, the unit heater is available, and the fan is continuous, then the fan will always run. This will produce air movement in the zone but also add some amount of heat to the energy balance since the fan generates some heat. But if the “**Yes**” control is selected and the “Supply Air Fan Operating Mode Schedule” values is 0 (for OnOff fan), then the fan will NOT run. This allows the user to schedule the operation of the fan when there is no load.

**1.31.4.1.12 Field: Maximum Hot Water or Steam Flow Rate**

This field allows the user to enter a maximum hot water or steam volumetric flow rate through the heating coil in  $\text{m}^3/\text{s}$ . The steam volume flow rate is calculated at 100C and 101325 Pa. This number should be some number greater than zero and greater than the minimum hot water or steam volumetric flow rate (see next field). Note that this parameter has no meaning for either an electric or a gas heating coil.

**1.31.4.1.13 Field: Minimum Hot Water or Steam Flow Rate**

This field allows the user to enter a minimum hot water or steam volumetric flow rate through the heating coil in  $\text{m}^3/\text{s}$ . The steam volume flow rate is calculated at 100C and 101325 Pa. This number should be some number greater than zero and less than the maximum hot water or steam volumetric flow rate (see previous field). Note that this parameter has no meaning for either an electric or a gas heating coil.

**1.31.4.1.14 Field: Heating Convergence Tolerance**

The convergence tolerance for the unit heating output. This field allows the user some control over how closely the heating coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point. This field is ignored for gas and electric heating coils.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit\ heater,out} - Q_{zoneload}|}{Q_{zoneload}} \leq HeatingConvergenceTolerance \quad (1.130)$$

#### 1.31.4.1.15 Field: Availability Manager List Name

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this unit heater object's fan. If the unit heater is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this unit heater object should be on or off.

#### 1.31.4.1.16 Field: Design Specification ZoneHVAC Sizing Object Name

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields *Maximum Supply Air Flow Rate* in this Unit Heater zone HVAC object. The scaled maximum supply air flow rates is used to size Maximum Hot Water or Steam Flow Rate if specified as autosize. The scaled Maximum Air Flow Rate in turn is used to size heating capacity of the unit.

An example input for a unit heater, including its constituent components, is shown below.

```

ZoneHVAC:UnitHeater,
    Zone1UnitHeat,          !- Name

### 1.31.4.2 Outputs

- HVAC,Average,Zone Unit Heater Heating Rate [W]
- HVAC,Sum,Zone Unit Heater Heating Energy [J]
- HVAC,Average,Zone Unit Heater Fan Electricity Rate [W]
- HVAC,Sum,Zone Unit Heater Fan Electricity Energy [J]
- HVAC,Average, Zone Unit Heater Fan Availability Status []
- HVAC,Average, Zone Unit Heater Fan Part Load Ratio []

#### 1.31.4.2.1 Zone Unit Heater Heating Rate [W]

This field reports the heating output rate of the unit heater system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit heater.

#### 1.31.4.2.2 Zone Unit Heater Heating Energy [J]

This field is the heating output of the unit heater system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit heater, and the timestep.

#### 1.31.4.2.3 Zone Unit Heater Fan Electricity Rate [W]

This field reports the electric power consumption rate of the fan of the unit heater in Watts.

#### 1.31.4.2.4 Zone Unit Heater Fan Electricity Energy [J]

This field reports the electric power consumed by the fan of the unit heater over the timestep in Joules.

#### 1.31.4.2.5 Zone Unit Heater Fan Availability Status []

This is the availability status of the unit heater fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the unit heater object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

#### 1.31.4.2.6 Zone Unit Heater Fan Part Load Ratio []

This is the fan’s part load ratio for the report timestep during which the fan had operated. This variable is available for OnOff supply air fan type only.

### 1.31.5 ZoneHVAC:EvaporativeCoolerUnit

The zone evaporative cooler unit is a compound object made up of a fan and one or two evaporative cooler components. This unit serves a single thermal zone as a forced-convection, cooling-only unit with supply fan. It always draws 100% of its supply air from the outside, passes the air through a supply fan and evaporative cooler(s) and then into the zone. The fan can be positioned upstream of the cooler(s) for a blow through placement. Or it can be positioned downstream of the cooler(s) for a draw through placement. If there is more than one evaporative cooler, then should be in series with the first cooler immediately upstream of the second cooler. There is an option to include a relief zone exhaust node to balance the air in the zone.

The unit can have either constant or variable speed fans. When a constant speed fan is specified and the Cooler Unit Control Method is either *ZoneTemperatureDeadbandOnOffCycling* or *ZoneCoolingLoad-OnOffCycling*, this zone unit runs just like other constant speed forced-air zone units in that its controls allow the unit to cycle based on a part-load formulation with averaged air flow rates. When a variable speed fan is specified and the Cooler Unit Control Method is *ZoneCoolingLoadVariableSpeedFan*, then the unit can modulate fan speed to meet cooling loads just like other zone HVAC units with variable speed fan.

#### 1.31.5.1 Inputs

##### 1.31.5.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a zone evaporative cooler unit. References to this unit by other objects will use this name.

##### 1.31.5.1.2 Field: Availability Schedule Name

This alpha field defines the name of a schedule that denotes whether the unit operates during a given time period. A schedule value equal to 0.0 denotes that the cooler unit must be off for that time period. A schedule value greater than 0.0 denotes that the cooler is available to operate during that time period. If this field is left blank, then the program assumes that the unit is always available as if the schedule was always set to 1.0.

##### 1.31.5.1.3 Field: Availability Manager List Name

This optional alpha input field is the name of an [AvailabilityManagerAssignmentList](#) object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this evaporative cooler unit's operation. If this field is used and the cooler unit is scheduled to be available, based on the previous input field, then the unit will operate based on the result of the availability managers in the list.

##### 1.31.5.1.4 Field: Outdoor Air Inlet Node Name

This alpha input field defines the name of the HVAC system node from which the evaporative cooler unit draws its supply air. This node is usually declared to be an outdoor air node using [OutdoorAir:Node](#) or [OutdoorAir:NodeList](#).

##### 1.31.5.1.5 Field: Cooler Outlet Node Name

This alpha input field defines the name of the HVAC system node to which the evaporative cooler sends its outlet air. This node name must be the name of a zone air inlet node (Ref. [ZoneHVAC:EquipmentConnections](#)).

**1.31.5.1.6 Field: Zone Relief Air Node Name**

This optional alpha input field defines the name of an HVAC system node which can extract air from the zone to balance the air supplied to the zone by the cooler outlet node. This node name would match the name of a zone exhaust air node.

**1.31.5.1.7 Field: Supply Air Fan Object Type**

This alpha input field defines the type of fan used by the zone evaporative cooler unit. There are five valid choices: **Fan:SystemModel**, **Fan:ComponentModel**, **Fan:ConstantVolume**, **Fan:OnOff**, or **Fan:VariableVolume**. (Note that **Fan:ConstantVolume**, **Fan:OnOff**, and **Fan:VariableVolume** may be deprecated in a future version and as of version 8.7 these are being replaced by **Fan:SystemModel**.) However the type of fan must be consistent with the control method defined below and a variable speed fan is needed with **ZoneCoolingLoadVariableSpeedFan**.

**1.31.5.1.8 Field: Supply Air Fan Name**

This alpha input field defines the user-defined name of the fan used by this cooler unit. The fan itself is defined elsewhere. Note that the fan's maximum flow rate should be greater than or equal to the Design Supply Air Flow Rate defined in the following field. For a blow-through fan placement, the fan's inlet node should be the same as the Outlet Air Inlet Node Name. For a draw-through fan placement, the fan's outlet node should be the same as the Cooler Outlet Node Name.

**1.31.5.1.9 Field: Design Supply Air Flow Rate [m<sup>3</sup>/s]**

This numeric input field defines the evaporative cooler unit's design supply air flow rate, in cubic meters per second. This value must be less than or equal to the maximum air flow rate of the fan.

**1.31.5.1.10 Field: Fan Placement**

This alpha input field defines how the supply fan is arranged. There are two choices, **BlowThrough** or **DrawThrough**. The **BlowThrough** choice indicates that the fan is located upstream of the evaporative cooler(s). The **DrawThrough** choice indicates that the fan is located downstream of the evaporative cooler(s). These are the only configurations that are available and the HVAC system nodes used as inlets and outlet in the components must be arranged consistent with the flow path.

**1.31.5.1.11 Field: Cooler Unit Control Method**

This alpha field is used to determine how the unit is to be controlled. There are three possible choices:

- **ZoneTemperatureDeadbandOnOffCycling.** This control method determines whether or not to operate the cooler based on the thermostat setpoint and the zone air temperature. This thermostatic control method uses a throttling temperature range, determined in the following input field, to model hysteresis-type control to avoid excessive short-cycling. If the zone air temperature is warmer than the cooling setpoint temperature plus one-half of the throttling range, then the unit is operated for the entire timestep at the design air mass flow rate. If the zone air temperature is cooler than the cooling setpoint temperature minus one-half of the throttling range, then the unit is off for the entire timestep. When the zone air temperatures are within the throttling range, then the unit will stay off if it was not running during the previous timestep and will stay on if it was already running. If the unit is On, then the unit is cycled such that it meets the current cooling load and avoids over-cooling the zone.
- **ZoneCoolingLoadOnOffCycling.** This control method determines whether or not to operate the cooler based on the predicted zone load to cooling setpoint. If there is a cooling load (and the unit is available), then the unit is operated for the entire timestep at the design air mass flow rate. If

there is no cooling load, then the unit is cycled at the design air mass flow rate such that it meets the current cooling load. The magnitude of the cooling load that will trigger the unit to operate can be controlled using the field below called Cooling Load Control Threshold Heat Transfer Rate.

- **ZoneCoolingLoadVariableSpeedFan.** This control method determines whether or not to operate the cooler based on the predicted zone load to cooling setpoint. If there is a cooling load (and the unit is available), then the unit is operated for the entire timestep at a fan speed that is controlled to meet the sensible cooling load (if possible). The magnitude of the cooling load that will trigger the unit to operate can be controlled using the field below called Cooling Load Control Threshold Heat Transfer Rate. This control method requires a variable speed fan and cannot be used with `Fan:ConstantVolume` or `Fan:OnOff`.

#### 1.31.5.1.12 Field: Throttling Range Temperature Difference [DeltaC]

This numeric input field defines the throttling range to use for zone-temperature based control, in degrees Celsius. This value is used when the unit's control method is `ZoneTemperatureDeadbandOnOffCycling`. This temperature range is used for hysteresis thermostatic control. It is modeled as symmetric about the cooling setpoint. The default is 1.0°C.

#### 1.31.5.1.13 Field: Cooling Load Control Threshold Heat Transfer Rate [W]

This numeric input field defines the magnitude, in Watts, of a significant zone cooling load to use with zone-load-to-setpoint based control. This value is used when the unit's control method is `ZoneCoolingLoadOnOffCycling` or `ZoneCoolingLoadVariableSpeedFan`. This is a sensible cooling load that is used as a threshold to determine when the cooling load is significant. When the predicted zone load to cooling setpoint is less than this threshold, the cooler unit's control will consider the load to be too small to trigger operation. The default is 100W.

#### 1.31.5.1.14 Field: First Evaporative Cooler Object Type

This alpha input field defines the type of evaporative cooler used in the unit. The zone evaporative cooler unit can have one or two separate cooler components and this field is for the first cooler. There are five types of evaporative cooler component models to choose from: `EvaporativeCooler:Direct:CelDekPad`, `EvaporativeCooler:Direct:ResearchSpecial`, `EvaporativeCooler:Indirect:CelDekPad`, `EvaporativeCooler:Indirect:WetCoil`, or `EvaporativeCooler:Indirect:ResearchSpecial`.

#### 1.31.5.1.15 Field: First Evaporative Cooler Object Name

This alpha input field defines the user-defined name of the first evaporative cooler component used by this zone unit. The cooler component itself is defined elsewhere. For a blow through fan placement, the inlet node for the evaporative cooler should be the same as the fan's outlet node. For a draw through fan placement, the inlet node for the evaporative cooler should be the same as the unit's Outdoor Air Inlet Node Name.

#### 1.31.5.1.16 Field: Second Evaporative Cooler Object Type

This optional alpha input field defines the type of evaporative cooler used in the unit. This field is used when the zone evaporative cooler unit has two separate evaporative cooler sections arranged in series. For example, some coolers are arranged with both direct and indirect evaporative coolers. If the unit has only one type of cooler, this field should be left blank. There are five types of evaporative cooler component models to choose from: `EvaporativeCooler:Direct:CelDekPad`, `EvaporativeCooler:Direct:ResearchSpecial`, `EvaporativeCooler:Indirect:CelDekPad`, `EvaporativeCooler:Indirect:WetCoil`, or `EvaporativeCooler:Indirect:ResearchSpecial`.

**1.31.5.1.17 Field: Second Evaporative Cooler Name**

This optional alpha input field defines the user-defined name of the second evaporative cooler component used by this zone unit. The cooler component itself is defined elsewhere. The inlet node for the second evaporative cooler should be the same as the outlet node for the first evaporative cooler. For a draw through fan placement, the outlet node for the second evaporative cooler should be the same as the unit's fan inlet node.

**1.31.5.1.18 Field: Design Specification ZoneHVAC Sizing Object Name**

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object defined elsewhere. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input field *Design Supply Air Flow Rate* in Evaportaive Cooler zone HVAC object. The scaled design supply air flow rates in turn is used to size capacity of the unit.

An example input object follows.

```
ZoneHVAC:EvaporativeCoolerUnit,
  Zone Evap Unit,           !- Name
  System Availability Schedule , !- Availability Schedule Name
  ,                          !- Availability Manager List Name

**1.31.5.2 Outputs**

- HVAC,Average,Zone Evaporative Cooler Unit Total Cooling Rate [W]
- HVAC,Sum,Zone Evaporative Cooler Unit Total Cooling Energy [J]
- HVAC,Average,Zone Evaporative Cooler Unit Sensible Cooling Rate [W]
- HVAC,Sum,Zone Evaporative Cooler Unit Sensible Cooling Energy [J]
- HVAC,Average,Zone Evaporative Cooler Unit Latent Heating Rate [W]
- HVAC,Sum,Zone Evaporative Cooler Unit Latent Heating Energy [J]
- HVAC,Average,Zone Evaporative Cooler Unit Latent Cooling Rate [W]
- HVAC,Sum,Zone Evaporative Cooler Unit Latent Cooling Energy [J]
- HVAC,Average,Zone Evaporative Cooler Unit Fan Speed Ratio []
- HVAC,Average,Zone Evaporative Cooler Unit Fan Availability Status []

**1.31.5.2.1 Zone Evaporative Cooler Unit Total Cooling Rate [W]**

This output is the total (enthalpy) heat extraction rate of the zone evaporative cooler unit from the zone it is serving, in Watts. This value is calculated using the enthalpy difference of the unit outlet air node and the zone air node and the air mass flow rate entering the zone.

**1.31.5.2.2 Zone Evaporative Cooler Unit Total Cooling Energy [J]**

This output is the total (enthalpy) heat extraction of the zone evaporative cooler unit from the zone it is serving, in Joules. This value is calculated using the enthalpy difference of the unit outlet air node and the zone air node and the air mass flow rate entering the zone.

**1.31.5.2.3 Zone Evaporative Cooler Unit Sensible Cooling Rate [W]**

This output is the moist air sensible-only heat extraction rate of the zone evaporative cooler unit from the zone it is serving, in Watts. This value is calculated using the enthalpy difference of the unit outlet air node and the zone air node based on a single, minimum humidity ratio along with the air mass flow rate entering the zone.

**1.31.5.2.4 Zone Evaporative Cooler Unit Sensible Cooling Energy [J]**

This output is the moist air sensible-only heat extraction of the zone evaporative cooler unit from the zone it is serving, in Joules. This value is calculated using the enthalpy difference of the unit outlet air node and the zone air node based on a single, minimum humidity ratio along with the air mass flow rate entering the zone.

**1.31.5.2.5 Zone Evaporative Cooler Unit Latent Heating Rate [W]**

This output is the latent heat addition (humidification) rate of the zone evaporative cooler unit to the zone it is serving in Watts. This value is calculated as the difference between the total cooling rate and the sensible cooling rate. Because an evaporative cooler can provide sensible cooling while adding moisture the zone air, a unit can operate with both a positive sensible cooling load and a positive latent heating rate.

**1.31.5.2.6 Zone Evaporative Cooler Unit Latent Heating Energy [J]**

This output is the latent heat addition (humidification) of the zone evaporative cooler unit to the zone it is serving in Joules. This value is calculated as the difference between the total cooling energy and the sensible cooling energy.

**1.31.5.2.7 Zone Evaporative Cooler Unit Latent Cooling Rate [W]**

This output is the latent heat extraction (dehumidification) rate of the zone evaporative cooler unit to the zone it is serving in Watts. This value is calculated as the difference between the total cooling rate and the sensible cooling rate.

**1.31.5.2.8 Zone Evaporative Cooler Unit Latent Cooling Energy [J]**

This output is the latent heat extraction (dehumidification) of the zone evaporative cooler unit to the zone it is serving in Joules. This value is calculated as the difference between the total cooling energy and the sensible cooling energy.

**1.31.5.2.9 Zone Evaporative Cooler Unit Fan Speed Ratio []**

This output is the speed ratio of the fan for the zone evaporative cooler unit. The speed ratio is defined as the current supply air mass flow rate divided by the design air mass flow rate.

#### 1.31.5.2.10 Zone Evaporative Cooler Unit Fan Availability Status []

This output is the availability status of the zone evaporative cooler unit's fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the zone evaporative cooler object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific manager. For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager)), rules to determine fan availability status are described in the section on system availability managers. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn(2), and CycleOneZoneFansOnly (3). It is recommend to report this output at the “Detailed” frequency because the integer status flags do not average out to meaningful values.

### 1.31.6 ZoneHVAC:OutdoorAirUnit

The zone outdoor air unit (ZoneHVAC:OutdoorAirUnit) in EnergyPlus is intended to model dedicated outdoor air systems (DOAS) and other similar systems which aim to provide either additional outside air or some limited amount of sensible and/or latent conditioning. The zone outdoor air unit is a piece of zone equipment that can consist of a supply fan, an exhaust fan (optional), heating and cooling coils, and heat recovery. The outdoor air unit input simply requires information about flow rates, schedules, node names, and a list of component that are part of the unit. These components require additional input as per the requirements for these components. In addition, the input includes information about controls for the unit. It should be noted that the components that make up the zone outdoor air unit do not require additional controls or setpoints. The unit input defines how the unit outlet temperature is controlled as described below.

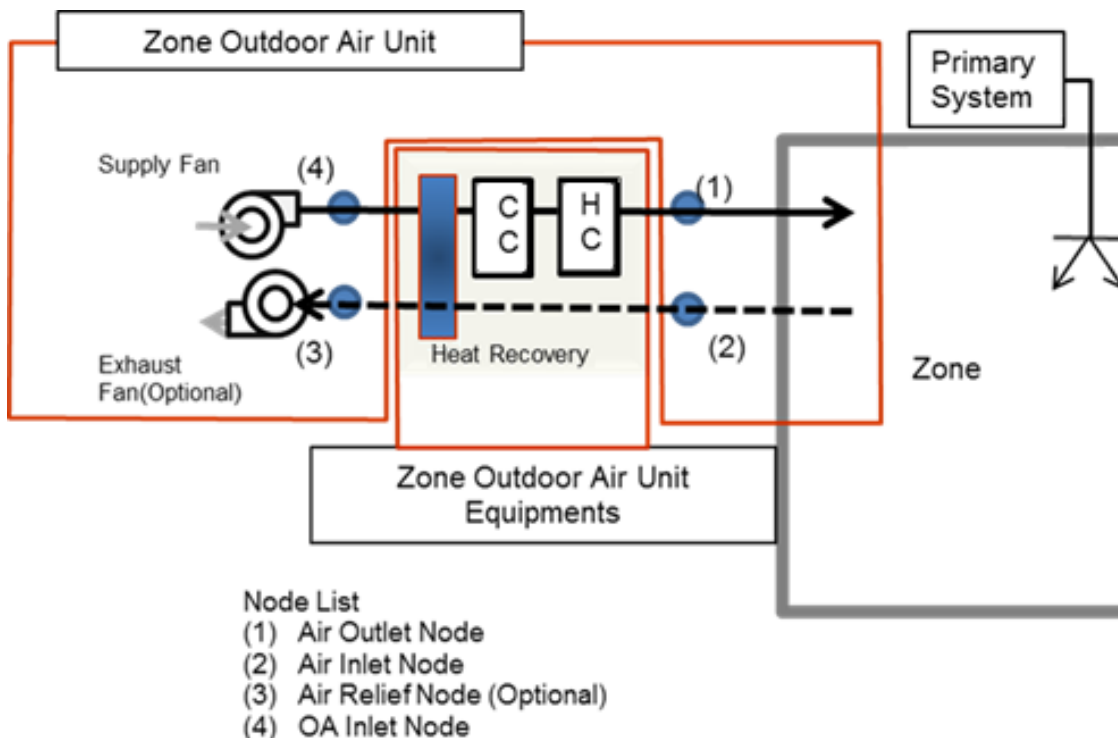

Figure 1.131: Zone Outdoor Air Unit Schematic

When an AirloopHVAC serves the same zone, it is strongly recommended that the outdoor and exhaust air flow rates are balanced. In addition, the exhaust airflow rate and air schedule should be the same as outdoor air flow rate and outdoor air schedule, respectively. Otherwise, possible unbalanced flows will cause improper return airflow unless **ZoneAirMassFlowConservation** is active.

The full input for zone outdoor air units is described below using a variety of fields.

### 1.31.6.1 Inputs

#### 1.31.6.1.1 Field: Name

This field is simply the identifying name that distinguishes one particular outdoor air unit from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other zone outdoor air units use this same name.

#### 1.31.6.1.2 Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the zone outdoor air unit is available to operate. A schedule value greater than 0 (usually 1 is used) indicates that the outdoor air unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the outdoor air unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods. For any schedule value greater than zero, the outdoor air unit is considered available and will operate at the supply and exhaust flow rates defined by input field described below.

#### 1.31.6.1.3 Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the outdoor air unit is located and intended to affect. Zone outdoor air units impact only a single zone.

#### 1.31.6.1.4 Field: Outdoor Air Flow Rate

This field allows the user to enter the volumetric flow rate of outdoor air (in m<sup>3</sup>/sec) that will be brought in through the outdoor air unit. The actual outdoor air flow rate will be this number multiplied by the schedule value from the outdoor air schedule. This field is autosizable. When autosized, the unit's outdoor air flow rate will match the minimum outdoor air requirements specified through the **Sizing:Zone** object.

#### 1.31.6.1.5 Field: Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that contains values for modifying the outdoor air flow rate. The supply air flow rate is the product of the outdoor air flow rate and the outdoor air schedule value for the time of interest. Note that if the outdoor air unit is scheduled off that the system will not operate regardless of the outdoor air schedule value. However, if the system is operating, it will always bring in this fraction of the outdoor air flow rate.

#### 1.31.6.1.6 Field: Supply Fan Name

This field is the name of a fan (ref: **Fan:SystemModel**, **Fan:ConstantVolume**, **Fan:VariableVolume**) that is part of the zone outdoor air unit. This name links the outdoor air unit to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the outdoor air control unit.

#### 1.31.6.1.7 Field: Fan Placement

This field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. It means that the unit consists of outdoor air node followed by a supply fan followed by the

equipment that are part of the system. The second choice stands for “draw through fan”. It means that the supply fan placed at the end of supply air stream and supply fan outlet node is identified with the air outlet node. The fan “draws air through” the equipment system.

- BlowThrough
- DrawThrough

If the user does not select a fan placement type, **DrawThrough** is assumed as default by EnergyPlus.

#### 1.31.6.1.8 Field: Exhaust Fan Name

This field is the name of a fan (ref: **Fan:SystemModel**, **Fan:ConstantVolume**, **Fan:VariableVolume**) that is part of the outdoor air unit. This name links the outdoor air unit to particular fan data entered elsewhere in the input data file. This field is optional.

#### 1.31.6.1.9 Field: Exhaust Air Flow Rate

This field allows the user to enter the volumetric flow rate of air (in m<sup>3</sup>/sec) that will be exhausted to the outdoors. The actual exhaust air flow rate will be this number multiplied by the schedule value from the exhaust air schedule. If the exhaust fan name is left blank, this field will be ignored and automatically set to be equal to zero.

#### 1.31.6.1.10 Field: Exhaust Air Schedule Name

This field contains a schedule name (ref: **Schedule**) that should contain values for modifying the exhaust air flow rate. The actual exhaust air flow rate equals the exhaust air flow rate input (previous field) multiplied by the exhaust air schedule value. If the exhaust fan name is left blank, this field will be ignored and automatically set to be equal to zero.

#### 1.31.6.1.11 Field: Unit Control Type

The unit control type field determines with conditions in the zone being served what the response of the zone outdoor air system will be. It is important to note that this only controls the temperature of the air being delivered to the space not whether or not the system will operate. There are two options for this field: **Neutral** or **Temperature**. **Neutral** control tries to have no energy impact on the zone by delivering air at the temperature of the zone. This allows air to be delivered to the zone without affecting the zone air heat balance and thus provides outside air without impacting any other system providing conditioning to this zone. The **temperature** control option will supply air to the zone based on the high and low air control temperature schedules (see next two fields). For **temperature** control, when the outside air temperature is less than the low air control temperature, the zone outdoor air unit will provide whatever heating is available from its components to achieve the low air temperature value. When the outside air temperature is above the high air control temperature, the zone outdoor air unit will provide whatever cooling is available from its components to achieve the high air temperature value. When the outdoor air temperature is between the high and low air control temperatures, the unit will simply provide air at whatever the outdoor air conditions are, modified by any fan heat added by the supply fan. In summary, the user must select from the following two options:

- NeutralControl
- TemperatureControl

If the user does not select a unit control type, **NeutralControl** is assumed as the default by EnergyPlus.

#### 1.31.6.1.12 Field: High Air Control Temperature Schedule Name

This field specifies the dry-bulb air temperature in degrees Celsius for the supply air temperature to the zone. When the outdoor air temperature or post-supply fan outlet temperature in the case of blow through is above the high air control temperature, a cooling coil, if available and specified by the user, is tuned on to conditioning the outdoor air to the high control temperature. This field only applies to zone outdoor air units that use Temperature Control (see previous field).

#### 1.31.6.1.13 Field: Low Air Control Temperature Schedule Name

This field specifies the dry-bulb air temperature in degrees Celsius for the supply air temperature to the zone. When the outdoor air temperature or post-supply fan outlet temperature is below the low air control temperature, a heating coil, if available and specified by the user, is tuned on to conditioning the outdoor air to the low control temperature. This field only applies to zone outdoor air units that use Temperature Control (see two previous fields).

#### 1.31.6.1.14 Field: Outdoor Air Node Name

This field is a node name used to identify the node associated with fresh air brought into the outdoor air unit from the outdoor environment. It should also be defined in an **OutdoorAir:Node** object with the same name and assigned an optional height (above ground).

#### 1.31.6.1.15 Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) from the zone outdoor air unit. In EnergyPlus, nodes represent points between components or at various points in the loops. In an outdoor air unit, the air outlet node from the system will typically be the same node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

#### 1.31.6.1.16 Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the exhaust side of the outdoor air unit. In EnergyPlus, nodes represent points between components or at various points in the loops. In an outdoor air unit, the air inlet node of the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

#### 1.31.6.1.17 Field: Supply Fan Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) of the supply fan for the zone outdoor air unit. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

#### 1.31.6.1.18 Field: Outdoor Air Unit List Name

This field is the name of an **ZoneHVAC:OutdoorAirUnit:EquipmentList** object. An **ZoneHVAC:OutdoorAirUnit:EquipmentList** is simply a list of components giving both component name and type. This equipment list specifies all the components that will be simulated in this unit. The order of the components in the list is significant: components are simulated sequentially in the order given in the Equipment List.

### 1.31.6.1.19 Field: Availability Manager List Name

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this outdoor air unit object's fan. If the outdoor air unit is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this outdoor air unit object should be on or off.

An example of this object defined in an input data file is shown below:

```
ZoneHVAC:OutdoorAirUnit,
  Zone5DXOutAir,          !- Name
  OASched,                !- Availability Schedule Name

- HVAC,Sum, Zone Outdoor Air Unit Fan Electricity Energy [J]
- HVAC,Average, Zone Outdoor Air Unit Air Mass Flow Rate [kg/s]
- HVAC,Average, Zone Outdoor Air Unit Fan Availability Status []
- Zone Outdoor Air Unit Latent Cooling Energy

#### 1.31.6.2.1 Zone Outdoor Air Unit Total Heating Rate [W]

This field reports the heating output rate of the outdoor air unit system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the zone outdoor air unit.

**1.31.6.2.2 Zone Outdoor Air Unit Total Heating Energy [J]**

This field is the heating output of the outdoor air unit system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

**1.31.6.2.3 Zone Outdoor Air Unit Total Cooling Rate [W]**

This field reports the total cooling (sensible plus latent) output rate of the outdoor air unit system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the zone outdoor air unit.

**1.31.6.2.4 Zone Outdoor Air Unit Total Cooling Energy [J]**

This field is the total cooling (sensible plus latent) output of the outdoor air unit system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

**1.31.6.2.5 Zone Outdoor Air Unit Sensible Cooling Energy [J]****1.31.6.2.6 Zone Outdoor Air Unit Sensible Cooling Rate [W]**

These reports are the sensible cooling output rate of the outdoor air unit system to the zone it is serving in Joules or Watts. This is determined by outlet and zone air conditions and the mass flow rate through the zone outdoor air unit.

**1.31.6.2.7 Zone Outdoor Air Unit Sensible Heating Energy [J]****1.31.6.2.8 Zone Outdoor Air Unit Sensible Heating Rate [W]**

These are the sensible heating output of the outdoor air unit system to the zone it is serving in Joules or Watts over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

**1.31.6.2.9 Zone Outdoor Air Unit Latent Cooling Energy [J]****1.31.6.2.10 Zone Outdoor Air Unit Latent Cooling Rate [W]**

These are the latent cooling output of the outdoor air unit system to the zone it is serving, in Joules and Watts. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

**1.31.6.2.11 Zone Outdoor Air Unit Latent Heating Energy [J]****1.31.6.2.12 Zone Outdoor Air Unit Latent Heating Rate [W]**

These are the latent heating output of the outdoor air unit system to the zone it is serving, in Joules and Watts. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

**1.31.6.2.13 Zone Outdoor Air Unit Fan Electricity Rate [W]**

This field reports the electric power consumption rate of the fan of the outdoor air unit in Watts.

**1.31.6.2.14 Zone Outdoor Air Unit Fan Electricity Energy [J]**

This field reports the electric power consumed by the fan of the outdoor air unit over the time step in Joules.

**1.31.6.2.15 Zone Outdoor Air Unit Air Mass Flow Rate [kg/s]**

This field reports the air mass flow rate of the zone outdoor air unit Outdoor Air Unit in kilograms per second.

**1.31.6.2.16 Zone Outdoor Air Unit Fan Availability Status []**

This is the availability status of the outdoor air unit fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the outdoor air unit object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

**1.31.7 ZoneHVAC:OutdoorAirUnit:EquipmentList**

This input syntax is used to specify the components in a zone outdoor air unit. The components will be simulated in the order in which they occur in this list.

**1.31.7.1 Inputs****1.31.7.1.1 Field: Name**

The user designated unique name of an instance of a zone outdoor air unit equipment list.

**1.31.7.1.2 Field Set (Component Object Type, Component Name, Control Node Name) up to 8**

After the identifying name, the list consists of up to 8 pairs of data items.

**1.31.7.1.3 Field: Component <x> Object Type**

This field specifies the keyword for the type of component used.

**1.31.7.1.4 Field: Component <x> Name**

This field is the unique name of the component specified in the previous field. This named object must appear in the IDF.

Note: If any of the components use the autosized option at the component level, input data for zone sizing purposes are required for the proper sizing of the components. Please refer to the [Sizing:Zone](#) object for more information.

An example from an IDF:

```

ZoneHVAC:OutdoorAirUnit:EquipmentList,
    Zone50AUEquip1,           !- Name
    Dehumidifier:Desiccant:NoFans, !- Component 1 Object Type
    Z5Dessicant,              !- Component 1 Name
    HeatExchanger:AirToAir:FlatPlate, !- Component 2 Object Type
    Zone5A2AHeat Recovery,    !- Component 2 Name
    CoilSystem:Cooling:DX,    !- Component 3 Object Type
    DX Cooling Coil System 5, !- Component 3 Name
    Coil:Heating:Electric,    !- Component 4 Object Type
    Zone5DESHCoil;           !- Component 4 Name

```

---

### 1.31.8 ZoneHVAC:WindowAirConditioner

The Window Air Conditioner is a unit of zone equipment made up of other components. Each window air conditioner consists of an outdoor air mixer, a fan, and a direct expansion (DX) cooling coil. These components are described elsewhere in this document. The input for a window air conditioner requires the names of these three pieces of equipment, which are then specified individually elsewhere in the input. The input for a window air conditioner also requires the name of an availability schedule, the maximum unit airflow rate, and the maximum outdoor airflow rate for the unit. The unit is connected to a zone by specifying an air inlet node, which must be the same as a zone exhaust node; and an air outlet node, which must be the same as a zone inlet node (ref. [ZoneHVAC:EquipmentConnections](#)).

A supply air fan operating mode schedule must also be specified. The supply air fan operating mode schedule value determines if the supply air fan can run continuously with the DX coil cycling on/off to match the zone cooling demand or the fan and DX coil can cycle on/off together to meet the cooling demand. The placement of the supply air fan, in relation to the DX coil, must also be specified (blow through or draw through). The cooling convergence tolerance is required, which is the tolerance denoting how closely the window air conditioner will meet the cooling load. The tolerance is always relative to the zone load (i.e., the unit will operate to meet the zone load to within the tolerance value times the zone load for each simulation timestep). Finally, the DX cooling coil type must be specified.

#### 1.31.8.1 Inputs

##### 1.31.8.1.1 Field: Name

A unique user assigned name for an instance of a window air conditioner unit. Any reference to this window air conditioner by another object will use this name.

##### 1.31.8.1.2 Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the window air conditioner unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.31.8.1.3 Field: Maximum Supply Air Flow Rate

The maximum volumetric airflow rate through the window air conditioner in cubic meters per second. Since the unit operates by cycling on/off, this is also the design, rated airflow rate of the unit.

##### 1.31.8.1.4 Field: Maximum Outdoor Air Flow Rate

If the window air conditioner uses outdoor air, this field specifies the outdoor air volumetric flow rate in cubic meters per second. This flow rate should be less than or equal to the maximum airflow rate. A value of zero specifies no outdoor air. Note that the outdoor airflow rate is fixed: it cannot change during the simulation

**1.31.8.1.5 Field: Air Inlet Node Name**

The name of the HVAC system node (see Node) from which the window air conditioner draws its indoor air. This should be one of the zone exhaust nodes for the zone which the window air conditioner is cooling.

**1.31.8.1.6 Field: Air Outlet Node Name**

The name of the HVAC system node (see Node) to which the window air conditioner sends its outlet air. This should be one of the inlet air nodes for the zone which is being cooled.

**1.31.8.1.7 Field: Outdoor Air Mixer Object Type**

This field specifies the type of outdoor air mixer used by this window air conditioner unit. The outdoor air mixer component is part of the window air conditioner compound object. The only available outdoor air mixer type is:

**OutdoorAir:Mixer**

**1.31.8.1.8 Field: Outdoor Air Mixer Name**

The name of an outdoor air mixer component which composes part of the window air conditioner unit. Note that the return air node of the outdoor air mixer should be the same node as the air inlet node of the window air conditioner. In addition, the outdoor air mixer's mixed air node should be the same as the window air conditioner's fan inlet air node (for blow through) or the air conditioner's DX coil inlet node (for draw through)

**1.31.8.1.9 Field: Supply Air Fan Object Type**

This field specifies the type of supply air fan used by window air conditioner. The supply air fan is part of the window air conditioner compound object. The only valid supply air fan types are:

- **Fan:SystemModel**
- **Fan:OnOff**
- **Fan:ConstantVolume**

Note that **Fan:SystemModel** was added as of version 8.7 and is recommended for use in new models. **Fan:OnOff** and **Fan:ConstantVolume** may be deprecated in a future version.

**1.31.8.1.10 Field: Supply Air Fan Name**

The name of the fan component that composes part of the window air conditioner. Note that the fan's maximum flow rate should be the same as the maximum airflow rate of the window air conditioner. A fan of type **Fan:SystemModel** or **Fan:OnOff** may be used with either cycling or continuous fan, and a fan of type **Fan:ConstantVolume** is used only with continuous fan (see Supply Air Fan Operating Mode Schedule field below). The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through) or the DX coil's outlet node (for draw through). The fan's outlet node should be the same as the DX coil's air inlet node (for blow through) or the window air conditioner's air outlet node (for draw through).

#### 1.31.8.1.11 Field: Cooling Coil Object Type

This field specifies the type of cooling coil to be modeled for this window air conditioner. The input requirements for these cooling coil objects are described elsewhere in this document. If the user wants to control the enhanced dehumidification performance of the Heat Exchanger Assisted coil type based on zone air humidity level, then the input file must include a humidistat object (ref. [ZoneControl:Humidistat](#)) for the zone being served by this air conditioner and a high humidity set point manager (ref. [SetpointManager:SingleZone:Humidity:Maximum](#)) with the high humidity set point placed on the outlet node of the heat exchanger assisted cooling coil. Only allowable coil types are:

- [Coil:Cooling:DX:SingleSpeed](#)
- [Coil:Cooling:DX:VariableSpeed](#)
- [CoilSystem:Cooling:DX:HeatExchangerAssisted](#)

#### 1.31.8.1.12 Field: DX Cooling Coil Name

The name of a DX cooling coil component that composes part of the window air conditioner unit. The DX coil air inlet node should be the same as the fan outlet node (for blow through) or the outdoor air mixer's mixed air node (for draw through). The DX coil air outlet node should be the same as the window air conditioner's air outlet node (for blow through) or the fan's inlet node (for draw through).

#### 1.31.8.1.13 Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation.

#### 1.31.8.1.14 Field: Fan Placement

This input field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of an outdoor air mixer followed by a fan followed by a DX coil. The fan “blows through” the DX coil. The second choice stands for “draw through fan”. This means that the unit consists of an outdoor air mixer followed by a DX coil followed by a fan. The fan “draws air through” the coil.

#### 1.31.8.1.15 Field: Cooling Convergence Tolerance

This input field defines the convergence tolerance for the unit's cooling output. This field allows the user some control over how closely the air conditioner will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The window air conditioner is controlled by matching its sensible (temperature) cooling output to the zone sensible load (demand). Because the performance of the DX coil is frequently non-linear, the air conditioner model must call the DX coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The cooling convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|Q_{ZoneLoad} - Q_{WindowAirConditioner,out})|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance \quad (1.131)$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

#### 1.31.8.1.16 Field: Availability Manager List Name

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this window air conditioner or object's fan. If the window air conditioner is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this window air conditioner object should be on or off.

#### 1.31.8.1.17 Field: Design Specification ZoneHVAC Sizing Object Name

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Maximum Air Flow Rate in this Window Air Conditioner zone HVAC object. The scaled Maximum Air Flow Rate in turn is used to size cooling capacity of the unit.

Following is an example input for the cycling window air conditioner, along with its constituent components.

```

### 1.31.8.2 Outputs

- HVAC,Average,Zone Window Air Conditioner Total Cooling Rate [W]
- HVAC,Sum,Zone Window Air Conditioner Total Cooling Energy [J]
- HVAC,Average,Zone Window Air Conditioner Sensible Cooling Rate [W]
- HVAC,Sum,Zone Window Air Conditioner Sensible Cooling Energy [J]
- HVAC,Average,Zone Window Air Conditioner Latent Cooling Rate [W]
- HVAC,Sum,Zone Window Air Conditioner Latent Cooling Energy [J]
- HVAC,Average,Zone Window Air Conditioner Electricity Rate [W]
- HVAC,Sum,Zone Window Air Conditioner Electricity Energy [J]
- HVAC,Average, Zone Window Air Conditioner Fan Part Load Ratio []
- HVAC,Average, Zone Window Air Conditioner Compressor Part Load Ratio []
- HVAC,Average,Zone Window Air Conditioner Fan Availability Status []

#### 1.31.8.2.1 Zone Window Air Conditioner Total Cooling Rate [W]

This field is the total (sensible and latent) heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

#### 1.31.8.2.2 Zone Window Air Conditioner Total Cooling Energy [J]

This is the total (sensible and latent) heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

**1.31.8.2.3 Zone Window Air Conditioner Sensible Cooling Rate [W]**

This field reports the moist air sensible heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

**1.31.8.2.4 Zone Window Air Conditioner Sensible Cooling Energy [J]**

This field reports the moist air sensible heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

**1.31.8.2.5 Zone Window Air Conditioner Latent Cooling Rate [W]**

This output is the latent heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

**1.31.8.2.6 Zone Window Air Conditioner Latent Cooling Energy [J]**

This is the latent heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

**1.31.8.2.7 Zone Window Air Conditioner Electricity Rate [W]**

This output is the electricity consumption rate of the window air conditioner unit in Watts. The consumption includes electricity used by the compressor and the fans (indoor supply air fan and the condenser fan).

**1.31.8.2.8 Zone Window Air Conditioner Electricity Energy [J]**

This output is the electricity consumption of the window air conditioner unit in Joules for the time period being reported. The consumption includes electricity used by the compressor and the fans (indoor supply air fan and the condenser fan).

**1.31.8.2.9 Zone Window Air Conditioner Fan Part Load Ratio []**

This is the fan's part load ratio for the report timestep during which the fan had operated.

**1.31.8.2.10 Zone Window Air Conditioner Compressor Part Load Ratio []**

This is the part load ratio of the report timestep during which the DX unit compressor had operated.

***Zone Window Air Conditioner Fan Availability Status []***

This is the availability status of the window air conditioner fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the window air conditioner object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used.

Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

### 1.31.9 ZoneHVAC:PackagedTerminalAirConditioner

The packaged terminal air conditioner (PTAC) is a compound object made up of other components. Each PTAC consists of an outdoor air mixer, direct expansion (DX) cooling coil, heating coil (gas, electric, hot water, or steam) and a supply air fan. While the figure below shows the PTAC with draw through fan placement, blow through fan placement can also be modeled by positioning the supply air fan between the outdoor air mixer and the DX cooling coil. The packaged terminal air conditioner coordinates the operation of these components and is modeled as a type of zone equipment (Ref. [ZoneHVAC:EquipmentList](#) and [ZoneHVAC:EquipmentConnections](#)).

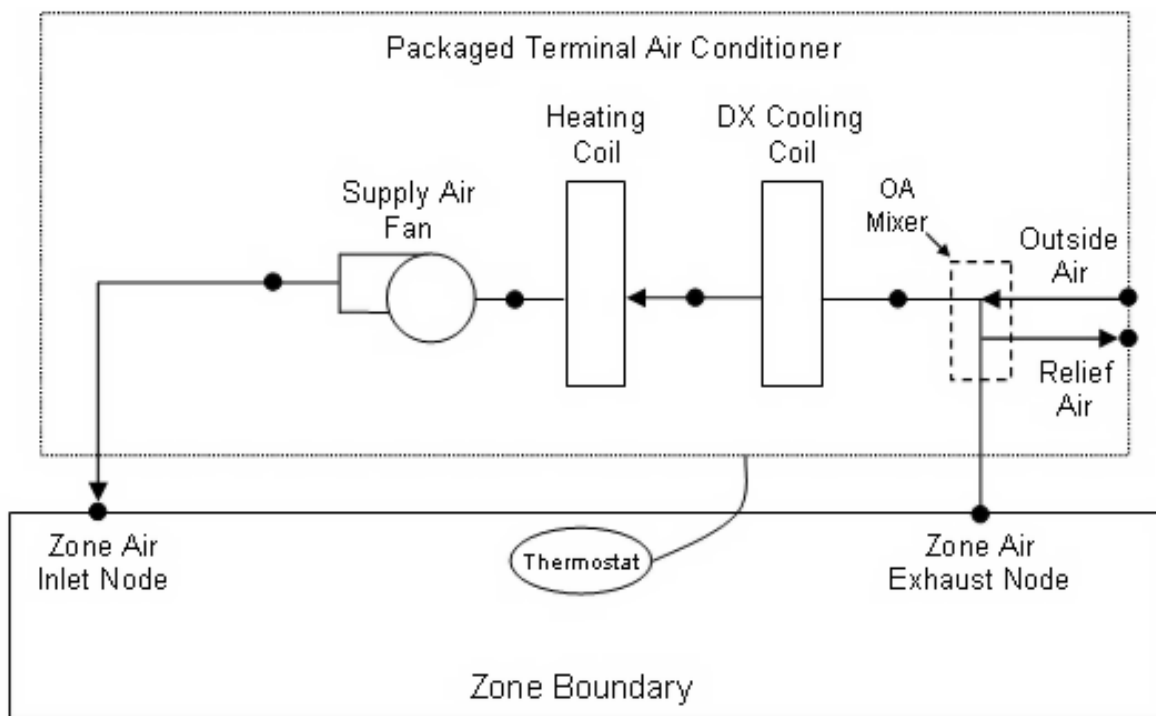

Figure 1.132: Schematic of a packaged terminal air conditioner with draw through fan placement

Links to the PTAC’s supply air fan, DX cooling coil, heating coil, and outdoor air mixer specifications are provided in the air conditioner’s input syntax. Additional inputs include supply and outdoor air flow rates during cooling operation, heating operation, and when neither cooling or heating is required. A description of each input field for the packaged terminal air conditioner compound object is provided below.

#### 1.31.9.1 Inputs

##### 1.31.9.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a packaged terminal air conditioner. Any reference to this air conditioner by another object will use this name.

#### 1.31.9.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the air conditioner operates during a given time period. A schedule value equal to 0 denotes that the air conditioner must be off for that time period. A value greater than 0 denotes that the air conditioner is available to operate during that time period. This schedule may be used to completely disable the air conditioner (all of its coils and the supply air fan) as required. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.31.9.1.3 Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the air conditioner draws its inlet air. This node name must be the name of a zone air exhaust node (Ref. *ZoneHVAC:EquipmentConnections*).

#### 1.31.9.1.4 Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the air conditioner sends its outlet air. This node name must be the name of a zone air inlet node (Ref. *ZoneHVAC:EquipmentConnections*).

#### 1.31.9.1.5 Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this PTAC. The outdoor air mixer component is part of the PTAC unit. The only available outdoor air mixer type is:

- *OutdoorAir:Mixer*

This input field should be left blank when the PTAC is connected to an *AirTerminal:SingleDuct:Mixer* object. If this field is left blank, an outdoor air mixer object is not simulated.

#### 1.31.9.1.6 Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the PTAC. The return air node of the outdoor air mixer should also be the same node as the air inlet node of the PTAC. Furthermore, the outdoor air mixer's mixed air node should be the same as the PTAC's fan inlet air node (for blow through fan placement) or the PTAC's DX cooling coil inlet node (for draw through fan placement). This field should be left blank when the PTAC is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.9.1.7 Field: Cooling Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

#### 1.31.9.1.8 Field: Heating Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when the heating coil is operating. Values must be greater than 0 or this field is autosizable.

#### 1.31.9.1.9 Field: No Load Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the air conditioner's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this

value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

#### 1.31.9.1.10 Field: Cooling Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the Cooling Outdoor Air Flow Rate is fixed; it cannot change during the simulation. In addition, the Cooling Outdoor Air Flow Rate cannot be greater than the air conditioner's supply air volumetric flow rate during cooling operation. This field is set to zero flow when the PTAC is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.9.1.11 Field: Heating Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when the heating coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the Heating Outdoor Air Flow Rate is fixed; it cannot change during the simulation. In addition, the Heating Outdoor Air Flow Rate cannot be greater than the air conditioner's supply air volumetric flow rate during heating operation. This field is set to zero flow when the PTAC is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.9.1.12 Field: No Load Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when neither cooling nor heating is required (i.e., cooling and heating coils are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate when no cooling/heating is needed cannot be greater than the air conditioner's supply air volumetric flow rate when no cooling/heating is needed. This field is only used when the air conditioner's supply air fan operating mode schedule specifies continuous fan operation. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and the field 'Supply air volumetric flow rate when no cooling or heating is needed' is set to zero or is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Cooling Outdoor Air Flow Rate] or heating operation [i.e., Heating Outdoor Air Flow Rate]) and this field is not used. This input field is set to zero flow when the PTAC is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.9.1.13 Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this PTAC. The only valid choices are **Fan:SystemModel**, **Fan:OnOff**, and **Fan:ConstantVolume**. A fan of type **Fan:SystemModel** or **Fan:OnOff** is used with cycling fan operating mode, and a fan of type **Fan:SystemModel** or **Fan:ConstantVolume** is used with continuous fan operating mode (see Supply Air Fan Operating Mode Schedule field below). The input requirements for these fan objects are described elsewhere in this document. Note that **Fan:SystemModel** was added as of version 8.7 and is recommended for use in new models. **Fan:OnOff** and **Fan:ConstantVolume** may be deprecated in a future version.

#### 1.31.9.1.14 Field: Supply Air Fan Name

The name of a constant volume fan component that composes part of the PTAC. Note that the fan's maximum flow rate should be greater than or equal to the maximum supply air flow rate for the PTAC.

The fan’s inlet node should be the same as the outdoor air mixer’s mixed air node (for blow through fan placement) or the heating coil’s outlet node (for draw through fan placement). The fan’s outlet node should be the same as the DX cooling coil’s air inlet node (for blow through fan placement) or the PTAC’s air outlet node (for draw through fan placement).

#### 1.31.9.1.15 Field: Heating Coil Object Type

This alpha field defines the type of heating coil to be used by this PTAC. The input requirements for this heating coil object are described elsewhere in this document. The hot water flow modulation through the heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (PTAC) itself provides the “controller” function of modulating water flow. Allowable heating coil types are:

- **Coil:Heating:Water**
- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Steam**

#### 1.31.9.1.16 Field: Heating Coil Name

This alpha field defines the name of the heating coil used by this PTAC, and this name should match the name specified in the corresponding heating coil object.

#### 1.31.9.1.17 Field: Cooling Coil Object Type

This alpha field defines the type of DX cooling coil used by this PTAC. The input requirements for these DX cooling coil objects are described elsewhere in this document. Only allowable coil types are:

- **Coil:Cooling:DX:SingleSpeed**
- **CoilSystem:Cooling:DX:HeatExchangerAssisted**
- **Coil:Cooling:DX:VariableSpeed**

#### 1.31.9.1.18 Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this PTAC, and this name should match the name specified in the corresponding DX cooling coil object.

#### 1.31.9.1.19 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of an outdoor air mixer followed by a fan followed by the DX cooling coil and heating coil. The fan “blows through” the DX cooling coil and the heating coil. The second choice stands for “draw through fan”. This means that the unit consists of an outdoor air mixer followed by the DX cooling coil and heating coil with the fan located at the outlet of the PTAC. The fan “draws air through” the DX cooling coil and the heating coil. If this field is left blank, the default is draw through.

Note: the packaged terminal air conditioner’s supply air fan, cooling coil and heating coil must be connected according to the configuration shown above (Figure 1.132) for the draw through fan configuration. The only other valid configuration is with a blow through fan placement, where the fan is located between the outdoor air mixer and the DX cooling coil.

#### 1.31.9.1.20 Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

#### 1.31.9.1.21 Field: Availability Manager List Name

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this packaged terminal air conditioner or object's fan. If the packaged terminal air conditioner is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this packaged terminal air conditioner object should be on or off.

#### 1.31.9.1.22 Field: Design Specification ZoneHVAC Sizing Object Name

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Cooling Supply Air Flow Rate in this Packaged Terminal Air Conditioner zone HVAC object. The scaled Supply Air Flow Rate in turn is used to size cooling and heating capacity of the unit.

#### 1.31.9.1.23 Field: Capacity Control Method

This input denotes how the unit's output is controlled in order to meet zone heating or cooling requirement. The choices are **None** or **SingleZoneVAV**. For **None**, the unit varies the fan and/or coil speed to meet the load. If constant fan operating mode is selected the fan operates at the design cooling or heating air flow rate while the coil modulates to meet the load. If cycling fan operating mode is selected the fan and coil modulate in unison to meet the load. For **SingleZoneVAV**, the fan air flow rate is reduced to the no load supply air flow rate when the zone sensible load is low such that the maximum supply air temperature limit is not exceeded. If the unit cannot meet the load at this lower air flow rate, the fan speed increases while maintaining the maximum supply air temperature. If the unit still cannot meet the load the unit will operate at the maximum supply air flow rate and the maximum supply air temperature limit can be exceeded. Supply air temperature limits are identified in the input fields for Minimum Supply Air Temperature in Cooling Mode and Maximum Supply Air Temperature in Heating Mode. Additionally, specific coil types are required for the SingleZoneVAV capacity control method. The cooling coil type is **Coil:Cooling:DX:SingleSpeed** while the heating coil types are **Coil:Heating:Water**, **Coil:Heating:Fuel** and **Coil:Heating:Electric**. If alternate coil types are used they are modeled using the load based control method.

#### 1.31.9.1.24 Field: Minimum Supply Air Temperature in Cooling Mode

When Capacity Control Method = SingleZoneVAV, enter the minimum air temperature limit for reduced fan speed in cooling mode. For SingleZoneVAV, this field's minimum supply air temperature is 0.0°C. This field is autosizable and the default is autosize.

#### 1.31.9.1.25 Field: Maximum Supply Air Temperature in Heating Mode

When Capacity Control Method = SingleZoneVAV, enter the maximum air temperature limit for reduced fan speed in heating mode. For SingleZoneVAV, this field's minimum supply air temperature is 0.0°C. This field is autosizable and the default is autosize.

As shown in the example below, correct specification of the packaged terminal air conditioner requires the following objects in addition to the compound object itself:

- 1) Fan (**Fan:OnOff** or **Fan:ConstantVolume**)
- 2) DX cooling coil (**Coil:Cooling:DX:SingleSpeed** or **CoilSystem:Cooling:DX:HeatExchangerAssisted**)
- 3) Heating coil (**Coil:Heating:Fuel**, **Coil:Heating:Electric**, **Coil:Heating:Water**, or **Coil:Heating:Steam**)
- 4) **OutdoorAir:Mixer**

**1.31.9.2.1 Zone Packaged Terminal Air Conditioner Total Heating Rate [W]**

This output field is the total (enthalpy) heat addition rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

**1.31.9.2.2 Zone Packaged Terminal Air Conditioner Total Heating Energy [J]**

This output field is the total (enthalpy) heat addition of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

**1.31.9.2.3 Zone Packaged Terminal Air Conditioner Total Cooling Rate [W]**

This output field is the total (enthalpy) heat extraction rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

**1.31.9.2.4 Zone Packaged Terminal Air Conditioner Total Cooling Energy [J]**

This output field is the total (enthalpy) heat extraction of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

**1.31.9.2.5 Zone Packaged Terminal Air Conditioner Sensible Heating Rate [W]**

This output field is the sensible heat addition rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

**1.31.9.2.6 Zone Packaged Terminal Air Conditioner Sensible Heating Energy [J]**

This output field is the sensible heat addition of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

**1.31.9.2.7 Zone Packaged Terminal Air Conditioner Sensible Cooling Rate [W]**

This output field reports the moist air sensible heat extraction rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate

through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

#### **1.31.9.2.8 Zone Packaged Terminal Air Conditioner Sensible Cooling Energy [J]**

This output field reports the moist air sensible heat extraction of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

#### **1.31.9.2.9 Zone Packaged Terminal Air Conditioner Latent Heating Rate [W]**

This output field is the latent heat addition (humidification) rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

#### **1.31.9.2.10 Zone Packaged Terminal Air Conditioner Latent Heating Energy [J]**

This output field is the latent heat addition (humidification) of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

#### **1.31.9.2.11 Zone Packaged Terminal Air Conditioner Latent Cooling Rate [W]**

This output field is the latent heat extraction (dehumidification) rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

#### **1.31.9.2.12 Zone Packaged Terminal Air Conditioner Latent Cooling Energy [J]**

This output field is the latent heat extraction (dehumidification) of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

#### **1.31.9.2.13 Zone Packaged Terminal Air Conditioner Electricity Rate [W]**

This output field is the electricity consumption rate of the packaged terminal air conditioner in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the heating coil (includes electricity consumption rate for electric heating coil or parasitic electricity consumption rate for non-electric coils). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.31.9.2.14 Zone Packaged Terminal Air Conditioner Electricity Energy [J]**

This output field is the electricity consumption of the packaged terminal air conditioner in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the heating coil (includes electricity consumption for electric heating coil or parasitic electricity consumption for non-electric coils). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

**1.31.9.2.15 Zone Packaged Terminal Air Conditioner Fan Part Load Ratio []**

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the timestep. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.31.9.2.16 Zone Packaged Terminal Air Conditioner Compressor Part Load Ratio []**

This output field is the part-load ratio used by the coils (cooling and heating). Part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.31.9.2.17 Zone Packaged Terminal Air Conditioner Fan Availability Status []**

This is the availability status of the packaged terminal air conditioner fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the packaged terminal air conditioner object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager.\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

**1.31.10 ZoneHVAC:PackagedTerminalHeatPump**

The packaged terminal heat pump (PTHP) is a compound object made up of other components. Each PTHP consists of an outdoor air mixer, direct expansion (DX) cooling coil, DX heating coil, supply air fan, and a supplemental heating coil as shown in the figure below. These individual components are described elsewhere in this document. The packaged terminal heat pump coordinates the operation of these components and is modeled as a type of zone equipment (Ref. [ZoneHVAC:EquipmentList](#) and [ZoneHVAC:EquipmentConnections](#)).

Links to the PTHP’s supply air fan, DX coils, supplemental heating coil, and outdoor air mixer specifications are provided in the heat pump’s input syntax. Additional inputs include supply and outdoor air flow rates during cooling operation, heating operation, and when neither cooling or heating is required. A description of each input field for the packaged terminal heat pump compound object is provided below.

Figure 1.133: Schematic of a packaged terminal heat pump (draw through fan placement)

### 1.31.10.1 Inputs

#### 1.31.10.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a packaged terminal heat pump. Any reference to this heat pump by another object will use this name.

#### 1.31.10.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value greater than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (all of its coils and the supply air fan) as required. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.31.10.1.3 Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the heat pump draws its inlet air. This node name must be the name of a zone air exhaust node (Ref. [ZoneHVAC:EquipmentConnections](#)).

#### 1.31.10.1.4 Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the heat pump sends its outlet air. This node name must be the name of a zone air inlet node (Ref. [ZoneHVAC:EquipmentConnections](#)).

#### 1.31.10.1.5 Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this PTHP. The outdoor air mixer component is part of the PTHP compound object. The only available outdoor air mixer type is:

- [OutdoorAir:Mixer](#)

This input field should be left blank when the PTHP is connected to an *AirTerminal:SingleDuct:Mixer* object. If this field is left blank, an outdoor air mixer object is not simulated.

#### 1.31.10.1.6 Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the PTHP. Note that the return air node of the outdoor air mixer should also be the same node as the air inlet node of the PTHP. Furthermore, the outdoor air mixer's mixed air node should be the same as the PTHP's fan inlet air node (for blow through fan placement) or the PTHP's DX cooling coil inlet node (for draw through fan placement). This field should be left blank when the PTHP is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.10.1.7 Field: Cooling Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

#### 1.31.10.1.8 Field: Heating Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

#### 1.31.10.1.9 Field: No Load Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

#### 1.31.10.1.10 Field: Cooling Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the Cooling Outdoor Air Flow Rate is fixed; it cannot change during the simulation. In addition, the Cooling Outdoor Air Flow Rate cannot be greater than the heat pump's supply air volumetric flow rate during cooling operation. This field is set to zero flow when the PTHP is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.10.1.11 Field: Heating Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the Heating Outdoor Air Flow Rate is fixed; it cannot change during the simulation. In addition, the Heating Outdoor Air Flow Rate cannot be greater than the heat pump's supply air volumetric flow rate during heating operation. This field is set to zero flow when the PTHP is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.10.1.12 Field: No Load Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate when no cooling/heating is needed cannot be greater than the heat pump's supply air volumetric flow rate when no cooling/heating is needed. This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and the field 'Supply air volumetric flow rate when no cooling or heating is needed' is set to zero or is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Cooling Outdoor Air Flow Rate] or heating operation [i.e., Heating Outdoor Air Flow Rate]) and this field is not used. This field is set to zero flow when the heat pump is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.10.1.13 Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this PTHP. The only valid choices are *Fan:OnOff* and *Fan:ConstantVolume*. A fan of type *Fan:OnOff* may be used with either cycling or continuous fan operating mode, and a fan of type *Fan:ConstantVolume* is used only with continuous fan operating mode (see Supply Air Fan Operating Mode Schedule field below). The input requirements for these fan objects are described elsewhere in this document.

#### 1.31.10.1.14 Field: Supply Air Fan Name

The name of a constant volume fan component that composes part of the PTHP. Note that the fan's maximum flow rate should be greater than or equal to the maximum supply air flow rate for the PTHP. The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through fan placement) or the DX heating coil's outlet node (for draw through fan placement). The fan's outlet node should be the same as the DX cooling coil's air inlet node (for blow through fan placement) or the supplemental heater's air inlet node (for draw through fan placement).

#### 1.31.10.1.15 Field: Heating Coil Object Type

This alpha field defines the type of DX heating coil to be used by this PTHP. The only valid choice are *Coil:Heating:DX:SingleSpeed* and *Coil:Heating:DX:VariableSpeed*. The input requirements for this DX heating coil object are described elsewhere in this document.

#### 1.31.10.1.16 Field: Heating Coil Name

This alpha field defines the name of the DX heating coil used by this PTHP, and this name should match the name specified in the corresponding DX heating coil object.

#### 1.31.10.1.17 Field: Heating Convergence Tolerance

This numeric field defines the convergence tolerance for the unit's heating output. This field allows the user some control over how closely the heat pump will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The heat pump is controlled by matching its sensible (temperature) heating output to the zone sensible load (demand). Because the performance of the DX heating coil is frequently non-linear, the heat pump

model must call the DX heating coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The heating convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|(Q_{ZoneLoad} - Q_{HeatPump,out})|}{Q_{ZoneLoad}} \leq HeatingConvergenceTolerance \quad (1.132)$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

#### 1.31.10.1.18 Field: Cooling Coil Object Type

This alpha field defines the type of DX cooling coil used by this PTHP. The input requirements for these DX cooling coil objects are described elsewhere in this document. Only allowable coil types are:

- Coil:Cooling:DX:SingleSpeed
- CoilSystem:Cooling:DX:HeatExchangerAssisted
- Coil:Cooling:DX:VariableSpeed

#### 1.31.10.1.19 Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this PTHP, and this name should match the name specified in the corresponding DX cooling coil object.

#### 1.31.10.1.20 Field: Cooling Convergence Tolerance

This numeric field defines the convergence tolerance for the unit's cooling output. This field allows the user some control over how closely the heat pump will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The heat pump is controlled by matching its sensible (temperature) cooling output to the zone sensible load (demand). Because the performance of the DX cooling coil is frequently non-linear, the heat pump model must call the DX cooling coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The cooling convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|(Q_{ZoneLoad} - Q_{HeatPump,out})|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance \quad (1.133)$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

#### 1.31.10.1.21 Field: Supplemental Heating Coil Object Type

This alpha field defines the type of supplemental heating coil to be used by this PTHP. The input requirements for these heating coil objects are described elsewhere in this document. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the supplemental heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (PTHP) itself provides the “controller” function of modulating water flow. Allowable coil types are:

- Coil:Heating:Electric

- Coil:Heating:Fuel
- Coil:Heating:Water
- Coil:Heating:Steam

#### 1.31.10.1.22 Field: Supplemental Heating Coil Name

This alpha field defines the name of the supplemental heating coil used by this PTHP, and this name should match the name specified in the corresponding heating coil object.

#### 1.31.10.1.23 Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum supply air temperature in degrees Celsius exiting the heat pump supplemental heater coil. The supplemental heater will be controlled so that its supply air temperature does not exceed this value. This field is autosizable.

#### 1.31.10.1.24 Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the maximum outdoor dry-bulb temperature in degrees Celsius for PTHP supplemental heater operation. The supplemental heater will not operate when the outdoor dry-bulb temperature is above this value. The maximum value must be less than or equal to 21°C. If this field is left blank, the default value is 21°C.

#### 1.31.10.1.25 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of an outdoor air mixer followed by a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of an outdoor air mixer followed by the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is draw through.

Note: the packaged terminal heat pump’s supply air fan, cooling coil, heating coil and supplementary heating coil must be connected according to the configuration shown above (Figure 1.133) for the draw through fan configuration. The only other valid configuration is with a blow through fan placement, where the fan is located between the outdoor air mixer and the DX cooling coil.

#### 1.31.10.1.26 Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation.

#### 1.31.10.1.27 Field: Availability Manager List Name

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this packaged terminal heat pump or object’s fan. If the packaged terminal heat pump is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this packaged terminal heat pump object should be on or off.

**1.31.10.1.28 Field: Design Specification ZoneHVAC Sizing Object Name**

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Cooling Supply Air Flow Rate in this PTHP zone HVAC object. The scaled Supply Air Flow Rate in turn is used to size cooling and heating capacity of the unit.

**1.31.10.1.29 Field: Capacity Control Method**

This input denotes how the unit's output is controlled in order to meet zone heating or cooling requirement. The choices are **None** or **SingleZoneVAV**. For **None**, the unit varies the fan and/or coil speed to meet the load. If constant fan operating mode is selected the fan operates at the design cooling or heating air flow rate while the coil modulates to meet the load. If cycling fan operating mode is selected the fan and coil modulate in unison to meet the load. For **SingleZoneVAV**, the fan air flow rate is reduced to the no load supply air flow rate when the zone sensible load is low such that the maximum supply air temperature limit is not exceeded. If the unit cannot meet the load at this lower air flow rate, the fan speed increases while maintaining the maximum supply air temperature. If the unit still cannot meet the load the unit will operate at the maximum supply air flow rate and the maximum supply air temperature limit can be exceeded. Supply air temperature limits are identified in the input fields for Minimum Supply Air Temperature in Cooling Mode and Maximum Supply Air Temperature in Heating Mode. Additionally, specific coil types are required for the SingleZoneVAV capacity control method. The cooling coil type is **Coil:Cooling:DX:SingleSpeed** while the heating coil type is **Coil:Heating:DX:SingleSpeed**.

**1.31.10.1.30 Field: Minimum Supply Air Temperature in Cooling Mode**

When Capacity Control Method = **SingleZoneVAV**, enter the minimum air temperature limit for reduced fan speed in cooling mode. For **SingleZoneVAV**, this field's minimum supply air temperature is 0.0°C. This field is autosizable and the default is autosize.

**1.31.10.1.31 Field: Maximum Supply Air Temperature in Heating Mode**

When Capacity Control Method = **SingleZoneVAV**, enter the maximum air temperature limit for reduced fan speed in heating mode. For **SingleZoneVAV**, this field's minimum supply air temperature is 0.0°C. This field is autosizable and the default is autosize.

As shown in the example below, correct specification of the packaged terminal heat pump requires the following objects in addition to the compound object itself:

- 1) Fan (**Fan:OnOff** or **Fan:ConstantVolume**)
- 2) DX cooling coil (**Coil:Cooling:DX:SingleSpeed** or **CoilSystem:Cooling:DX:HeatExchangerAssisted**)
- 3) DX heating coil (**Coil:Heating:DX:SingleSpeed**)
- 4) Supplemental heating coil (**Coil:Heating:Fuel** or **Coil:Heating:Electric**)
- 5) **OutdoorAir:Mixer**

**1.31.10.2.1 Zone Packaged Terminal Heat Pump Total Heating Rate [W]**

This output field is the total (enthalpy) heat addition rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

**1.31.10.2.2 Zone Packaged Terminal Heat Pump Total Heating Energy [J]**

This output field is the total (enthalpy) heat addition of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

**1.31.10.2.3 Zone Packaged Terminal Heat Pump Total Cooling Rate [W]**

This output field is the total (enthalpy) heat extraction rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

**1.31.10.2.4 Zone Packaged Terminal Heat Pump Total Cooling Energy [J]**

This output field is the total (enthalpy) heat extraction of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

**1.31.10.2.5 Zone Packaged Terminal Heat Pump Sensible Heating Rate [W]**

This output field is the sensible heat addition rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

**1.31.10.2.6 Zone Packaged Terminal Heat Pump Sensible Heating Energy [J]**

This output field is the sensible heat addition of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

**1.31.10.2.7 Zone Packaged Terminal Heat Pump Sensible Cooling Rate [W]**

This output field reports the moist air sensible heat extraction rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

**1.31.10.2.8 Zone Packaged Terminal Heat Pump Sensible Cooling Energy [J]**

This output field reports the moist air sensible heat extraction of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

**1.31.10.2.9 Zone Packaged Terminal Heat Pump Latent Heating Rate [W]**

This output field is the latent heat addition (humidification) rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

**1.31.10.2.10 Zone Packaged Terminal Heat Pump Latent Heating Energy [J]**

This output field is the latent heat addition (humidification) of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

**1.31.10.2.11 Zone Packaged Terminal Heat Pump Latent Cooling Rate [W]**

This output field is the latent heat extraction (dehumidification) rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

**1.31.10.2.12 Zone Packaged Terminal Heat Pump Latent Cooling Energy [J]**

This output field is the latent heat extraction (dehumidification) of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

**1.31.10.2.13 Zone Packaged Terminal Heat Pump Electricity Rate [W]**

This output field is the electricity consumption rate of the packaged terminal heat pump in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.31.10.2.14 Zone Packaged Terminal Heat Pump Electricity Energy [J]**

This output field is the electricity consumption of the packaged terminal heat pump in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

#### 1.31.10.2.15 Zone Packaged Terminal Heat Pump Fan Part Load Ratio []

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the timestep. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

#### 1.31.10.2.16 Zone Packaged Terminal Heat Pump Compressor Part Load Ratio []

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). Compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

#### 1.31.10.2.17 Zone Packaged Terminal Heat Pump Fan Availability Status []

This is the availability status of the packaged terminal heat pump fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the packaged terminal heat pump object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

### 1.31.11 ZoneHVAC:RefrigerationChillerSet

The ZoneHVAC:RefrigerationChillerSet object works in conjunction with one or multiple air chillers, compressor racks, refrigeration systems, or refrigeration secondary system objects (Ref. [Refrigeration:AirChiller](#), [Refrigeration:CompressorRack](#), [Refrigeration:System](#), or [Refrigeration:SecondarySystem](#)) to simulate the performance of a group of air chillers cooling a single zone. The chiller set model passes information about the zone conditions to determine the performance of individual chiller coils within the set, thus providing the sensible and latent heat exchange with the zone environment.

The refrigeration chiller set object inputs include a name, an availability schedule name, the name of the zone cooled by the chiller set, the air inlet node name, the air outlet node name, and an extensible list of air chiller names (Ref. [Refrigeration:AirChiller](#)).

#### 1.31.11.1 Inputs

##### 1.31.11.1.1 Field: Name

A unique user-assigned name for an instance of a refrigeration chiller. Any reference to this refrigeration chiller by another object (may be listed in a [Refrigeration:CaseAndWalkInList](#), [Refrigeration:System](#), [Refrigeration:SecondarySystem](#), or [Refrigeration:CompressorRack](#)) will use this name.

**1.31.11.1.2 Field: Availability Schedule Name**

The name of the schedule (ref: Schedule) that denotes whether the refrigeration chiller can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the refrigeration chiller will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the refrigeration chiller will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, refrigeration chillers require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the default schedule has a value of 1 for all time periods.

**1.31.11.1.3 Field: Zone Name**

A unique user-assigned name for the zone cooled by this refrigeration chiller. This zone must represent a conditioned space, that is, it must appear in a **ZoneHVAC:EquipmentConnections** object.

**1.31.11.1.4 Field: Air Inlet Node Name**

Not used, reserved for future use. Current version exchanges energy directly with the zone, external of any air system. (Future: The name of the zone exhaust node (see Node) from which the refrigeration chiller draws its indoor air. This should be one of the zone exhaust nodes for the zone cooled by the chiller set.)

**1.31.11.1.5 Field: Air Outlet Node Name**

Not used, reserved for future use. Current version exchanges energy directly with the zone, external of any air system. (Future: The name of the node where the chiller coil sends its outlet air, which must be one of the inlet air nodes for the zone which is being cooled.)

**1.31.11.1.6 Field: Air Chiller #1 Name**

The name of the first air chiller that will be used to meet the zone cooling load.

**1.31.11.1.7 Field: Air Chiller #2 Name**

The name of the second air chiller that will be used to meet the zone cooling load.

**1.31.11.1.8 Field: Air Chiller #3 Name**

The name of the third air chiller that will be used to meet the zone cooling load.

**1.31.11.1.9 Field: Air Chiller #n Name (Extensible list, 20 provided in the IDD)**

The name of the nth air chiller that will be used to meet the zone cooling load.

The following is an example input for a refrigeration chiller set.

```
ZoneHVAC:RefrigerationChillerSet,
  SubFreezerChillerSet ,      !- Name
  ,                            !- Availability Schedule Name
  SubFreezer,                 !- Zone Name
  NODE_142,                    !- Air Inlet Node Name
  NODE_141,                    !- Air Outlet Node Name

  SubFreezerAirChiller_2,     !- Air Chiller \#2 Name
  SubFreezerAirChiller_3;     !- Air Chiller \#3 Name
```

There are no outputs variables for a ZoneHVAC:RefrigerationChillerSet. Outputs for the refrigeration impact on any zone are listed in the Group:Refrigeration.

### 1.31.12 ZoneHVAC:WaterToAirHeatPump

The zone water-to-air heat pump is a compound component consisting of a fan, water-to-air cooling and heating coils, and a supplemental heating coil. Links to the fan, WaterToAirHeatPump cooling coil, WaterToAirHeatPump heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. The heat pump switches between cooling and heating depending on the zone's demand. The load side (air) of the zone water-to-air heat pump consists of an On/Off fan component, a WaterToAirHeatPump cooling coil component, a WaterToAirHeatPump heating coil component, and a Gas or Electric supplemental heating coil component. The source side (water) of the heat pump is connected to a condenser loop with a heat exchanger (ground heat exchanger or other type) or a plant loop with a heating source such as a boiler and a cooling source such as a chiller or cooling tower. The diagram below shows the setup and connection of the heat pump for the source side and load side for a ground heat exchanger configuration. Note that on the load side, the WaterToAirHeatPump cooling coil must always be placed before the WaterToAirHeatPump heating coil.

For this zone heat pump, there are two types of WaterToAirHeatPump coil model allowed:

- `Coil:Cooling:WaterToAirHeatPump:EquationFit`
- `Coil:Heating:WaterToAirHeatPump:EquationFit`
- `Coil:Cooling:WaterToAirHeatPump:VariableSpeedEquationFit`
- `Coil:Heating:WaterToAirHeatPump:VariableSpeedEquationFit`

#### 1.31.12.1 Inputs

##### 1.31.12.1.1 Field: Name

This alpha field contains the identifying name for the zone system heat pump.

##### 1.31.12.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value greater than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (all of its coils and the supply air fan) as required. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.31.12.1.3 Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air. This node must be a zone exhaust node as specified in a `ZoneHVAC:EquipmentConnections` object.

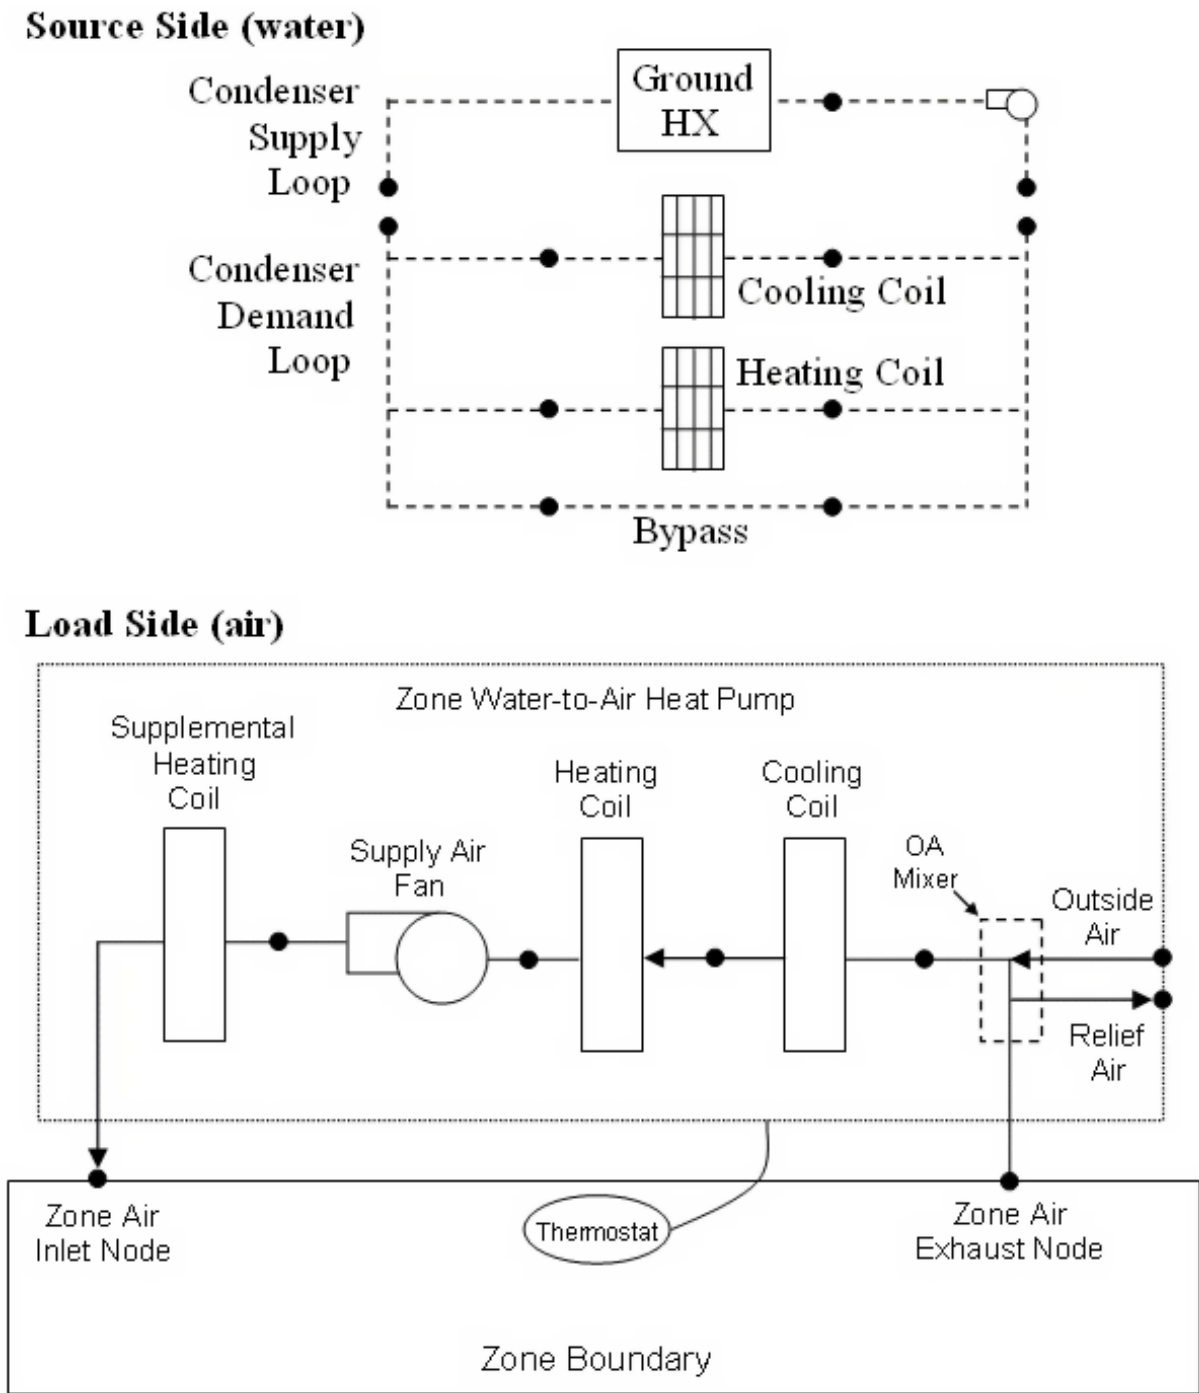

##### 1.31.12.1.4 Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air. This node must be a zone inlet node as specified in a `ZoneHVAC:EquipmentConnections` object.

##### 1.31.12.1.5 Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this WaterToAirHeatPump unit. The outdoor air mixer component is part of the WaterToAirHeatPump compound object. The only available outdoor air mixer type is:

- `OutdoorAir:Mixer`

This input field should be left blank when the WaterToAirHeatPump is connected to an *AirTerminal:SingleDuct:Mixer* object. If this field is left blank, an outdoor air mixer object is not simulated.

#### 1.31.12.1.6 Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the zone WaterToAirHeatPump. The return air stream node of the outdoor air mixer should also be the same node as the air inlet node of the WaterToAirHeatPump. Furthermore, the outdoor air mixer's mixed air node should be the same as the WaterToAirHeatPump's fan inlet air node (for blow through fan placement) or the WaterToAirHeatPump's cooling coil inlet node (for draw through fan placement). This input field should be left blank when the WaterToAirHeatPump is connected to an *AirTerminal:SingleDuct:Mixer* object. If this field is left blank, an outdoor air mixer object is not simulated.

#### 1.31.12.1.7 Field: Cooling Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

#### 1.31.12.1.8 Field: Heating Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

#### 1.31.12.1.9 Field: No Load Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

#### 1.31.12.1.10 Field: Cooling Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outside air flow rate during cooling operation is fixed; it cannot change during the simulation. In addition, the outside air flow rate during cooling operation cannot be greater than the heat pump's supply air flow rate during cooling operation. This input field is set to zero flow when the WaterToAirHeatPump is connected to an *AirTerminal:SingleDuct:Mixer* object.

#### 1.31.12.1.11 Field: Heating Outdoor Air Flow Rate

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outside air flow rate during heating operation is fixed; it cannot change during the simulation. In addition, the outside air flow rate during heating operation cannot be greater than the heat pump's supply air flow rate during heating operation. This input field is set to zero flow when the WaterToAirHeatPump is connected to an *AirTerminal:SingleDuct:Mixer* object.

**1.31.12.1.12 Field: No Load Outdoor Air Flow Rate When No Cooling or Heating is Needed**

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the no load outdoor air flow rate cannot change during the simulation. In addition, the no load outdoor air flow rate cannot be greater than the heat pump's no load supply air flow rate. This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and the field "No Load Supply Air Flow Rate" is set to zero or is left blank, then the model assumes that the no load outdoor air flow rate is equal to the outdoor air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Cooling outdoor air flow rate] or heating operation [i.e., Heating outdoor air flow rate]) and this field is not used. This input field is set to zero flow when the WaterToAirHeatPump is connected to an *AirTerminal:SingleDuct:Mixer* object.

**1.31.12.1.13 Field: Supply Air Fan Object Type**

This alpha field contains the identifying type of supply air fan specified in the heat pump. Fan type must be *Fan:OnOff*.

**1.31.12.1.14 Field: Supply Air Fan Name**

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

**1.31.12.1.15 Field: Heating Coil Object Type**

This alpha field contains the identifying type of heating coil specified in the heat pump. The only valid types are *Coil:Heating:WaterToAirHeatPump:EquationFit* *Coil:Heating:WaterToAirHeatPump:VariableSpeedEquationFit*

**1.31.12.1.16 Field: Heating Coil Name**

This alpha field contains the identifying name given to the WaterToAirHeatPump heating coil, and should match the name specified in the corresponding WaterToAirHeatPump heating coil object.

**1.31.12.1.17 Field: Cooling Coil Object Type**

This alpha field contains the identifying type of cooling coil specified in the heat pump. The only valid types are *Coil:Cooling:WaterToAirHeatPump:EquationFit* and *Coil:Cooling:WaterToAirHeatPump:VariableSpeedEquationFit*

**1.31.12.1.18 Field: Cooling Coil Name**

This alpha field contains the identifying name given to the WaterToAirHeatPump cooling coil, and should match the name specified in the corresponding WaterToAirHeatPump cooling coil object.

**1.31.12.1.19 Field: Maximum Cycling Rate**

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown below (Henderson et al. 1999):

**1.31.12.1.20 Field: Heat Pump Time Constant**

This numeric field contains the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Figure 1.135:

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Figure 1.136:

#### 1.31.12.1.21 Field: Fraction of On-Cycle Power Use

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	0.01
Good	0.01
Poor	0.03

Figure 1.137:

#### 1.31.12.1.22 Field: Heat Pump Fan Delay Time

This numeric field contains the time delay in seconds for the heat pump supply air fan to shut off after compressor cycle off. This value can be obtained from the manufacturer or the heat pump catalog. Suggested value is 60 seconds. This value is disregarded at times when the WaterToAirHeatPump's fan operating mode schedule value is greater than 0 (i.e., continuous fan mode).

#### 1.31.12.1.23 Field: Supplemental Heating Coil Object Type

This is the object type of the supplemental heating coil. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the supplemental heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Zone Water to Air Heat Pump) itself provides the “controller” function of modulating water flow. The valid choices are:

- Coil:Heating:Electric
- Coil:Heating:Fuel
- Coil:Heating:Water
- Coil:Heating:Steam

#### 1.31.12.1.24 Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the supplemental heating coil, and should match the name specified in the corresponding supplemental heating coil object.

#### 1.31.12.1.25 Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil in degrees Celsius. If this input field is left blank, the value defaults to autosize.

#### 1.31.12.1.26 Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature in degrees Celsius above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21°C. If this input field is left blank, the default value is 21°C.

#### 1.31.12.1.27 Field: Outdoor Dry-Bulb Temperature Sensor Node Name

This alpha field specifies the name of the outdoor node which controls the operation of the supplemental heating coil. If this field is left blank, the outdoor temperature is based solely on the weather data. If this field is not blank, the node name specified must also be listed in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an **OutdoorAir:NodeList** object where the outdoor temperature is taken directly from the weather data.

#### 1.31.12.1.28 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply fan is between the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

#### 1.31.12.1.29 Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation.

As shown in the example below, correct specifications of the WaterToAirHeatPump requires specification of the following objects in addition to the ZoneHVAC:WaterToAirHeatPump object:

- On/Off fan
- WaterToAirHeatPump cooling coil (EquationFit only)

- WatertoAirHeatPump heating coil (EquationFit only)
- Supplementary heating coil
- Outdoor air mixer
- Condenser loop or plant loop demand branches

#### 1.31.12.1.30 Field: Availability Manager List Name

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this WatertoAirHeatPump or object's fan. If the WatertoAirHeatPump is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this WatertoAirHeatPump object should be on or off.

#### 1.31.12.1.31 Field: Heat Pump Coil Water Flow Mode

This field specifies the way in which water flow through the heat pump coils will be modeled. This field is only used when WatertoAirHeatPump:EquationFit coils are used. There are three options:

- Cycling
- Constant
- CyclingOnDemand

**Cycling** varies water flow through the coil based on the heat pump Part Load Ratio. This control method is appropriate for modeling heat pumps that are outfitted with a solenoid valve which allows water to flow through the coil only when the compressor is active. This is the default for EnergyPlus V8 and later.

**Constant** provides a constant water flow regardless of heat pump operation. Remember that EnergyPlus has two coils (a heating coil and a cooling coil) to approximate the operation of one coil that can operate in either heating mode or cooling mode. Therefore, when the water flow mode is constant, there will be full flow through either the heating coil or the cooling coil, but not both at the same time.

**ConstantOnDemand** provides full flow through the coil whenever there is a load. When there is no load, there is zero flow through the coil. This control strategy represents the way EnergyPlus modeled heat pump water flow prior to Version 8.

#### 1.31.12.1.32 Field: Design Specification ZoneHVAC Sizing Object Name

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Sepcification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Cooling Supply Air Flow Rate in this Water To Air Heat Pump zone HVAC object. The scaled Supply Air Flow Rate in turn is used to size cooling and heating capacity of the unit.

Examples of IDF use:

**1.31.12.2.1 Zone Water to Air Heat Pump Total Heating Rate [W]**

This output field is the total (enthalpy) heat addition rate of the Water to Air Heat Pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy addition only) are averaged for the time step being reported.

**1.31.12.2.2 Zone Water to Air Heat Pump Total Heating Energy [J]**

This output field is the total (enthalpy) heat addition of the Water to Air Heat Pump to the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy addition only) are summed for the time step being reported.

**1.31.12.2.3 Zone Water to Air Heat Pump Total Cooling Rate [W]**

This output field is the total (enthalpy) heat extraction rate of the Water to Air Heat Pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy extraction only) are averaged for the time step being reported.

**1.31.12.2.4 Zone Water to Air Heat Pump Total Cooling Energy [J]**

This output field is the total (enthalpy) heat extraction of the Water to Air Heat Pump from the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy extraction only) are summed for the time step being reported.

**1.31.12.2.5 Zone Water to Air Heat Pump Sensible Heating Rate [W]**

This output field is the sensible heat addition rate of the Water to Air Heat Pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (heating only) are averaged for the time step being reported.

**1.31.12.2.6 Zone Water to Air Heat Pump Sensible Heating Energy [J]**

This output field is the sensible heat addition of the Water to Air Heat Pump to the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (heating only) are summed for the time step being reported.

**1.31.12.2.7 Zone Water to Air Heat Pump Sensible Cooling Rate [W]**

This output field reports the moist air sensible heat extraction rate of the Water to Air Heat Pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (cooling only) are averaged for the time step being reported.

**1.31.12.2.8 Zone Water to Air Heat Pump Sensible Cooling Energy [J]**

This output field reports the moist air sensible heat extraction of the Water to Air Heat Pump from the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (cooling only) are summed for the time step being reported.

**1.31.12.2.9 Zone Water to Air Heat Pump Latent Heating Rate [W]**

This output field is the latent heat addition (humidification) rate of the Water to Air Heat Pump to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat addition only) are averaged for the time step being reported.

**1.31.12.2.10 Zone Water to Air Heat Pump Latent Heating Energy [J]**

This output field is the latent heat addition (humidification) of the Water to Air Heat Pump to the zone it is serving in Joules over the time step being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat addition only) are summed for the time step being reported.

**1.31.12.2.11 Zone Water to Air Heat Pump Latent Cooling Rate [W]**

This output field is the latent heat extraction (dehumidification) rate of the Water to Air Heat Pump from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat extraction only) are averaged for the time step being reported.

**1.31.12.2.12 Zone Water to Air Heat Pump Latent Cooling Energy [J]**

This output field is the latent heat extraction (dehumidification) of the Water to Air Heat Pump from the zone it is serving in Joules over the time step being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat extraction only) are summed for the time step being reported.

**1.31.12.2.13 Zone Water to Air Heat Pump Electricity Rate [W]**

This output field is the electricity consumption rate of the Water to Air Heat Pump in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.31.12.2.14 Zone Water to Air Heat Pump Electricity Energy [J]**

This output field is the electricity consumption of the Water to Air Heat Pump in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric).

This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported.

#### 1.31.12.2.15 Zone Water to Air Heat Pump Fan Part Load Ratio []

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the time step. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.31.12.2.16 Zone Water to Air Heat Pump Compressor Part Load Ratio []

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). Compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.31.12.2.17 Zone Water to Air Heat Pump Fan Availability Status []

This is the availability status of the zone water source heat pump fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the zone water source heat pump object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager.\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

### 1.31.13 ZoneHVAC:Dehumidifier:DX

This object can be used for modeling conventional mechanical dehumidifiers. These systems use a direct expansion (DX) cooling coil to cool and dehumidify an airstream. Heat from the DX system’s condenser section is rejected into the cool/dehumidified airstream, resulting in warm dry air being supplied from the unit. In EnergyPlus, this object is modeled as a type of zone equipment (ref. [ZoneHVAC:EquipmentList](#) and [ZoneHVAC:EquipmentConnections](#)).

The model has inputs for water removal, energy factor and air flow rate at rated conditions (26.7°C, 60% RH). Curve objects must be specified to describe performance at off-rated conditions. A part-load cycling curve input must also be specified to account for inefficiencies due to cycling. Other inputs including minimum and maximum operating temperatures for dehumidifier operation, off-cycle parasitic load, and an input to direct the removed water to a storage tank.

The model assumes that this equipment dehumidifies and heats the air. If used in tandem with another system that cools and dehumidifies the zone air, then the zone dehumidifier should be specified as the lowest cooling priority in the [ZoneHVAC:EquipmentList](#) object for best control of zone temperature and humidity levels (e.g., if there are 3 pieces of equipment in [ZoneHVAC:EquipmentList](#), then the zone dehumidifier should have Cooling Priority = 3). With this zone equipment prioritization, the other cooling and dehumidification system would operate first to meet the temperature setpoint (and possibly meet the

Figure 1.138: Schematic of a mechanical dehumidifier

high humidity setpoint as well). If additional dehumidification is needed, then the zone dehumidifier would operate. The sensible heat generated by the dehumidifier is carried over to the zone air heat balance for the next HVAC time step.

### 1.31.13.1 Inputs

#### 1.31.13.1.1 Field: Name

A unique user-assigned name for an instance of a zone DX dehumidifier unit. Any reference to this dehumidifier by another object will use this name.

#### 1.31.13.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the dehumidifier operates during a given time period. A schedule value equal to 0 denotes that the dehumidifier will not operate for that time period. A value greater than 0 denotes that the dehumidifier is available to operate during that time period. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.31.13.1.3 Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the dehumidifier draws its inlet air. This node name must be the name of a zone air exhaust node (ref. [ZoneHVAC:EquipmentConnections](#)).

#### 1.31.13.1.4 Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the dehumidifier sends its outlet air. This node name must be the name of a zone air inlet node (ref. [ZoneHVAC:EquipmentConnections](#)).

#### 1.31.13.1.5 Field: Rated Water Removal

This numeric input is the full load water removal rate, in liters per day, at rated conditions (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field

“Rated Air Flow Rate” below). This is a required input field and the entered value must be greater than zero.

#### 1.31.13.1.6 Field: Rated Energy Factor

This numeric input is the energy factor (liters of water removed per kWh of electricity consumed) at rated conditions (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field “Rated Air Flow Rate” below). This is a required input field and the entered value must be greater than zero.

#### 1.31.13.1.7 Field: Rated Air Flow Rate

This numeric input is the volumetric air flow rate through the dehumidifier, in m<sup>3</sup> per second, at rated conditions (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity). This is a required input field and the entered value must be greater than zero.

#### 1.31.13.1.8 Field: Water Removal Curve Name

This alpha field defines the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of water removal as a function of the dry-bulb temperature (°C) and relative humidity (%) of the air entering the dehumidifier. The output of this curve is multiplied by the Rated Water Removal to give the water removal of the dehumidifier at specific operating conditions (i.e., at temperatures and relative humidity levels different from the rating point conditions). The curve should be normalized to have the value of 1.0 at the rating point (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field “Rated Air Flow Rate” above).

#### 1.31.13.1.9 Field: Energy Factor Curve Name

This alpha field defines the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy factor as a function of the dry-bulb temperature (°C) and relative humidity (%) of the air entering the dehumidifier. The output of this curve is multiplied by the Rated Energy Factor to give the energy factor of the dehumidifier at specific operating conditions (i.e., at temperatures and relative humidity levels different from the rating point conditions). The curve should be normalized to have the value of 1.0 at the rating point (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field “Rated Air Flow Rate” above).

#### 1.31.13.1.10 Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of electrical power input to the dehumidifier as a function of the part load ratio (PLR, defined as the water removal load to be met (kg/s) divided by the dehumidifier’s water removal rate (kg/s) at the current operating conditions). The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the dehumidifier runs continuously for the simulation timestep). For PLR values between 0 and 1 ( $0 \leq \text{PLR} < 1$ ), the following rules apply:

$$0.7 \leq \text{PLF} \leq 1.0 \quad \text{and} \quad \text{PLF} \geq \text{PLR}$$

If  $\text{PLF} < 0.7$  a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the dehumidifier is defined as  $\text{PLR}/\text{PLF}$ . If  $\text{PLF} < \text{PLR}$ , then a warning message is issued and the runtime fraction of the dehumidifier is set to 1.0.

Mechanical dehumidifier typically have long runtimes with minimal compressor cycling. So, a typical part load fraction correlation might be:

$$\text{PLF} = 0.95 + 0.05(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

#### 1.31.13.1.11 Field: Minimum Dry-Bulb Temperature for Dehumidifier Operation

This numeric field defines the minimum inlet air dry-bulb temperature for dehumidifier operation. The dehumidifier will not operate if the inlet air temperature is below this value. This input value must be less than the Maximum Dry-Bulb Temperature for Dehumidifier Operation, and the default value is 10°C.

#### 1.31.13.1.12 Field: Maximum Dry-Bulb Temperature for Dehumidifier Operation

This numeric field defines the maximum inlet air dry-bulb temperature for dehumidifier operation. The dehumidifier will not operate if the inlet air temperature is above this value. This input value must be greater than the Minimum Dry-Bulb Temperature for Dehumidifier Operation, and the default value is 35°C.

#### 1.31.13.1.13 Field: Off-Cycle Parasitic Electric Load

This numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the dehumidifier. This parasitic electric load is consumed whenever the dehumidifier is available to operate, but is not operating. The model assumed that this parasitic power contributes to heating the zone air (i.e., affects the zone air heat balance). The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

#### 1.31.13.1.14 Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to specify where condensate from the dehumidifier is collected. If blank or omitted, then any water (condensate) removed is discarded. Enter the name of a Water Storage Tank (ref. [WaterUse:Storage](#)) object defined elsewhere and the condensate will then be collected in that tank.

Following is an example input for a zone DX dehumidifier object. A [ZoneControl:Humidistat](#) object must also be specified for the zone to which the dehumidifier is connected (connect via a zone air exhaust node and a zone air inlet node, ref. [ZoneHVAC:EquipmentConnections](#)).

- HVAC,Sum,Zone Dehumidifier Condensate Volume [m3]

#### 1.31.13.2.1 Zone Dehumidifier Sensible Heating Rate [W]

This output field is the sensible heating rate output of the dehumidifier in Watts. This is determined by the water removal rate, enthalpy of water evaporation, and the zone dehumidifier electric power. To reduce simulation time, this heating is carried over to the zone air heat balance for the next HVAC time step (i.e., it is reported here for the current time step but actually impacts the zone air heat balance on the following HVAC time step). This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.31.13.2.2 Zone Dehumidifier Sensible Heating Energy [J]

This output field is the sensible heating output of the dehumidifier in Joules over the timestep being reported. This is determined by the water removal rate, enthalpy of water evaporation, and the zone dehumidifier electric power. To reduce simulation time, this heating is carried over to the zone air heat balance for the next HVAC time step (i.e., it is reported here for the current time step but actually impacts the zone air heat balance on the following HVAC time step). This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported.

#### 1.31.13.2.3 Zone Dehumidifier Removed Water Mass Flow Rate [kg/s]

This output field is the water removal rate by the dehumidifier in kg/s. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.31.13.2.4 Zone Dehumidifier Removed Water Mass [kg]

This output field is the water removed by the dehumidifier in kg. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported.

#### 1.31.13.2.5 Zone Dehumidifier Electricity Rate [W]

#### 1.31.13.2.6 Zone Dehumidifier Electricity Energy [J]

These outputs are the electric power and electric consumption of the dehumidifier for the time period being reported. They include all electricity used by the dehumidifier (including off-cycle electric parasitics). These values are calculated for each HVAC system timestep, and the results are averaged (power) or summed (consumption) for the timestep being reported. The electric consumption output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

#### 1.31.13.2.7 Zone Dehumidifier Off Cycle Parasitic Electricity Rate [W]

#### 1.31.13.2.8 Zone Dehumidifier Off Cycle Parasitic Electricity Energy [J]

These outputs are the parasitic electric power and electric consumption for controls or other electrical devices associated with the dehumidifier. This parasitic electric load is consumed whenever the dehumidifier is available to operate, but is not operating. The model assumes that this parasitic power contributes to heating the zone air (i.e., affects the zone air heat balance). These outputs values are included in the Zone Dehumidifier Electric Power and Zone Dehumidifier Electricity Energy output variables.

#### 1.31.13.2.9 Zone Dehumidifier Part Load Ratio []

This output field is the part-load ratio for the dehumidifier. Part-load ratio is defined as the water removal load to be met (kg/s) divided by the dehumidifier's water removal rate (kg/s) at the current operating conditions. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.31.13.2.10 Zone Dehumidifier Runtime Fraction []

This output field is the runtime fraction for the dehumidifier. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.31.13.2.11 Zone Dehumidifier Outlet Air Temperature [°C]

This output field is dry-bulb temperature of the air leaving the dehumidifier in Celsius. This value represents the dry-bulb temperature of the air leaving the dehumidifier when it is operating. For periods when the dehumidifier is not operating, the outlet air temperature is set equal to the inlet air temperature. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

#### 1.31.13.2.12 Zone Dehumidifier Condensate Volume Flow Rate [m3/s]

#### 1.31.13.2.13 Zone Dehumidifier Condensate Volume [m3]

These outputs are the rate and volume of water removed as condensate by the dehumidifier. These reports only appear if a water storage tank is named in the input object. The condensate volume output is also added to a meter with Resource Type = OnSiteWater, End Use Key = Condensate, Group Key = System (ref. Output:Meter objects).

### 1.31.14 ZoneHVAC:EnergyRecoveryVentilator

The ZoneHVAC:EnergyRecoveryVentilator - stand alone energy recovery ventilator (ERV) is a single-zone HVAC component used for exhaust air heat recovery (Figure 1.139). This compound object consists of 3 required components: a generic air-to-air heat exchanger (see object Heat Exchanger:Air to Air:Generic), a supply air fan, and an exhaust air fan (see object Fan:OnOff).

An optional controller (see object **ZoneHVAC:EnergyRecoveryVentilator:Controller**) may be used to simulate economizer (free cooling) operation, modify air flow rates based on high indoor humidity, or simulate a “push-button” type economizer controller.

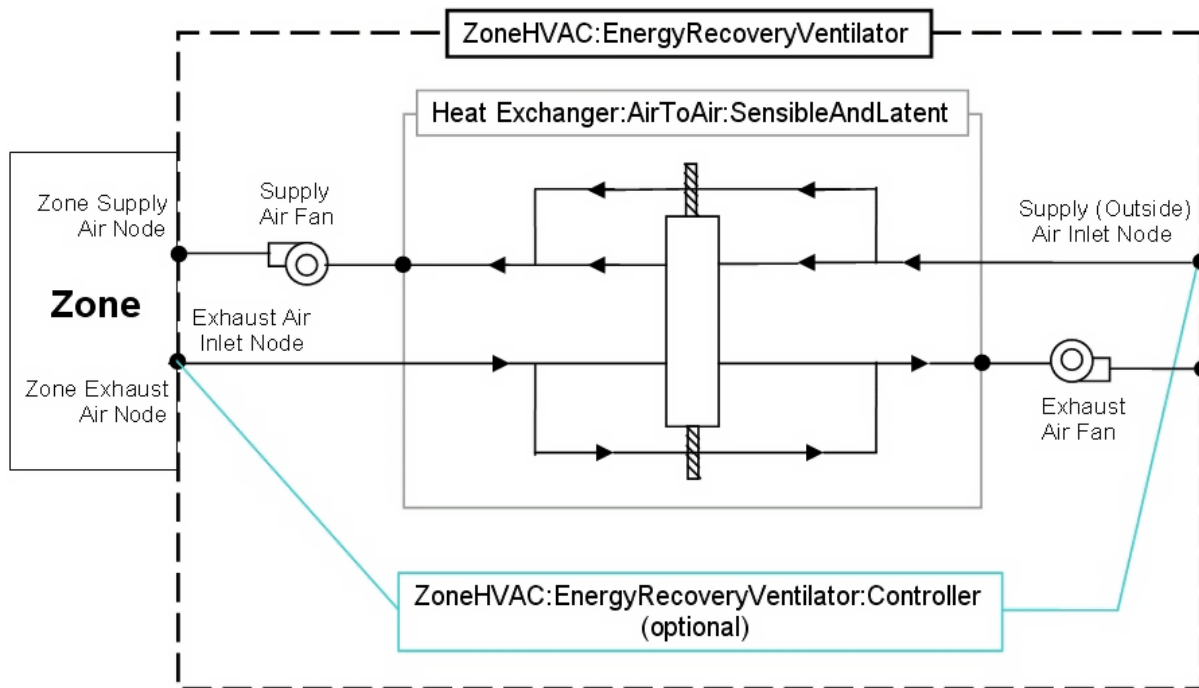

Figure 1.139: ZoneHVAC:EnergyRecoveryVentilator compound object Schematic

This compound object models the basic operation of supply and exhaust air fans and an air-to-air heat exchanger. The stand alone ERV operates whenever the unit is scheduled to be available (Availability schedule). The stand alone ERV object can be used in conjunction with an economizer feature whereby heat exchange is suspended whenever free cooling is available (i.e., air flow is fully bypassed around a fixed-plate heat exchanger or the rotation of a rotary heat exchanger is stopped). The economizer feature may also be activated based on a time-of-day schedule. Heat exchange is also suspended when air flow rates through the heat exchanger are modified in response to a zone humidistat. When an economizer is used in conjunction with high humidity control, high humidity control has the priority.

To model a stand alone ERV connected to a single zone, the input data file should include the following objects:

- **ZoneHVAC:EnergyRecoveryVentilator**
- **HeatExchanger:AirToAir:SensibleAndLatent**
- **Fan:OnOff** (supply air)
- **Fan:OnOff** (exhaust air)
- **ZoneHVAC:EnergyRecoveryVentilator:Controller** (if economizer [free cooling] mode or high humidity control operation is desired)
- **ZoneControl:Humidistat** (required for high humidity control option)
- **SetpointManager:Scheduled** (if supply air outlet temperature control is used, Ref. Heat Exchanger:Air to Air:Generic for additional guidance)

- `ZoneHVAC:EquipmentConnections`
- `ZoneHVAC:EquipmentList`
- `OutdoorAir:NodeList`

A description of each input field for this compound object is provided below.

### 1.31.14.1 Inputs

#### 1.31.14.1.1 Field: Name

A unique user-assigned name for the stand alone ERV unit. Any reference to this unit by another object will use this name.

#### 1.31.14.1.2 Field: Availability Schedule Name

The name of the schedule (ref: `Schedule`) that denotes whether the unit can operate during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can operate during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit will not operate. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.31.14.1.3 Field: Heat Exchanger Name

The user-assigned name corresponding to the air-to-air heat exchanger used in this compound object. The only allowable type is:

`HeatExchanger:AirToAir:SensibleAndLatent`

#### 1.31.14.1.4 Field: Supply Air Flow Rate

The supply air flow rate through the ERV unit in cubic meters per second at standard temperature and pressure (dry air at 20°C drybulb). The program uses local barometric pressure to account for altitude using the equation for “standard atmospheric” pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z) ** 5.2559$$

where p = pressure in Pa and Z = altitude in m

Note that this flow rate must be within the valid air flow range for the heat exchanger (ref: `HeatExchanger:AirToAir:SensibleAndLatent` in the Engineering Document). In addition, this flow rate must be less than or equal to the supply fan air flow rate (`Fan:OnOff`). If the supply air flow rate is less than the exhaust air flow rate, the zone infiltration (ref: `ZoneInfiltration`) should be specified accordingly (the infiltration induced by imbalanced air flows is not accounted for automatically). The ERV supply air flow rate may also be autosized using the ventilation rate per floor area and/or ventilation rate per occupant fields below. When autosizing, the heat exchanger and fan air flow rates should also be autosized.

Note: The supply air inlet node specified in the generic heat exchanger object must be an outdoor air node (ref: `OutdoorAir:Node` and `OutdoorAir:NodeList`). The supply air outlet node specified in the generic heat exchanger object must be a zone air inlet node (ref: `ZoneHVAC:EquipmentConnections`).

#### 1.31.14.1.5 Field: Exhaust Air Flow Rate

The exhaust air flow rate through the ERV unit in cubic meters per second at standard temperature and pressure (dry air at 20°C drybulb). The program uses local barometric pressure to account for altitude using the equation for “standard atmospheric” pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z) ** 5.2559$$

where p = pressure in Pa and Z = altitude in m

Note that this flow rate must be within the valid air flow range for the heat exchanger (ref: [HeatExchanger:AirToAir:SensibleAndLatent](#) in the Engineering Document). In addition, this flow rate must be less than or equal to the exhaust fan air flow rate ([Fan:OnOff](#)). If the exhaust air flow rate is greater than the supply air flow rate, the zone infiltration (ref: [ZoneInfiltration](#)) should be specified accordingly (the infiltration induced by imbalanced air flows is not accounted for automatically). The ERV exhaust air flow rate may also be autosized using the ventilation rate per floor area and/or ventilation rate per occupant fields below. When autosizing, the heat exchanger and fan air flow rates should also be autosized.

Note: The exhaust air inlet node specified in the generic heat exchanger object must be a zone air exhaust node (ref: [ZoneHVAC:EquipmentConnections](#)).

#### 1.31.14.1.6 Field: Supply Air Fan Name

The name of the supply air fan used in this object. Fan type must be [Fan:OnOff](#).

#### 1.31.14.1.7 Field: Exhaust Air Fan Name

The name of the exhaust air fan used in this object. Fan type must be [Fan:OnOff](#).

#### 1.31.14.1.8 Field: Controller Name

This optional field specifies the name of the controller used by this compound component if economizer (free cooling) mode or high humidity control operation is desired. Controller type must be [ZoneHVAC:EnergyRecoveryVentilator:Controller](#).

#### 1.31.14.1.9 Field: Ventilation Rate per Unit Floor Area

This optional numeric field defines the ventilation rate per unit floor area in cubic meters per second per square meter. This field is only used when the supply and exhaust air flow rates are autosized.

#### 1.31.14.1.10 Field: Ventilation Rate per Occupant

This optional numeric field defines the ventilation rate per occupant in cubic meters per second per occupant. This field is only used when the supply and exhaust air flow rates are autosized.

#### 1.31.14.1.11 Field: Availability Manager List Name

This optional input field is the name of an [AvailabilityManagerAssignmentList](#) object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this Stand Alone ERV object's fan. If the Stand Alone ERV is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this Stand Alone ERV object should be on or off.

Following is an example input for this compound object and associated objects that may be defined:

```
ZoneHVAC:EnergyRecoveryVentilator,
  Stand Alone ERV 1,          !- Stand alone ERV name
  FanAndCoilAvailSched,      !- Availability schedule name
  OA Heat Recovery 1,        !- Heat exchanger name
  0.05,                      !- Supply air flow rate {m3/s}
  0.05,                      !- Exhaust air flow rate {m3/s}
  Stand Alone ERV Supply Fan, !- Supply air fan name
  Stand Alone ERV Exhaust Fan, !- Exhaust air fan name
  ERV OA Controller 1;       !- ERV controller name

OutdoorAir:NodeLine,
  OutsideAirInletNodes;      !- 1st Node name or node list name
```

- HVAC,Sum,Zone Ventilator Latent Heating Energy [J]
- HVAC,Average,Zone Ventilator Supply Fan Availability Status []

#### **1.31.14.2.1 Zone Ventilator Electricity Rate [W]**

This output field is the electric consumption rate of the stand alone energy recovery ventilator in Watts. This rate includes the electric consumption by the supply air fan, exhaust air fan and the generic air-to-air heat exchanger.

#### **1.31.14.2.2 Zone Ventilator Electricity Energy [J]**

This output field is the electric consumption of the stand alone energy recovery ventilator in Joules for the timestep being reported. This value includes the electric consumption by the supply air fan, exhaust air fan and the generic air-to-air heat exchanger.

#### **1.31.14.2.3 Zone Ventilator Total Cooling Rate [W]**

This output field is the total (enthalpy) heat extraction rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

#### **1.31.14.2.4 Zone Ventilator Total Cooling Energy [J]**

This output field is the total (enthalpy) heat extraction of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

#### **1.31.14.2.5 Zone Ventilator Total Heating Rate [W]**

This output field is the total (enthalpy) heat addition rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

#### **1.31.14.2.6 Zone Ventilator Total Heating Energy [J]**

This output field is the total (enthalpy) heat addition of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

#### **1.31.14.2.7 Zone Ventilator Sensible Cooling Rate [W]**

This output is the moist air sensible heat extraction rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

**1.31.14.2.8 Zone Ventilator Sensible Cooling Energy [J]**

This output is the moist air sensible heat extraction of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

**1.31.14.2.9 Zone Ventilator Sensible Heating Rate [W]**

This output is the sensible heat addition rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

**1.31.14.2.10 Zone Ventilator Sensible Heating Energy [J]**

This output is the sensible heat addition of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

**1.31.14.2.11 Zone Ventilator Latent Cooling Rate [W]**

This output is the latent heat extraction (dehumidification) rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

**1.31.14.2.12 Zone Ventilator Latent Cooling Energy [J]**

This output is the latent heat extraction (dehumidification) of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

**1.31.14.2.13 Zone Ventilator Latent Heating Rate [W]**

This output is the latent heat addition (humidification) rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

**1.31.14.2.14 Zone Ventilator Latent Heating Energy [J]**

This output is the latent heat addition (humidification) of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

### 1.31.14.2.15 Zone Ventilator Supply Fan Availability Status []

This is the availability status of the Stand Alone ERV fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the Stand Alone ERV object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

### 1.31.15 ZoneHVAC:TerminalUnit:VariableRefrigerantFlow

Terminal units with variable refrigerant flow compound HVAC object are used exclusively with variable refrigerant flow (VRF) air conditioning systems (Ref. [AirConditioner:VariableRefrigerantFlow](#) objects). The VRF terminal unit may be used as zone, air loop or outside air system equipment. The VRF terminal unit compound object contains an optional outdoor air mixer, a DX cooling coil, a DX heating coil, a supply fan (optional for air loop and outdoor air system equipment), and an optional supplemental heating coil object.

Note: The terminal unit may be used in the air loop and/or outdoor air system, however, at this time only constant flow (or limited variation within the limits allowed for DX coils) through the unit is allowed. Using a wide range of outdoor air flow rates will cause the DX coil model to fail. For example, if the minimum outdoor air flow rate is allowed to fall near 0, the DX coil model will calculate very low, even very negative, coil outlet temperatures. This can cause psychrometric warnings to occur and cause the simulation to end prematurely.

For zone equipment the terminal units are connected to a zone using the inlet and exhaust node names specified in a [ZoneHVAC:EquipmentConnections](#) object. The zone exhaust node has the same name as the terminal unit air inlet node. The zone inlet node has the same name as the terminal unit air outlet node. The zone terminal unit is also listed in a zone’s equipment list and will typically be the first equipment operating for both cooling and heating (i.e., Sequence = 1 in the [ZoneHVAC:EquipmentList](#)). Other ZoneHVAC equipment may be used in the same zone and should be sequenced to operate after the zone terminal units (i.e., sequence = 2 or higher).

For air loop equipment and outdoor air system equipment the VRF terminal unit inlet and outlet nodes define the location of the system in the air loop and outdoor air system. The node names must define the path of the air stream in order from the beginning of the air loop or outdoor air system to the outlet of that system.

This VRF terminal unit can be controlled based on a load or set point. When the system is used as zone equipment load control is always used. When the VRF terminal unit is used in an air loop and the control zone name or thermostat location is specified, the system is controlled based on zone load. If the control zone name or thermostat location is not specified the VRF terminal unit will be controlled based on terminal unit or coil outlet node set point temperature. When set point based control is used the node temperature set points may be placed at the outlet of the terminal unit or at individual coil outlet nodes.

If the VRF terminal unit is used in an air loop's outdoor air system, control is always based on a terminal unit or coil outlet node temperature set point.

The terminal units operate to satisfy a heating or cooling load in a zone based on a zone thermostat temperature set point. A direct-expansion (DX) cooling and/or DX heating coil is specified depending on the operating mode required. Both a DX cooling and DX heating coil will typically be installed in the terminal unit, however only one may be used if desired. An optional supplemental heating coil can also be added to the terminal unit to provide additional heating when the main DX heating coil could not meet the entire heating load of a zone during cold outdoor conditions. The Supplemental Heating Coil Object Type must be **Coil:Heating:Electric**, **Coil:Heating:Fuel**, **Coil:Heating:Water**, or **Coil:Heating:Steam**. Outdoor ventilation air is modeled with the use of an optional outside air mixer object. Outside air may be provided to the zone only when the coil is operating or can be supplied continuously even when the coil is not operating.

A supply air fan can be modeled as either draw through or blow through. The supply air fan is required for zone equipment and optional for air loop and outdoor air system equipment. The Supply Air Fan Object Type must be **Fan:SystemModel**, **Fan:OnOff**, or **Fan:ConstantVolume** if **AirConditioner:VariableRefrigerantFlow** is used to model the VRF outdoor unit. The Supply Air Fan Object Type must be **Fan:SystemModel** or **Fan:VariableVolume** if **AirConditioner:VariableRefrigerantFlow:-FluidTemperatureControl** or **AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl:HR** is used to model the VRF outdoor unit.

### 1.31.15.1 Inputs

#### 1.31.15.1.1 Field: Zone Terminal Unit Name

This alpha field defines a unique user-assigned name for an instance of a variable refrigerant flow zone terminal unit. Any reference to this terminal unit by another object will use this name. The zone terminal unit name must be specified in a **ZoneTerminalUnitList** object to connect this terminal unit to an **AirConditioner:VariableRefrigerantFlow** object.

#### 1.31.15.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the terminal unit operates during a given time period. A schedule value equal to 0 denotes that the terminal unit must be off for that time period. A value greater than 0 denotes that the terminal unit is available to operate during that time period. This schedule may be used to completely disable the terminal unit as required. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.31.15.1.3 Field: Terminal Unit Air Inlet Node Name

This alpha field defines the name of the terminal unit air inlet node. This node name should be the same as a zone exhaust node (ref: **ZoneHVAC:EquipmentConnections**).

#### 1.31.15.1.4 Field: Terminal Unit Air Outlet Node Name

This alpha field defines the name of the terminal unit air outlet node. This node name should be the same as a zone inlet node (ref: **ZoneHVAC:EquipmentConnections**).

#### 1.31.15.1.5 Field: Cooling Supply Air Flow Rate

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in cooling mode.

**1.31.15.1.6 Field: No Cooling Supply Air Flow Rate**

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit's cooling coil is not operating and the previous mode was cooling.

**1.31.15.1.7 Field: Heating Supply Air Flow Rate**

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in heating mode.

**1.31.15.1.8 Field: No Heating Supply Air Flow Rate**

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit's heating coil is not operating and the previous mode was heating.

**1.31.15.1.9 Field: Cooling Outdoor Air Flow Rate**

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in cooling mode. This input field is set to zero flow when the VRF terminal unit is connected to an *AirTerminal:SingleDuct:Mixer* object.

**1.31.15.1.10 Field: Heating Outdoor Air Flow Rate**

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in heating mode. This input field is set to zero flow when the VRF terminal unit is connected to an *AirTerminal:SingleDuct:Mixer* object.

**1.31.15.1.11 Field: No Load Outdoor Air Flow Rate**

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is not operating in cooling or heating mode. This input field is set to zero flow when the VRF terminal unit is connected to an *AirTerminal:SingleDuct:Mixer* object.

**1.31.15.1.12 Field: Supply Air Fan Operating Mode Schedule Name**

This alpha field defines the name of the supply air fan operating mode schedule. Schedule values equal to 0 denote cycling fan/cycling coil operation. All other schedule values denote constant fan/cycling coil operation.

**1.31.15.1.13 Field: Supply Air Fan Placement**

This alpha field has two choices: *BlowThrough* or *DrawThrough*. If this field is left blank, the default is blow through.

The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils. The fan “blows through” the cooling and heating coils. If an outside air mixer is used, the fan inlet connects to the outdoor air mixer's mixed air node. If an outdoor air mixer is not used, the fan inlet connects to the zone exhaust node. For this configuration, the fan outlet always connects to the DX cooling coil inlet node (or if a DX cooling coil is not used, the DX heating coil inlet node).

The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan. The fan “draws air through” the DX coil(s). In this case the fan inlet always connects to the DX heating coil outlet node (or if a DX heating coil is not use, the DX cooling coil outlet node) and the fan outlet node always connects to the zone inlet node.

**1.31.15.1.14 Field: Supply Air Fan Object Type**

This choice field contains the identifying type of supply air fan specified for the furnace. Fan type must be *Fan:OnOff*, *Fan:ConstantVolume*, *Fan:SystemModel* or *Fan:VariableVolume*. The Supply Air Fan Object Type must be *Fan:SystemModel*, *Fan:OnOff*, or *Fan:ConstantVolume* if *AirConditioner:VariableRefrigerantFlow* is used to model the VRF outdoor unit. The Supply Air Fan Object Type must be *Fan:SystemModel* or *Fan:VariableVolume* if *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* or *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl:HR* is used to model the VRF outdoor unit.

*Fan:ConstantVolume* is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. *Fan:OnOff* is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0). The *Fan:SystemModel* may be used to model either of these fan operating characteristics.

This field may be left blank when the VRF terminal unit is used as air loop or outdoor air system equipment.

**1.31.15.1.15 Field: Supply Air Fan Object Name**

This alpha field defines the name of the terminal unit's supply air fan. This field may be left blank when the VRF terminal unit is used as air loop or outdoor air system equipment.

**1.31.15.1.16 Field: Outdoor Air Mixer Object Type**

This alpha field contains the identifying type of outdoor air mixer specified for the terminal unit. Outdoor air mixer type must be *OutdoorAir:Mixer*. This input field should be left blank when the VRF terminal unit is connected to an *AirTerminal:SingleDuct:Mixer* object. If this field is left blank, an outdoor air mixer is not simulated. If the VRF terminal unit is used as air loop equipment and this terminal unit's outdoor air flow rates are autosized then the autosized flow rates will be set to 0 when an outdoor air system is used in the air loop (ref *AirloopHVAC:OutdoorAirSystem*).

**1.31.15.1.17 Field: Outdoor Air Mixer Object Name**

This alpha field defines the name of the terminal unit's outdoor air mixer. This input field should be left blank when the VRF terminal unit is connected to an *AirTerminal:SingleDuct:Mixer* object. If this field is left blank, an outdoor air mixer is not simulated.

**1.31.15.1.18 Field: DX Cooling Coil Object Type**

This choice field contains the identifying type of the terminal unit's DX cooling coil. The only valid DX cooling coil type is *Coil:Cooling:DX:VariableRefrigerantFlow*. This field should be left blank when a DX cooling coil is not simulated.

**1.31.15.1.19 Field: DX Cooling Coil Name**

This alpha field defines the name of the terminal unit's DX cooling coil. If this field is left blank, a DX cooling coil is not simulated.

**1.31.15.1.20 Field: DX Heating Coil Object Type**

This choice field contains the identifying type of the terminal unit's DX heating coil. The only valid DX heating coil type is *Coil:Heating:DX:VariableRefrigerantFlow*. This field should be left blank when a DX heating coil is not simulated.

**1.31.15.1.21 Field: DX Heating Coil Object Name**

This alpha field defines the name of the terminal unit's DX heating coil. This field should be left blank when a DX heating coil is not simulated.

**1.31.15.1.22 Field: Zone Terminal Unit On Parasitic Electric Energy Use**

This numeric field defines the parasitic electrical energy use of the zone terminal unit when either terminal unit coil is operating. When in cooling mode, this electric energy use is reported in a zone terminal unit cooling electric consumption output variable. When in heating mode, this electric energy use is reported in a zone terminal unit heating electric consumption output variable.

**1.31.15.1.23 Field: Zone Terminal Unit Off Parasitic Electric Energy Use**

This numeric field defines the parasitic electrical energy use of the zone terminal unit when the terminal unit coil(s) is not operating. When the previous mode was cooling, this electric energy use is reported in a zone terminal unit cooling electric consumption output variable. When the previous mode was heating, this electric energy use is reported in a zone terminal unit heating electric consumption output variable.

**1.31.15.1.24 Field: Rated Total Heating Capacity Sizing Ratio**

This numeric field defines the ratio of the heating coil to cooling coil size when autosizing is used. The model assumes that when used, this value will be greater than 1. This field supersedes the Rated Total Heating Capacity Sizing Ratio entered in the **AirConditioner:VariableRefrigerantFlow** object. If this field is left blank, the value entered in the parent object is used for sizing. If neither field is used, the sizing ratio is assumed to be 1.

**1.31.15.1.25 Field: Availability Manager List Name**

This optional input field is the name of an **AvailabilityManagerAssignmentList** object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this Zone Terminal Unit object's fan. If the Zone Terminal Unit is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this Zone Terminal Unit object should be on or off.

**1.31.15.1.26 Field: Design Specification ZoneHVAC Sizing Object Name**

This optional input field is the name of a **DesignSpecification:ZoneHVAC:Sizing** object. The name must correspond to unique name of a **DesignSpecification:ZoneHVAC:Sizing** object. A Design Specification Zone HVAC Sizing object defines scalable sizing methods for sizing input fields such as Cooling Supply Air Flow Rate in this VRF terminal unit zone HVAC object. The scaled Supply Air Flow Rate in turn is used to size cooling and heating capacity of the unit.

**1.31.15.1.27 Field: Supplemental Heating Coil Object Type**

This alpha field defines the type of supplemental heating coil to be used by this VRF terminal unit. The input requirements for these heating coil objects are described elsewhere in this document. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the supplemental heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (VRF terminal unit) itself provides the "controller" function of modulating water flow. Supplemental Heating Coil Object Type must be **Coil:Heating:Electric**, **Coil:Heating:Fuel**, **Coil:Heating:Water**, or **Coil:Heating:Steam**.

**1.31.15.1.28 Field: Supplemental Heating Coil Name**

This alpha field defines the name of the supplemental heating coil used by this VRF terminal unit, and this name should match the name specified in the corresponding heating coil object.

**1.31.15.1.29 Field: Maximum Supply Air Temperature from Supplemental Heater**

This numeric field defines the maximum supply air temperature in degrees Celsius leaving the VRF terminal unit supplemental heater coil. The supplemental heater will be controlled so that its supply air temperature does not exceed this value. This field is autosizable. If this input field is left blank, the value defaults to autosize.

**1.31.15.1.30 Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation**

This numeric field defines the maximum outdoor dry-bulb temperature in degrees Celsius for this VRF terminal unit supplemental heating coil operation. The supplemental heater will not operate when the outdoor dry-bulb temperature is above this value. The maximum value must be less than or equal to 21°C. If this field is left blank, the default value of 21°C will be used.

**1.31.15.1.31 Field: Controlling Zone or Thermostat Location**

This alpha field is only used when this VRF terminal unit is used as air loop equipment with load based operational control. When the terminal unit is used in an air loop and this terminal unit is load controlled, this zone's thermostat will control operation. When this terminal unit is used in an air loop and is set point controlled, this field must be blank (i.e., when the controlling zone name is present the system will be load controlled).

Following is an example input for a ZoneHVAC:TerminalUnit:VariableRefrigerantFlow object.

#### 1.31.15.2.1 Zone VRF Air Terminal Total Cooling Rate [W]

This field is the total (sensible and latent) cooling rate output of the terminal unit in Watts. This is determined by terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total energy rate delivered to the zone.

#### 1.31.15.2.2 Zone VRF Air Terminal Total Cooling Energy [J]

This is the total (sensible plus latent) cooling output of the terminal unit in Joules over the time step being reported. This is determined by the terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total cooling energy delivered to the zone.

#### 1.31.15.2.3 Zone VRF Air Terminal Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate output of the terminal unit in Watts. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible cooling energy rate delivered to the zone.

**1.31.15.2.4 Zone VRF Air Terminal Sensible Cooling Energy [J]**

This is the moist air sensible cooling output of the terminal unit in Joules for the time step being reported. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible cooling energy delivered to the zone.

**1.31.15.2.5 Zone VRF Air Terminal Latent Cooling Rate [W]**

This is the latent cooling rate output of the terminal unit in Watts. This is determined by the inlet and outlet air humidity ratios and the air mass flow rate through the unit. This value describes the latent cooling energy rate delivered to the zone.

**1.31.15.2.6 Zone VRF Air Terminal Latent Cooling Energy [J]**

This is the latent cooling output of the terminal unit in Joules for the time step being reported. This is determined by the inlet and outlet air humidity ratios and the air mass flow rate through the unit. This value describes the latent cooling energy delivered to the zone.

**1.31.15.2.7 Zone VRF Air Terminal Total Heating Rate [W]**

This field is the total enthalpic heating rate output of the terminal unit in Watts. This is determined by the terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total heating energy rate delivered to the zone.

**1.31.15.2.8 Zone VRF Air Terminal Total Heating Energy [J]**

This is the total enthalpic heating output of the terminal unit in Joules over the time step being reported. This is determined by the terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total heating energy delivered to the zone.

**1.31.15.2.9 Zone VRF Air Terminal Sensible Heating Rate [W]**

This output is the moist air sensible heating rate output of the terminal unit in Watts. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible heating energy rate delivered to the zone.

**1.31.15.2.10 Zone VRF Air Terminal Sensible Heating Energy [J]**

This is the moist air sensible heating output of the terminal unit in Joules for the time step being reported. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible heating energy delivered to the zone.

**1.31.15.2.11 Zone VRF Air Terminal Latent Heating Rate [W]**

This is the latent heating rate output of the terminal unit in Watts. This is determined by the inlet and outlet air specific humidity ratios and the air mass flow rate through the unit. This value describes the latent heating energy rate delivered to the zone.

**1.31.15.2.12 Zone VRF Air Terminal Latent Heating Energy [J]**

This is the latent heating output of the terminal unit in Joules for the time step being reported. This is determined by the inlet and outlet air specific humidity ratios and the air mass flow rate through the unit. This value describes the latent heating energy delivered to the zone.

**1.31.15.2.13 Zone VRF Air Terminal Cooling Electricity Rate [W]**

This output field is the parasitic electricity consumption rate of the zone terminal unit in Watts. The consumption rate includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The terminal unit parasitic on and off electricity is reported in this cooling output variable when the unit operates in cooling mode or the most recent operation was for cooling.

**1.31.15.2.14 Zone VRF Air Terminal Cooling Electricity Energy [J]**

This output field is the electricity consumption of the zone terminal unit in Joules for the time period being reported. The consumption includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. The terminal unit parasitic on and off electricity consumption is reported in this cooling output variable when the unit operates in cooling mode or the most recent operation was for cooling. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

**1.31.15.2.15 Zone VRF Air Terminal Heating Electricity Rate [W]**

This output field is the parasitic electricity consumption rate of the zone terminal unit in Watts. The consumption rate includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The terminal unit parasitic on and off electricity is reported in this heating output variable when the unit operates in heating mode or the most recent operation was for heating.

**1.31.15.2.16 Zone VRF Air Terminal Heating Electricity Energy [J]**

This output field is the electricity consumption of the zone terminal unit in Joules for the time period being reported. The consumption includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. The terminal unit parasitic on and off electricity consumption is reported in this heating output variable when the unit operates in heating mode or the most recent operation was for heating. This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.31.15.2.17 Zone VRF Air Terminal Fan Availability Status []**

This is the availability status of the Zone Terminal Unit fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the Zone Terminal Unit object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:\* Outputs). For multiple availability managers in an Availability Manager Assignment List along with Hybrid Ventilation Manager, rules to determine fan availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the "detailed" reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

### 1.31.16 ZoneHVAC:HybridUnitaryHVAC

ZoneHVAC:Hybrid UnitaryHVAC is a black-box model for packaged forced air equipment with multiple discrete operating modes. Generally, a "hybrid" is any system that exhibits both continuous and discrete dynamic behavior – a system that can both flow (as could be described by a differential equation) and jump (as must be described by distinct modes). Equipment in this category may utilize a wide variety of technologies including, but not limited to: indirect evaporative cooling, desiccant dehumidification, heat recovery, vapor compression, adsorption, or ventilation cooling. Each hybrid system packages multiple technologies into a single integrated system. There are a multitude of unique hybrid system architectures, and each unique system may have numerous unique operating modes.

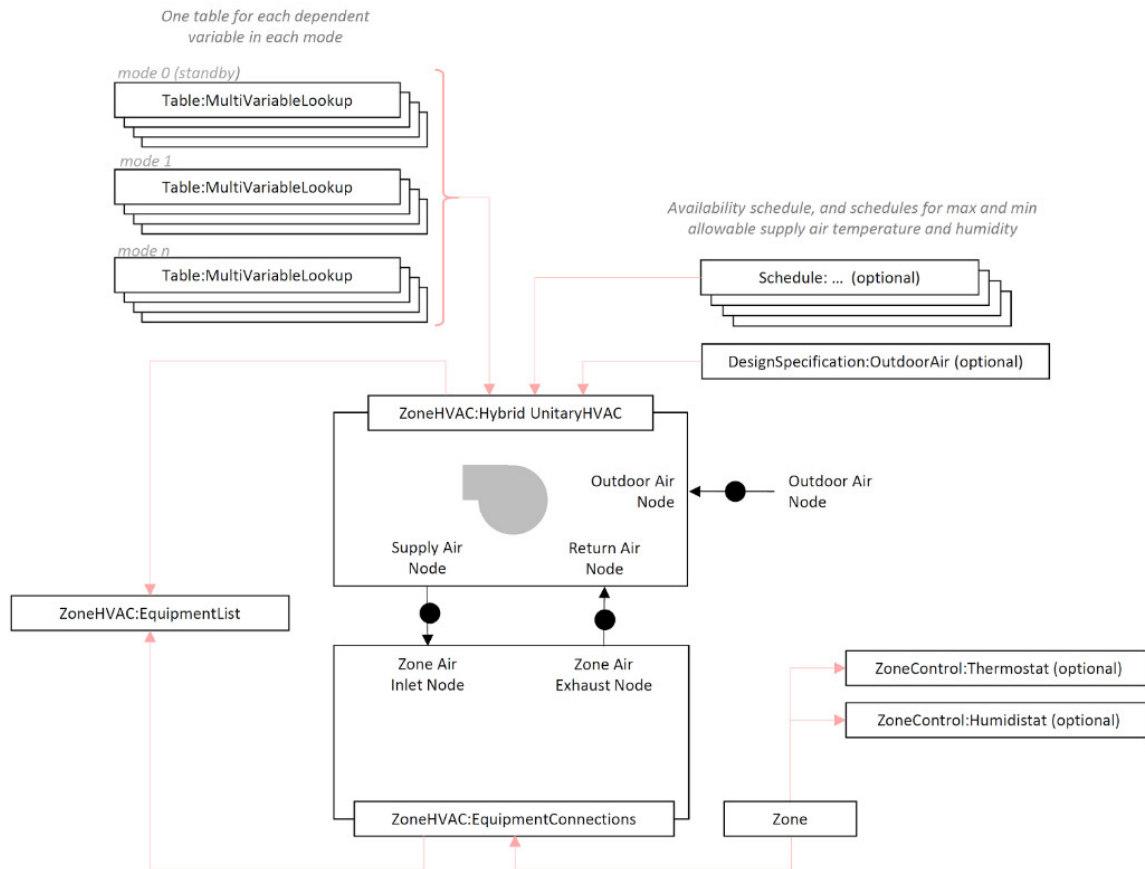

Figure 1.140: Schematic of object links for ZoneHVAC:HybridUnitaryHVAC

ZoneHVAC:HybridUnitaryHVAC is a black-box model designed to allow empirical representation of a wide variety of hybrid unitary systems. The model does not require information about internal system architecture, however it requires extensive data to describe the performance of a product in every operating mode. The model is intended for packed forced air equipment and can represent unitary systems that consume electricity, water, and up to two additional fuel types.

Uncontrolled independent variables include outdoor and indoor air temperature and humidity ratio. Controlled independent variables include: operating mode, supply air flow rate, outdoor air fraction, and part runtime fraction. Dependent variables include supply air temperature, supply air humidity, electricity use, fuel uses, water use, fan electricity use, and external static pressure. Empirical data tables (see [Table:Lookup](#)) are required to map each dependent variable in each discrete operating mode. The model

can accommodate up to 26 discrete operating modes, including a standby mode. Each mode is limited to operate within independently specified ranges of indoor and outdoor psychrometric conditions. The standby mode is not limited by either indoor or outdoor psychrometric conditions.

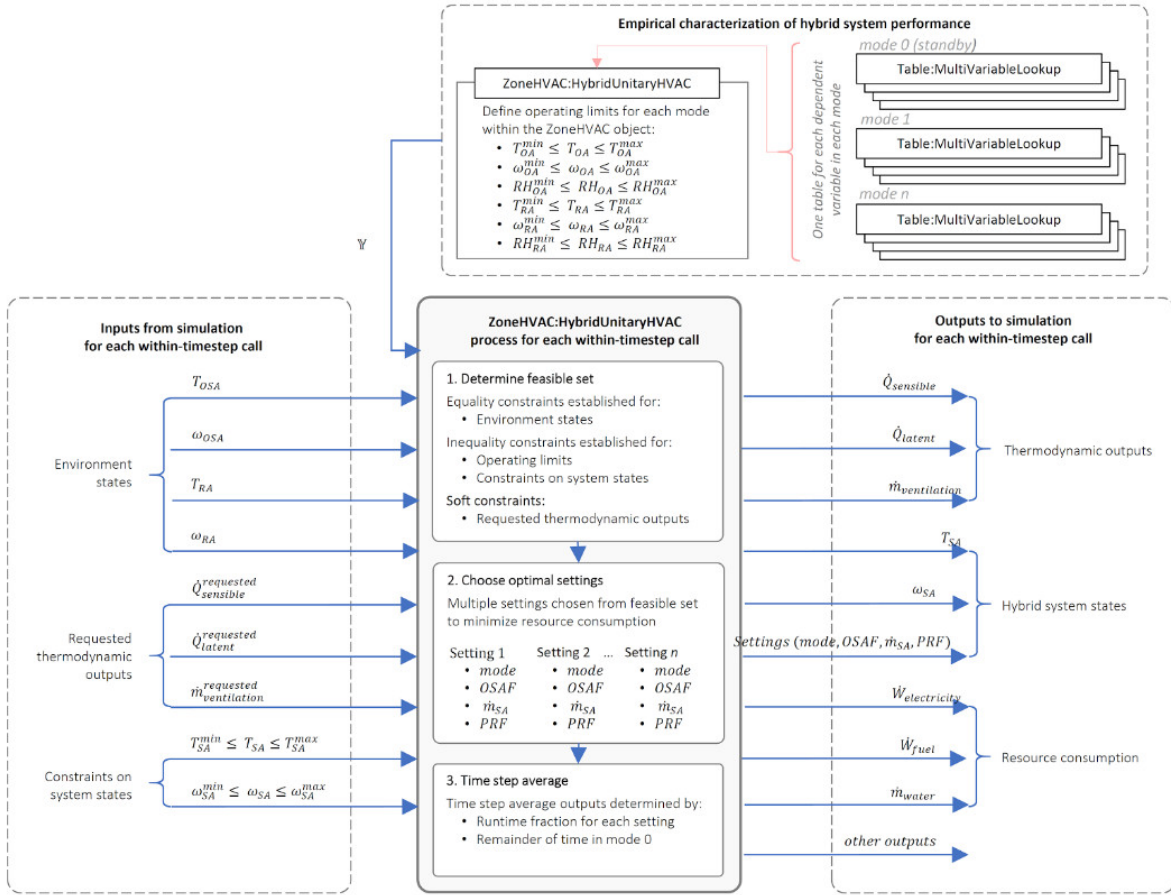

Figure 1.141: Schematic explanation of the architecture and function of `ZoneHVAC:HybridUnitaryHVAC`

`ZoneHVAC:HybridUnitaryHVAC` is structured as a constrained optimization problem – in each time step the model will choose one or more combinations of the controlled independent variables so as to best provide the predicted sensible load, the predicted latent load, and the scheduled zone ventilation requirement, with the least amount of resource consumption.

A setting is defined as any unique combination of mode, outdoor air fraction, and supply air flow rate. The system may operate with multiple settings in each time step. The portion of each time step spent in a setting is described as the part runtime fraction for that setting. During any time step that the combination of settings can satisfy all of the soft constraints with part runtime fractions that sum to less than one, the system will operate in a standby mode (Mode 0) for the remainder of the timestep. If no combination of settings will satisfy all of the soft constraints the system will choose the combination of settings that most nearly satisfies all soft constraints. If the indoor and outdoor psychrometric conditions are beyond the constraints that limit each operating mode, or if no setting will satisfy all constraints on supply air temperature and absolute humidity, the system will operate in standby mode (Mode 0).

### 1.31.16.1 Inputs

#### 1.31.16.1.1 Field: Name

This alpha input field specifies a unique user-assigned name for one ZoneHVAC:HybridUnitaryHVAC unit. Any reference to this unit by another object will use this name. The name must be specified in a ZoneHVAC:EquipmentList object to connect this unit to a zone.

**1.31.16.1.2 Field: Availability Schedule Name** This alpha input field specifies the name of the schedule (ref: Group – Schedules) that specifies when the ZoneHVAC:HybridUnitaryHVAC unit can operate. A schedule value greater than 0 means the unit can be available. A schedule value equal to zero means the unit cannot operate. Availability of the unit is governed by the availability schedule and by availability managers. The availability schedule may be used to completely disable the unit. If this field is blank, the unit can always be available. If the unit is available but there is no sensible load, no latent load, and no need for ventilation, the unit will operate in a standby mode (mode 0).

**1.31.16.1.3 Field: Availability Manager List Name** This optional alpha input field is the name of an AvailabilityManagerAssignmentList object. (ref: Group - Air Distribution, AvailabilityManagerAssignmentList, and Group - System Availability Managers). Availability of the unit is governed by the availability schedule and by availability managers specified in the list named here. If the unit is available but there is no sensible load, no latent load, and no need for ventilation, the unit will operate in a standby mode (mode 0).

**1.31.16.1.4 Field: Minimum Supply Air Temperature Schedule Name** This optional alpha input field specifies the name of the schedule (ref: Group – Schedules) that specifies the minimum supply air temperature allowed in each time step. Values in this schedule are used as a constraint in choosing the feasible settings for supply air flow rate and outdoor air fraction in each operating mode. If this field is blank, no minimum is imposed.

**1.31.16.1.5 Field: Maximum Supply Air Temperature Schedule Name** This optional alpha input field specifies the name of the schedule (ref: Group – Schedules) that specifies the maximum supply air temperature allowed in each time step. Values in this schedule are used as a constraint in choosing the feasible settings for supply air flow rate and outdoor air fraction in each operating mode. If this field is blank, no maximum is imposed.

**1.31.16.1.6 Field: Minimum Supply Air Humidity Ratio Schedule Name** This optional alpha input field specifies the name of the schedule (ref: Group – Schedules) that specifies the minimum supply air humidity ratio allowed in each time step. Values in this schedule are used as a constraint in choosing the feasible settings for supply air flow rate and outdoor air fraction in each operating mode. If this field is blank, no minimum is imposed.

**1.31.16.1.7 Field: Maximum Supply Air Humidity Ratio Schedule Name** This optional alpha input field specifies the name of the schedule (ref: Group – Schedules) that specifies the maximum supply air humidity ratio allowed in each time step. Values in this schedule are used as a constraint in choosing the feasible settings for supply air flow rate and outdoor air fraction in each operating mode. If this field is blank, no maximum is imposed.

**1.31.16.1.8 Field: Method to Choose Controlled Inputs and Part Runtime Fraction** This alpha input field specifies the method that will be used to choose operating mode(s), supply air flow rate(s), outdoor air fraction(s) and part runtime fraction(s) in each time step. The only valid choices are "Automatic" and "User Defined", "Automatic" chooses the controlled independent variables to minimize resource use within each time step, subject to constraints, while best satisfying zone sensible loads, latent

loads, and the scheduled ventilation rate. "User Defined" indicates that the user will provide a custom control sequence, using Energy Management System objects or other means, to choose the controlled independent variables and determine system outputs in each time step.

**1.31.16.1.9 Field: Return Air Node Name** This alpha input field specifies the name of the HVAC system node from which the hybrid unit draws return air. This node name must also be specified as a zone return air node in a **ZoneHVAC:EquipmentConnections** object. It may also be included in **NodeList** object that is specified as a zone return air node in a **ZoneHVAC:EquipmentConnections** object. (Ref. Group - Zone Equipment **ZoneHVAC:EquipmentConnections** and Group - Node-Branch Management **NodeList**).

**1.31.16.1.10 Field: Outdoor Air Node Name** This alpha input field specifies the name of the HVAC system node from which the hybrid unit draws outdoor air. This node name must also be specified in an **OutdoorAir:Node** or **OutdoorAir:NodeList** object. (Ref. Group - Node-Branch Management **OutdoorAir:Node** and **OutdoorAir:NodeList**).

**1.31.16.1.11 Field: Supply Air Node Name** This alpha input field specifies the name of the HVAC system node to which the hybrid unit sends supply air. This node name must also be specified as zone inlet node in a **ZoneHVAC:EquipmentConnections** object. It may also be included in **NodeList** object that is specified as a zone inlet node in a **ZoneHVAC:EquipmentConnections** object. (Ref. Group - Zone Equipment **ZoneHVAC:EquipmentConnections** and Group - Node-Branch Management **NodeList**).

**1.31.16.1.12 Field: Relief Node Name** This optional alpha input field specifies the name of an HVAC system node which can extract air from the zone to balance the air supplied to the zone by the unit. This node name would match the name of a zone exhaust air node.

**1.31.16.1.13 Field: System Maximum Supply Air Volume Flow Rate** This numeric input field specifies the maximum standard density supply air volume flow rate among all operating modes. The field allows custom resizing of the hybrid unit. The values specified in each **Table:Lookup** object associated with a hybrid unit represent performance data for a specific product of a particular size, but the value output from each **Table:Lookup** object is augmented by a normalization reference (Ref: Group - Performance Tables **Table:Lookup**). The normalization reference specified for all **Table:Lookup** objects associated with a hybrid unit should be the maximum supply air mass flow rate for the real hybrid unit that was used to create the performance data included in each table object. The value in this field is used to rescale the normalized values output from tables for extensive dependent variables. If the standard density supply air volume flow rate input to this field is equivalent to the system maximum supply air mass flow rate used as the normalization reference – given appropriate unit conversions – then the resulting output from the model will exactly match the original performance data specified in each table. If the value in this field is larger or smaller, the values for extensive dependent variables will be scaled proportionally. The values of intensive dependent variables are rescaled by the normalization reference value, so will always match the original performance data specified in each table object. The value in this field should be specified as standard density volume flow rate. Standard density in EnergyPlus corresponds to dry air at 20°C drybulb, and 101,325 Pa.

**1.31.16.1.14 Field: External Static Pressure at System Maximum Supply Air Flow Rate** This optional numeric input field specifies the external static pressure at the system maximum supply air flow rate specified in the previous field. Fan affinity laws are used to scale supply fan power from the scenario used to create the performance data included in each **Table:Lookup** object, to a scenario

that corresponds to the value specified in this field. The result is also used to adjust the system electric power accordingly. If this field is blank, the supply fan power is not scaled from the values specified in lookup tables.

**1.31.16.1.15 Field: Fan Heat Included in Lookup Tables** This alpha field specifies if the fan heat gain was taken into account in the lookup tables specified for each mode. Valid choices are **Yes** and **No**. If No, the fan heat is calculated based on the fan power and the next two fields specify the location and fraction of the fan heat gain to the air stream, otherwise the fan heat gain is not calculated.

**1.31.16.1.16 Field: Fan Heat Gain Location** This optional alpha field specifies the location that the fan heat gain should be applied if not included in the lookup tables. Valid choices include: **MixedAirStream** and **SupplyAirStream**. MixedAirStream is upstream of the cooling medium while SupplyAirStream is downstream of the cooling medium.

**1.31.16.1.17 Field: Fan Heat Gain in Airstream Fraction** This optional numeric field is the fraction of the fan heat that is added to the air stream if not included in the lookup tables. A value of 0 means that the fan heat is completely outside the air stream. A value of 1 means that all of the fan heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

**1.31.16.1.18 Field: Scaling Factor** This optional numeric field scales all extensive dependent variables including: supply air mass flow rate, electricity use, fuel uses, and water use. The value in this field acts together with the value in field System Maximum Standard Density Supply Air Volume Flow Rate to allow custom resizing of the hybrid unit.

**1.31.16.1.19 Field: Minimum Time Between Mode Change** This numeric field specifies the minimum time that must pass before the hybrid unit can change mode. If the value in this field is larger than each timestep, the mode selected in one time step will persist in later time steps until the minimum time between mode change is satisfied. If the value in this field is smaller than each timestep, it will determine the minimum part runtime fraction allowed for any mode. Supply air mass flow rate and outdoor air fraction within a mode are not subject to minimum runtime and may change in every time step, or with any part runtime fraction. Mode 0 does not have a minimum time. If this field is blank, the default minimum time between mode change is 10 minutes.

**1.31.16.1.20 Field: First Fuel Type** This alpha field specifies the fuel type associated with the **Table:Lookup** object specified in field "System Electric Power Power Lookup Table". Valid choices include: None, Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, Other-Fuel1, OtherFuel2, Steam, **DistrictHeating** and **DistrictCooling**. If this field is blank, the default first fuel type is Electricity.

**1.31.16.1.21 Field: Second Fuel Type** This alpha field specifies the fuel type associated with the **Table:Lookup** object specified in field "System Second Fuel Consumption Lookup Table". Valid choices include: None, Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, Other-Fuel1, OtherFuel2, Steam, **DistrictHeating** and **DistrictCooling**. If this field is blank, the default second fuel type is None.

**1.31.16.1.22 Field: Third Fuel Type** This alpha field specifies the fuel type associated with the **Table:Lookup** object specified in field "System Third Fuel Consumption Lookup Table". Valid choices include: None, Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, OtherFuel1, OtherFuel2, Steam, **DistrictHeating** and **DistrictCooling**. If this field is blank, the default second fuel type is None.

**1.31.16.1.23 Field: Objective Function to Minimize** In each time step Zone-HVAC:HybridUnitaryHVAC will choose one or more combinations of the controlled independent variables, subject to constraints, so as to best satisfy sensible load, latent load, and scheduled ventilation with the least amount of resource consumption. This alpha field specifies which resource will be minimized by the optimization. Valid choices include: Electricity Use, Second Fuel Use, Third Fuel Use, and Water Use. If this field is blank, the objective function will minimize electricity use.

**1.31.16.1.24 Field: Design Specification Outdoor Air Object Name** This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the a schedule for the required standard density volume of outdoor air. If this field is blank, the system may still supply outdoor air, if it is capable, when doing so is the most efficient way to satisfy other constraints.

**1.31.16.1.25 Field: Mode 0 Name** This alpha input field specifies a unique user-assigned descriptive name for Mode 0. Mode 0 describes performance when the hybrid unit is in standby. Mode 0 is usually characterized by electricity use for controls and crankcase heaters, or other standby resource consumption. Mode 0 will be chosen for any timestep, or portion of timestep, when the unit is available, but there is no sensible load, latent load, or scheduled ventilation. Mode 0 is not constrained by limits on indoor or outdoor conditions.

**1.31.16.1.26 Field: Mode 0 Supply Air Temperature Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes supply air temperature for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode 0 will not be considered for any period that requires ventilation, heating, cooling, humidification, or dehumidification. If this field is blank, when Mode 0 is chosen (during standby periods) the supply air temperature will equal the return air temperature.

**1.31.16.1.27 Field: Mode 0 Supply Air Humidity Ratio Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes supply air humidity ratio for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode 0 will not be considered for any period that requires ventilation, heating, cooling, humidification, or dehumidification. If this field is blank, when Mode 0 is chosen (during standby periods) the supply air humidity ratio will equal the return air humidity ratio.

**1.31.16.1.28 Field: Mode 0 System Electric Power Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes electric power consumption for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode 0 does not consume electricity.

**1.31.16.1.29 Field: Mode 0 Supply Fan Electric Power Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes supply fan electric power consumption for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode 0 does not consume electricity for supply fan.

**1.31.16.1.30 Field: Mode 0 External Static Pressure Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes external static pressure for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, external static pressure will not be reported.

**1.31.16.1.31 Field: Mode 0 System Second Fuel Consumption Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes second fuel consumption for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode 0 does not consume a second fuel.

**1.31.16.1.32 Field: Mode 0 System Third Fuel Consumption Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes third fuel consumption for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode 0 does not consume a third fuel.

**1.31.16.1.33 Field: Mode 0 System Water Use Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes water consumption for Mode 0 as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode 0 does not consume water.

**1.31.16.1.34 Field: Mode 0 Outdoor Air Fraction** This optional numeric input field specifies the outdoor air fraction for Mode 0. Outdoor air fraction is not a controlled independent variable in Mode 0, it must be set to a particular value for all times that Mode 0 operates. Typically Mode 0 would have zero supply air, in which case this value would be irrelevant. If this field is blank, the outdoor air fraction for Mode 0 will be 0.00.

**1.31.16.1.35 Field: Mode 0 Supply Air Mass Flow Rate Ratio** This optional numeric field specifies the supply air mass flow rate ratio for Mode 0. Mass flow rate is not a controlled independent variable in Mode 0, it must be set to a particular value for all times that Mode 0 operates. Supply air mass flow rate ratio describes supply air mass flow rate as a fraction of the mass flow rate associated with the value in field: "System Maximum Standard Density Supply Air Volume Flow Rate". If this field is blank, the supply air mass flow rate ratio for Mode 0 will be 0.00.

**1.31.16.1.36 Field-Set: Mode Definition (extensible object)** The definition of each operating mode is given as inputs to 25 fields. The first field specifies a unique name for the mode. The following eight fields specify the names of **Table:Lookup** objects that describe hybrid unit performance parameters. The remaining sixteen fields specify constraints on controlled independent variables, and constraints to describe the indoor and outdoor psychrometric conditions at which the mode is allowed. The definition of

operating modes is extensible. To define multiple modes, repeat the following 25 fields with appropriate input values for each mode. The object does not require that modes be defined in a particular order. Up to 25 modes can be defined in this way.

**1.31.16.1.37 Field: Mode # Name** This alpha input field specifies a unique user-assigned descriptive name for Mode #. Each desired mode must have a mode name in order for that mode to be included in the simulation.

**1.31.16.1.38 Field: Mode # Supply Air Temperature Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes supply air temperature for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode # will not be considered for any time step that requires ventilation, heating, cooling, humidification, or dehumidification.

**1.31.16.1.39 Field: Mode # Supply Air Humidity Ratio Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes supply air humidity ratio for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode # will not be considered for any period that requires ventilation, heating, cooling, humidification, or dehumidification.

**1.31.16.1.40 Field: Mode # System Electric Power Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes system electric power consumption for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode # does not consume electricity.

**1.31.16.1.41 Field: Mode # Supply Fan Electric Power Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes supply fan electric power consumption for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode # does not consume electricity for supply fan.

**1.31.16.1.42 Field: Mode # External Static Pressure Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes external static pressure for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, external static pressure will not be reported for Mode #.

**1.31.16.1.43 Field: Mode # System Second Fuel Consumption Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes second fuel consumption for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode # does not consume a second fuel.

**1.31.16.1.44 Field: Mode # System Third Fuel Consumption Lookup Table Name**

This optional alpha input field specifies the name of a **Table:Lookup** object that describes third fuel consumption for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode # does not consume a third fuel.

**1.31.16.1.45 Field: Mode # System Water Use Lookup Table Name** This optional alpha input field specifies the name of a **Table:Lookup** object that describes water consumption for Mode # as a function of six independent variables: outdoor air temperature, outdoor air humidity ratio, return air temperature, return air humidity ratio, supply air mass flow rate, and outdoor air fraction. If this field is blank, Mode # does not consume water.

**1.31.16.1.46 Field: Mode # Minimum Outdoor Air Temperature** This optional numeric input field specifies the minimum outdoor air temperature at which Mode # is allowed. When outdoor air temperature is below this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in **Table:Lookup** objects associated with Model, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no lower constraint on outdoor air temperature for Mode #.

**1.31.16.1.47 Field: Mode # Maximum Outdoor Air Temperature** This optional numeric input field specifies the maximum outdoor air temperature at which Mode # is allowed. When outdoor air temperature is above this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in **Table:Lookup** objects associated with Model, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no upper constraint on outdoor air temperature for Mode #.

**1.31.16.1.48 Field: Mode # Minimum Outdoor Air Humidity Ratio** This optional numeric input field specifies the minimum outdoor air humidity ratio at which Mode # is allowed. When outdoor air humidity ratio is below this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in **Table:Lookup** objects associated with Model, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no lower constraint on outdoor air humidity ratio for Mode #.

**1.31.16.1.49 Field: Mode # Maximum Outdoor Air Humidity Ratio** This optional numeric input field specifies the maximum outdoor air humidity ratio at which Mode # is allowed. When outdoor air humidity ratio is above this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in **Table:Lookup** objects associated with Model, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no upper constraint on outdoor air humidity ratio for Mode #.

**1.31.16.1.50 Field: Mode # Minimum Outdoor Air Relative Humidity** This optional numeric input field specifies the minimum outdoor air relative humidity at which Mode # is allowed. When outdoor air relative humidity is below this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in **Table:Lookup** objects associated with Model, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the lower constraint on outdoor air relative humidity will be 0.00

**1.31.16.1.51 Field: Mode # Maximum Outdoor Air Relative Humidity** This optional numeric input field specifies the maximum outdoor air relative humidity at which Mode # is allowed. When outdoor air relative humidity is above this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the upper constraint on outdoor air relative humidity will be 100

**1.31.16.1.52 Field: Mode # Minimum Return Air Temperature** This optional numeric input field specifies the minimum return air temperature at which Mode # is allowed. When return air temperature is below this value all settings in Mode # will be excluded from the feasible set. This value may be beyond than the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no lower constraint on outdoor air temperature for Mode #.

**1.31.16.1.53 Field: Mode # Maximum Return Air Temperature** This optional numeric input field specifies the maximum return air temperature at which Mode # is allowed. When return air temperature is above this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no upper constraint on outdoor air temperature for Mode #.

**1.31.16.1.54 Field: Mode # Minimum Return Air Humidity Ratio** This optional numeric input field specifies the minimum return air humidity ratio at which Mode # mode one is allowed. When return air humidity ratio is below this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no lower constraint on return air humidity ratio for Mode #.

**1.31.16.1.55 Field: Mode # Maximum Return Air Humidity Ratio** This optional numeric input field specifies the maximum return air humidity ratio at which Mode # is allowed. When return air humidity ratio is above this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, there will be no upper constraint on return air humidity ratio for Mode #.

**1.31.16.1.56 Field: Mode # Minimum Return Air Relative Humidity** This optional numeric input field specifies the minimum return air relative humidity at which Mode # is allowed. When return air relative humidity is below this value all settings in Mode # will be excluded from the feasible set. This value may be beyond the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the lower constraint on return air relative humidity will be 0.00

**1.31.16.1.57 Field: Mode # Maximum Return Air Relative Humidity** This optional numeric input field specifies the maximum return air relative humidity at which Mode # is allowed. When return air relative humidity is above this value all settings in Mode # will be excluded from the feasible set. This value may be beyond than the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the upper constraint on return air relative humidity will be 100

**1.31.16.1.58 Field: Mode # Minimum Outdoor Air Fraction** This optional numeric input field specifies the minimum outdoor air fraction allowed in Mode #. Outdoor air fractions below this value will be excluded from the feasible set within Mode #. This value may be beyond than the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the lower constraint on outdoor air fraction will be 0.00 for Mode #.

**1.31.16.1.59 Field: Mode # Maximum Outdoor Air Fraction** This optional numeric input field specifies the maximum outdoor air fraction allowed in Mode #. Outdoor air fractions above this value will be excluded from the feasible set within Mode #. This value may be beyond than the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the upper constraint on outdoor air fraction will be 1.00 for Mode #.

**1.31.16.1.60 Field: Mode # Minimum Supply Air Mass Flow Rate Ratio** This optional numeric input field specifies the minimum supply air mass flow rate ratio allowed in Mode #. Supply air mass flow rate ratios below this value will be excluded from the feasible set within Mode #. This value may be beyond the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the lower constraint on supply air mass flow rate ratio will be 0.00 for Mode #.

**1.31.16.1.61 Field: Mode # Maximum Supply Air Mass Flow Rate Ratio** This optional numeric input field specifies the maximum supply air mass flow rate ratio allowed in Mode #. Supply air mass flow rate ratios above this value will be excluded from the feasible set within Mode #. This value may be beyond the extents of the data in [Table:Lookup](#) objects associated with Model1, in which case this value sets the limit for extrapolation from the data table. If this field is blank, the upper constraint on supply air mass flow rate ratio will be 1.00 for Mode #.

## 1.31.16.2 Outputs

**1.31.16.2.1 Zone Hybrid Unitary HVAC System Total Cooling Rate [W]** This output reports the rate at which enthalpy is removed by the system. It is calculated as the difference between the enthalpy of the mixture of return air and outdoor air and the enthalpy of the supply air. This output is positive when enthalpy is removed by the system, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.2 Zone Hybrid Unitary HVAC System Total Cooling Energy [J]** This output reports the amount of enthalpy removed by the system. It is calculated as the difference between the enthalpy of the mixture of return air and outdoor air, and the enthalpy of the supply air. This output is positive when enthalpy is removed by the system, otherwise the output is zero. This output is a sum over the reporting period.

**1.31.16.2.3 Zone Hybrid Unitary HVAC System Sensible Cooling Rate [W]** This output reports the rate at which sensible heat is removed by the system. It is calculated as the difference between the enthalpy of dry air at the temperature of the mixture of return air and outdoor air, and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is removed by the system, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.4 Zone Hybrid Unitary HVAC System Sensible Cooling Energy [J]** This output reports the amount of sensible heat removed by the system. It is calculated as the difference between the enthalpy of dry air at the temperature of the mixture of return air and outdoor air, and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is removed by the system, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.5 Zone Hybrid Unitary HVAC System Latent Cooling Rate [W]** This output reports the rate at which latent heat is removed by the system. It is calculated as the enthalpy difference associated with the difference between absolute humidity of the mixture of return air and outdoor air, and the absolute humidity of the supply air. This is the phase change energy associated with moisture removed by the system. This output is positive when latent heat is removed by the system, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.6 Zone Hybrid Unitary HVAC System Latent Cooling Energy [J]** This output reports the amount of latent heat removed by the system. It is calculated as the enthalpy difference associated with the difference between absolute humidity of the mixture of return air and outdoor air, and the absolute humidity of the supply air. This is the phase change energy associated with moisture removed by the system. This output is positive when latent heat is removed by the system, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.7 Zone Hybrid Unitary HVAC Zone Total Cooling Rate [W]** This output reports the rate at which enthalpy is removed from the zone. It is calculated as the difference between the enthalpy of the return air and the enthalpy of the supply air. This output is positive when enthalpy is removed from the zone, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.8 Zone Hybrid Unitary HVAC Zone Total Cooling Energy [J]** This output reports the amount of enthalpy removed from the zone. It is calculated as the difference between the enthalpy of the return air and the enthalpy of the supply air. This output is positive when enthalpy is removed from the zone, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.9 Zone Hybrid Unitary HVAC Zone Sensible Cooling Rate [W]** This output reports the rate at which sensible heat is removed from the zone. It is calculated as the difference between the enthalpy of dry air at the temperature of the return air and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is removed from the zone, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.10 Zone Hybrid Unitary HVAC Zone Sensible Cooling Energy [J]** This output reports the amount of sensible heat removed from the zone. It is calculated as the difference between the enthalpy of dry air at the temperature of the return air and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is removed from the zone, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.11 Zone Hybrid Unitary HVAC Zone Latent Cooling Rate [W]** This output reports the rate at which latent heat is removed from the zone. It is calculated as the enthalpy difference associated with the difference between the absolute humidity of the return air, and the absolute humidity of the supply air. This is the phase change energy associated with moisture removed from the zone. This output is positive when latent heat is removed from the zone, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.12 Zone Hybrid Unitary HVAC Zone Latent Cooling Energy [J]** This output reports the amount of latent heat removed from the zone. It is calculated as the enthalpy difference associated with the difference between the absolute humidity of the return air, and the absolute humidity of the supply air. This is the phase change energy associated with moisture removed from the zone. This output is positive when latent heat is removed from the zone, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.13 Zone Hybrid Unitary HVAC System Total Heating Rate [W]** This output reports the rate at which enthalpy is added by the system. It is calculated as the difference between the enthalpy of the mixture of return air and outdoor air and the enthalpy of the supply air. This output is positive when enthalpy is added by the system, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.14 Zone Hybrid Unitary HVAC System Total Heating Energy [J]** This output reports the amount of enthalpy added by the system. It is calculated as the difference between the enthalpy of the mixture of return air and outdoor air, and the enthalpy of the supply air. This output is positive when enthalpy is added by the system, otherwise the output is zero. This output is a sum over the reporting period.

**1.31.16.2.15 Zone Hybrid Unitary HVAC System Sensible Heating Rate [W]** This output reports the rate at which sensible heat is added by the system. It is calculated as the difference between the enthalpy of dry air at the temperature of the mixture of return air and outdoor air, and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is added by the system, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.16 Zone Hybrid Unitary HVAC System Sensible Heating Energy [J]** This output reports the amount of sensible heat added by the system. It is calculated as the difference between the enthalpy of dry air at the temperature of the mixture of return air and outdoor air, and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is added by the system, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.17 Zone Hybrid Unitary HVAC System Latent Heating Rate [W]** This output reports the rate at which latent heat is added by the system. It is calculated as the enthalpy difference associated with the difference between absolute humidity of the mixture of return air and outdoor air, and the absolute humidity of the supply air. This is the phase change energy associated with moisture added by the system. This output is positive when latent heat is added by the system, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.18 Zone Hybrid Unitary HVAC System Latent Heating Energy [J]** This output reports the amount of latent heat added by the system. It is calculated as the enthalpy difference associated with the difference between absolute humidity of the mixture of return air and outdoor air, and

the absolute humidity of the supply air. This is the phase change energy associated with moisture added by the system. This output is positive when latent heat is added by the system, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.19 Zone Hybrid Unitary HVAC Zone Total Heating Rate [W]** This output reports the rate at which enthalpy is added to the zone. It is calculated as the difference between the enthalpy of the return air and the enthalpy of the supply air. This output is positive when enthalpy is added to the zone, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.20 Zone Hybrid Unitary HVAC Zone Total Heating Energy [J]** This output reports the amount of enthalpy added to the zone. It is calculated as the difference between the enthalpy of the return air and the enthalpy of the supply air. This output is positive when enthalpy is added to the zone, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.21 Zone Hybrid Unitary HVAC Zone Sensible Heating Rate [W]** This output reports the rate at which sensible heat is added to the zone. It is calculated as the difference between the enthalpy of dry air at the temperature of the return air and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is added to the zone, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.22 Zone Hybrid Unitary HVAC Zone Sensible Heating Energy [J]** This output reports the amount of sensible heat added to the zone. It is calculated as the difference between the enthalpy of dry air at the temperature of the return air and the enthalpy of dry air at the temperature of the supply air. This output is positive when sensible heat is added to the zone, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.23 Zone Hybrid Unitary HVAC Zone Latent Heating Rate [W]** This output reports the rate at which latent heat is added to the zone. It is calculated as the enthalpy difference associated with the difference between the absolute humidity of the return air, and the absolute humidity of the supply air. This is the phase change energy associated with moisture added to the zone. This output is positive when latent heat is added to the zone, otherwise it is zero. This output is an average rate over the reporting period.

**1.31.16.2.24 Zone Hybrid Unitary HVAC Zone Latent Heating Energy [J]** This output reports the amount of latent heat added to the zone. It is calculated as the enthalpy difference associated with the difference between the absolute humidity of the return air, and the absolute humidity of the supply air. This is the phase change energy associated with moisture added to the zone. This output is positive when latent heat is added to the zone, otherwise it is zero. This output is a sum over the reporting period.

**1.31.16.2.25 Zone Hybrid Unitary HVAC Predicted Sensible Load to Setpoint Heat Transfer Rate [W]** This output reports the predicted sensible heat transfer rate required to meet the current zone thermostat setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. For a dual setpoint thermostat, the value is zero when the controlled zone's temperature is between the defined heating and cooling setpoints. See [ZoneControl:Thermostat](#) for further information. This value is used as a soft inequality constraint in the constrained optimization problem that determines system settings in each time step. The output is the average over the reporting period.

**1.31.16.2.26 Zone Hybrid Unitary HVAC Predicted Latent Load to Humidistat Setpoint Heat Transfer Rate [W]** This output reports the predicted latent heat transfer rate required to meet the current zone humidistat setpoint. A positive value indicates a humidification load, a negative value indicates a dehumidification load. For a dual setpoint humidistat, the value is zero when the controlled zone's relative humidity is between the defined humidifying and dehumidifying setpoint. See [ZoneControl:Humidistat](#) for further information. This value is used as a soft inequality constraint in the constrained optimization problem that determines system settings in each time step. The output is the average over the reporting period.

**1.31.16.2.27 Zone Hybrid Unitary HVAC Predicted Moisture Load to Humidistat Setpoint Moisture Transfer Rate [kgWater/s]** This output reports the predicted moisture transfer rate required to meet the current zone humidistat setpoint. A positive value indicates a humidification load, a negative value indicates a dehumidification load. For a dual setpoint humidistat, the value is zero when the controlled zone's relative humidity is between the defined humidifying and dehumidifying setpoints. See [ZoneControl:Humidistat](#) for further information. This value is used as a soft inequality constraint in the constrained optimization problem that determines system settings in each time step. The output is the average over the reporting period.

**1.31.16.2.28 Zone Hybrid Unitary HVAC Supply Air Temperature [°C]** This output reports the supply air temperature. For each timestep the value is calculated as a supply air mass weighted average of the supply air temperature for each of the settings selected for the time step. For example, if the system operates for half of the timestep with supply air mass flow rate of 1 kg/s and supply air temperature of 16°C, and for half of the timestep at 2 kg/s and 10°C, the supply air temperature calculated for the time step would be 12 °C. The output is the average over the reporting period.

**1.31.16.2.29 Zone Hybrid Unitary HVAC Return Air Temperature [°C]** This output reports the return air temperature. The return air temperature is inherited from the associated zone outlet node in each timestep. The output is the average over the reporting period.

**1.31.16.2.30 Zone Hybrid Unitary HVAC Outdoor Air Temperature [°C]** This output reports the outdoor air temperature. The outdoor air temperature is inherited from the associated outdoor air node in each timestep. The output is the average over the reporting period.

**1.31.16.2.31 Zone Hybrid Unitary HVAC Supply Air Humidity Ratio [kgWater/kgDryAir]** This output reports the supply air humidity ratio. For each timestep the value is calculated as a supply air mass weighted average of the supply air humidity ratio for each of the settings selected for the time step. For example, if the system operates for half of the timestep with supply air mass flow rate of 1 kg/s and supply air humidity ratio of 0.016 kgWater/kgDryAir, and for half of the timestep at 2 kg/s and 0.010 kgWater/kgDryAir, the supply air humidity ratio calculated for the time step would be 0.012 kgWater/kgDryAir. The output is the average over the reporting period.

**1.31.16.2.32 Zone Hybrid Unitary HVAC Return Air Humidity Ratio [kgWater/kgDryAir]** This output reports the return air humidity ratio. The return air humidity ratio is inherited from the associated zone outlet node in each timestep. The output is the average over the reporting period.

**1.31.16.2.33 Zone Hybrid Unitary HVAC Outdoor Air Humidity Ratio [kgWater/kgDryAir]** This output reports the outdoor air humidity ratio. The outdoor air humidity ratio is inherited from the associated outdoor air node in each timestep. The output is the average over the reporting period.

**1.31.16.2.34 Zone Hybrid Unitary HVAC Supply Air Relative Humidity [%]** This output reports the supply air relative humidity. For each timestep the value is calculated from the supply air temperature and supply air humidity ratio according to standard psychrometric relationships. The output is the time weighted average over the reporting period.

**1.31.16.2.35 Zone Hybrid Unitary HVAC Return Air Relative Humidity [%]** This output reports the return air relative humidity. The return air relative humidity is inherited from the associated zone outlet node in each timestep. The output is the average over the reporting period.

**1.31.16.2.36 Zone Hybrid Unitary HVAC Outdoor Air Relative Humidity [%]** This output reports the outdoor air relative humidity. The outdoor air relative humidity is inherited from the associated outdoor air node in each timestep. The output is the average over the reporting period.

**1.31.16.2.37 Zone Hybrid Unitary HVAC Supply Air Mass Flow Rate [kg/s]** This output reports the supply air mass flow rate. For each timestep the value is calculated as a time weighted average of the supply air mass flow rate for each of the settings selected for the time step. The output is the average over the reporting period.

**1.31.16.2.38 Zone Hybrid Unitary HVAC Supply Air Standard Density Volume Flow Rate [m3/s]** This output reports the supply air flow as a standard density volume flow rate. Standard density in EnergyPlus corresponds to dry air at 20°C drybulb, and 101,325 Pa. The output is the average over the reporting period.

**1.31.16.2.39 Zone Hybrid Unitary HVAC Ventilation Air Standard Density Volume Flow Rate [m3/s]** This output reports the outdoor air (ventilation) flow as a standard density volume flow rate. Standard density in EnergyPlus corresponds to dry air at 20°C drybulb, and 101,325 Pa. The output is the average over the reporting period.

**1.31.16.2.40 Zone Hybrid Unitary HVAC Electricity Rate [W]** This output reports the electric power input to the system. For each timestep the value is calculated as a time weighted average of the electric power for each of the settings selected for the time step. The output is the average over the reporting period.

**1.31.16.2.41 Zone Hybrid Unitary HVAC Electricity Energy [J]** This output reports the electric energy consumed by the system. For each timestep the value is calculated from the average electric power. The output is the sum over the reporting period.

**1.31.16.2.42 Zone Hybrid Unitary HVAC Requested Outdoor Air Ventilation Mass Flow Rate [kg/s]** This output reports the mass flow rate of outdoor air (ventilation) that would be required to meet the standard density volume flow rate of ventilation air scheduled by **DesignSpecification:OutdoorAir**. This value is used as a soft constraint in the constrained optimization problem that determines system settings in each time step. The output is the average over the reporting period.

**1.31.16.2.43 Zone Hybrid Unitary HVAC Ventilation Mass Flow Rate [kg/s]** This output reports the mass flow rate of outdoor air (ventilation) supplied by the system. The output is the average over the reporting period.

**1.31.16.2.44 Zone Hybrid Unitary HVAC Availability Status []** This output reports whether or not the system is available. A value of 1.0 means the system will operate in an attempt to satisfy the predicted sensible load, latent load, and requested ventilation rate. For standby periods – when the system is available, but there are no loads, and no request for ventilation – the system operates in Mode 0. A value of 0.0 means the system will not operate under any circumstance.

**1.31.16.2.45 Zone Hybrid Unitary HVAC Outdoor Air Fraction []** This output reports the outdoor air fraction – the portion of the supply air mass flow rate that is composed of ventilation air. For each timestep the value is calculated as a time weighted average of the outdoor air fraction for each of the settings selected for the time step. The output is the average over the reporting period.

**1.31.16.2.46 Zone Hybrid Unitary HVAC Runtime Fraction in Setting X []** Thy hybrid system may operate in multiple settings within each time step. Each setting represents a combination of operating mode, supply air mass flow rate, and outdoor air fraction. The combination associated with each setting number may be unique in each time step. These outputs report the fraction of the time step that the system operates in each setting in each time step.

**1.31.16.2.47 Zone Hybrid Unitary HVAC Mode in Setting X []** Thy hybrid system may operate in multiple settings within each time step. Each setting represents a combination of operating mode, supply air mass flow rate, and outdoor air fraction. The combination associated with each setting number may be unique in each time step. These outputs report the mode number associated with each setting in each time step.

**1.31.16.2.48 Zone Hybrid Unitary HVAC Outdoor Air Fraction in Setting X []** Thy hybrid system may operate in multiple settings within each time step. Each setting represents a combination of operating mode, supply air mass flow rate, and outdoor air fraction. The combination associated with each setting number may be unique in each time step. These outputs report the outdoor air fraction associated with each setting in each time step.

**1.31.16.2.49 Zone Hybrid Unitary HVAC Supply Air Mass Flow Rate in Setting X [kg/s]** Thy hybrid system may operate in multiple settings within each time step. Each setting represents a combination of operating mode, supply air mass flow rate, and outdoor air fraction. The combination associated with each setting number may be unique in each time step. These outputs report the supply air mass flow rate associated with each setting in each time step.

**1.31.16.2.50 Zone Hybrid Unitary HVAC Supply Air Mass Flow Rate Ratio in Setting X []** Thy hybrid system may operate in multiple settings within each time step. Each setting represents a combination of operating mode, supply air mass flow rate, and outdoor air fraction. The combination associated with each setting number may be unique in each time step. These output reports the supply air mass flow rate ratio associated with each setting in each time step. The supply air mass flow rate ratio is the ratio of the current supply air mass flow rate to the system maximum supply air flow rate.

## 1.32 Group – Unitary Equipment

### 1.32.1 Furnace and Unitary Systems

The components

- `AirLoopHVAC:UnitarySystem`
- `AirLoopHVAC:Unitary:Furnace:HeatOnly`
- `AirLoopHVAC:Unitary:Furnace:HeatCool`
- `AirLoopHVAC:UnitaryHeatOnly`
- `AirLoopHVAC:UnitaryHeatCool`
- `AirLoopHVAC:UnitaryHeatPump:AirToAir`
- `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed`

are compound components usually placed in the primary air loop as the sole component. On the zone equipment side they are usually connected to one or more zones through uncontrolled terminal units (i.e., `AirTerminal:SingleDuct:ConstantVolume:NoReheat` objects). The maximum or design air flow rate through the furnace or unitary system should usually be set equal to the sum of the maximum air flow rates through the terminal unit objects. However, the simulation program can usually account for unequal air flows if the user wishes to model this scenario.

The following HVAC equipment types are allowed in the air loop. The component matrix shows which coils and fans are allowed with which equipment models.

### 1.32.2 `AirLoopHVAC:UnitarySystem`

The `AirLoopHVAC:UnitarySystem` object is intended to replace all other air loop equipment, although other system types are still available. This system is unique in that it can accommodate all fan and coil types whereas other system types are specific to the type of fan and coil available for simulation. Additionally, although the `AirLoopHVAC:UnitarySystem` is intended for use in the primary airloop, this object can be modeled as zone equipment (i.e., listed in a `ZoneHVAC:EquipmentList`) or as an outside air system component (i.e., listed in a `AirLoopHVAC:OutdoorAirSystem:EquipmentList`). Water coil controllers are not required when these coil types are used with the `AirLoopHVAC:UnitarySystem` object (i.e., leave the controller list name blank in the `AirLoopHVAC` object if water coils are used exclusively within the Unitary System).

The `AirLoopHVAC:UnitarySystem` object is a “virtual” component that consists of a fan component (OnOff, ConstantVolume, VariableVolume, or ComponentModel), a cooling coil component, a heating coil component, and a reheat coil as shown in Figure 1.143. When a draw through configuration is desired, the fan is placed directly after the heating coil. If dehumidification control is selected, a reheat coil component is also required. If the reheat coil is present and the dehumidification control type input is not specified as CoolReheat, the reheat coil will not be active. All of the fan and coil components are optional which allows the `AirLoopHVAC:UnitarySystem` object to be configured for fan-only, heating-only, cooling-only, or both heating and cooling. It may also be applied without a fan, controlling one or more coils, similar to the function of `CoilSystem:Cooling:DX`.

Links to the fan, cooling coil, heating coil and reheat coil specifications are provided in the unitary system input data syntax. In addition, the control zone name and the system design operating conditions are specified by the unitary system inputs.

Figure 1.142:

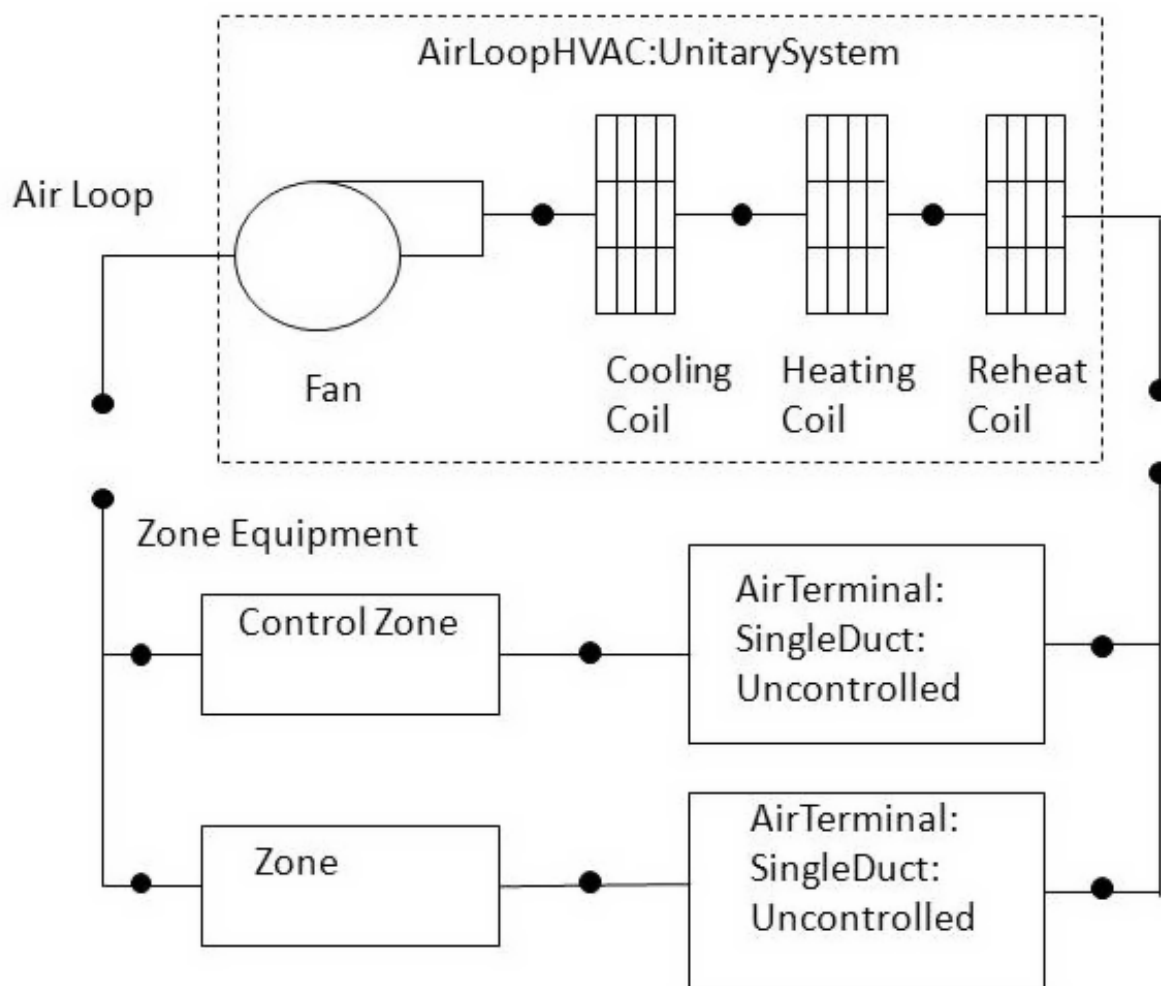

Figure 1.143: Schematic of the EnergyPlus Unitary System

### 1.32.2.0.1 Schedules And Availability Manager

For unitary systems, don't use the night cycle manager. Use a scheduled availability manager and let the system be always on. Then use the Supply Air Fan Operating Mode Schedule Name in the unitary system to switch between continuous fan (for ventilation) during occupied periods and switch to cycling fan for unoccupied. The system will cycle on as the thermostat requests, and this way it will run just enough to meet the load - no need for a minimum cycle time.

Multi-speed fan chilled and hot water coils Air Handling Unit (AHU) can be modeled using Airloop Unitary System HVAC object (AirloopHVAC:UnitarySystem). AHU with chilled and hot water coils is setup by specifying **Fan:OnOff** and **DesignSpecificationPerformance:MultiSpeed** objects in Unitary System. The design specification performance object allows running the chilled and hot water coils capacity control using a multi-speed supply air fan. The multi-speed fan capacity control for chilled and hot water coil AHU is performed by modulating the supply air flow rate while maintaining a constant water flow rate. The chilled or hot water flow rates is set at maximum fixed flow rate when there is cooling or heating load and the water flow rate is set to zero when there is no load. Such control strategy is called two-position cooling or heating coil control. The fan speed selection depends on the current load, at lower load the fan is operated at minimum speed (Speed = 1) and the fan speed level increases progressively as the load increases until it reaches the maximum speed level specified. The multi-speed fan operation is modulated between the speeds to meet the current load. When the supply air fan is cycling between consecutive speeds levels, the speed ratio is calculated that indicates what fraction of the time step that the system run at the higher of the two speeds. At lower load, the fan may cycle on-off or run continuously depending the fan operating schedule specified. When the fan is cycling a part-load ratio is calculated to reflect the proportion of the system timestep the fan and coils were operating. In continuous fan operating mode only the coil cycles on-off and the part-load ratio applies to the coil only. Multi-speed fan capacity control is allowed with load based control type only.

### 1.32.2.1 Inputs

#### 1.32.2.1.1 Field: Name

This alpha field contains the identifying name for the unitary system.

#### 1.32.2.1.2 Field: Control Type

This alpha field contains control type i.e. load based or setpoint based for the unitary system. Valid choices are **Load**, **SetPoint** and **SingleZoneVAV**. Load and SingleZoneVAV control requires a Controlling Zone name. SetPoint control requires set points at each coil outlet node. A single set point at the outlet of the system is allowed but not recommended. If setpoint control is used and the system represents a heat pump (i.e., cooling and heating coils are both DX coils) then only one of these coils may operate at a time. SingleZoneVAV requires two distinct fan flow rates, namely the Cooling and Heating Supply Air Flow Rate and a lower No Load Supply Air Flow Rate which is used during times of reduced cooling or heating loads. SingleZoneVAV allows load control at low speed fan until the load exceeds available capacity or the outlet air temperature exceeds the specified limits where the fan speed is then increased. For the SingleZoneVAV control type, temperature limits are identified in the input fields for Minimum and Maximum Supply Air Temperature. Additionally, specific coil types are required for the SingleZoneVAV control type. The cooling coil types are **Coil:Cooling:Water**, **Coil:Cooling:Water:DetailedGeometry** and **Coil:Cooling:DX:SingleSpeed** while the heating coil types are **Coil:Heating:Water**, **Coil:Heating:Fuel**, **Coil:Heating:Electric** and **Coil:Heating:DX:SingleSpeed**. If alternate coil types are used they are modeled using the load based control method.

#### 1.32.2.1.3 Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the unitary system is located. This field is required when Load or SingleZoneVAV control type is selected.

#### 1.32.2.1.4 Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

**None** - meet sensible load only, no active dehumidification control. None is required when Control Type = SingleZoneVAV.

**Multimode** - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = **CoilSystem:Cooling:DX:HeatExchangerAssisted**.

**CoolReheat** - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. If cooling coil type = **CoilSystem:Cooling:DX:HeatExchangerAssisted**, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is used. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. If the dehumidification control type is specified as **CoolReheat**, then two additional inputs (reheat coil type and name) are also required as shown below. Although the reheat coil is required only when **CoolReheat** is selected, the optional reheat coil may be present for any of the allowed Dehumidification Control Types. If the reheat coil is present and the dehumidification control type is not specified as **CoolReheat**, the reheat coil will not be active,

#### 1.32.2.1.5 Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the unitary system to operate. A schedule value equal to 0 denotes that the unitary system must be off for that time period. A value greater than 0 denotes that the unitary system is available to operate during that time period. This schedule may be used to completely disable the unitary system as required. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.32.2.1.6 Field: Unitary System Air Inlet Node Name

This alpha field contains the unitary system air inlet node name.

#### 1.32.2.1.7 Field: Unitary System Air Outlet Node Name

This alpha field contains the unitary system air outlet node name.

#### 1.32.2.1.8 Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the unitary system. Fan type must be **Fan:OnOff**, **Fan:ConstantVolume**, **Fan:VariableVolume**, or **Fan:ComponentModel**. **Fan:ConstantVolume** is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. **Fan:OnOff** is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0). **Fan:VariableVolume** is used for variable air volume systems or multi- or variable-speed coils. The **Fan:ComponentModel** may be used in place of the ConstantVolume or VariableVolume fan types to more accurately represent fan performance.

#### 1.32.2.1.9 Field: Supply Fan Name

This alpha field contains the unique identifying name given to the unitary system fan.

#### 1.32.2.1.10 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the main cooling and heating coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the main cooling/heating coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the cooling/heating coil(s). If this field is left blank, the default is blow through.

#### 1.32.2.1.11 Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. The SingleZoneVAV control type is only active when the supply air fan runs continuously (i.e., during cycling fan operation the Control Type = Load model is used).

#### 1.32.2.1.12 Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. Only specific coil types are allowed when Control Type = SingleZoneVAV as noted. Allowable coil types are:

- Coil:Heating:DX:SingleSpeed
- Coil:Heating:DX:TwoSpeed
- Coil:Heating:DX:MultiSpeed
- Coil:Heating:DX:VariableSpeed
- Coil:Heating:WaterToAirHeatPump:ParameterEstimation
- Coil:Heating:WaterToAirHeatPump:EquationFit
- Coil:Heating:WaterToAirHeatPump:VariableSpeedEquationFit
- Coil:Heating:Fuel
- Coil:Heating:Gas:MultiStage
- Coil:Heating:Electric
- Coil:Heating:Electric:MultiStage
- Coil:Heating:Water
- Coil:Heating:Steam
- Coil:Heating:Desuperheater
- Coil:UserDefined

**1.32.2.1.13 Field: Heating Coil Name**

This alpha field contains the identifying name given to the unitary system heating coil.

**1.32.2.1.14 Field: DX Heating Coil Sizing Ratio**

This numeric field is used to adjust heat pump heating capacity with respect to DX cooling capacity. It is used only for DX heat pump configurations (i.e., a DX cooling and heating coil is used).

**1.32.2.1.15 Field: Cooling Coil Object Type**

This alpha field contains the identifying type of cooling coil specified in the unitary system. Allowable coil types are:

- Coil:Cooling:DX:SingleSpeed
- Coil:Cooling:DX:SingleSpeed:ThermalStorage
- Coil:Cooling:DX:TwoSpeed
- Coil:Cooling:DX:MultiSpeed
- Coil:Cooling:DX:VariableSpeed
- Coil:Cooling:DX:TwoStageWithHumidityControlMode
- CoilSystem:Cooling:DX:HeatExchangerAssisted
- Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
- Coil:Cooling:WaterToAirHeatPump:EquationFit
- Coil:Cooling:WaterToAirHeatPump:VariableSpeedEquationFit
- Coil:Cooling:Water
- Coil:Cooling:Water:DetailedGeometry
- CoilSystem:Cooling:Water:HeatExchangerAssisted
- Coil:UserDefined

**1.32.2.1.16 Field: Cooling Coil Name**

This alpha field contains the identifying name given to the unitary system cooling coil.

**1.32.2.1.17 Field: Use DOAS DX Cooling Coil**

This input field enables DX Cooling coils to be used for 100% outdoor air dedicated outdoor air system applications. There are two choices Yes or No. If Yes, the DX coil is used as 100% outdoor DX coil. If No, the DX coil is used as regular DX coil. This input field is optional and the default is No. No should be specified when selecting the SingleZoneVAV control type.

#### 1.32.2.1.18 Field: Minimum Supply Air Temperature

When Use DOAS DX Cooling Coil is specified as Yes, this input field is the DX Cooling coils leaving minimum air temperature for frost control. The DX cooling coil leaving air temperature is not allowed to exceed this minimum air temperature. The DX cooling coil frost controller adjusts or limits the desired coil outlet air setpoint temperature when the coil outlet temperature exceeds this minimum temperature limit specified. The minimum and maximum values of this input field are 0.0°C and 7.5°C, and the default value is 2.0°C. This field is not autosizable when the input for Use DOAS DX Cooling Coil = Yes. When Control Type = SingleZoneVAV, enter the minimum air temperature limit for reduced fan speed in cooling mode. For SingleZoneVAV, the maximum limit for the minimum supply air temperature is 20.0°C. Additionally, for the SingleZoneVAV model this input does not limit the minimum supply air temperature resulting from cooling coil operation at high fan speed.

#### 1.32.2.1.19 Field: Latent Load Control

This alpha field defines the latent load control method. Available choices are SensibleOnlyLoadControl, LatentOnlyLoadControl, LatentWithSensibleLoadControl, or LatentOrSensibleLoadControl. The default choice is SensibleOnlyLoadControl. The SensibleOnlyLoadControl choice will operate to meet only a sensible load and is also required when SingleZoneVAV control is selected. The LatentOnlyLoadControl will operate to meet only a latent load. The LatentWithSensibleLoadControl will operate to meet the latent load only if there is a sensible load. The LatentOrSensibleLoadControl will operate to meet either a latent or sensible load.

#### 1.32.2.1.20 Field: Supplemental Heating Coil Object Type

This alpha field contains the identifying type of supplemental heating coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plant loop. The **Coil:UserDefined** object must be configured as a heating coil. Supplemental heating type must be one of:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Desuperheater**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**
- **Coil:UserDefined**

#### 1.32.2.1.21 Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the unitary system supplemental or reheat coil object. This coil provides supplemental heat during heating mode operation, or reheats the supply air during dehumidification mode operation. For set point based control, all coils will control to their respective outlet air temperature set point.

#### 1.32.2.1.22 Field: Cooling Supply Air Flow Rate Method

This alpha field defines the supply air flow method during cooling operation. Available choices are SupplyAirFlowRate, FlowPerFloorArea, FractionOfAutosizedCoolingValue, FlowPerCoolingCapacity. For each of the choices, a corresponding air flow rate for cooling must be specified. If the system does not have a cooling coil a 0 may be entered for cooling air flow rate and/or no load supply air flow rate to turn the fan off when cooling is not required.

**1.32.2.1.23 Field: Cooling Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the cooling coil is operating. Values must be greater than 0 if the cooling coil is present or this field is autosizable. Required field when Cooling Supply Air Flow Rate Method is **SupplyAirFlowRate**.

**1.32.2.1.24 Field: Cooling Supply Air Flow Rate Per Floor Area**

This numeric field defines the supply air flow rate per floor area leaving the unitary system in meters per second when the cooling coil is operating. Values must be greater than 0 if the cooling coil is present or this field is autosizable. Required field when Cooling Supply Air Flow Rate Method is **FlowPerFloorArea**.

**1.32.2.1.25 Field: Cooling Fraction of Autosized Design Cooling Supply Air Flow Rate**

This numeric field defines the fraction of autosized supply air flow rate leaving the unitary system when the cooling coil is operating. Values must be greater than 0 if the cooling coil is present or this field is autosizable. Required field when Cooling Supply Air Flow Rate Method is **FractionOfAutosizedCoolingValue**.

**1.32.2.1.26 Field: Cooling Supply Air Flow Rate Per Unit of Capacity**

This numeric field defines the supply air flow rate per unit of capacity leaving the unitary system when the cooling coil is operating. Values must be greater than 0 if the cooling coil is present or this field is autosizable. Required field when Cooling Supply Air Flow Rate Method is **FlowPerCoolingCapacity**.

**1.32.2.1.27 Field: Heating Supply Air Flow Rate Method**

This alpha field defines the supply air flow method during heating operation. Available choices are SupplyAirFlowRate, FlowPerFloorArea, FractionOfAutosizedHeatingValue, FlowPerHeatingCapacity. For each of the choices, a corresponding air flow rate for heating must be specified. If the system does not have a heating coil a 0 may be entered for heating air flow rate and/or no load supply air flow rate to turn the fan off when heating is not required.

**1.32.2.1.28 Field: Heating Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the heating coil is operating. Values must be greater than 0 if the heating coil is present or this field is autosizable. Required field when Heating Supply Air Flow Rate Method is **SupplyAirFlowRate**.

**1.32.2.1.29 Field: Heating Supply Air Flow Rate Per Floor Area**

This numeric field defines the supply air flow rate per floor area leaving the unitary system in meters per second when the heating coil is operating. Values must be greater than 0 if the heating coil is present or this field is autosizable. Required field when Heating Supply Air Flow Rate Method is **FlowPerFloorArea**.

**1.32.2.1.30 Field: Heating Fraction of Autosized Design Heating Supply Air Flow Rate**

This numeric field defines the fraction of autosized supply air flow rate leaving the unitary system when the heating coil is operating. Values must be greater than 0 if the heating coil is present or this field is autosizable. Required field when Heating Supply Air Flow Rate Method is **FractionOfAutosizedHeatingValue**.

**1.32.2.1.31 Field: Heating Supply Air Flow Rate Per Unit of Capacity**

This numeric field defines the supply air flow rate per unit of capacity leaving the unitary system when the heating coil is operating. Values must be greater than 0 if the heating coil is present or this field is autosizable. Required field when Heating Supply Air Flow Rate Method is **FlowPerHeatingCapacity**.

**1.32.2.1.32 Field: No Load Supply Air Flow Rate Method**

This alpha field defines the supply air flow method when neither cooling or heating is required. Available choices are SupplyAirFlowRate, FlowPerFloorArea, FractionOfAutosizedCoolingValue, FractionOfAutosizedHeatingValue, FlowPerCoolingCapacity, FlowPerHeatingCapacity. For each of the choices, a corresponding air flow rate must be specified. The following fields are also used to specify the lower air flow rate for the SingleZoneVAV control method with recommendations of greater than or equal to 67% of the Cooling or Heating Supply Air Flow Rate when any DX coil is used and 50% for other coil types.

**1.32.2.1.33 Field: No Load Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when neither cooling or heating is required (i.e., main cooling/heating coils and supplemental heater are off but the supply air fan operates). This field is only used when the unitary system operating mode is specified as continuous fan operation or when the Control Type is specified as SingleZoneVAV. Values must be greater than or equal to 0, or this field is autosizable. If this field is autosized, then it is sized to the minimum of the heating and cooling lowest speed supply air flow rate. If the Control Type is specified as SingleZoneVAV and this field is autosized, then the no load supply air flow rate is set equal to 0.5 or 0.667 times the maximum flow rate for water or coils, respectively. If the unitary system operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation). This field should not be set to 0 when Control Type is specified as SingleZoneVAV.

**1.32.2.1.34 Field: No Load Supply Air Flow Rate Per Floor Area**

This numeric field defines the supply air flow rate per floor area leaving the unitary system in meters per second when neither cooling or heating coil is operating. Values must be greater than or equal to 0 or this field is autosizable. Required field when No Load Supply Air Flow Rate Method During is **FlowPerFloorArea**.

**1.32.2.1.35 Field: No Load Fraction of Autosized Cooling Supply Air Flow Rate**

This numeric field defines the fraction of autosized supply air flow rate leaving the unitary system when neither cooling or heating coil is operating. Values must be greater than or equal to 0 or this field is autosizable. Required field when No Load Supply Air Flow Rate Method is **FractionOfAutosizedCoolingValue**.

**1.32.2.1.36 Field: No Load Fraction of Autosized Heating Supply Air Flow Rate**

This numeric field defines the fraction of autosized supply air flow rate leaving the unitary system when the neither cooling or heating coil is operating. Values must be greater than or equal to 0 or this field is autosizable. Required field when No Load Supply Air Flow Rate Method is **FractionOfAutosizedHeatingValue**.

**1.32.2.1.37 Field: No Load Supply Air Flow Rate Per Unit of Capacity During Cooling Operation**

This numeric field defines the supply air flow rate per unit of capacity leaving the unitary system when neither cooling or heating is operating. Values must be greater than or equal to 0 or this field is autosizable. Required field when No Load Supply Air Flow Rate Method is **FlowPerCoolingCapacity**.

#### 1.32.2.1.38 Field: No Load Supply Air Flow Rate Per Unit of Capacity During Heating Operation

This numeric field defines the supply air flow rate per unit of capacity leaving the unitary system when neither cooling or heating is operating. Values must be greater than or equal to 0 or this field is autosizable. Required field when No Load Supply Air Flow Rate Method is **FlowPerHeatingCapacity**.

#### 1.32.2.1.39 Field: Maximum Supply Air Temperature

This numeric field contains the design operating air outlet temperature in degrees C when the unitary system is heating. If this input field is left blank, the default value is 80 C. When Control Type = SingleZoneVAV, enter the maximum air temperature limit for reduced fan speed in heating model. For the SingleZoneVAV model this input does not limit the maximum supply air temperature resulting from heating or supplemental heating coil operation at high fan speed. This field is autosizable.

#### 1.32.2.1.40 Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

#### 1.32.2.1.41 Field: Outdoor Dry-Bulb Temperature Sensor Node Name

This alpha field specifies the name of the outdoor node which controls the operation of the supplemental heating coil. If this field is left blank, the outdoor temperature is based solely on the weather data. If this field is not blank, the node name specified must also be listed in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an **OutdoorAir:NodeList** object where the outdoor temperature is taken directly from the weather data.

#### 1.32.2.1.42 Field: Maximum Cycling Rate

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown in Figure 1.144. (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Figure 1.144: Suggested values for maximum cycling rate

**1.32.2.1.43 Field: Heat Pump Time Constant**

This numeric field contains the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown in Figure 1.145. (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Figure 1.145: Suggested values for heat pump time constant

**1.32.2.1.44 Field: Fraction of On-Cycle Power Use**

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are shown in Figure 1.146. (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Figure 1.146: Suggested values for fraction of on cycle power use

**1.32.2.1.45 Field: Heat Pump Fan Delay Time**

This numeric field contains the time delay for the heat pump supply air fan to shut off after the compressor cycles off in seconds. This value can be obtained from the manufacturer or the heat pump catalog. Enter a value of zero when the heat pump's fan operating mode is continuous. Suggested value is 60 seconds.

**1.32.2.1.46 Field: Ancillary On-Cycle Electric Power**

This field defines ancillary electrical power (W) consumed during the on-cycle period (i.e., when the cooling or heating coil is operating). The model assumes that this ancillary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

**1.32.2.1.47 Field: Ancillary Off-Cycle Electric Power**

This field defines ancillary electrical power (W) consumed during the off-cycle period (i.e., when the cooling and heating coil are not operating). The model assumes that this ancillary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

**1.32.2.1.48 Field: Design Heat Recovery Water Flow Rate**

This optional input field defines the design water flow rate used if the heat recovery option is being simulated. If this value is greater than 0.0 then a heat recovery loop must be specified and attached to the multispeed heat pump using the next 2 node fields. To determine how the heat recovery algorithm works, refer to the EnergyPlus Engineering Reference in the AirLoopHVAC:UnitarySystem with Heat Recovery section. The units for this input value are cubic meters per second.

**1.32.2.1.49 Field: Maximum Temperature for Heat Recovery**

This field sets the maximum temperature (in degrees C) that this heat pump can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperature leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

**1.32.2.1.50 Field: Heat Recovery Water Inlet Node Name**

This alpha field contains the identifying name for the heat recovery side inlet node.

**1.32.2.1.51 Field: Heat Recovery Water Outlet Node Name**

This alpha field contains the identifying name for the heat recovery side outlet node.

**1.32.2.1.52 Field: Design Specification Multispeed Object Type**

This alpha field contains the identifying type for the design specification multispeed object. This field is only needed when multispeed cooling or heating coil is specified.

**1.32.2.1.53 Field: Design Specification Multispeed Object Name**

This alpha field contains the identifying name for the design specification multispeed object. This field is only needed when multispeed cooling or heating coil is specified.

As shown in the example below, correct specification of the heat/cool unitary system requires specification of the following objects in addition to the unitary system object:

- 1) Fan (**Fan:OnOff** or **Fan:ConstantVolume**)
- 2) Cooling coil
- 3) Heating coil
- 4) Reheat coil

- 5) Direct air unit (**AirTerminal:SingleDuct:ConstantVolume:NoReheat**) for each zone served by the unitary system when used in an air loop

#### 1.32.2.2.1 Unitary System Fan Part Load Ratio []

This output variable is the ratio of actual air mass flow rate through the unitary system to the unitary system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state unitary system heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the unitary system fan may be different from the fan part-load ratio reported here due the part-load performance of the unitary system's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff). When the speed number is greater than 1, the value is 1.0.

#### 1.32.2.2.2 Unitary System Compressor Part Load Ratio []

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the unitary system's DX heating or cooling coil at Speed 1. The runtime fraction for the unitary system compressor may be different from the compressor part-load ratio reported here due the part-load performance of the heating/cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate. When the speed number is greater than 1, the value is 1.0.

### 1.32.2.2.3 Unitary System DX Coil Cycling Ratio []

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the unitary system's DX heating or cooling coil (Speed 1) for the entire system timestep. The value is between 0.0 and 1.0 when the unitary system is cycling on and off its lowest speed (Speed 1) and 1.0 when the unitary system operates at speeds above 1.

When Single Mode Operation is specified, the value is between 0.0 and 1.0 when the heat pump is cycling on at any given speed.

### 1.32.2.2.4 Unitary System DX Coil Speed Ratio []

This output variable is the ratio of time in a system timestep that the compressor is at rated speed between two consecutive speed numbers ( [Compressor Speed - Compressor speed at Speed i-1] / [Compressor speed at Speed i - Compressor speed at Speed i-1]). The compressor speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep. The value is 0.0 during Speed 1 operation.

The physical meaning of the speed ratio is dependent on the compressor configuration defined in the field of child coil object: Apply Part Load Fraction to Speeds greater than 1. The allowed choice is either Yes or No. When No is entered, one compressor is assumed for all speeds. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep. When Yes is entered, multiple compressors are assumed, and each compressor has associated speed. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the low speed runs in a whole system timestep.

When Single Mode Operation is specified, the speed ratio is set to 0 at Speed 1 and 1 at Speed > 1.

### 1.32.2.2.5 Unitary System DX Coil Speed Level []

This output variable reports the maximum speed needed when the unitary system operates to meet the sensible load (heating or cooling) in a system timestep. When the value is 1, the unitary system operates at Speed 1 (lowest speed). For this case the cycling ratio is between 0.0 and 1.0, while the speed ratio is 0.0. When the speed number output variable is above one, such as i, the unitary system operation is determined by the speed ratio through linear interpolation. For example, when the speed ratio is 0.4 and the speed number is 3, the unitary system operates at Speed 3 for 40% of a system timestep and at Speed 2 for 60% of a system timestep for a single compressor. For multiple compressors, the unitary system operates at Speed 3 in the 40% of a system timestep and at Speed 2 in the whole system timestep.

### 1.32.2.2.6 Unitary System Total Heating Rate [W]

This output field is the total (enthalpy) heat addition rate of the unitary system to the zones it is serving in Watts. For set point control, this value is calculated using the enthalpy difference of the unitary system outlet air and inlet air streams, and the air mass flow rate through the unitary system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported. For load or single zone VAV control this value is calculated using the outlet air and zone air conditions.

### 1.32.2.2.7 Unitary System Total Cooling Rate [W]

This output field is the total (enthalpy) heat extraction rate of the unitary system from the zones it is serving in Watts. For set point control, this value is calculated using the enthalpy difference of the unitary system outlet air and inlet air streams, and the air mass flow rate through the unitary system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported. For load or single zone VAV control this value is calculated using the outlet air and zone air conditions.

#### 1.32.2.2.8 Unitary System Sensible Heating Rate [W]

This output field reports the sensible heat addition rate of the unitary system to the zones it is serving in Watts. For set point control, this value is calculated using the enthalpy difference of the unitary system outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the unitary system. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported. For load or single zone VAV control this value is calculated using the outlet air and zone air conditions.

#### 1.32.2.2.9 Unitary System Sensible Cooling Rate [W]

This output field reports the moist air sensible heat extraction rate of the unitary system from the zones it is serving in Watts. For set point control, this value is calculated using the enthalpy difference of the unitary system outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the unitary system. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported. For load or single zone VAV control this value is calculated using the outlet air and zone air conditions.

#### 1.32.2.2.10 Unitary System Latent Heating Rate [W]

This output field is the latent heat addition (humidification) rate of the unitary system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the unitary system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

#### 1.32.2.2.11 Unitary System Latent Cooling Rate [W]

This output field is the latent heat extraction (dehumidification) rate of the unitary system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the unitary system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

#### 1.32.2.2.12 Unitary System Electricity Rate [W]

This output field is the electricity consumption rate of the unitary system in Watts. The consumption includes electricity used by the DX coils (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported. Any non-electric energy use is not reported by the unitary system object but is reported in the associated coil objects as appropriate.

#### 1.32.2.2.13 Unitary System Electricity Energy [J]

This output field is the electricity consumption of the unitary system in Joules for the timestep being reported. The consumption includes electricity used by the DX compressor (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported. Any non-electric energy use is not reported by the unitary system object but is reported in the associated coil objects as appropriate.

**1.32.2.2.14 Unitary System Ancillary Electricity Rate [W]**

This output field is the average auxiliary electricity consumption rate (including both on-cycle and off-cycle) in Watts for the timestep being reported.

**1.32.2.2.15 Unitary System Cooling Ancillary Electricity Energy [J]**

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the unitary system is providing cooling (DX cooling coil is operating). This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

**1.32.2.2.16 Unitary System Heating Ancillary Electricity Energy [J]**

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the unitary system is providing heating (DX heating coil is operating). This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

**1.32.2.2.17 Unitary System Predicted Sensible Load to Setpoint Heat Transfer Rate [W]**

This output variable is available only for load based and single zone VAV control and is the adjusted sensible load requested from the zone thermostat in watts. This value is calculated by adjusting the zone predicted sensible load to setpoint heat transfer rate based on the controlling zone air flow fraction and the impact of fan heat and outdoor air so that the thermostat setpoints are met. This value is used for control purposes within the Unitary System model. Positive values denote a heating load while negative values denote a cooling load. Positive and negative values do not necessarily represent which coil type is active (e.g., a positive heating load does not necessarily mean the heating coil will turn on). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.2.2.18 Unitary System Predicted Moisture Load to Setpoint Heat Transfer Rate [W]**

This output variable is available only for load based control and is the adjusted moisture load requested from the zone humidistat in watts. This value is calculated by adjusting the zone predicted moisture load to setpoint heat transfer rate based on the heat of vaporization of water, controlling zone air flow fraction and the dehumidification control type (i.e., the moisture load is set to 0 for non-dehumidification systems). When this value is non-zero and dehumidification is requested, the Unitary System Predicted Moisture Load to Setpoint Heat Transfer Rate is compared to the result of sensible only control and if the coil does not provide sufficient dehumidification the coil capacity is increased to meet this moisture load. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.2.2.19 Unitary System Heat Recovery Inlet Temperature [C]****1.32.2.2.20 Unitary System Heat Recovery Outlet Temperature [C]****1.32.2.2.21 Unitary System Heat Recovery Fluid Mass Flow Rate [kg/s]**

These outputs are the heat recovery inlet and outlet temperatures and water mass flow rate for unitary systems with heat recovery.

**1.32.2.2.22 Unitary System Heat Recovery Rate [W]****1.32.2.2.23 Unitary System Heat Recovery Energy [J]**

For multispeed unitary systems with heat recovery, these outputs are the recoverable energy rate (in Watts) and energy (in Joules).

**1.32.2.2.24 Unitary System Requested Sensible Cooling Rate [W]**

This output variable is the sensible cooling requested from the zone thermostat in watts. This value is calculated using the unitary system outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.2.2.25 Unitary System Requested Latent Cooling Rate [W]**

This output variable is the latent cooling requested from the zone humidistat in watts. This value is calculated using the unitary system outlet air and zone conditions, the heat of vaporization of water at the current zone conditions, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.2.2.26 Unitary System Requested Heating Rate [W]**

This output variable is the sensible heating requested from the zone thermostat in watts. This value is calculated using the unitary system outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.2.2.27 Unitary System Water Coil Cycling Ratio []**

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the multispeed fan chilled water or hot water coil for the entire system timestep. The value is between 0.0 and 1.0 when the AHU is cycling on and off its lowest speed (fan speed 1) and 1.0 when the multispeed fan chilled water or hot water AHU operates at speed levels above 1.

**1.32.2.2.28 Unitary System Water Coil Speed Ratio []**

This output variable is the ratio of time in a system timestep that the AHU fan is at rated speed between two consecutive speed levels ( $[\text{System Load} - \text{Capacity at Fan Speed } i-1] / [\text{Capacity at Fan Speed } i - \text{Capacity at Fan Speed } i-1]$ ). The fan speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep. The value is 0.0 during Speed 1 operation. AHU speed ratio depends on the system load and the supply air fan speed. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep.

**1.32.2.2.29 Unitary System Water Coil Speed Level []**

This output variable reports the maximum speed needed when the system operates to meet the sensible load (heating or cooling) in a system timestep. When the value is 1, the AHU operates at Speed 1 (lowest speed). For this case the cycling ratio is between 0.0 and 1.0, while the speed ratio is 0.0. When the speed level is above the minimum (speed = 1), the system operation is determined by the speed ratio. For example, when the speed ratio is 0.4 and the speed lever is 3, then the supply air fan and water coil operate at Speed 3 for 40% of a system timestep and at Speed 2 for 60% of a system timestep.

**1.32.2.2.30 Unitary System Zone Load Sensible Heat Ratio []**

This output variable reports the load sensible heat ratio, defined as sensible load / (sensible load + latent load) for a subcool reheat coil. The value is used to determine required coil output sensible heat ratio.

**1.32.2.2.31 Unitary System Cooling Coil Load Sensible Heat Ratio []**

This output variable reports the cooling coil load sensible heat ratio, defined as sensible output / (sensible output + latent output) for a subcool reheat coil. The value is used to determine mode ratio between coil normal operation mode and subcool or reheat operation mode.

**1.32.3 UnitarySystemPerformance:Multispeed****1.32.3.1 Inputs****1.32.3.1.1 Field: Name**

This alpha field contains the identifying name for the multispeed performance specification.

**1.32.3.1.2 Field: Number of Speeds for Heating**

This field defines the number of heating speeds for the heat pump, and must match the number of heating speeds defined in the associated heating coil. The value for this input field defines the number of airflow rate ratios that must be defined for heating in the fields below. The minimum value for this field is one and the maximum value is the number specified in the coil object. If the heating coil type used in the unitary system object is not a multispeed coil type, then this field should be 1.

**1.32.3.1.3 Field: Number of Speeds for Cooling**

This field defines the number of cooling speeds for the heat pump, and must match the number of cooling speeds defined in the associated DX cooling coil. The value for this input field defines the number of airflow rate ratios that must be defined for cooling in the fields below. The minimum value for this field is one and the maximum value is the number specified in the coil object. If the cooling coil type used in the unitary system object is not a multispeed coil type, then this field should be 1.

**1.32.3.1.4 Field: Single Mode Operation**

This field specifies the coil operation mode for multiple speed DX cooling and heating coils during each HVAC timestep. The allowed choice is Yes or No. The No choice allows a coil works between two adjacent speeds when a system load is greater than the coil capacity at speed 1. The Yes choice allows a coil works with a single capacity at a different speed. The speed number is determined by a system load.

The allowed cooling and heating coil types are restricted to the following combinations:

**Coil:Cooling:DX:MultiSpeed** and **Coil:Heating:DX:MultiSpeed** or **Coil:Cooling:DX:MultiSpeed** and **Coil:Heating:Fuel**.

**1.32.3.1.5 Field: No Load Supply Air Flow Rate Ratio**

This field defines the no load operating air flow rate when the system fan is specified to operate continuously. The allowed fractions are between 0 and 1 with a default value of 1. This fraction is usually set to the minimum of heating and cooling operation lowest speed supply air flow fraction. The no load air flow rate will be calculated as this fraction multiplied by the minimum of the cooling and heating high speed supply air flow rate. If the cooling or heating coil is not present, this fraction is multiplied by the operating supply air flow rate.

### 1.32.3.1.6 Field Group: Heating and Cooling Speeds 1 to 10

The air flow through a multispeed coil system is specified as a group of two air flow ratio inputs, one each for heating and cooling. If the number of speeds for heating and cooling are different, inputs for both heating and cooling are still required for a given speed yet one input may be blank. The maximum of the inputs for Number of Speeds for Cooling and Number of Speeds for Heating specified above determines how many groups of heating and cooling supply air flow ratio inputs are required. Both inputs for Speed 1 are required and specify the air flow ratio for the lowest speed, followed by the inputs for Speed 2, Speed 3, etc. up to a maximum of 10 speeds. These inputs are applicable only to multispeed or variable speed coils.

### 1.32.3.1.7 Field: Heating Speed <x> Supply Air Flow Ratio

This numeric field defines the ratio of supply air flow rate leaving the unitary system to the maximum air flow rate specified in the coil object at maximum speed when the heating coil is operating at Speed <x>. Values must be greater than 0. The entered value must be greater or equal to the flow rate ratio specified for the previous heating speed. If the ‘Number of Speeds for Heating’ is less than <x>, then this field can be left blank.

### 1.32.3.1.8 Field: Cooling Speed <x> Supply Air Flow Ratio

This numeric field defines the ratio of supply air flow rate leaving the unitary system to the maximum air flow rate specified in the coil object at maximum speed when the cooling coil is operating at Speed <x>. Values must be greater than 0. The entered value must be greater or equal to the flow rate ratio specified for the previous cooling speed. If the ‘Number of Speeds for Cooling’ is less than <x>, then this field can be left blank.

## 1.32.4 AirLoopHVAC:Unitary:Furnace:HeatCool

The heat/cool furnace is a “virtual” component that consists of a fan component (OnOff or ConstantVolume), a DX cooling coil component, and a Gas or Electric heating coil component. The blow through furnace configuration is shown in Figure 1.147 below. When a draw through furnace configuration is desired, the fan is placed directly after the heating coil. If the dehumidification control type is specified as CoolReheat, a reheat coil component is also required. If the reheat coil is present and the dehumidification control type input is not specified as CoolReheat, the reheat coil will not be active,

Note: the coil order shown here has been revised from previous versions (prior to V4.0) of Energyplus to configure the cooling coil upstream of the heating coil. This configuration provides uniformity with all unitary equipment. However, for unitary HeatCool systems that do not use a reheat coil, the heating coil can also be placed upstream of the cooling coil. This optional coil placement is retained to allow compatibility with previous versions of Energyplus. For input files developed using previous versions of Energyplus, it is recommended that the coil order be revised according to the figure above.

Links to the fan, heating coil, DX cooling coil and optional reheat coil specifications are provided in the furnace input data syntax. In addition, the control zone name and the furnace design operating conditions are specified by the furnace inputs.

### 1.32.4.1 Inputs

#### 1.32.4.1.1 Field: Name

This alpha field contains the identifying name for the unit.

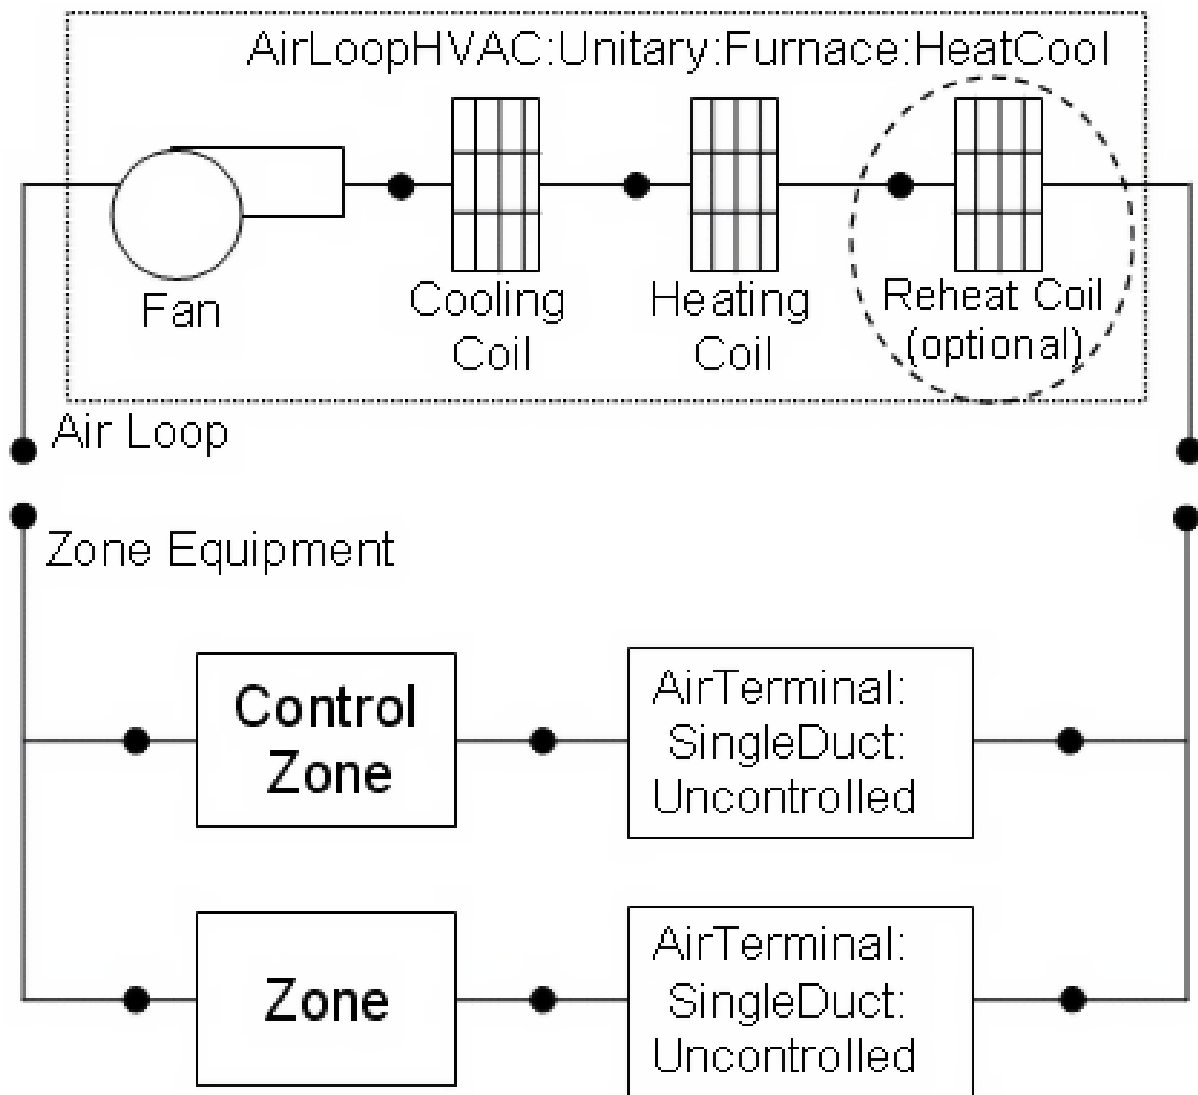

Figure 1.147: Schematic of EnergyPlus Heat/Cool Furnace

#### **1.32.4.1.2 Field: Availability Schedule Name**

This alpha field contains the schedule name which contains information on the availability of the furnace to operate. A schedule value equal to 0 denotes that the furnace must be off for that time period. A value greater than 0 denotes that the furnace is available to operate during that time period. This schedule may be used to completely disable the furnace as required. If this field is left blank, the schedule has a value of 1 for all time periods.

#### **1.32.4.1.3 Field: Furnace Air Inlet Node Name**

This alpha field contains the furnace inlet node name.

#### **1.32.4.1.4 Field: Furnace Air Outlet Node Name**

This alpha field contains the furnace outlet node name.

#### **1.32.4.1.5 Field: Supply Air Fan Operating Mode Schedule Name**

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

#### **1.32.4.1.6 Field: Maximum Supply Air Temperature**

This numeric field contains the design operating furnace air outlet temperature in degrees C when the furnace is heating. If this input field is left blank, the default value is 80 C.

#### **1.32.4.1.7 Field: Cooling Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

#### **1.32.4.1.8 Field: Heating Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

#### **1.32.4.1.9 Field: No Load Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the furnace operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the furnace operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

#### **1.32.4.1.10 Field: Controlling Zone or Thermostat Location**

This alpha field contains the identifying zone name where the thermostat controlling the furnace is located.

#### 1.32.4.1.11 Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the furnace. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. **Fan:ConstantVolume** is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. **Fan:OnOff** is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

#### 1.32.4.1.12 Field: Supply Fan Name

This alpha field contains the identifying name given to the furnace fan.

#### 1.32.4.1.13 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is blow through.

#### 1.32.4.1.14 Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the furnace. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Unitary Heat and Cool Furnace) itself provides the “controller” function of modulating water flow. Allowable coil types are:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

#### 1.32.4.1.15 Field: Heating Coil Name

This alpha field contains the identifying name given to the furnace heating coil.

#### 1.32.4.1.16 Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the furnace. Only allowable coil types are:

- **Coil:Cooling:DX:SingleSpeed**
- **CoilSystem:Cooling:DX:HeatExchangerAssisted**
- **Coil:Cooling:DX:VariableSpeed**

#### 1.32.4.1.17 Field: Cooling Coil Name

This alpha field contains the identifying name given to the furnace cooling coil.

#### 1.32.4.1.18 Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

- **None** - meet sensible load only, no active dehumidification control
- **Multimode** - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = **CoilSystem:Cooling:DX:HeatExchangerAssisted**.
- **CoolReheat** - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. If cooling coil type = **CoilSystem:Cooling:DX:HeatExchangerAssisted**, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is used. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. If the dehumidification control type is specified as **CoolReheat**, then two additional inputs (reheat coil type and name) are also required as shown below. Although the reheat coil is required only when **CoolReheat** is selected, the optional reheat coil may be present for any of the allowed Dehumidification Control Types. If the reheat coil is present and the dehumidification control type is not specified as **CoolReheat**, the reheat coil will not be active,

#### 1.32.4.1.19 Field: Reheat Coil Object Type

This alpha field contains the identifying type of reheat coil specified in the furnace. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the reheat coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Unitary Heat and Cool Furnace) itself provides the “controller” function of modulating water flow. Reheat coil type must be one of:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Desuperheater**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

#### 1.32.4.1.20 Field: Reheat Coil Name

This alpha field contains the identifying name given to the furnace reheat coil.

As shown in the example below, correct specification of the heat/cool furnace requires specification of the following objects in addition to the furnace object:

- 1) fan (**Fan:OnOff** or **Fan:ConstantVolume**)
- 2) cooling coil (**Coil:Cooling:DX:SingleSpeed** or **CoilSystem:Cooling:DX:HeatExchangerAssisted**)
- 3) heating coil (**Coil:Heating:Fuel** or **Coil:Heating:Electric**)

- 4) reheat coil (optional, `Coil:Heating:Fuel`, `Coil:Heating:Electric`, or `Coil:Heating:Desuperheater`)
- 5) terminal unit (`AirTerminal:SingleDuct:ConstantVolume:NoReheat`) for each zone served by the furnace

Note: the furnace's fan, cooling coil, heating coil and optional reheat coil must be connected in the air loop according to the configuration shown above (Figure 1.147) when `CoolReheat` is selected as the dehumidification control type. In addition, the volumetric air flow rate specified in the terminal air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the furnace object.

Example of Heat/Cool Furnace Specification

### 1.32.4.2 Outputs

HVAC,Average,Unitary System Fan Part Load Ratio []

HVAC,Average,Unitary System Compressor Part Load Ratio []

#### 1.32.4.2.1 Unitary System Fan Part Load Ratio

This output variable is the ratio of actual air mass flow rate through the furnace to the furnace's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state furnace heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the furnace fan may be different from the fan part-load ratio reported here due the part-load performance of the furnace's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

Unitary System Compressor Part Load Ratio []

### 1.32.5 AirLoopHVAC:UnitaryHeatCool

The AirLoopHVAC:UnitaryHeatCool object is the identical model to the AirLoopHAVC:Unitary:Furnace:HeatCool object. The heat/cool unitary system is a “virtual” component that consists of a fan component (OnOff or ConstantVolume), a DX cooling coil component and a Gas or Electric heating coil component as shown in Figure 1.148. When a draw through configuration is desired, the fan is placed directly after the heating coil. If dehumidification control is selected, a reheat coil component is also required. If the reheat coil is present and the dehumidification control type input is not specified as CoolReheat, the reheat coil will not be active,

Note: the coil order shown here has been revised from previous versions (prior to V4.0) of Energyplus to configure the cooling coil upstream of the heating coil. This configuration provides uniformity with all unitary equipment. However, for unitary HeatCool systems that do not use a reheat coil, the heating coil can also be placed upstream of the cooling coil. This optional coil placement is retained to allow

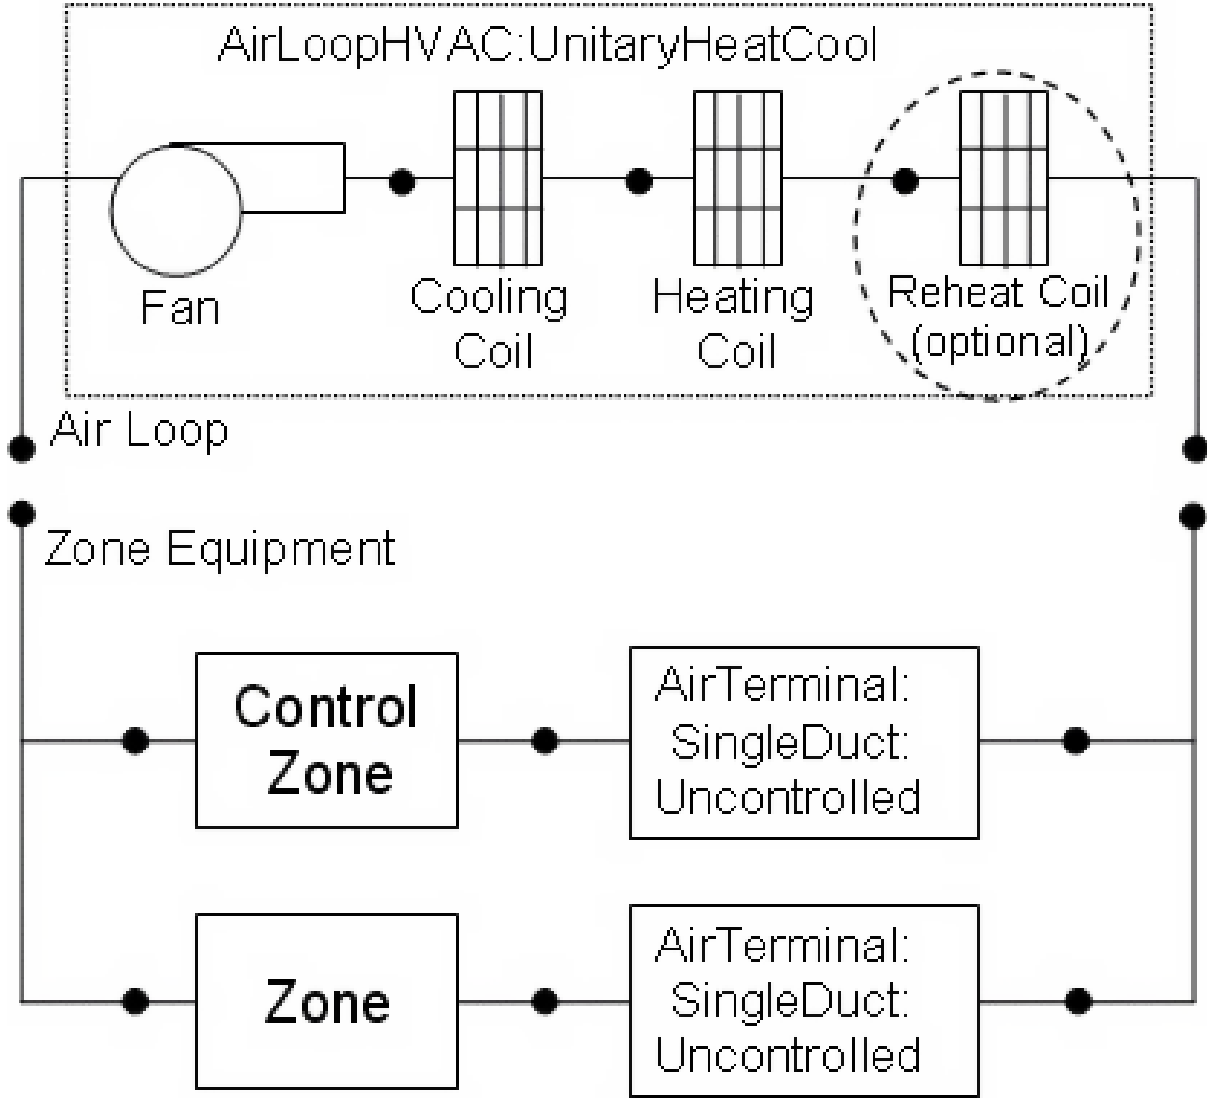

Figure 1.148: Schematic of Blow Through Heat/Cool Unitary System

compatibility with previous versions of Energyplus. For input files developed using previous versions of Energyplus, it is recommended that the coil order be revised according to the figure above.

Links to the fan, DX cooling coil, heating coil and optional reheat coil specifications are provided in the unitary system input data syntax. In addition, the control zone name and the system design operating conditions are specified by the unitary system inputs.

#### **1.32.5.1 Field: Name**

This alpha field contains the identifying name for the unitary system.

#### **1.32.5.2 Field: Availability Schedule Name**

This alpha field contains the schedule name which contains information on the availability of the unitary system to operate. A schedule value equal to 0 denotes that the unitary system must be off for that time period. A value greater than 0 denotes that the unitary system is available to operate during that time period. This schedule may be used to completely disable the unitary system as required. If this field is left blank, the schedule has a value of 1 for all time periods.

#### **1.32.5.3 Field: Unitary System Air Inlet Node Name**

This alpha field contains the unitary system inlet node name.

#### **1.32.5.4 Field: Unitary System Air Outlet Node Name**

This alpha field contains the unitary system outlet node name.

##### ***Field: Supply Air Fan Operating Mode Schedule Name***

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

#### **1.32.5.5 Field: Maximum Supply Air Temperature**

This numeric field contains the design operating air outlet temperature in degrees C when the unitary system is heating. If this input field is left blank, the default value is 80 C.

#### **1.32.5.6 Field: Cooling Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

#### **1.32.5.7 Field: Heating Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

### 1.32.5.8 Field: No Load Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the unitary system operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the unitary system operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

### 1.32.5.9 Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the unitary system is located.

### 1.32.5.10 Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the unitary system. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. **Fan:ConstantVolume** is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. **Fan:OnOff** is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

### 1.32.5.11 Field: Supply Fan Name

This alpha field contains the identifying name given to the unitary system fan.

### 1.32.5.12 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is blow through.

### 1.32.5.13 Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Unitary Heat and Cool System) itself provides the “controller” function of modulating water flow. Allowable coil types are:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

#### 1.32.5.14 Field: Heating Coil Name

This alpha field contains the identifying name given to the unitary system heating coil.

#### 1.32.5.15 Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the unitary system. Only allowable coil types are:

- `Coil:Cooling:DX:SingleSpeed`
- `CoilSystem:Cooling:DX:HeatExchangerAssisted`
- `Coil:Cooling:DX:VariableSpeed`

#### 1.32.5.16 Field: Cooling Coil Name

This alpha field contains the identifying name given to the unitary system cooling coil.

#### 1.32.5.17 Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

- **None** - meet sensible load only, no active dehumidification control
- **Multimode** - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = `CoilSystem:Cooling:DX:HeatExchangerAssisted`.
- **CoolReheat** - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. If cooling coil type = `CoilSystem:Cooling:DX:HeatExchangerAssisted`, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is used. This must be set using a `ZoneControl:Humidistat` object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. If the dehumidification control type is specified as **CoolReheat**, then two additional inputs (reheat coil type and name) are also required as shown below. Although the reheat coil is required only when **CoolReheat** is selected, the optional reheat coil may be present for any of the allowed Dehumidification Control Types. If the reheat coil is present and the dehumidification control type is not specified as **CoolReheat**, the reheat coil will not be active,

#### 1.32.5.18 Field: Reheat Coil Object Type

This alpha field contains the identifying type of reheat coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the reheat coil does not require additional controller or `Controller:WaterCoil` object. The parent object (Unitary Heat and Cool System) itself provides the “controller” function of modulating water flow. Reheat coil type must be one of:

- Coil:Heating:Electric
- Coil:Heating:Fuel
- Coil:Heating:Desuperheater
- Coil:Heating:Water
- Coil:Heating:Steam

### 1.32.5.19 Field: Reheat Coil Name

This alpha field contains the identifying name given to the unitary system reheat coil.

As shown in the example below, correct specification of the heat/cool unitary system requires specification of the following objects in addition to the unitary system object:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) Cooling coil (Coil:Cooling:DX:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)
- 3) Heating coil (Coil:Heating:Fuel or Coil:Heating:Electric)
- 4) Reheat coil (optional, Coil:Heating:Fuel, Coil:Heating:Electric, or Coil:Heating:Desuperheater)
- 5) Direct air unit (AirTerminal:SingleDuct:ConstantVolume:NoReheat) for each zone served by the unitary system

Note: the unitary system's fan, cooling coil, heating coil and optional reheat coil must be connected in the air loop according to the configuration shown above (Figure 1.148). In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the unitary system object.

Example of Heat/Cool Unitary System Specification

### 1.32.6 Unitary System Heat and Cool (AirLoopHVAC) Outputs

- HVAC,Average, Unitary System Fan Part Load Ratio []
- HVAC,Average, Unitary System Compressor Part Load Ratio

#### 1.32.6.1 Unitary System Fan Part Load Ratio []

This output variable is the ratio of actual air mass flow rate through the unitary system to the system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state unitary system heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the unitary system fan may be different from the fan part-load ratio reported here due the part-load performance of the system's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., **Fan:OnOff**).

### 1.32.6.2 Unitary System Compressor Part Load Ratio []

This output variable is the ratio of the sensible cooling load to the steady-state cooling capacity of the unitary system's DX cooling coil. The runtime fraction for the DX cooling coil compressor may be different from the compressor part-load ratio reported here due the part-load performance of the cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

### 1.32.7 AirLoopHVAC:UnitaryHeatPump:AirToAir

The unitary air-to-air heat pump is a “virtual” component that consists of a fan component (OnOff or ConstantVolume), a DX cooling coil component, a DX heating coil component, and a Gas or Electric supplementary heating coil component as shown in the Figure below.

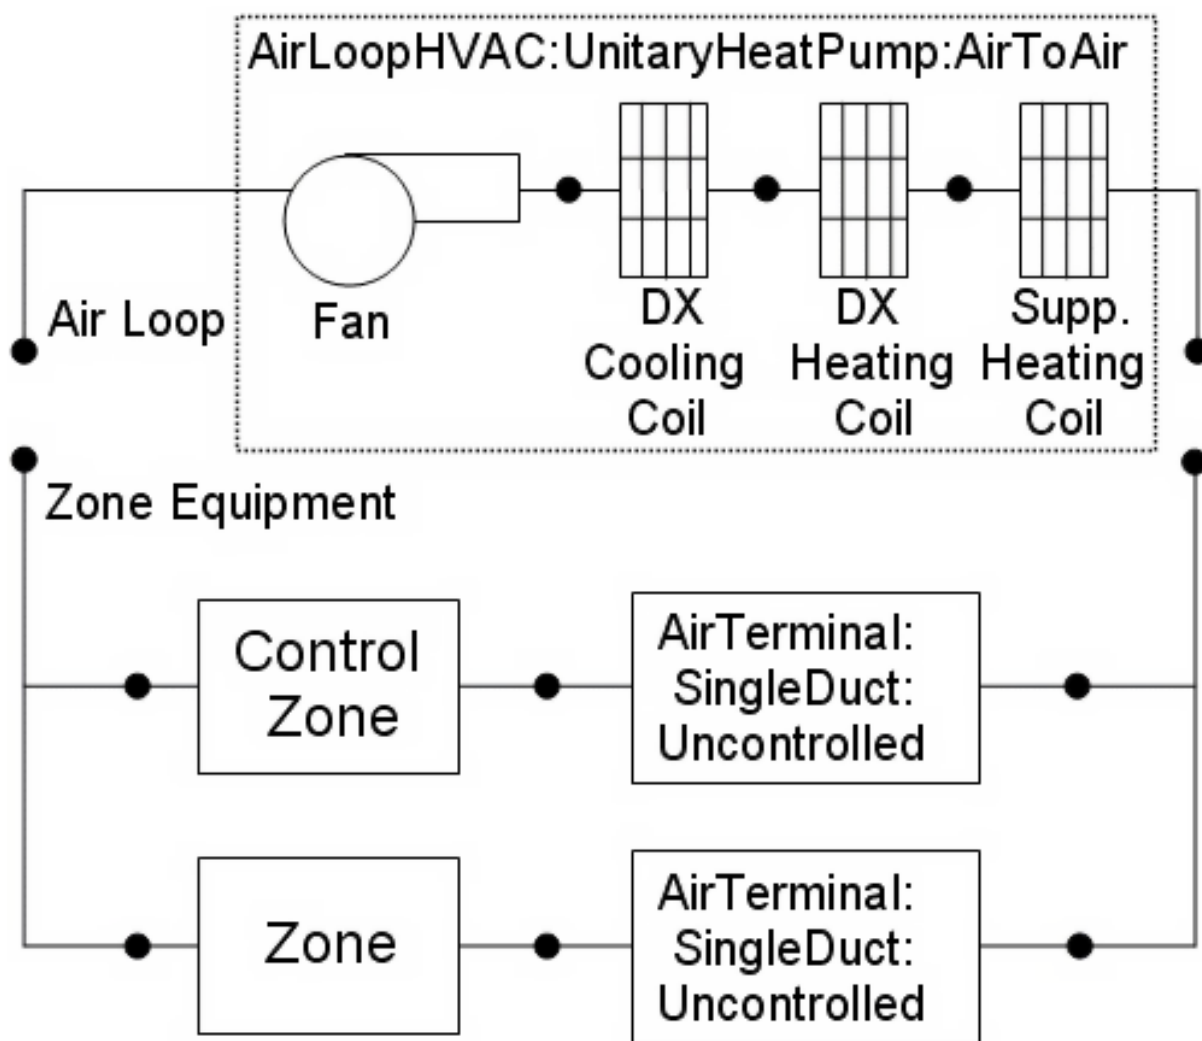

Figure 1.149: Schematic of EnergyPlus Unitary Air-to-Air Heat Pump (Blow Through Configuration)

Links to the fan, DX cooling coil, DX heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. In addition the control zone name and the system design operating conditions are specified by the heat pump inputs.

### 1.32.7.1 Inputs

#### 1.32.7.1.1 Field: Name

This alpha field contains the identifying name for the unitary system heat pump.

#### 1.32.7.1.2 Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule objects) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.32.7.1.3 Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

#### 1.32.7.1.4 Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

#### 1.32.7.1.5 Field: Cooling Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

#### 1.32.7.1.6 Field: Heating Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

#### 1.32.7.1.7 Field: No Load Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

#### 1.32.7.1.8 Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the heat pump is located.

#### 1.32.7.1.9 Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the heat pump. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. **Fan:ConstantVolume** is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. **Fan:OnOff** is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

**1.32.7.1.10 Field: Supply Air Fan Name**

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

**1.32.7.1.11 Field: Heating Coil Object Type**

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil type must be either **Coil:Heating:DX:SingleSpeed** or **Coil:Heating:DX:VariableSpeed**.

**1.32.7.1.12 Field: Heating Coil Name**

This alpha field contains the identifying name given to the heat pump DX heating coil, and should match the name specified in the corresponding DX heating coil object.

**1.32.7.1.13 Field: Cooling Coil Object Type**

This alpha field contains the identifying type of cooling coil specified in the heat pump. There are three valid choices for this field:

- **Coil:Cooling:DX:SingleSpeed**
- **CoilSystem:Cooling:DX:HeatExchangerAssisted**
- **Coil:Cooling:DX:VariableSpeed**

**1.32.7.1.14 Field: Cooling Coil Name**

This alpha field contains the identifying name given to the heat pump cooling coil, and should match the name specified in the corresponding DX cooling coil object.

**1.32.7.1.15 Field: Supplemental Heating Coil Object Type**

This alpha field contains the identifying type of supplemental heating coil specified in the heat pump. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the supplemental heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Airloop Air to Air Heat Pump) itself provides the “controller” function of modulating water flow. Heating coil type must be:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

**1.32.7.1.16 Field: Supplemental Heating Coil Name**

This alpha field contains the identifying name given to the heat pump supplemental heating coil, and should match the name specified in the corresponding heating coil object.

**1.32.7.1.17 Field: Maximum Supply Air Temperature from Supplemental Heater**

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil.

### 1.32.7.1.18 Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

### 1.32.7.1.19 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the DX cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply air fan is between the DX cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

#### *Field: Supply Air Fan Operating Mode Schedule Name*

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

As shown in the example below, correct specification of the air-to-air heat pump requires specification of the following objects in addition to the heat pump object:

- 1) Fan (**Fan:OnOff** or **Fan:ConstantVolume**)
- 2) Heating coil (**Coil:Heating:DX:SingleSpeed**)
- 3) Cooling coil (**Coil:Cooling:DX:SingleSpeed** or **CoilSystem:Cooling:DX:HeatExchangerAssisted**)
- 4) Supplemental heating coil (**Coil:Heating:Fuel** or **Coil:Heating:Electric**)
- 5) Direct air unit (**AirTerminal:SingleDuct:ConstantVolume:NoReheat**) for each zone served by the unitary system

### 1.32.7.1.20 Field: Dehumidification Control Type

This alpha input field contains the type of dehumidification control. The following options are valid for this field:

- **None** - meet sensible load only, no active dehumidification control
- **Multimode** - activate enhanced dehumidification mode as needed and meet sensible cooling load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = **CoilSystem:Cooling:DX:HeatExchangerAssisted**.
- **CoolReheat** - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. The excess cooling beyond the cooling set point temperature is offset by the supplemental heating coil. If cooling coil type = **CoilSystem:Cooling:DX:HeatExchangerAssisted**, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is required. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. Supplemental heating coil (supplemental heating coil type and name) is a required input in **AirToAir HeatPumps**. The supplemental heating coil capacity must be adequate enough to meet the heating coil

load and offset the excess cooling load due to extra dehumidification required to meet the high relative humidity setpoint.

Note: the air-to-air heat pump's fan, cooling coil, heating coil and supplementary heating coil must be connected in the air loop according to the configuration shown above (Figure 118) for the blow-through fan configuration. The only other valid configuration is with a draw-through fan placement, where the fan is located between the DX heating coil and the supplementary heating coil.

### 1.32.7.2 Outputs

- HVAC, Average, Unitary System Fan Part Load Ratio []
- HVAC, Average, Unitary System Compressor Part Load Ratio []
- HVAC, Average, Unitary System Dehumidification Induced Heating Demand Rate [W]

#### 1.32.7.2.1 Unitary System Fan Part Load Ratio []

This output variable is the ratio of actual air mass flow rate through the heat pump to the heat pump's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on

the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state heat pump heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the heat pump fan may be different from the fan part-load ratio reported here due the part-load performance of the heat pump's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

#### 1.32.7.2.2 Unitary System Compressor Part Load Ratio []

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the heat pump's DX heating or cooling coil. The runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due the part-load performance of the heating/cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

#### 1.32.7.2.3 Unitary System Dehumidification Induced Heating Demand Rate [W]

This output variable is the additional heating demand rate of the supplemental heating coil of an Air-to-Air heat pumps in Watts. This additional heating demand is induced when zone air overshoots the heating setpoint due to extra dehumidification requirement to meet the high humidity setpoint. This value is always positive. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

### 1.32.8 AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed

The multispeed air-to-air heat pump is a “virtual” component that consists of a fan component (On/Off or ConstVolume), a DX multispeed cooling coil component, a DX multispeed heating coil component, and a Gas or Electric supplemental heating coil component. This system also includes the option to use available waste energy to heat water. A schematic diagram of the air-to-air multispeed heat pump is shown below. The component connection sequence for the blow through option (shown below) from inlet to outlet is fan, cooling coil, heating coil, and supplemental heater. The connection sequence for the draw through option is cooling coil, heating coil, fan, and supplemental heater.

The main difference between this heat pump object and other EnergyPlus heat pump objects is that this object allows from two to four discrete compressor speeds for heating and cooling operation (instead of a single speed for each mode). The lowest speed is called Speed 1, and the highest speed is called Speed n (2, 3 or 4 as specified in the input syntax). This object allows a different number of speeds for cooling and heating, and each speed has an associated airflow rate. The airflow rates for the various heating speeds can be different from the airflow rates for the cooling speeds. In addition, the airflow rate when no cooling or heating is needed can also be defined. The number of cooling and heating speeds defined by the user in this heat pump object must equal the number of speeds defined in the associated coils (child objects). For example, the number of speeds for cooling defined in this heat pump object must be equal to the number of speeds defined in the associated cooling coil object.

Links to the fan, DX multispeed cooling coil, DX multispeed heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. In addition, the control zone name and airflow rates at the corresponding compressor speeds are specified by the heat pump syntax.

If the `ZoneControl:Thermostat:StagedDualSetpoint` object and other zone control thermostat and humidistat are assigned to the same controlled zone in the Controlling Zone or Thermostat Location field, the `ZoneControl:Thermostat:StagedDualSetpoint` object takes precedence and the stage number provided by the `ZoneControl:Thermostat:StagedDualSetpoint` object is used to set the speed number.

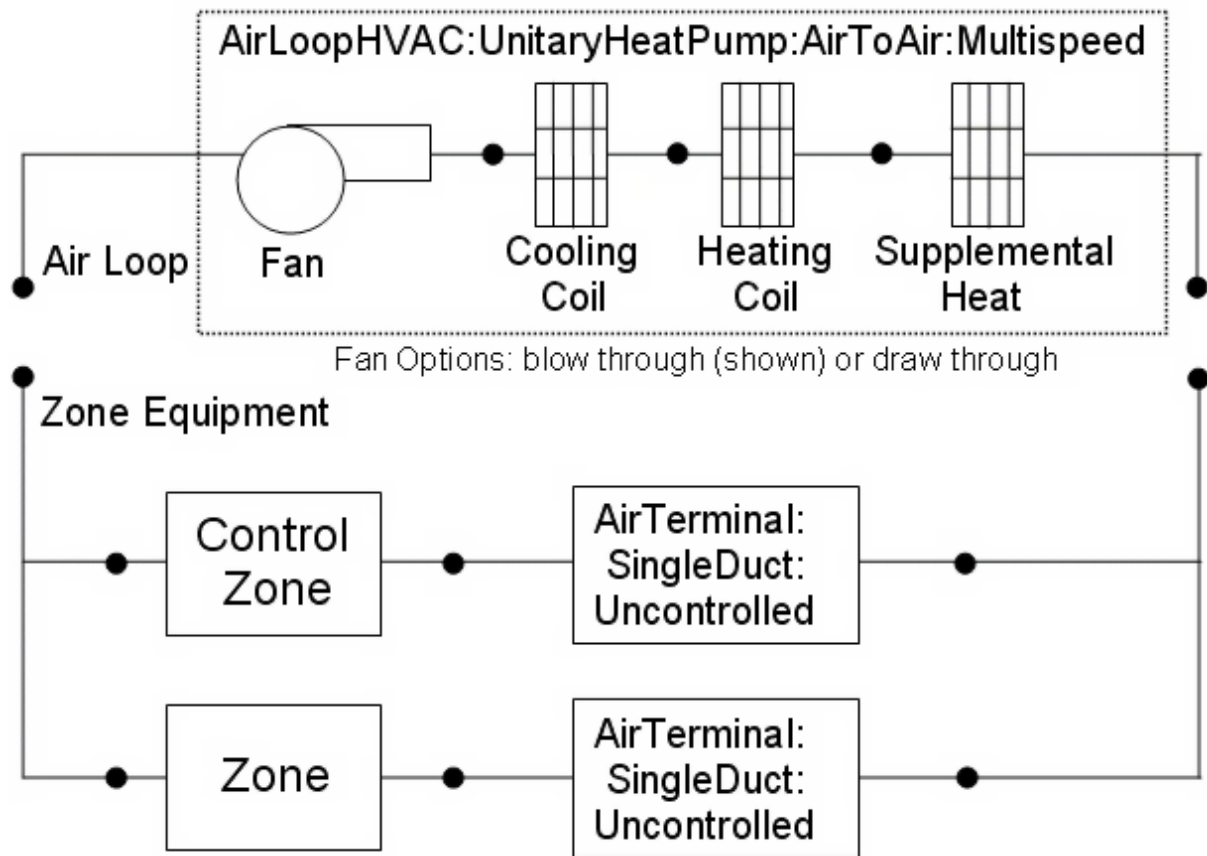

Figure 1.150: Schematic of EnergyPlus Unitary Air-to-Air Multi Speed Heat Pump

### 1.32.8.1 Inputs

#### 1.32.8.1.1 Field: Name

This alpha field contains the identifying name for the multispeed heat pump.

#### 1.32.8.1.2 Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule objects) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.32.8.1.3 Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

#### 1.32.8.1.4 Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

#### 1.32.8.1.5 Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the multispeed heat pump is located.

#### 1.32.8.1.6 Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the heat pump. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. **Fan:ConstantVolume** can only be used when the supply air fan operating mode is continuous (see field ‘Supply air fan operating mode schedule name’).

#### 1.32.8.1.7 Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

#### 1.32.8.1.8 Field: Supply Air Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by a DX multispeed cooling coil, DX multispeed heating coil, and a supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX cooling and heating coils followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws” air through the DX coils.

**Note:** the multispeed heat pump’s supply air fan, cooling coil, heating coil and supplemental heating coil must be connected according to the configuration shown above (Figure 1.150) for the ‘blow through’ fan configuration. For the ‘draw through’ fan configuration the fan must be located between the DX heating coil and the supplemental heater, whose outlet node is the system outlet node. In addition, the DX cooling coil and DX heating coil operation mode must be specified consistently with the heat pump’s supply air fan operating mode (e.g., with the heat pump’s supply air fan set to cycle on and off with the cooling/heating load, the DX cooling and heating coil operation mode must be **CyclingFanAndCompressor**). If the operation modes in the parent (heat pump) and child (coil) objects are specified differently, the operation mode in the parent object prevails.

#### 1.32.8.1.9 Field: Supply Air Fan Operating Mode Schedule Name

This alpha field contains the schedule name (ref. Schedule objects) that contains information to control the supply air fan. Schedule values of zero mean that the supply air fan will cycle off if there is no cooling or heating load in the control zone. Non-zero schedule values mean that the supply air fan will operate continuously even if there is no cooling or heating load in the control zone. If this field is left blank, the supply air fan will operate continuously for the entire simulation period.

#### 1.32.8.1.10 Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. Allowable choices for Heating coil type are **Coil:Heating:DX:MultiSpeed**, **Coil:Heating:Electric:MultiStage**, **Coil:Heating:Gas:MultiStage**, **Coil:Heating:Water**, and **Coil:Heating:Steam**.

#### 1.32.8.1.11 Field: Heating Coil Name

This alpha field contains the identifying name given to the DX heating coil, and should match the name specified in the corresponding DX heating coil object.

#### 1.32.8.1.12 Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

**Deprecated field.** The Minimum Outdoor Dry-Bulb Temperature for Compressor Operation is now controlled by the **Coil:Cooling:DX:MultiSpeed** and **Coil:Heating:DX:MultiSpeed** (if used) coil objects.

#### 1.32.8.1.13 Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. Cooling coil type must be **Coil:Cooling:DX:MultiSpeed**.

#### 1.32.8.1.14 Field: Cooling Coil Name

This alpha field contains the identifying name given to the heat pump cooling coil, and should match the name specified in the corresponding DX cooling coil object.

#### 1.32.8.1.15 Field: Supplemental Heating Coil Object Type

This alpha field contains the identifying type of supplemental heating coil specified in the heat pump. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the supplemental heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Unitary MultiSpeed Air to Air Heat Pump) itself provides the “controller” function of modulating water flow. Heating coil type must be:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

#### 1.32.8.1.16 Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the heat pump supplemental heating coil, and should match the name specified in the corresponding heating coil object.

**1.32.8.1.17 Field: Maximum Supply Air Temperature from Supplemental Heater**

This numeric field defines the maximum allowed supply air temperature (in degrees C) exiting the heat pump supplemental heating coil. If the calculated supply air temperature exiting the supplemental heater exceeds this value, then it is reset to this maximum temperature. This field is autosizable.

**1.32.8.1.18 Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

**1.32.8.1.19 Field: Auxiliary On-Cycle Electric Power**

This field defines auxiliary electrical power (W) consumed during the on-cycle period (i.e., when the cooling or heating coil is operating). The model assumes that this auxiliary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

**1.32.8.1.20 Field: Auxiliary Off-Cycle Electric Power**

This field defines auxiliary electrical power (W) consumed during the off-cycle period (i.e., when the cooling and heating coil are not operating). The model assumes that this auxiliary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

**1.32.8.1.21 Field: Design Heat Recovery Water Flow Rate**

This optional input field defines the design water flow rate used if the heat recovery option is being simulated. If this value is greater than 0.0 then a heat recovery loop must be specified and attached to the multispeed heat pump using the next 2 node fields. To determine how the heat recovery algorithm works, refer to the EnergyPlus Engineering Reference in the AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed with Heat Recovery section. The units for this input value are cubic meters per second.

**1.32.8.1.22 Field: Maximum Temperature for Heat Recovery**

This field sets the maximum temperature (in degrees C) that this heat pump can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperature leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

**1.32.8.1.23 Field: Heat Recovery Water Inlet Node Name**

This alpha field contains the identifying name for the heat recovery side inlet node.

**1.32.8.1.24 Field: Heat Recovery Water Outlet Node Name**

This alpha field contains the identifying name for the heat recovery side outlet node.

**1.32.8.1.25 Field: No Load Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling nor heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump supply air fan is scheduled to operate continuously regardless of DX coil operation (ref. field “Supply Air Fan Operating Mode Schedule”). Values must be greater than or equal to zero, or this field is autosizable. If the heat pump supply air fan is scheduled to operate continuously and the input value for this field is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

**1.32.8.1.26 Field: Number of Speeds for Heating**

This field defines the number of heating speeds for the heat pump, and must match the number of heating speeds defined in the associated heating coil. The value for this input field defines the number of airflow rates that must be defined for heating in the field below. The minimum value for this field is one and the maximum value is four. If the Heating Coil Object Type above are **Coil:Heating:Water** or **Coil:Heating:Steam**, then this field should be 1.

**1.32.8.1.27 Field: Number of Speeds for Cooling**

This field defines the number of cooling speeds for the heat pump, and must match the number of cooling speeds defined in the associated DX cooling coil. The value for this input field defines the number of airflow rates that must be defined for cooling in the field below. The minimum value for this field is two and the maximum value is four.

**1.32.8.1.28 Field: Heating Speed 1 Supply Air Flow Rate**

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 1 (lowest speed). Values must be greater than 0 or this field is autosizable.

**1.32.8.1.29 Field: Heating Speed 2 Supply Air Flow Rate**

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 2. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 1.

**1.32.8.1.30 Field: Heating Speed 3 Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 3. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 2. If the ‘Number of Speeds for Heating’ is less than 3, then this field can be left blank.

**1.32.8.1.31 Field: Heating Speed 4 Supply Air Flow Rate**

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 4 (high speed). Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal

to the flow rate specified for heating Speed 3. If the ‘Number of Speeds for Heating’ is less than 4, then this field can be left blank.

**Note:** When autosizable is selected for any of the supply air volumetric flow rate fields, all supply air flow fields at the different speeds must be specified as autosizable. Otherwise, a fatal error will be issued and the simulation will terminate.

#### 1.32.8.1.32 Field: Cooling Speed 1 Supply Air Flow Rate

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 1 (lowest speed). Values must be greater than 0 or this field is autosizable.

#### 1.32.8.1.33 Field: Cooling Speed 2 Supply Air Flow Rate

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 2. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 1.

#### 1.32.8.1.34 Field: Cooling Speed 3 Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 3. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 2. If the ‘Number of Speeds for Cooling’ is less than 3, then this field can be left blank.

#### 1.32.8.1.35 Field: Cooling Speed 4 Supply Air Flow Rate

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 4 (highest speed). Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 3. If the ‘Number of Speeds for Cooling’ is less than 4, then this field can be left blank.

Following is an example input for the object and its associated components.

#### 1.32.8.2.1 Unitary System Fan Part Load Ratio []

This output variable is the ratio of actual air mass flow rate through the multispeed heat pump to the heat pump's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate) at Speed 1. For continuous fan operation mode, this variable is always 1.0 when the heat pump is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state heat pump heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the heat pump fan may be different from the fan part-load ratio reported here due the part-load performance of the heat pump's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff). When the speed number is greater than 1, the value is 1.0.

#### 1.32.8.2.2 Unitary System Compressor Part Load Ratio []

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the multispeed heat pump's DX heating or cooling coil at Speed 1. The runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due the part-load performance of the heating/cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate. When the speed number is greater than 1, the value is 1.0.

#### 1.32.8.2.3 Unitary System DX Coil Cycling Ratio []

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the multispeed heat pump's DX heating or cooling coil (Speed 1) for the entire system timestep. The value is between 0.0 and 1.0 when the heat pump is cycling on and off its lowest speed (Speed 1) and 1.0 when the multispeed heat pump operates at speeds above 1.

When Single Mode Operation is specified, the value is between 0.0 and 1.0 when the heat pump is cycling on at any given speed.

#### 1.32.8.2.4 Unitary System DX Coil Speed Ratio []

This output variable is the ratio of time in a system timestep that the compressor is at rated speed between two consecutive speed numbers (  $[\text{Compressor Speed} - \text{Compressor speed at Speed } i-1] / [\text{Compressor speed at Speed } i - \text{Compressor speed at Speed } i-1]$  ). The compressor speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep. The value is 0.0 during Speed 1 operation.

The physical meaning of the speed ratio is dependent on the compressor configuration defined in the field of child coil object: Apply Part Load Fraction to Speeds greater than 1. The allowed choice is either Yes or No. When No is entered, one compressor is assumed for all speeds. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep. When Yes is entered, multiple compressors are assumed, and each compressor has associated speed. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the low speed runs in a whole system timestep.

When Single Mode Operation is specified, the speed ratio is set to 0 at Speed 1, and 1 at Speed > 1

#### 1.32.8.2.5 Unitary System DX Coil Speed Level []

This output variable reports the maximum speed needed when the heat pump operates to meet the sensible load (heating or cooling) in a system timestep. When the value is 1, the heat pump operates at Speed 1 (lowest speed). For this case the cycling ratio is between 0.0 and 1.0, while the speed ratio is 0.0. When the speed number output variable is above one, such as *i*, the heat pump operation is determined by the speed ratio through linear interpolation. For example, when the speed ratio is 0.4 and the speed number is 3, the heat pump operates at Speed 3 for 40% of a system timestep and at Speed 2 for 60% of a system timestep for a single compressor. For multiple compressors, the heat pump operates at Speed 3 in the 40% of a system timestep and at Speed 2 in the whole system timestep.

#### 1.32.8.2.6 Unitary System Total Heating Rate [W]

This output field is the total (enthalpy) heat addition rate of the multispeed heat pump to the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

**1.32.8.2.7 Unitary System Total Cooling Rate [W]**

This output field is the total (enthalpy) heat extraction rate of the multispeed heat pump from the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

**1.32.8.2.8 Unitary System Sensible Heating Rate [W]**

This output field reports the sensible heat addition rate of the multispeed heat pump to the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

**1.32.8.2.9 Unitary System Sensible Cooling Rate [W]**

This output field reports the moist air sensible heat extraction rate of the multispeed heat pump from the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

**1.32.8.2.10 Unitary System Latent Heating Rate [W]**

This output field is the latent heat addition (humidification) rate of the multispeed heat pump in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the multispeed heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

**1.32.8.2.11 Unitary System Latent Cooling Rate [W]**

This output field is the latent heat extraction (dehumidification) rate of the multispeed heat pump in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the multispeed heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

**1.32.8.2.12 Unitary System Electricity Rate [W]**

This output field is the electricity consumption rate of the multispeed heat pump in Watts. The consumption includes electricity used by the DX coils (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported. Any non-electric energy use is not reported by the heat pump object but is reported in the associated coil objects as appropriate.

**1.32.8.2.13 Unitary System Electricity Energy [J]**

This output field is the electricity consumption of the multispeed heat pump in Joules for the timestep being reported. The consumption includes electricity used by the DX compressor (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for

the timestep being reported. Any non-electric energy use is not reported by the heat pump object but is reported in the associated coil objects as appropriate.

#### **1.32.8.2.14 Unitary System Ancillary Electricity Rate [W]**

This output field is the average auxiliary electricity consumption rate (including both on-cycle and off-cycle) in Watts for the timestep being reported.

#### **1.32.8.2.15 Unitary System Cooling Ancillary Electricity Energy [J]**

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the heat pump is providing cooling (DX cooling coil is operating). This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

#### **1.32.8.2.16 Unitary System Heating Ancillary Electricity Energy [J]**

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the heat pump is providing heating (DX heating coil is operating). This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Output:Meter objects).

#### **1.32.8.2.17 Unitary System Heat Recovery Inlet Temperature [C]**

#### **1.32.8.2.18 Unitary System Heat Recovery Outlet Temperature [C]**

#### **1.32.8.2.19 Unitary System Heat Recovery Fluid Mass Flow Rate [kg/s]**

These outputs are the heat recovery inlet and outlet temperatures and water mass flow rate for multispeed heat pumps with heat recovery.

#### **1.32.8.2.20 Unitary System Heat Recovery Rate [W]**

#### **1.32.8.2.21 Unitary System Heat Recovery Energy [J]**

For multispeed heat pumps with heat recovery, these outputs are the recoverable energy rate (in Watts) and energy (in Joules).

### **1.32.9 AirLoopHVAC:Unitary:Furnace:HeatOnly**

The EnergyPlus furnace is a “virtual” component that consists of a fan component (OnOff or Constant Volume) and a Gas or Electric heating coil component. The blow through furnace configuration is shown in the Figure below.

Links to the fan and heating coil specifications are provided in the furnace input data syntax. In addition the control zone name and the furnace design operating conditions are specified by the furnace inputs.

#### **1.32.9.1 Inputs**

##### **1.32.9.1.1 Field: Name**

This alpha field contains the identifying name for the furnace.

Figure 1.151: Schematic of Blow Through Furnace Model

#### 1.32.9.1.2 Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the furnace to operate. A schedule value equal to 0 denotes that the furnace must be off for that time period. A value greater than 0 denotes that the furnace is available to operate during that time period. This schedule may be used to completely disable the unitary system as required. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.32.9.1.3 Field: Furnace Inlet Node Name

This alpha field contains the furnace inlet node name.

#### 1.32.9.1.4 Field: Furnace Outlet Node Name

This alpha field contains the furnace outlet node name.

##### *Field: Supply Air Fan Operating Mode Schedule Name*

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating coil cycle on and off together to meet the heating load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating coil cycles to meet the load.

#### 1.32.9.1.5 Field: Maximum Supply Air Temperature

This numeric field contains the design operating furnace air outlet temperature in degrees C when the furnace is heating. If this input field is left blank, the default value is 80 C.

#### 1.32.9.1.6 Field: Heating Supply Air Flow Rate

This numeric field contains the design volumetric flow rate of the furnace in cubic meters per second. This volumetric flow rate should match the flow rate specified for the furnace fan.

#### 1.32.9.1.7 Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the furnace is located.

#### 1.32.9.1.8 Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the furnace. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. **Fan:ConstantVolume** is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. **Fan:OnOff** is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

#### 1.32.9.1.9 Field: Supply Fan Name

This alpha field contains the identifying name given to the furnace fan.

#### 1.32.9.1.10 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the heating coil. The fan “blows through” the heating coil. The second choice stands for “draw through fan”. This means that the unit consists of the heating coil followed by a fan. The fan “draws air through” the heating coil. If this field is left blank, the default is blow through.

### 1.32.9.1.11 Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the furnace. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Unitary Heat Only Furnace) itself provides the “controller” function of modulating water flow. Heating coil type must be:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

### 1.32.9.1.12 Field: Heating Coil Name

This alpha field contains the identifying name given to the furnace heating coil.

As shown in the example below, correct specification of the furnace requires specification of the following objects in addition to the furnace object:

- 1) fan (**Fan:OnOff** or **Fan:ConstantVolume**)
- 2) heating coil (**Coil:Heating:Fuel** or **Coil:Heating:Electric**)
- 3) direct air unit (**AirTerminal:SingleDuct:ConstantVolume:NoReheat**) for each zone served by the furnace

Note: the furnace’s fan and heating coil must be connected in the air loop according to the configuration shown above (Figure 1.151) when a blow through fan configuration is specified. If a draw through fan is used, the fan is located down stream of the heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the furnace object.

Example of Heat-Only Furnace Specification

### 1.32.9.2 Outputs

- HVAC,Average,Unitary System Fan Part Load Ratio []

#### 1.32.9.2.1 Unitary System Fan Part Load Ratio []

This output variable is the ratio of actual air mass flow rate through the furnace to the furnace's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating load to the furnace heating capacity. For the cycling fan mode, the runtime fraction for the furnace fan may be different from the fan part-load ratio reported here due the part-load performance of the furnace's heating coil (delay at start-up to reach steady-state heating output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

### 1.32.10 AirLoopHVAC:UnitaryHeatOnly

The AirLoopHVAC:UnitaryHeatOnly is identical to the **AirLoopHVAC:Unitary:Furnace:HeatOnly** model. The heat-only unitary system is a “virtual” component that consists of a fan component (OnOff or ConstantVolume) and a Gas or Electric heating coil component. The blow through unitary system configuration is shown in the Figure below.

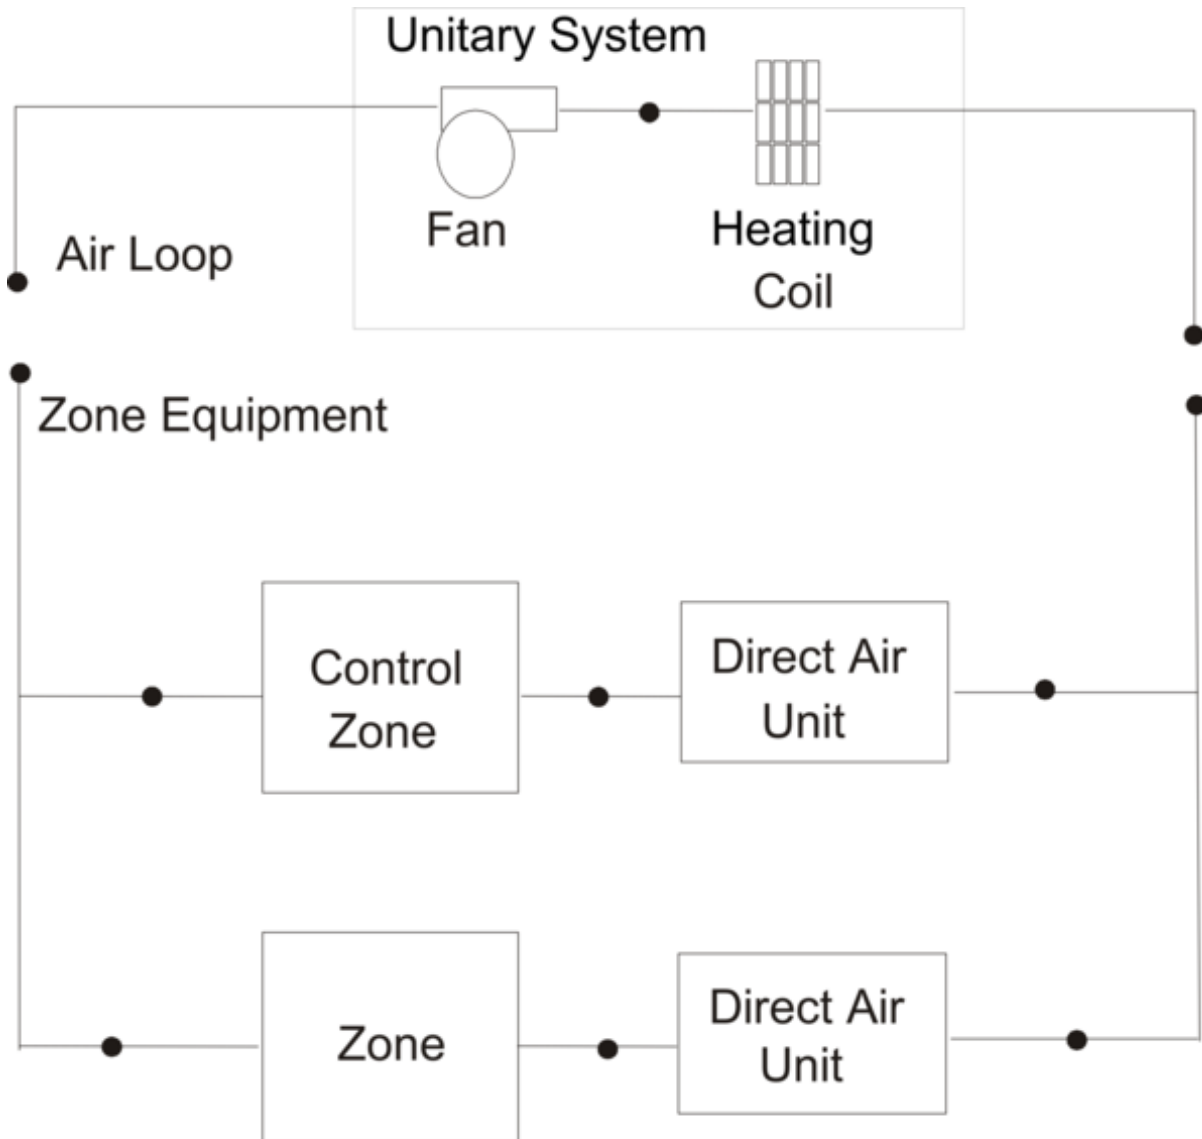

Figure 1.152: Schematic of Blow Through Heat-Only Unitary System

Links to the fan and heating coil specifications are provided in the unitary system input data syntax. In addition, the control zone name and the unitary system design operating conditions are specified by the unitary system syntax.

#### 1.32.10.1 Inputs

##### 1.32.10.1.1 Field: Name

This alpha field contains the identifying name for the unitary system.

#### 1.32.10.1.2 Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the unitary system to operate. A schedule value equal to 0 denotes that the unitary system must be off for that time period. A value greater than 0 denotes that the unitary system is available to operate during that time period. This schedule may be used to completely disable the unitary system as required. If this field is left blank, the schedule has a value of 1 for all time periods.

#### 1.32.10.1.3 Field: Unitary System Air Inlet Node Name

This alpha field contains the unitary system inlet node name.

#### 1.32.10.1.4 Field: Unitary System Air Outlet Node Name

This alpha field contains the unitary system outlet node name.

##### *Field: Supply Air Fan Operating Mode Schedule Name*

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating coil cycle on and off together to meet the heating load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating coil cycles to meet the load.

#### 1.32.10.1.5 Field: Maximum Supply Air Temperature

This numeric field contains the design air outlet temperature in degrees C when the unitary system is heating. If this input field is left blank, the default value is 80 C.

#### 1.32.10.1.6 Field: Heating Supply Air Flow Rate

This numeric field contains the design volumetric flow rate of the unitary system in cubic meters per second. This volumetric flow rate should match the flow rate specified for the unitary system fan.

#### 1.32.10.1.7 Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the unitary system is located.

#### 1.32.10.1.8 Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the unitary system. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. **Fan:ConstantVolume** is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. **Fan:OnOff** is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

#### 1.32.10.1.9 Field: Supply Fan Name

This alpha field contains the identifying name given to the unitary system fan.

#### 1.32.10.1.10 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the heating coil. The fan “blows through” the heating coil. The second choice stands for “draw through fan”. This means that the unit

consists of the heating coil followed by a fan. The fan “draws air through” the heating coil. If this field is left blank, the default is blow through.

#### 1.32.10.1.11 Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (Unitary Heat Only) itself provides the “controller” function of modulating water flow. Heating coil type must be:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

#### 1.32.10.1.12 Field: Heating Coil Name

This alpha field contains the identifying name given to the unitary system heating coil.

As shown in the example below, correct specification of the heat-only unitary system requires specification of the following objects in addition to the unitary system object:

- 1) fan (**Fan:OnOff** or **Fan:ConstantVolume**)
- 2) heating coil (**Coil:Heating:Fuel** or **Coil:Heating:Electric**)
- 3) direct air unit (**AirTerminal:SingleDuct:ConstantVolume:NoReheat**) for each zone served by the furnace

Note: the unitary system’s fan and heating coil must be connected in the air loop according to the configuration shown above (Figure 1.152) when a blow through fan configuration is specified. If a draw through fan is used, the fan is located down stream of the heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the unitary system object.

Example of Heat-Only Unitary System Specification

### 1.32.10.2 Outputs

- HVAC,Average,Unitary System Fan Part Load Ratio []

#### 1.32.10.2.1 Unitary System Fan Part Load Ratio []

This output variable is the ratio of actual air mass flow rate through the unitary system to the unitary system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating load to the unitary system heating capacity. For the cycling fan mode, the runtime fraction for the unitary system fan may be different from the fan part-load ratio reported here due the part-load performance of the unitary system's heating coil (delay at start-up to

reach steady-state heating output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

### 1.32.11 AirLoopHVAC:UnitaryHeatPump:WaterToAir

The unitary water-to-air heat pump is similar to the unitary air-to-air heat pump except water is used on the source side. Links to the fan, WaterToAirHeatPump cooling coil, WaterToAirHeatPump heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. The heat pump switches between cooling and heating depending on the zone's demand. The load side (air) of the unitary water-to-air heat pump consists of an On/Off fan component, a WaterToAirHeatPump cooling coil component, a WaterToAirHeatPump heating coil component, and a Gas, Electric, Steam, or Hot Water supplemental heating coil component. The source side (water) of the heat pump is connected to a condenser loop with a heat exchanger (ground heat exchanger or other type) or a plant loop with a heating source such as a boiler and a cooling source such as a chiller or cooling tower. The diagram below shows the setup and connection of the heat pump for the source side and load side for a ground heat exchanger configuration. Note that on the load side, the WaterToAirHeatPump cooling coil must always be placed before the WaterToAirHeatPump heating coil.

There are three type of WaterToAirHeatPump coil models available:

- Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
- Coil:Heating:WaterToAirHeatPump:ParameterEstimation
- Coil:Cooling:WaterToAirHeatPump:EquationFit
- Coil:Heating:WaterToAirHeatPump:EquationFit
- Coil:Cooling:WatertoAirHeatPump:VariableSpeedEquationFit
- Coil:Heating:WatertoAirHeatPump:VariableSpeedEquationFit

In addition, the control zone name and the system design operating conditions are specified by the heat pump inputs.

#### 1.32.11.1 Inputs

##### 1.32.11.1.1 Field: Name

This alpha field contains the identifying name for the unitary system heat pump.

##### 1.32.11.1.2 Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule objects) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the time period. If this field is left blank, the schedule has a value of 1 for all time periods.

##### 1.32.11.1.3 Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

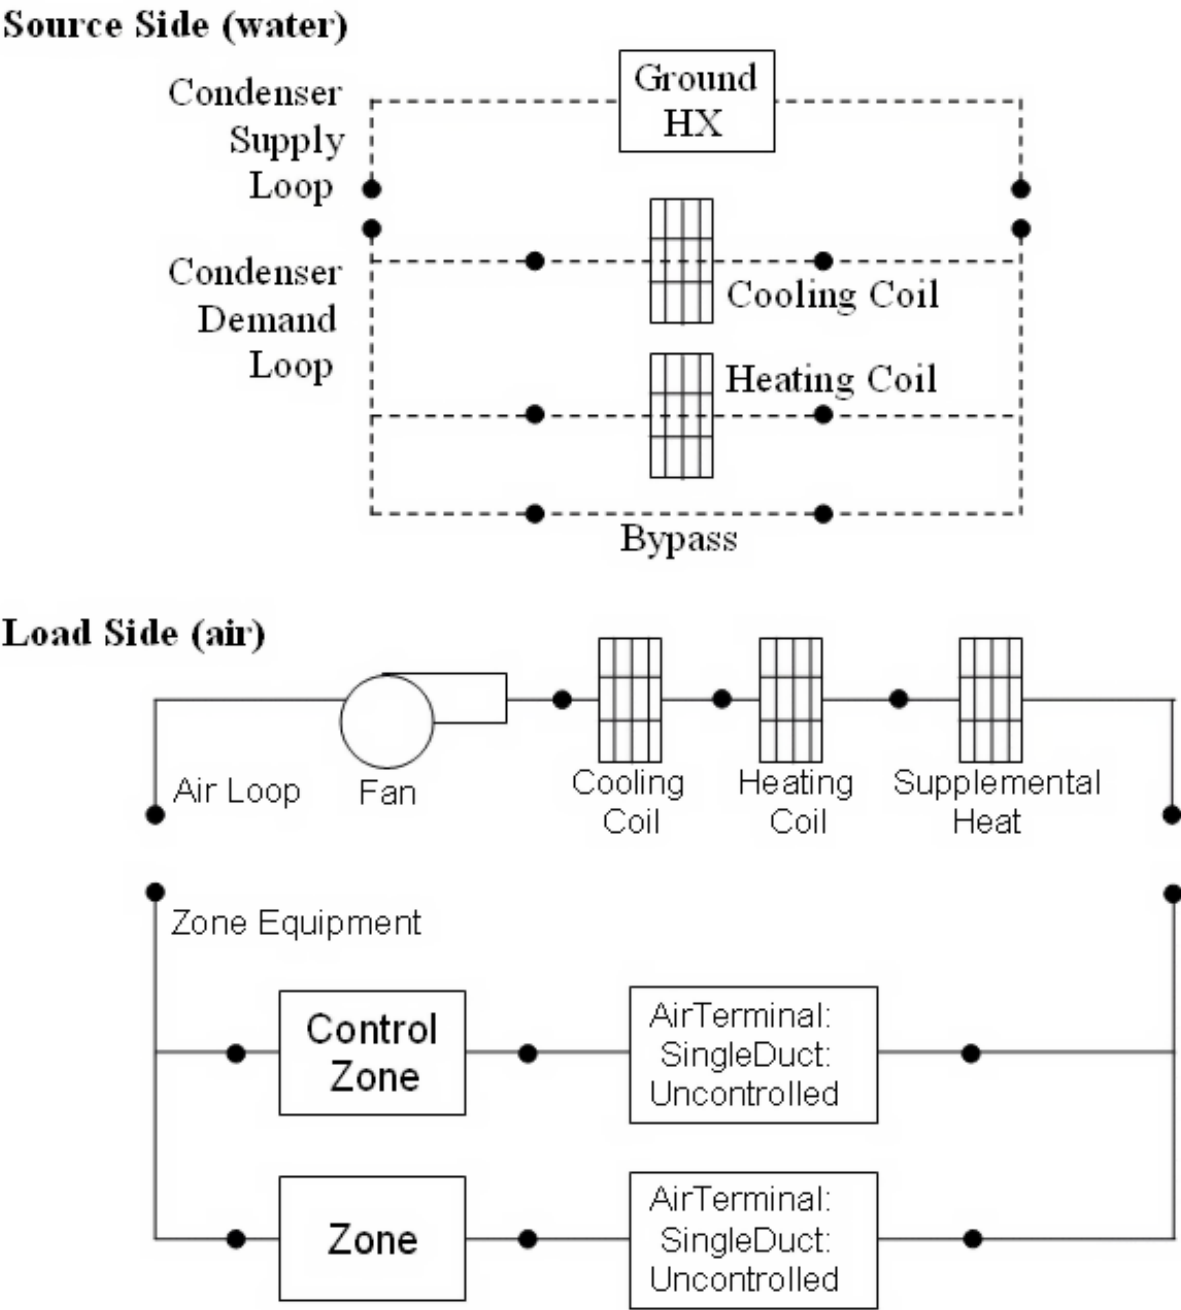

Figure 1.153: Water to Air Heat Pump Schematic for a BlowThrough Configuration with Ground Heat Exchanger

**1.32.11.1.4 Field: Air Outlet Node Name**

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

**1.32.11.1.5 Field: Supply Air Flow Rate**

This numeric field contains the design volumetric flow rate through the heat pump in cubic meters per second. This volume flow rate is only used when the cooling and heating coil object type is `Coil:*,WaterToAirHeatPump:ParameterEstimation`. Although a value greater than 0 is required (input cannot be blank or 0), this input is not used for the `EquationFit` model. Instead, the supply air flow rate is determined by the input in the corresponding `Coil:*,WaterToAirHeatPump:EquationFit` objects.

**1.32.11.1.6 Field: Controlling Zone or Thermostat Location**

This alpha field contains the identifying zone name where the thermostat controlling the heat pump is located.

**1.32.11.1.7 Field: Supply Air Fan Object Type**

This alpha field contains the identifying type of supply air fan specified in the heat pump. Fan type must be `Fan:OnOff`.

**1.32.11.1.8 Field: Supply Air Fan Name**

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

**1.32.11.1.9 Field: Heating Coil Object Type**

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil types are:

- `Coil:Heating:WaterToAirHeatPump:ParameterEstimation`
- `Coil:Heating:WaterToAirHeatPump:EquationFit`
- `Coil:Heating:WaterToAirHeatPump:VariableSpeedEquationFit`

**1.32.11.1.10 Field: Heating Coil Name**

This alpha field contains the identifying name given to the `WaterToAirHeatPump` heating coil, and should match the name specified in the corresponding `WaterToAirHeatPump` heating coil object.

**1.32.11.1.11 Field: Heating Convergence**

This numeric value allows the user to determine how close the air side has to be controlled. Lower the value of convergence better the control of air side conditions and less the zone temperature fluctuations. However in a poorly designed system, a lower convergence might result in warning errors which are caused due to the iteration limit for run time fraction calculation is limited to 20.

**1.32.11.1.12 Field: Cooling Coil Object Type**

This alpha field contains the identifying type of cooling coil specified in the heat pump. Cooling coil types are:

- `Coil:Cooling:WaterToAirHeatPump:ParameterEstimation`
- `Coil:Cooling:WaterToAirHeatPump:EquationFit`
- `Coil:Cooling:WaterToAirHeatPump:VariableSpeedEquationFit`

**1.32.11.1.13 Field: Cooling Coil Name**

This alpha field contains the identifying name given to the WaterToAirHeatPump cooling coil, and should match the name specified in the corresponding WaterToAirHeatPump cooling coil object.

**1.32.11.1.14 Field: Cooling Convergence**

This numeric value allows the user to determine how close the air side has to be controlled. Lower the value of convergence better the control of air side conditions and less the zone temperature fluctuations. However in a poorly designed system, a lower convergence might result in warning errors which are caused due to the iteration limit for run time fraction calculation is limited to 20.

**1.32.11.1.15 Field: Maximum Cycling Rate**

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Figure 1.154:

**1.32.11.1.16 Field: Heat Pump Time Constant**

This numeric field contains the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Figure 1.155:

**1.32.11.1.17 Field: Fraction of On-Cycle Power Use**

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	0.01
Good	0.01
Poor	0.03

Figure 1.156:

**1.32.11.1.18 Field: Heat Pump Fan Delay Time**

This numeric field contains the time delay for the heat pump supply air fan to shut off after the compressor cycles off in seconds. This value can be obtained from the manufacturer or the heat pump catalog. Enter a value of zero when the heat pump’s fan operating mode is continuous. Suggested value is 60 seconds.

**1.32.11.1.19 Field: Supplemental Heating Coil Object Type**

This is the object type of the supplemental heating coil. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the supplemental heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (AirLoop Unitary Water to Air Heat Pump) itself provides the “controller” function of modulating water flow. The valid choices are:

- **Coil:Heating:Electric**
- **Coil:Heating:Fuel**
- **Coil:Heating:Water**
- **Coil:Heating:Steam**

**1.32.11.1.20 Field: Supplemental Heating Coil Name**

This alpha field contains the identifying name given to the supplemental heating coil, and should match the name specified in the corresponding supplemental heating coil object.

**1.32.11.1.21 Field: Maximum Supply Air Temperature from Supplemental Heater**

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil in degrees Celsius.

**1.32.11.1.22 Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation**

This numeric field defines the outdoor air dry-bulb temperature in degrees Celsius above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21°C. If this input field is left blank, the default value is 21°C.

#### 1.32.11.1.23 Field: Outdoor Dry-Bulb Temperature Sensor Node Name

This alpha field specifies the name of the outdoor node which controls the operation of the supplemental heating coil. If this field is left blank, the outdoor temperature is based solely on the weather data. If this field is not blank, the node name specified must also be listed in an **OutdoorAir:Node** object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an **OutdoorAir:NodeList** object where the outdoor temperature is taken directly from the weather data.

#### 1.32.11.1.24 Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply fan is between the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

#### 1.32.11.1.25 Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating/cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation period.

As shown in the example below, correct specification of the water-to-air heat pump requires specification of the following objects in addition to the AirLoopHVAC:UnitaryHeatPump:WaterToAir object:

- On/Off fan
- WaterToAirHeatPump cooling coil
- WaterToAirHeatPump heating coil
- Supplementary heating coil
- Direct air unit for each zone served by the heat pump
- Condenser demand branches

It should be noted that the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the heat pump object.

#### 1.32.11.1.26 Field: Dehumidification Control Type

This alpha input field contains the type of dehumidification control. The following options are valid for this field:

**None** - meet sensible load only, no active dehumidification control

**CoolReheat** - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. The excess cooling beyond the cooling set point temperature is offset by the supplemental heating coil.

The default is **None**. For **CoolReheat** dehumidification control modes, the maximum humidity setpoint is required. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. Supplemental heating coil (supplemental heating coil type and name) is a required

input in WaterToAir HeatPumps. When dehumidification control is active the heating and the reheat load due to extra dehumidification are met with supplemental heating coil. The supplemental heating coil capacity must be adequate enough to meet the heating coil load and offset the excess cooling load due to extra dehumidification. The dehumidification control type CoolReheat works only with **Coil:Cooling:WaterToAirHeatPump:EquationFit** cooling coil type.

#### 1.32.11.1.27 Field: Heat Pump Coil Water Flow Mode

This field specifies the way in which water flow through the heat pump coils will be modeled. This field is only used when WaterToAirHeatPump:EquationFit coils are used. There are three options:

- Cycling
- Constant
- CyclingOnDemand

**Cycling** varies water flow through the coil based on the heat pump Part Load Ratio. This control method is appropriate for modeling heat pumps that are outfitted with a solenoid valve which allows water to flow through the coil only when the compressor is active. This is the default for EnergyPlus V8 and later.

**Constant** provides a constant water flow regardless of heat pump operation. Remember that EnergyPlus has two coils (a heating coil and a cooling coil) to approximate the operation of one coil that can operate in either heating mode or cooling mode. Therefore, when the water flow mode is constant, there will be full flow through either the heating coil or the cooling coil, but not both at the same time.

**ConstantOnDemand** provides full flow through the coil whenever there is a load. When there is no load, there is zero flow through the coil. This control strategy represents the way EnergyPlus modeled heat pump water flow prior to Version 8.

Following is an example of IDF usage:

### 1.32.11.2 Outputs

Energy use reporting for the water-to-air heat pump is documented under the heat pump coil object types:

- Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
- Coil:Heating:WaterToAirHeatPump:ParameterEstimation
- Coil:Cooling:WaterToAirHeatPump:EquationFit

- Coil:Heating:WaterToAirHeatPump:EquationFit

The heat pump *demand* as well as the compressor and fan part-load ratios may be obtained with the output variables shown below.

- HVAC,Average, Unitary System Requested Sensible Cooling Rate [W]
- HVAC,Average, Unitary System Requested Latent Cooling Rate [W]
- HVAC,Average, Unitary System Requested Heating Rate [W]
- HVAC,Average, Unitary System Compressor Part Load Ratio []
- HVAC,Average, Unitary System Fan Part Load Ratio
- HVAC,Average, Unitary System Dehumidification Induced Heating Demand Rate [W]

#### 1.32.11.2.1 Unitary System Requested Sensible Cooling Rate [W]

This output variable is the sensible cooling requested from the zone thermostat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

#### 1.32.11.2.2 Unitary System Requested Latent Cooling Rate [W]

This output variable is the latent cooling requested from the zone humidistat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the heat of vaporization of water at the current zone conditions, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

#### 1.32.11.2.3 Unitary System Requested Heating Rate [W]

This output variable is the sensible heating requested from the zone thermostat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

#### 1.32.11.2.4 Unitary System Compressor Part Load Ratio []

This output variable is the ratio of actual load on the unitary system to the unitary system's steady state output. This ratio is based on the nominal capacity of the unit.

#### 1.32.11.2.5 Unitary System Fan Part Load Ratio []

This output variable is the ratio of actual air mass flow rate through the unitary system to the unitary system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule).

#### 1.32.11.2.6 Unitary System Dehumidification Induced Heating Demand Rate [W]

This output variable is the additional heating demand rate of the supplemental heating coil of a Water-to-Air heat pumps in Watts. This additional heating demand is induced when zone air overshoots the heating setpoint due to extra dehumidification requirement to meet the high humidity setpoint. This value is always positive. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

### 1.32.12 AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass

The changeover-bypass variable air volume (CBVAV) unitary system is a compound object made up of other components. Each CBVAV system consists of an outdoor air mixer, direct expansion (DX) cooling coil, heating coil, and a supply air fan as shown in the figures below. Zone thermostats and terminal units are required in each zone served by this system. The terminal units are specific to this system type and are either [AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat](#) or [AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat](#). A zone humidistat and single zone max humidity set point manager may also be specified to help control high humidity levels. These individual components are described elsewhere in this document. The system may also be connected to an inlet node of either the [AirLoopHVAC:ZoneMixer](#) or [AirLoopHVAC:ReturnPlenum](#) to more accurately model the [AirLoopHVAC:OutdoorAirSystem](#). The CBVAV unitary system object coordinates the operation of these components and is modeled as a type of air loop equipment (Ref. [AirLoopHVAC](#)).

Figure 1.157: Schematic of a CBVAV unitary system (draw through fan placement)

Links to the CBVAV system's supply air fan, coils, and outdoor air mixer specifications are provided in the object's input syntax. Additional inputs include system and outdoor air flow rates during heating and cooling operation, the priority control mode, and dehumidification control type. A description of each input field for the CBVAV unitary system compound object is provided below.

#### 1.32.12.1 Inputs

##### 1.32.12.1.1 Field: Name

This alpha field defines a unique user-assigned name for an instance of a changeover-bypass VAV system. Any reference to this system by another object will use this name.

##### 1.32.12.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the system operates during a given time period. A schedule value equal to 0 denotes that the system must be off

Figure 1.158: Schematic of a CBVAV unitary system (blow through fan placement)

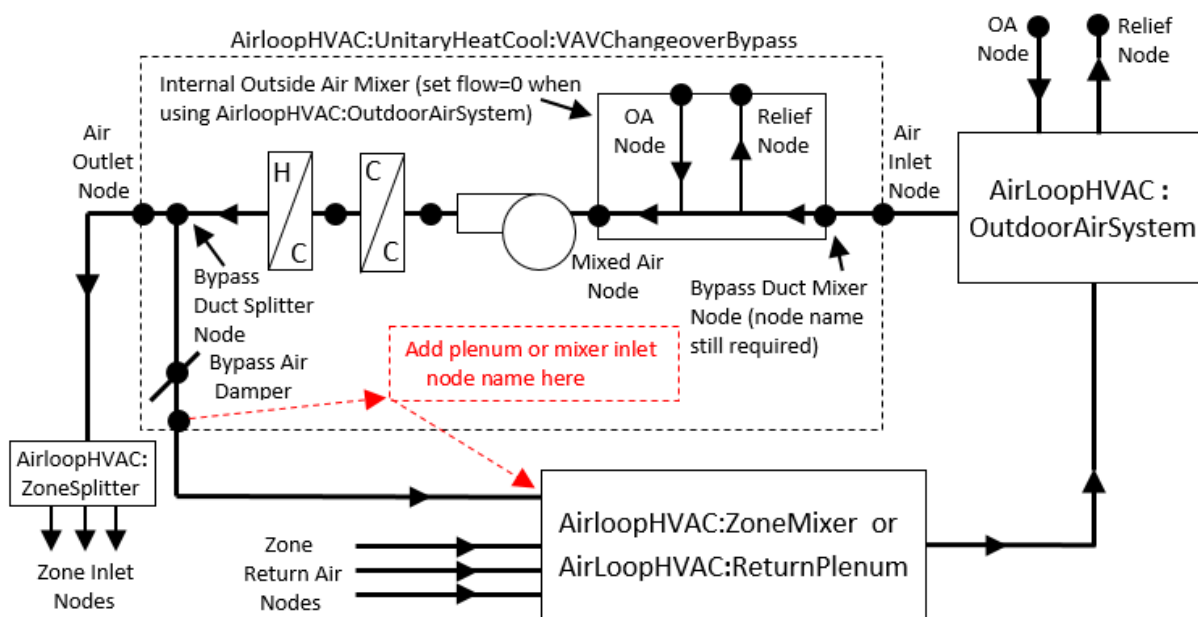

Figure 1.159: Schematic of a CBVAV unitary system used with outdoor air system

for that time period, and a schedule value greater than 0 denotes that the system is available to operate during that time period. This schedule may be used to completely disable the system (all of its coils and the supply air fan) as required. If this field is left blank, the schedule has a value of 1 for all time periods.

#### **1.32.12.1.3 Field: Cooling Supply Air Flow Rate**

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0, or this field is autosizable.

#### **1.32.12.1.4 Field: Heating Supply Air Flow Rate**

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when the heating coil is operating. Values must be greater than 0, or this field is autosizable.

#### **1.32.12.1.5 Field: No Load Supply Air Flow Rate**

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when neither cooling nor heating is required (i.e., the DX cooling coil and heating coil are off but the supply air fan operates). Values must be greater than or equal to zero, or this field is autosizable. This field is only used when the unitary system's supply air fan operating mode is specified as continuous fan operation (Ref. Field: Supply air fan operating mode schedule name). If the system's supply air fan operating mode is specified as continuous fan operation and this value is set to zero or the field is left blank, then the model assumes that the system air flow rate when no heating/cooling is needed is equal to the system air flow rate when the coils were last operating (for cooling operation or heating operation).

#### **1.32.12.1.6 Field: Cooling Outdoor Air Flow Rate**

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside\_Air\_Stream\_Node) in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the Cooling Outdoor Air Flow Rate can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the Cooling Outdoor Air Flow Rate cannot exceed the system air volumetric flow rate during cooling operation.

#### **1.32.12.1.7 Field: Heating Outdoor Air Flow Rate**

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside\_Air\_Stream\_Node) in cubic meters per second when the heating coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the Heating Outdoor Air Flow Rate can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the Heating Outdoor Air Flow Rate cannot exceed the system air volumetric flow rate during heating operation.

#### **1.32.12.1.8 Field: No Load Outdoor Air Flow Rate When No Cooling or Heating is Needed**

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside\_Air\_Stream\_Node) in cubic meters per second when neither cooling nor heating is required (i.e., the DX cooling coil and heating coil are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the no load outdoor air flow rate can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate

multiplier schedule name). For any simulation timestep, the no load outdoor air flow rate cannot exceed the no load supply air flow rate. This field is only used when the unitary system's supply air fan operating mode is specified as continuous fan operation (Ref. Field: Supply air fan operating mode schedule name). If the system's supply air fan operating mode is specified as continuous fan operation and this value is set to zero or the field is left blank, then the model assumes that the no load outdoor air flow rate is equal to the outdoor air flow rate when the coils were last operating (for cooling operation [i.e. Cooling outdoor air flow rate] or heating operation [i.e. Heating outdoor air flow rate]) and this field is not used.

#### 1.32.12.1.9 Field: Outdoor Air Flow Rate Multiplier Schedule Name

This alpha field defines the name of a schedule (ref: Schedule) that contains multipliers for the outdoor air volume flow rates (heating, cooling, no heating/cooling). Schedule values must be from zero to 1. If this field is left blank, then the model assumes that the outdoor air multiplier is 1 for the entire simulation period.

#### 1.32.12.1.10 Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the system draws its inlet air.

#### 1.32.12.1.11 Field: Bypass Duct Mixer Node Name

This alpha field defines the name of the HVAC system node where the bypass air mixes with the unitary system's inlet air. This name should match the name of the Return Air Stream Node Name for the **OutdoorAir:Mixer** associated with this system. This node name must be different from the system's air inlet node name.

#### 1.32.12.1.12 Field: Bypass Duct Splitter Node Name

This alpha field defines the name of the HVAC system node where the conditioned air is split into bypass air and supply air leaving the system (e.g., delivered to the terminal units). This splitter air node name should match the outlet node name for the last component (furthest downstream) in this unitary system. For blow through fan placement, the splitter air node is the outlet node of the heating coil. For draw through fan placement, the splitter node is the outlet node of the supply air fan.

#### 1.32.12.1.13 Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the system sends its outlet air.

#### 1.32.12.1.14 Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this CBVAV unitary system. The outdoor air mixer component is part of the CBVAV unitary compound object. The only available outdoor air mixer type is:

- **OutdoorAir:Mixer**

#### 1.32.12.1.15 Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component that composes part of the CBVAV system. The name of the outdoor air mixer's Return\_Air\_Stream\_Node should match the bypass duct mixer node name, and be different from the CBVAV system's air inlet node name. The Mixed Air Node Name of the outdoor air mixer should be the same as the CBVAV system's supply fan inlet air node (for blow through fan placement) or the system's DX cooling coil inlet node (for draw through fan placement).

**1.32.12.1.16 Field: Supply Air Fan Object Type**

This alpha field defines the type of fan used by this unitary system. The only valid choices are **Fan:SystemModel**, **Fan:OnOff**, and **Fan:ConstantVolume**. The input requirements for these fan objects are described elsewhere in this document.

**1.32.12.1.17 Field: Supply Air Fan Name**

This alpha field defines the name of the fan component that composes part of this unitary system. Note that the fan component’s maximum flow rate should be greater than or equal to the largest system air volumetric flow rate specified for this unitary system (heating, cooling, and no heating/cooling). In addition, the fan’s inlet air node should be the same as the outdoor air mixer’s Mixed Air Node (for blow through fan placement) or the heating coil’s outlet node (for draw through fan placement). The fan outlet air node should be the same as the DX cooling coil’s air inlet node (for blow through fan placement) or the system’s bypass duct splitter node (for draw through fan placement).

**1.32.12.1.18 Field: Supply Air Fan Placement**

This alpha field defines the placement of the supply air fan within this unitary system. The only valid choices are **BlowThrough** and **DrawThrough**. With blow through placement, the supply air fan is located immediately upstream of the system’s cooling coil. With draw through placement, the supply air fan is located immediately downstream of the heating coil.

**1.32.12.1.19 Field: Supply Air Fan Operating Mode Schedule Name**

This alpha field defines the name of a schedule that specifies the supply air fan operating mode during the simulation. A schedule value of 0 denotes the fan cycles off when no cooling or heating is required, and any other value denotes that the fan runs continuously regardless of the need for heating or cooling. If this field is left blank, the model assumes continuous supply air fan operation for the entire simulation period.

**1.32.12.1.20 Field: Cooling Coil Object Type**

This alpha field defines the type of cooling coil used by this unitary system. There are three valid choices for this field:

- **Coil:Cooling:DX:SingleSpeed**
- **Coil:Cooling:DX:VariableSpeed**
- **CoilSystem:Cooling:DX:HeatExchangerAssisted**
- **Coil:Cooling:DX:TwoStageWithHumidityControlMode**

The input requirements for these cooling coil objects are described elsewhere in this document.

**1.32.12.1.21 Field: Cooling Coil Name**

This alpha field defines the name of the cooling coil used by this unitary system, and this name should match the name specified in the corresponding cooling coil object.

**1.32.12.1.22 Field: Heating Coil Object Type**

This alpha field defines the type of heating coil used by this unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The hot water flow modulation through the heating coil does not require additional controller or **Controller:WaterCoil** object. The parent object (CBVAV Unitary System) itself provides the “controller” function of modulating water flow. The valid choices are:

- Coil:Heating:Electric
- Coil:Heating:Fuel
- Coil:Heating:DX:SingleSpeed
- Coil:Heating:DX:VariableSpeed
- Coil:Heating:Water
- Coil:Heating:Steam

The input requirements for these heating coil objects are described elsewhere in this document.

#### 1.32.12.1.23 Field: Heating Coil Name

This alpha field defines the name of the heating coil used by this unitary system, and this name should match the name specified in the corresponding heating coil object.

#### 1.32.12.1.24 Field: Priority Control Mode

This choice field defines the cooling or heating priority control mode for the unitary system. Valid choices are:

- CoolingPriority
- HeatingPriority
- ZonePriority
- LoadPriority

If CoolingPriority is selected, the system operates to meet the cooling load if any zone served by this system (air loop) requires cooling. If no zones require cooling, then the system operates in heating mode if needed. If HeatingPriority is selected, the system operates to meet the heating load if any zone requires heating. If no zones require heating, then the system operates in cooling mode if needed. If ZonePriority is selected, the system operates based on the maximum number of zones requiring either heating or cooling. If the number of zones requiring cooling is greater than the number of zones requiring heating, then the system operates in cooling mode. If the number of zones requiring heating is greater than the number of zones requiring cooling, then the system operates in heating mode. If the number of zones requiring cooling equals the number of zones requiring heating, then the largest combined load (i.e., the sum of the cooling loads for zones requiring cooling compared to the sum of the heating loads for zones that require heating) sets the cooling or heating operating mode for the system during that simulation timestep. If LoadPriority is selected, the system operates based on the largest combined load (i.e., the sum of the cooling loads for zones requiring cooling compared to the sum of the heating loads for zones that require heating). If the total load for zones requiring cooling is greater than the total load for zones requiring heating, then the system operates in cooling mode. Similar logic is used for heating mode selection. If the total cooling load equals the total heating load, then cooling or heating operation reverts to the total number of zones requiring cooling or heating (and if equal reverts to cooling mode if the cooling load is non-zero, otherwise, heating mode).

#### 1.32.12.1.25 Field: Minimum Outlet Air Temperature During Cooling Operation

This numeric field defines the minimum outlet air temperature leaving the system when the unit is operating to provide cooling. Values are specified in degrees Celsius and must be greater than 0. The default value is 8°C. This value must be less than or equal to the maximum outlet air temperature during heating operation.

**1.32.12.1.26 Field: Maximum Outlet Air Temperature During Heating Operation**

This numeric field defines the maximum outlet air temperature leaving the system when the unit is operating to provide heating. Values are specified in degrees Celsius and must be greater than 0. The default value is 50°C. This value must be greater than or equal to the minimum outlet air temperature during cooling operation.

**1.32.12.1.27 Field: Dehumidification Control Type**

This alpha field contains the type of dehumidification control. The following options are valid for this field:

**None** - meet sensible load only, no active dehumidification control

**Multimode** - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = **Coil:Cooling:DX:TwoStageWithHumidityControlMode**.

**CoolReheat** - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. It is valid only with cooling coil type = **Coil:Cooling:DX:TwoStageWithHumidityControlMode**.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint on the CBVAV system's air outlet node is used. This must be set using a **ZoneControl:Humidistat** and one of:

- **SetpointManager:SingleZone:Humidity:Maximum**
- **SetpointManager:MultiZone:Humidity:Maximum**
- **SetpointManager:MultiZone:MaximumHumidity:Average**

objects. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate.

**1.32.12.1.28 Field: Plenum or Mixer Inlet Node Name**

This alpha field defines the name of the HVAC system node where the bypass air enters the zone mixer or return plenum. This node name must be different from the system's **Air Outlet Node Name** and **Bypass Duct Splitter Node Name**. This name should match the name of the inlet node in the **AirLoopHVAC:ZoneMixer** or **AirLoopHVAC:ReturnPlenum** associated with this system.

**1.32.12.1.29 Field: Minimum Runtime Before Operating Mode Change**

This numeric field defines the amount of time, in hours, the HVAC system operates before a mode change is allowed. The value entered must be greater than or equal to 0. The default value is 0.25 hours if this input is present and blank. If this field is not present the minimum runtime is 0 hours (i.e., immediate change over as needed).

As shown in the example below, correct specification of the CBVAV unitary system requires specification of the following objects in addition to the **AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass** object:

- 1) outdoor air mixer (**OutdoorAir:Mixer**)
- 2) fan (**Fan:SystemModel**, **Fan:OnOff**, or **Fan:ConstantVolume**)
- 3) cooling coil (**Coil:Cooling:DX:SingleSpeed**, **CoilSystem:Cooling:DX:HeatExchangerAssisted**, or **Coil:Cooling:DX:TwoStageWithHumidityControlMode**)
- 4) heating coil (**Coil:Heating:Fuel**, **Coil:Heating:Electric**, or **Coil:Heating:DX:SingleSpeed**)
- 5) terminal unit for each zone being served by this system (**AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat** or **AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat**)

6) When the Plenum or Mixer Inlet Node Name is specified, this node name must connect to either the `AirLoopHVAC:ZoneMixer` or `AirLoopHVAC:ReturnPlenum` and the `AirLoopHVAC:OutdoorAirSystem` may then be used to control the outdoor air flow rates. When using the `AirLoopHVAC:OutdoorAirSystem` it is recommended that the Cooling, Heating and No Load Outdoor Air Flow Rate inputs are set to 0, otherwise the amount of outdoor air is increased and the coils may not autosize properly.

Note: The fan, heating coil, cooling coil, and outdoor air mixer must be connected in the air loop according to the configurations shown above (Figure 1.157, Figure 1.158 or Figure 1.159).

#### **1.32.12.2.1 Unitary System Total Heating Rate [W]**

This output field is the total (enthalpy) heat addition rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

#### **1.32.12.2.2 Unitary System Total Heating Energy [J]**

This output field is the total (enthalpy) heat addition of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

#### **1.32.12.2.3 Unitary System Total Cooling Rate [W]**

This output field is the total (enthalpy) heat extraction rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

#### **1.32.12.2.4 Unitary System Total Cooling Energy [J]**

This output field is the total (enthalpy) heat extraction of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

**1.32.12.2.5 Unitary System Sensible Heating Rate [W]**

This output field is the sensible heat addition rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

**1.32.12.2.6 Unitary System Sensible Heating Energy [J]**

This output field is the sensible heat addition of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

**1.32.12.2.7 Unitary System Sensible Cooling Rate [W]**

This output field reports the moist air sensible heat extraction rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

**1.32.12.2.8 Unitary System Sensible Cooling Energy [J]**

This output field reports the moist air sensible heat extraction of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

**1.32.12.2.9 Unitary System Latent Heating Rate [W]**

This output field is the latent heat addition (humidification) rate of the CBVAV system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

**1.32.12.2.10 Unitary System Latent Heating Energy [J]**

This output field is the latent heat addition (humidification) of the CBVAV system in Joules over the timestep being reported. This value is calculated as the difference between the total energy and the sensible energy delivered by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

**1.32.12.2.11 Unitary System Latent Cooling Rate [W]**

This output field is the latent heat extraction (dehumidification) rate of the CBVAV system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

**1.32.12.2.12 Unitary System Latent Cooling Energy [J]**

This output field is the latent heat extraction (dehumidification) of the CBVAV system in Joules over the timestep being reported. This value is calculated as the difference between the total energy and the sensible energy delivered by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

**1.32.12.2.13 Unitary System Electricity Rate [W]**

This output field is the electricity consumption rate of the CBVAV system in Watts. The consumption includes electricity used by the DX compressor (including crankcase heater), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), and the heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.12.2.14 Unitary System Electricity Energy [J]**

This output field is the electricity consumption of the CBVAV system in Joules for the time period being reported. The consumption includes electricity used by the DX compressor (including crankcase heater), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), and the heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

**1.32.12.2.15 Unitary System Fan Part Load Ratio []**

This output field is the part-load ratio of the supply air fan, which will be either zero or 1 for each simulation timestep. For this system, the fan will operate continuously for the simulation timestep if the system is available (ref. Field: Availability schedule name) and there is a cooling or heating load to be met (i.e., fan part-load ratio will equal 1). When the system is available but there is no cooling or heating load to be met, the fan will either be off for the entire timestep or on for the entire timestep depending on the supply air fan operating mode schedule (ref. Field: Supply Air Fan Operating Mode Schedule Name). This value is set for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.12.2.16 Unitary System Compressor Part Load Ratio []**

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). The compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity (steady-state capacity of first stage for multi-mode coils). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.12.2.17 Unitary System Bypass Air Mass Flow Rate [kg/s]**

This output field is the mass flow rate of air, in kg/s, being bypassed from the supply air path and blended with the air entering the CBVAV system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

**1.32.12.2.18 Unitary System Air Outlet Setpoint Temperature [C]**

This output field is the dry-bulb set point temperature in degrees Celsius. This set point temperature is calculated by the model based on the zone cooling/heating loads calculated by EnergyPlus, and the priority control mode and the dehumidification control type specified for this unitary system. The CBVAV system attempts to achieve the outlet air set point temperature to the extent possible.

**1.32.12.2.19 Unitary System Operating Mode Index []**

This output field is the current operating mode, either cooling, heating or no cooling or heating. A value of 0 represents no cooling or heating is required, a value of 1 represents cooling and a value of 2 represents heating. These specific values can be seen using the detailed time step reporting frequency. If longer reporting frequencies are used (e.g., timestep, hourly, etc.) then this output is averaged over the reporting interval and the result is dependent on the value selected for *Minimum Runtime Before Operating Mode Change*.

**1.33 Group – Variable Refrigerant Flow Equipment**

This group of EnergyPlus input objects describes the configurations of Variable Refrigerant Flow (VRF, or Variable Refrigerant Volume) air-conditioning systems.

A VRF system is an air-conditioning system that varies the refrigerant flow rate using variable speed compressor(s) in the outdoor unit, and the electronic expansion valves (EEVs) located in each terminal unit. For zone equipment the system meets the space cooling or heating load requirements by maintaining the zone air temperature at the setpoint or in the case of air loop equipment can meet a control zone load or maintain a terminal unit or coil outlet air temperature set point. The terminal unit may also be used in the air loop's outdoor air system where a terminal unit or coil outlet air temperature set point must be used. The ability to control the refrigerant mass flow rate according to the cooling and/or heating load enables the use of as many as 20 or more terminal units with differing capacities in conjunction with one single outdoor unit. This unlocks the possibility of having individualized comfort control, simultaneous heating and cooling in different zones, and heat recovery from one zone to another.

There are two alternative VRF models in EnergyPlus:

1. **System curve based model (VRF-SysCurve)**. In this model, a number of system level curves are used to describe the VRF system performance. This model corresponds to the *AirConditioner:VariableRefrigerantFlow* object.
2. **Physics based model (VRF-FluidTCtrl)**. This model is able to consider the dynamics of more operational parameters and is applicable for fluid temperature control. This model corresponds to the *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object.

(Please refer to the engineering reference for more technical details of the two models).

In the VRF system model, direct-expansion cooling and/or heating coils with an optional supplemental heating coil are configured in a zone terminal unit, which is connected to a zone via the zone inlet and exhaust nodes, connected to an air loop main branch or installed in the air loop's outdoor air system. The terminal units are identified in a *ZoneTerminalUnitList* object, the name of which is entered as an input to the *AirConditioner:VariableRefrigerantFlow* or *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object.

The EnergyPlus connection methodology is shown as dashed and greyed arrows in Figure 1.160 according to the following rules:

- For zone equipment the zone inlet and zone exhaust node names are defined in a *ZoneHVAC:EquipmentConnections* object (bottom of figure) and the terminal unit type and name are specified in a *ZoneHVAC:EquipmentList* object. For air loop equipment the terminal unit type and name and inlet and outlet node names are defined in the *AirLoopHVAC* branch (top left of figure). For outside air system equipment the terminal unit type and name are defined in the *AirLoopHVAC:OutdoorAirSystem:EquipmentList* (top right of figure) and the terminal unit inlet node will typically (but not necessarily) be an outside air node and the terminal unit outlet node will typically connect to the *OutdoorAir:Mixer* object.

- A *ZoneHVAC:TerminalUnit:VariableRefrigerantFlow* object will specify the terminal unit's air inlet and air outlet node names. For zone equipment the zone exhaust node is the terminal unit inlet node and the zone inlet node is the terminal unit outlet node. For air loop and outdoor air system equipment the terminal unit inlet and outlet node names identify the order of the equipment in the air loop.
- All zone terminal units that are connected to the same *AirConditioner:VariableRefrigerantFlow* or *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object are listed in a *ZoneTerminalUnitList* object.
- The name of the *ZoneTerminalUnitList* object is an input to the *AirConditioner:VariableRefrigerantFlow* or *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object.
- The *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* or *AirConditioner:VariableRefrigerantFlow* object is not listed in an AirloopHVAC object, and therefore, can only be simulated if the terminal units are connected to the *AirConditioner:VariableRefrigerantFlow* or *AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl* object using the *ZoneTerminalUnitList*.
- Secondary ZoneHVAC equipment objects may be used in the same zones as the terminal units for other purposes (e.g., code compliance)

The following schematic demonstrates these connection rules.

EnergyPlus object type and object name, and node name relationships are also shown in the following figure to aid in the assembly of this HVAC system type.

### 1.33.1 AirConditioner:VariableRefrigerantFlow

#### 1.33.1.1 Inputs

##### 1.33.1.1.1 Field: Heat Pump Name

This alpha field defines a unique user-assigned name for an instance of a variable refrigerant flow heat pump. Any reference to this heat pump will use this name. Since this object is not listed in an AirloopHVAC object, the most likely use of this name would be for reporting purposes.

##### 1.33.1.1.2 Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value other than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (and all of its terminal units) as required. If this field is blank, the unit is enabled the entire simulation.

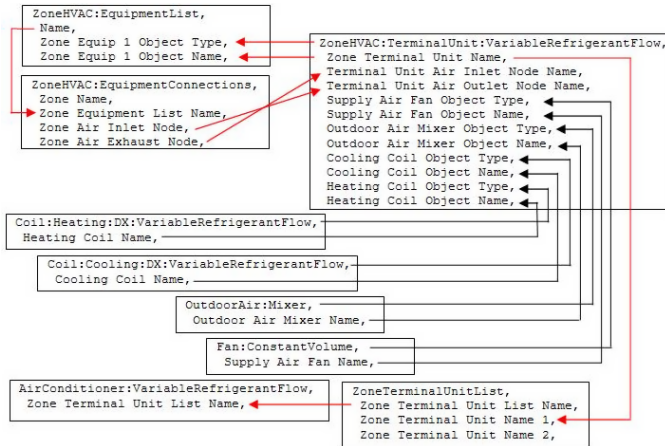

##### 1.33.1.1.3 Field: Gross Rated Total Cooling Capacity

This numeric field defines the total cooling capacity (sensible + latent) of the heat pump at rated conditions in watts. The cooling capacity must be greater than 0 or set to autosize.

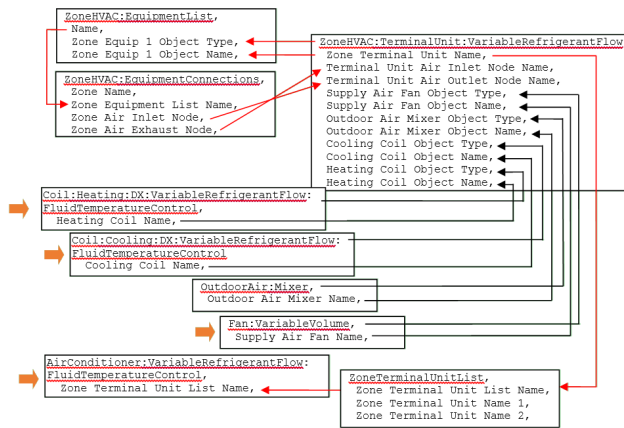

##### 1.33.1.1.4 Field: Gross Rated Cooling COP

This numeric field defines the cooling coefficient of performance at rated conditions. The cooling coefficient of performance includes compressor power and condenser fan power. This COP value does not account for impacts due to the supply air fan. The nominal heat pump cooling COP must be greater than 0. If this field is left blank, a default coefficient of performance of 3.3 is assumed.

(a) VRF model based on system curves

(VRF-SysCurve)

(b) VRF model based on

physics (VRF-FluidTCtrl)

Figure 1.161: Variable Refrigerant Flow Object Links

**1.33.1.1.5 Field: Minimum Outdoor Temperature in Cooling Mode**

This numeric field defines the minimum source temperature allowed for cooling operation. For air-cooled equipment outdoor dry-bulb temperature is used. For water-cooled equipment inlet water temperature is used. Below this temperature, cooling is disabled. If this field is left blank, the default value is -6°C.

**1.33.1.1.6 Field: Maximum Outdoor Temperature in Cooling Mode**

This numeric field defines the maximum source temperature allowed for cooling operation. For air-cooled equipment outdoor dry-bulb temperature is used. For water-cooled equipment inlet water temperature is used. Above this temperature, cooling is disabled. If this field is left blank, the default value is 43°C.

**1.33.1.1.7 Field: Cooling Capacity Ratio Modifier Function of Low Temperature Curve Name**

This alpha field defines the cooling capacity ratio modifier at low outdoor dry-bulb temperatures. This curve is a bi-quadratic equation using weighted average indoor wet-bulb temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air dry-bulb temperature as the independent variables. If the *Condenser Type* is WaterCooled, then the cooling capacity modifier curve will be function of weighted average indoor air wet-bulb temperature and outdoor condenser entering water temperature. This performance curve can be used to describe the cooling capacity ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used). For this system type it is likely that all three of these performance curves will be required. See the Engineering Reference for more discussion on using this input field.

**1.33.1.1.8 Field: Cooling Capacity Ratio Boundary Curve Name**

This alpha field defines the cooling capacity ratio boundary curve name. This curve is a linear, quadratic or cubic curve that defines a change in cooling capacity at a specific condenser entering air dry-bulb temperature as a function of indoor air wet-bulb temperature. This curve is used when the trend in cooling capacity changes dramatically as outdoor temperature changes. If the cooling capacity does not change dramatically with changes in outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

**1.33.1.1.9 Field: Cooling Capacity Ratio Modifier Function of High Temperature Curve Name**

This alpha field defines the cooling capacity ratio modifier at high outdoor temperatures. This curve is a bi-quadratic equation using weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables. This curve is used when the trend in cooling capacity changes dramatically as outdoor temperature changes. If the cooling capacity does not change dramatically with changes in outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

**1.33.1.1.10 Field: Cooling Energy Input Ratio Modifier Function of Low Temperature Curve Name**

This alpha field defines the cooling energy input ratio modifier at low outdoor temperatures. This curve is a bi-quadratic equation with a weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables. If the *Condenser Type* is WaterCooled, then the cooling energy input ratio modifier curve will be function of weighted average indoor air wet-bulb temperature and outdoor condenser entering water temperature. This performance curve can be used to describe the

cooling energy input ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used). For this system type it is likely that all three of these performance curves will be required. See the Engineering Reference for more discussion on using this input field.

#### **1.33.1.1.11 Field: Cooling Energy Input Ratio Boundary Name**

This alpha field defines the cooling energy input ratio boundary curve name. This curve is a linear, quadratic or cubic curve that defines a change in cooling energy at a specific condenser entering air dry-bulb temperature as a function of indoor air wet-bulb temperature. This curve is used when the trend in cooling energy changes dramatically as outdoor temperature changes. If the cooling energy does not change dramatically with changes in outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

#### **1.33.1.1.12 Field: Cooling Energy Input Ratio Modifier Function of High Temperature Curve Name**

This alpha field defines the cooling energy input ratio modifier at high outdoor temperatures. This curve is a bi-quadratic equation with weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables. This curve is used when the trend in cooling energy changes dramatically as outdoor temperature changes. If the cooling energy does not change dramatically with changes in outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

#### **1.33.1.1.13 Field: Cooling Energy Input Ratio Modifier Function of Low Part-Load Ratio Curve Name**

This alpha field defines the cooling energy input ratio modifier (function of part-load ratio when PLR is less than or equal to 1) curve name. This curve is a linear, quadratic or cubic equation with cooling part-load ratio used as the independent variable. The cooling energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the operating part-load ratio is less than or equal to 1. This curve's minimum PLR value must be less or equal to the value in the field Minimum Heat Pump Part-Load Ratio.

#### **1.33.1.1.14 Field: Cooling Energy Input Ratio Modifier Function of High Part-Load Ratio Curve Name**

This alpha field defines the cooling energy input ratio modifier (function of part-load ratio when PLR is greater than 1) curve name. This curve is a linear, quadratic or cubic equation with cooling part-load ratio used as the independent variable. The cooling energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the operating part-load ratio is greater than 1.

#### **1.33.1.1.15 Field: Cooling Combination Ratio Correction Factor Curve Name**

This alpha field defines the cooling combination ratio (CR) correction factor curve name for combination ratios greater than or equal to 1. The combination ratio is defined as the total rated indoor terminal unit cooling capacity divided by this heat pump's gross rated total cooling capacity. The curve is a linear, quadratic or cubic equation and uses the minimum value of x in the curve object to determine the maximum part-load ratio which is linearly proportional to capacity (i.e., the minimum value of x [CR] in the curve object must be 1). The output of this curve provides a multiplier ( $>1$ ) which is applied to this heat pump's Gross Rated Total Cooling Capacity. Between a combination ratio of 1 and the curve's minimum value of x, the multiplier is linearly interpolated. For combination ratio's less than 1 (i.e., the total indoor

terminal unit capacity is less than this heat pump's rated total capacity), capacity is directly proportional to part-load ratio and this curve will not be used.

#### 1.33.1.1.16 Field: Cooling Part-Load Fraction Correlation Curve Name

This alpha field defines the cooling part-load fraction correlation curve name. This curve is used to define the cycling losses when the condenser's compressors cycle on and off. The compressor cycles when the cooling part-load ratio is less than the Minimum Heat Pump Part-Load Ratio specified later in this object's inputs.

#### 1.33.1.1.17 Field: Gross Rated Heating Capacity

This numeric field defines the gross total heat pump heating capacity at rated conditions in watts. The nominal heat pump heating capacity must be greater than 0 or set to autosize.

#### 1.33.1.1.18 Field: Rated Heating Capacity Sizing Ratio

This numeric field defines the ratio of gross heating to gross cooling capacity. The model assumes that when used, this value will be greater than 1. A similar input is available in the **Zone-HVAC:TerminalUnit:VariableRefrigerantFlow** object. When the heating capacity is autosized, if this field is non-blank, this ratio is used to scale the heating capacity to the gross rated total cooling capacity regardless of the value entered in the terminal unit objects. When the heating capacity is not autosized, the gross rated heating capacity will be equal to the value specified in the Gross Rated Heating Capacity input field and this value will be compared to the sum of the terminal unit heating coil size. If these values are more than 10% different, a warning will be issued when **Output:Diagnostics**, DisplayExtraWarnings; is included in the input file. If this field is blank and the terminal unit sizing ratio input is also blank, then the heating capacity sizing ratio is assumed to be 1. If this field is not blank and the heating capacity sizing ratio in the terminal unit object(s) is blank, then this ratio also applies to each heating coil. If this field is not blank and the heating capacity sizing ratio in the terminal units is also not blank, then the terminal unit heating coil capacity sizing ratio input applies to each heating coil.

#### 1.33.1.1.19 Field: Gross Rated Heating COP

This numeric field defines the heating coefficient of performance at rated conditions. The heating coefficient of performance includes compressor power and condenser fan power. This gross COP value does NOT account for the supply air fan. The nominal heat pump heating COP must be greater than 0. If this field is left blank, a coefficient of performance of 3.4 is assumed.

#### 1.33.1.1.20 Field: Minimum Outdoor Temperature in Heating Mode

This numeric field defines the minimum outdoor temperature allowed for heating operation. Below this temperature, heating is disabled. If this field is left blank, the default value is -20°C.

#### 1.33.1.1.21 Field: Maximum Outdoor Temperature in Heating Mode

This numeric field defines the maximum outdoor temperature allowed for heating operation. Above this temperature, heating is disabled. If this field is left blank, the default value is 16°C.

#### 1.33.1.1.22 Field: Heating Capacity Ratio Modifier Function of Low Temperature Curve Name

This alpha field defines the heating capacity ratio modifier at low temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air dry-bulb or wet-bulb temperature as

the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This performance curve can be used to describe the heating capacity ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used). For this system type it is likely that all three of these performance curves will be required. See the Engineering Reference for more discussion on using this input field.

#### **1.33.1.1.23 Field: Heating Capacity Ratio Boundary Curve Name**

This alpha field defines the heating capacity ratio boundary curve name. This curve is a quadratic or cubic curve that defines a change in heating capacity at a specific condenser entering air dry-bulb or wet-bulb temperature as a function of indoor air dry-bulb temperature. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This curve is used when the trend in heating capacity changes dramatically as outdoor temperature changes. If the heating capacity does not change dramatically with changes in outdoor conditions, this field may be left blank.

#### **1.33.1.1.24 Field: Heating Capacity Ratio Modifier Function of High Temperature Curve Name**

This alpha field defines the heating capacity ratio modifier at high temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature and condenser entering air dry-bulb or wet-bulb temperature as the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This curve is used when the trend in heating capacity changes dramatically as outdoor temperature changes. If the heating capacity does not change dramatically with changes in outdoor conditions, this field may be left blank.

#### **1.33.1.1.25 Field: Heating Energy Input Ratio Modifier Function of Low Temperature Curve Name**

This alpha field defines the heating energy input ratio modifier at low temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature and condenser entering air dry-bulb or wet-bulb temperature as the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This performance curve can be used to describe the heating energy input ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used).

#### **1.33.1.1.26 Field: Heating Energy Input Ratio Boundary Curve Name**

This alpha field defines the heating energy input ratio boundary curve name. This curve is a quadratic or cubic curve that defines a change in heating energy at a specific condenser entering air dry-bulb or wet-bulb temperature as a function of indoor air dry-bulb temperature. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This curve is used when the trend in heating energy changes dramatically as outdoor temperature changes. If the heating energy does not change dramatically with changes in outdoor conditions, this field may be left blank.

**1.33.1.1.27 Field: Heating Energy Input Ratio Modifier Function of High Temperature Curve Name**

This alpha field defines the heating energy input ratio modifier at high temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature and condenser entering air dry-bulb or wet-bulb temperature as the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This curve is used when the trend in heating energy changes dramatically as outdoor temperature changes. If the heating energy does not change dramatically with changes in outdoor conditions, this field may be left blank.

**1.33.1.1.28 Field: Heating Performance Curve Outdoor Temperature Type**

This choice field defines the outdoor temperature type used for all performance curves. The valid choices are DryBulbTemperature and WetBulbTemperature. The default value is WetBulbTemperature. Manufacturers will typically provide heating performance data as a function of outdoor air wet-bulb temperatures. This means that the performance (e.g., capacity and energy input ratio) curves will use outdoor wet-bulb temperature as one of the independent variables. At times, manufacturers will only provide performance data as a function of outdoor dry-bulb temperatures. In this case, all performance curves shall be developed using outdoor dry-bulb temperature and this field shall be selected as DryBulbTemperature. If the *Condenser Type* specified is *WaterCooled*, then the value of this field should be *DryBulbTemperature*.

**1.33.1.1.29 Field: Heating Energy Input Ratio Modifier Function of Low Part-Load Ratio Curve Name**

This alpha field defines the heating energy input ratio modifier (function of part-load ratio when PLR is less than or equal to 1) curve name. This curve is a linear, quadratic, or cubic equation with heating part-load ratio used as the independent variable. The heating energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the part-load ratio is less than or equal to 1. This curve's minimum PLR value must be less or equal to the value in the field Minimum Heat Pump Part-Load Ratio.

**1.33.1.1.30 Field: Heating Energy Input Ratio Modifier Function of High Part-Load Ratio Curve Name**

This alpha field defines the heating energy input ratio modifier (function of part-load ratio when PLR is greater than 1) curve name. This curve is a linear, quadratic, or cubic equation with heating part-load ratio used as the independent variable. The heating energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the part-load ratio is greater than 1.

**1.33.1.1.31 Field: Heating Combination Ratio Correction Factor Curve Name**

This alpha field defines the heating combination ratio (CR) correction factor curve name for combination ratios greater than or equal to 1. The combination ratio is defined as the total rated indoor heating capacity divided by the rated heat pump heating capacity. The curve is either quadratic or cubic and uses the minimum value of x in the curve object to determine the maximum part-load ratio which is linearly proportional to capacity (i.e., the minimum value of x in the curve object must be 1). The output of this curve provides a multiplier (>1) which is applied to the Nominal Heat Pump Heating Capacity. Between a combination ratio of 1 and the curve's minimum value of x, the multiplier is linearly interpolated. For combination ratio's less than 1, capacity is directly proportional to part-load ratio and this curve will not be used. If this field is left blank, the Cooling Combination Ratio Correction factor will be used.

#### 1.33.1.1.32 Field: Heating Part-Load Fraction Correlation Curve Name

This alpha field defines the heating part-load fraction correlation curve name. This curve is used to define the cycling losses when the condenser's compressors cycle on and off. The compressor cycles when the indoor to outdoor heating capacity ratio is less than the Minimum Heat Pump Part-Load Ratio specified in the following field.

#### 1.33.1.1.33 Field: Minimum Heat Pump Part-Load Ratio

This numeric field specifies the minimum operating part-load ratio (PLR) of the heat pump. When the heat pump operates at a PLR below this value, the heat pump's compressor will cycle to meet the cooling or heating demand. Above this value, the heat pump's compressor operates the entire time step to meet the cooling or heating demand. The minimum value for this field is 0. If this field is left blank, the default value is 0.15. When the heat pump compressor cycles, the previous field is used to determine cycling losses.

#### 1.33.1.1.34 Field: Zone Name for Master Thermostat Location

This alpha field defines the name of the zone where the "master" thermostat is located. When the heat pump is connected to multiple zone terminal units, one terminal unit must be selected as the master thermostat. The remaining thermostats are slaves and can operate only in the same mode as the master thermostat.

#### 1.33.1.1.35 Field: Master Thermostat Priority Control Type

This choice field determines the logic used to simulate the "master" thermostat. Valid choices are LoadPriority, ZonePriority, ThermostatOffsetPriority, MasterThermostatPriority, and Scheduled. The default value is MasterThermostatPriority. When LoadPriority is selected, the total zone load is used to choose the operating mode as either cooling or heating. When ZonePriority is selected, the number of zones requiring cooling or heating determines the operating mode. When ThermostatOffsetPriority is selected, the zone farthest from the thermostat set point determines the operating mode. The MasterThermostatPriority choice operates the system according the zone load where the master thermostat is located. The heat pump can also be scheduled to operate in either cooling or heating mode. For scheduled operation, a schedule name is entered in the following field. When all terminal units connected to this system are set point controlled (set point control is only allowed in air loops and outdoor air systems) this field is not used.

#### 1.33.1.1.36 Field: Thermostat Priority Schedule Name

This alpha field identifies the schedule used when the previous field is set to Scheduled. Schedule values of 0 denote heating mode while values of 1 denote cooling mode. Any other values will force the system off.

#### 1.33.1.1.37 Field: Zone Terminal Unit List Name

This alpha field defines the name of the zone terminal unit list. The name specified here should match the name of a valid `ZoneTerminalUnitList` object. In addition, each name specified in this list should match the name of a valid `ZoneHVAC:TerminalUnit:VariableRefrigerantFlow` object. All terminal units connected to this heat pump must be listed in this `ZoneTerminalUnitList` object.

Note: the previous field is designated at the last field necessary to simulate the variable refrigerant flow heat pump. The following fields do not have to be entered, however, piping losses, defrost operation, crankcase heater operation, and basin heater operation will not be modeled. Defaults for fields not entered may also not apply. These remaining fields must be entered if that portion of the model is to be simulated.

**1.33.1.1.38 Field: Heat Pump Waste Heat Recovery**

This choice field defines the configuration of the heat pump refrigeration system. Valid choices are **Yes** and **No**. If Yes is selected, heat recovery is enabled and the heat pump can independently cool and heat different zones. If No is selected, the heat pump is only able to cool or heat for any given time step.

**1.33.1.1.39 Field: Equivalent Piping Length used for Piping Correction Factor in Cooling Mode**

This numeric field defines the equivalent pipe length in meters between the farthest terminal unit and the heat pump condenser. This value includes the gas refrigerant line length (for both horizontal and vertical distances), fitting losses, pipe bends, and other connections that contribute to piping losses. This field is used to calculate the piping correction factor in cooling mode. This value defines the head losses due to the pipe length between the farthest terminal unit and the heat pump condenser and impacts the maximum available capacity in cooling mode.

**1.33.1.1.40 Field: Vertical Height used for Piping Correction Factor**

This numeric field defines the vertical pipe height in meters between the highest or lowest terminal unit and the heat pump condenser. This value defines the gravitational losses due to a change in height between the highest (positive value), or lowest (negative value) terminal unit and the heat pump condenser. The distance specified here is applied to the piping correction factor calculation for both cooling and heating. If the distance between the highest terminal unit above the heat pump condenser is greater than the distance between the lowest terminal unit below the condenser enter the difference between the highest and lowest terminal units as a positive distance, otherwise enter this difference as a negative distance. Example: if the distance from the heat pump condenser to the highest terminal unit above the condenser is 10 m and the distance from the heat pump condenser to the lowest terminal unit below the condenser is -15 m, then enter a value of -5 m in this field. This head loss impacts the maximum available capacity in cooling mode.

**1.33.1.1.41 Field: Piping Correction Factor for Length in Cooling Mode Curve Name**

This alpha field defines the linear, quadratic, or cubic curve name used to calculate the piping correction factor for length in cooling mode. Piping losses are a function of piping length. If sufficient piping loss information is available where piping losses are also a function of combination ratio (i.e., in addition to length), a biquadratic performance curve may be used.

**1.33.1.1.42 Field: Piping Correction Factor for Height in Cooling Mode Coefficient**

This numeric field defines the coefficient used to calculate the piping correction factor for height in cooling mode.

**1.33.1.1.43 Field: Equivalent Piping Length used for Piping Correction Factor in Heating Mode**

This numeric field defines the equivalent pipe length in meters between the farthest terminal unit and the heat pump condenser. This value includes the liquid refrigerant line length (for both horizontal and vertical distances), fitting losses, pipe bends, and other connections that contribute to piping losses. This field is used to calculate the piping correction factor in heating mode. This value defines the head losses due to the pipe length between the farthest terminal unit and the heat pump condenser and impacts the maximum available capacity in heating mode.

**1.33.1.1.44 Field: Piping Correction Factor for Length in Heating Mode Curve Name**

This alpha field defines the linear, quadratic, or cubic curve name used to calculate the piping correction factor for length in heating mode. Piping losses are a function of piping length. If sufficient piping loss information is available where piping losses are also a function of combination ratio (i.e., in addition to length), a biquadratic performance curve may be used.

**1.33.1.1.45 Field: Piping Correction Factor for Height in Heating Mode Coefficient**

This numeric field defines the coefficient used to calculate the piping correction factor for height in heating mode.

**1.33.1.1.46 Field: Crankcase Heater Power per Compressor**

This numeric field defines the electrical power consumed by the crankcase heater in watts for *each* compressor. This crankcase heater power is consumed when the outdoor temperature is below the maximum outdoor dry-bulb temperature for crankcase heater operation. The minimum value for this field is 0. If this field is left blank, the default value is 33 watts. Crankcase heater electrical consumption is applied only when the compressor is off or is applied during the off cycle when the compressor is cycling below the Minimum Heat Pump Part-Load Ratio. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.1.1.47 Field: Number of Compressors**

This numeric field defines the number of compressors in the heat pump condensing unit and is used exclusively to determine the operating characteristics of the crankcase heater. For example, if the number of compressors is 3, one crankcase heater will operate when the heat pump condensing unit's part-load ratio is less than or equal to 0.67 (when the ratio of compressor size to total compressor capacity input is 0.33) and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. Similarly, two crankcase heaters will operate when the heat pump condensing unit's PLR is less than or equal to 0.33 and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. If the heat pump condensing unit is off, all 3 crankcase heaters will operate if the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. The minimum value for this field is 1. If this field is left blank, the default value is 2. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.1.1.48 Field: Ratio of Compressor Size to Total Compressor Capacity**

This numeric field defines the size of the first stage compressor to the total compressor capacity and is used exclusively for calculating crankcase heater energy. If this field and the previous field are left blank, the default value is 0.5. If this field is left blank and the previous field is not blank, the compressors are assumed to be equally sized. When the number of compressors is greater than 2, the 2<sup>nd</sup> stage compressor and all additional compressors are assumed to be equally sized. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.1.1.49 Field: Maximum Outdoor Dry-bulb Temperature for Crankcase Heater**

This numeric field defines the maximum outdoor temperature, in degrees Celsius, below which the crankcase heater will operate. If this field is left blank, the default value is 0°C. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.1.1.50 Field: Defrost Strategy**

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle. Defrost can be disabled by entering a resistive defrost strategy using a timed defrost control, a 0 defrost time period fraction and a 0 resistive defrost heater capacity in the following inputs fields. This method is used when the Maximum Outdoor Dry-Bulb Temperature for Defrost Operation field value is greater than the expected minimum outdoor dry-bulb temperature simulated in the weather file.

**1.33.1.1.51 Field: Defrost Control**

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value of compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

**1.33.1.1.52 Field: Defrost Energy Input Ratio Modifier Function of Temperature Curve Name**

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the weighted average wet-bulb temperature of the air entering the indoor terminal units (variable x) and the outdoor air dry-bulb temperature (variable y). The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. The curve is normalized to a value of 1.0 at the rating point conditions.

**1.33.1.1.53 Field: Defrost Time Period Fraction**

This numeric field defines the fraction of compressor runtime when the defrost cycle is active. For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter  $3.5/60 = 0.058333$ . The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

**1.33.1.1.54 Field: Resistive Defrost Heater Capacity**

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

**1.33.1.1.55 Field: Maximum Outdoor Dry-bulb Temperature for Defrost Operation**

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. If this input field is left blank, the default value is 5 C. Defrost can be completely eliminated by selecting a temperature lower than the minimum expected outdoor temperature found in the weather file.

### 1.33.1.1.56 Field: Condenser Type

This choice field defines the configuration of the heat pump condenser. Valid choices are **AirCooled**, **EvaporativelyCooled**, and **WaterCooled**.

### 1.33.1.1.57 Field: Condenser Inlet Node Name

This alpha field defines the name of the condenser inlet air or water node. For Condenser type = AirCooled, this node name should also be listed in an **OutdoorAir:Node** or **OutdoorAir:NodeList** object. If this field is blank, the model assumes an air-cooled condenser and the weather file is used to define the outdoor conditions entering the condenser. If this field is not blank, the node conditions are used to define the outdoor air or inlet water conditions entering the condenser. A node name is typically entered here for air-cooled systems when conditions other than those found in the weather file should be used (ref. **OutdoorAir:Node** related to height above ground).

### 1.33.1.1.58 Field: Condenser Outlet Node Name

This alpha field defines the name of the condenser outlet water node. This field is only used for water-cooled systems.

### 1.33.1.1.59 Field: Water Condenser Volume Flow Rate

This numeric field defines the condenser water volume flow rate in cubic meters per second. This field is autosizable and only used for water-cooled systems.

### 1.33.1.1.60 Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{condinlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o}) \quad (1.134)$$

where

$T_{condinlet}$  = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$  = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$  = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled and the simulation is calculating heating performance.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = EvapCooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = EvapCooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier

Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Cooling Capacity and Cooling EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

#### **1.33.1.1.61 Field: Evaporative Condenser Air Flow Rate**

The air volume flow rate, in  $\text{m}^3$  per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to  $0.000144 \text{ m}^3/\text{s}$  per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = AirCooled.

#### **1.33.1.1.62 Field: Evaporative Condenser Pump Rated Power Consumption**

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to  $0.004266 \text{ W}$  per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = AirCooled.

#### **1.33.1.1.63 Field: Supply Water Storage Tank Name**

This alpha field defines the name of the water storage tank when an evaporatively-cooled condenser is used.

#### **1.33.1.1.64 Field: Basin Heater Capacity**

This numeric field contains the capacity of the heat pump's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the heat pump compressor(s) is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **1.33.1.1.65 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature ( $^{\circ}\text{C}$ ) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the heat pump is off. This set point temperature must be greater than or equal to  $2^{\circ}\text{C}$ , and the default value is  $2^{\circ}\text{C}$  if this field is left blank.

#### **1.33.1.1.66 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the heat pump is off.

**1.33.1.1.67 Field: Fuel Type**

This alpha field determines the type of fuel that this variable refrigerant flow system uses. This field has seven choices: Electricity, NaturalGas, Propane, Diesel, Gasoline, FuelOilNo1, FuelOilNo2, OtherFuel1, and OtherFuel2. The default is Electricity. The use of alternate fuel types assumes an engine drives the variable speed compression system and also accounts for condenser air flow (i.e., a fan attached to the engine provides air flow through the outdoor condenser).

**1.33.1.1.68 Field: Minimum Outdoor Temperature in Heat Recovery Mode**

This numeric field defines the minimum outdoor dry-bulb temperature allowed for heat recovery operation. Below this temperature, heat recovery is disabled. This input must be greater than the larger of the minimum outdoor temperature in cooling or heating mode. If this field is left blank, the default value is the higher of the Minimum Outdoor Temperature in Cooling Mode or Minimum Outdoor Temperature in Heating Mode inputs. This system may still operate in cooling or heating only mode when outdoor temperatures are below the minimum outdoor temperature in heat recovery mode. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes.

**1.33.1.1.69 Field: Maximum Outdoor Temperature in Heat Recovery Mode**

This numeric field defines the maximum outdoor dry-bulb temperature allowed for heat recovery operation. Above this temperature, heat recovery is disabled. This input must be less than the smaller of the maximum outdoor temperature in cooling or heating mode. If this field is left blank, the default value is the lower of the Maximum Outdoor Temperature in Cooling Mode or Maximum Outdoor Temperature in Heating Mode inputs.. This system may still operate in cooling or heating only mode when outdoor temperatures are above the maximum outdoor temperature in heat recovery mode. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes.

**1.33.1.1.70 Field: Heat Recovery Cooling Capacity Modifier Curve Name**

This alpha field defines the cooling capacity modifier when heat recovery mode is active. This modifier is used as a multiplier for available cooling capacity, and when in heat recovery mode, this modifier is usually less than 1. This curve is either a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables or a cubic curve based on part-load ratio. This performance curve can be used to describe the cooling capacity modifier as either a constant (e.g., temperature or part-load ratio term coefficients are 0), a cooling modifier that varies with either indoor temperature and/or outdoor temperature, or part-load ratio (e.g., one or more temperature or part-load ratio term coefficients are 0), or varies with both indoor and outdoor temperatures or part-load ratio (e.g., all temperature or part-load ratio term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 0.9. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in cooling performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode.

**1.33.1.1.71 Field: Initial Heat Recovery Cooling Capacity Fraction**

This numeric field defines the fraction of cooling capacity available when the system transitions from cooling only operation to simultaneous cooling and heating. It is common for the cooling capacity to decrease before the system recovers. If this field is left blank, a default value of 0.5 is used (50% reduction in cooling capacity at the start of heat recovery mode). The system will recovery according to the time constant entered in Heat Recovery Cooling Capacity Time Constant input field. If the transition period

will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

#### **1.33.1.1.72 Field: Heat Recovery Cooling Capacity Time Constant**

This numeric field defines the cooling capacity time constant, in hours, used to model the time it takes for the system to change from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.083 is used. If the transition period will not be modeled, the Initial Heat Recovery Cooling Capacity Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

#### **1.33.1.1.73 Field: Heat Recovery Cooling Energy Modifier Curve Name**

This alpha field defines the cooling energy modifier when heat recovery mode is active. This modifier is used as a multiplier for operating cooling energy, and when in heat recovery mode, this modifier is usually greater than 1. This curve is a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables. This performance curve can be used to describe the cooling energy modifier as either a constant (e.g., temperature term coefficients are 0), a cooling energy modifier that varies with indoor and/or outdoor temperatures (e.g., one or more temperature term coefficients are 0), or varies with both indoor and outdoor temperatures (e.g., temperature term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 1.1. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in cooling performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode.

#### **1.33.1.1.74 Field: Initial Heat Recovery Cooling Energy Fraction**

This numeric field defines the fraction of cooling energy consumed when the system transitions from cooling only operation to simultaneous cooling and heating. It is common for the cooling energy to drop before the system recovers. If this field is left blank, a default value of 1 is used (no change in energy at the start of heat recovery mode). If the transition period will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

#### **1.33.1.1.75 Field: Heat Recovery Cooling Energy Time Constant**

This numeric field defines the cooling energy time constant, in hours, used to model the time it takes for the system to transition from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Cooling Energy Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the

variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

#### **1.33.1.1.76 Field: Heat Recovery Heating Capacity Modifier Curve Name**

This alpha field defines the heating capacity modifier when heat recovery mode is active. This modifier is used as a multiplier for available heating capacity, and when in heat recovery mode, this modifier is usually less than 1. This curve is a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables. This performance curve can be used to describe the heating capacity modifier as either a constant (e.g., temperature term coefficients are 0), a heating modifier that varies with indoor and/or outdoor temperatures (e.g., one or more temperature term coefficients are 0), or varies with both indoor and outdoor temperatures (e.g., temperature term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 0.9. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in heating performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode.

#### **1.33.1.1.77 Field: Initial Heat Recovery Heating Capacity Fraction**

This numeric field defines the fraction of heating capacity available when the system changes from heating only operation to simultaneous heating and cooling. It is common for the heating capacity to decrease before the system recovers. If this field is left blank, a default value of 0.5 is used (50% reduction in heating capacity at the start of heat recovery mode). The system will recovery according to the time constant entered in Heat Recovery Heating Capacity Time Constant input field. If the transition period will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

#### **1.33.1.1.78 Field: Heat Recovery Heating Capacity Time Constant**

This numeric field defines the heating capacity time constant, in hours, used to model the time it takes for the system to transition from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.083 is used. If the transition period will not be modeled, the Initial Heat Recovery Heating Capacity Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

#### **1.33.1.1.79 Field: Heat Recovery Heating Energy Modifier Curve Name**

This alpha field defines the heating energy modifier when heat recovery mode is active. This modifier is used as a multiplier for operating heating energy, and when in heat recovery mode, this modifier is usually greater than 1. This curve is a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables. This performance curve can be used to describe the heating energy modifier as either a constant (e.g., temperature term coefficients are 0), a heating energy modifier that varies with indoor and/or outdoor temperatures (e.g., one or more temperature term coefficients are 0), or varies with

both indoor and outdoor temperatures (e.g., temperature term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 1.1. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in heating performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode.

### 1.33.1.1.80 Field: Initial Heat Recovery Heating Energy Fraction

This numeric field defines the fraction of heating energy consumed when the system changes from heating only operation to simultaneous heating and cooling. It is common for the heating energy to decrease before the system recovers. If this field is left blank, a default value of 0.5 is used (50% reduction in heating energy at the start of heat recovery mode). The system will recovery according to the time constant entered in Heat Recovery Heating Energy Time Constant input field. If the transition period will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

### 1.33.1.1.81 Field: Heat Recovery Heating Energy Time Constant

This numeric field defines the heating energy time constant, in hours, used to model the time it takes for the system to change from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Heating Energy Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

- HVAC,Average, VRF Heat Pump Condenser Heat Transfer Rate [W]

Electric Fuel type (default):

- HVAC,Average,VRF Heat Pump Cooling Electricity Rate [W]
- HVAC,Sum,VRF Heat Pump Cooling Electricity Energy [J]
- HVAC,Average,VRF Heat Pump Heating Electricity Rate [W]
- HVAC,Sum,VRF Heat Pump Heating Electricity Energy [J]

Electric defrost always used for Defrost Strategy = Resistive regardless of fuel type

- HVAC,Average,VRF Heat Pump Defrost Electricity Rate [W]
- HVAC,Sum,VRF Heat Pump Defrost Electricity Energy [J]

Alternate Fuel types (e.g., FuelType = NaturalGas):

- HVAC,Average,VRF Heat Pump Cooling <FuelType> Rate [W]
- HVAC,Sum,VRF Heat Pump Cooling <FuelType> Energy [J]
- HVAC,Average,VRF Heat Pump Heating <FuelType> Rate [W]
- HVAC,Sum,VRF Heat Pump Heating <FuelType> Energy [J]
- HVAC,Average,VRF Heat Pump Defrost <FuelType> Rate [W]
- HVAC,Sum,VRF Heat Pump Defrost <FuelType> Energy [J]

Note: refer to the rdd file after a simulation for exact output variable names

#### **1.33.1.2.1 VRF Heat Pump Total Cooling Rate [W]**

This output field is the operating total cooling capacity of the variable refrigerant flow heat pump in Watts. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value should match the sum of the individual zone terminal unit output variables for Zone VRF Air Terminal Total Cooling Rate.

#### **1.33.1.2.2 VRF Heat Pump Total Heating Rate [W]**

This output field is the operating total heating capacity of the variable refrigerant flow heat pump in Watts. The capacity includes any degradation due to defrost mode. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value should match the sum of the individual zone terminal unit output variables for Zone VRF Air Terminal Total Heating Rate.

#### **1.33.1.2.3 VRF Heat Pump Cooling Electricity Rate [W]**

This output field is the cooling mode electricity consumption rate of the variable refrigerant flow heat pump in Watts. The consumption includes electricity used by the compressor and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Cooling NaturalGas Consumption Rate).

**1.33.1.2.4 VRF Heat Pump Cooling Electricity Energy [J]**

This output field is the cooling mode electricity consumption of the variable refrigerant flow heat pump in Joules for the time period being reported. The consumption includes electricity used by the compressor and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects). The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Cooling NaturalGas Consumption). The resource type meter will also be modified to reflect the chosen fuel type (e.g., Resource Type = NaturalGas).

**1.33.1.2.5 VRF Heat Pump Heating Electricity Rate [W]**

This output field is the heating mode electricity consumption rate of the variable refrigerant flow heat pump in Watts. The consumption includes electricity used by the compressor and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Heating NaturalGas Consumption Rate).

**1.33.1.2.6 VRF Heat Pump Heating Electricity Energy [J]**

This output field is the heating mode electricity consumption of the variable refrigerant flow heat pump in Joules for the time period being reported. The consumption includes electricity used by the compressor and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (Ref. Output:Meter objects). The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Heating NaturalGas Consumption). The resource type meter will also be modified to reflect the chosen fuel type (e.g., Resource Type = NaturalGas).

**1.33.1.2.7 VRF Heat Pump Cooling COP[]**

This is the operating cooling coefficient of performance for the heat pump. This value is calculated using the ratio of VRF Heat Pump Total Cooling Rate and Variable Refrigerant Flow Heat Pump Cooling Electric Consumption Rate output variables. Crankcase heater (usually 0 in cooling mode), evaporative condenser water pump, and defrost (usually 0 in cooling mode) consumption rate output variables are included in this calculation. This value is specific to outdoor unit performance in cooling mode, is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.33.1.2.8 VRF Heat Pump Heating COP[]**

This is the operating heating coefficient of performance for the heat pump. This value is calculated using the ratio of VRF Heat Pump Total Heating Rate and Variable Refrigerant Flow Heat Pump Heating Electric Consumption Rate output variables. Crankcase heater, evaporative condenser water pump (usually 0 in heating mode), and defrost consumption rate output variables are included in this calculation. This value is specific to outdoor unit performance in heating mode, is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.33.1.2.9 VRF Heat Pump COP[]**

This is the operating coefficient of performance for the heat pump. This value is calculated using the ratio of the total terminal unit coil capacity (cooling plus heating and accounts for piping losses) and total system electric consumption rate (compressor, crankcase heater, evaporative condenser water pump,

defrost, and terminal unit parasitic electric consumption rate). This output variable does not include pump power for a water-cooled system. This value is specific to overall system performance, is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.33.1.2.10 VRF Heat Pump Defrost Electricity Rate [W]**

This is the electricity consumption rate of the heat pump defrost in Watts when the unit is in defrost mode (timed, reverse-cycle). . The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump NaturalGas Defrost Consumption Rate).

#### **1.33.1.2.11 VRF Heat Pump Defrost Electricity Energy [J]**

This is the electricity consumption of the heat pump in Joules for the time step being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive). This output is also added to a meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (Ref. Output:Meter objects). The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump NaturalGas Defrost Consumption). The resource type meter will also be modified to reflect the chosen fuel type (e.g., Resource Type = NaturalGas).

#### **1.33.1.2.12 VRF Heat Pump Part Load Ratio**

This output field is the part-load ratio of the heat pump condenser. Heat pump part-load ratio is defined as the total coil load divided by the heat pump's maximum available capacity at the current operating conditions. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.33.1.2.13 VRF Heat Pump Runtime Fraction []**

This output field is the runtime fraction of the heat pump condenser's first stage compressor. Heat pump runtime fraction is defined as the fraction of time the first stage compressor is on during a given time period and includes cycling losses. This value is calculated as the ratio of the VRF Heat Pump Cycling Ratio and the output of the Cooling Part-Load Fraction Correlation Curve object as the specific cycling ratio. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.33.1.2.14 VRF Heat Pump Cycling Ratio []**

This output field is the cycling ratio of the heat pump condenser's first stage compressor. Heat pump cycling ratio is defined as the fraction of time the first stage compressor is on during a given time period. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.33.1.2.15 VRF Heat Pump Operating Mode []**

This output field is an integer representation of the operating mode of the variable refrigerant flow heat pump. The operating mode for cooling mode is indicated by a 1 and heating mode is indicated by a 2. A value of 0 is reported if the heat pump is off. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.33.1.2.16 VRF Heat Pump Condenser Inlet Temperature [C]**

This is the inlet air temperature entering the condenser coil in degrees C. This value can represent the outdoor air dry-bulb temperature, wet-bulb temperature, or somewhere in between from the weather

data being used, depending on the value used in the input field “Evaporative Condenser Effectiveness”. The temperature reported here is used in the various modifier curves related to temperature (e.g., Total Cooling Capacity Modifier Curve [function of temperature]). (The use of the word *Condenser* here is taken from cooling operation – the same device can also be an evaporator during heating operation.)

#### **1.33.1.2.17 VRF Heat Pump Condenser Outlet Temperature [C]**

This is the condenser coil outlet water temperature in degrees C. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value is only reported for water-cooled systems. (The use of the word *Condenser* here is taken from cooling operation – the same device can also be an evaporator during heating operation.)

#### **1.33.1.2.18 VRF Heat Pump Condenser Mass Flow Rate [kg/s]**

This is the condenser coil outlet water mass flow rate in kilograms per second. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value is only reported for water-cooled systems. (The use of the word *Condenser* here is taken from cooling operation – the same device can also be an evaporator during heating operation.)

#### **1.33.1.2.19 VRF Heat Pump Condenser Heat Transfer Rate [W]**

This is the condenser coil heat transfer rate in Watts. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value is only reported for water-cooled systems. (The use of the word *Condenser* here is taken from cooling operation – the same device can also be an evaporator during heating operation.)

#### **1.33.1.2.20 VRF Heat Pump Condenser Heat Transfer Energy [J]**

This is the condenser coil heat transfer in Joules. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. This value is only reported for water-cooled systems. (The use of the word *Condenser* here is taken from cooling operation – the same device can also be an evaporator during heating operation.)

#### **1.33.1.2.21 VRF Heat Pump Maximum Capacity Cooling Rate [W]**

This output field is the maximum available terminal unit cooling capacity in Watts allowed for the current time step being reported. If the terminal units request more capacity than is actually available from the variable refrigerant flow heat pump, the individual terminal units will be limited to this value. A maximum limit of 1E+20 is reported when there is sufficient capacity available to meet all requests from the terminal units. This output variable easily identifies times when the total terminal unit cooling load exceeds the heat pump’s available cooling capacity.

#### **1.33.1.2.22 VRF Heat Pump Maximum Capacity Heating Rate [W]**

This output field is the maximum available terminal unit heating capacity in Watts allowed for the current time step being reported. If the terminal units request more capacity than is actually available from the variable refrigerant flow heat pump, the individual terminal units will be limited to this value. A maximum limit of 1E+20 is reported when there is sufficient capacity available to meet all requests from the terminal units. This output variable easily identifies times when the total terminal unit heating load exceeds the heat pump’s available heating capacity.

#### **1.33.1.2.23 VRF Heat Pump Terminal Unit Cooling Load Rate [W]**

This output field is the sum of the terminal unit cooling coil loads in Watts for the current time step being reported. This value is derived directly from the cooling coils and represents the total cooling load

on the VRF system after piping losses have been accounted for. The total cooling load will be less than the variable refrigerant flow total cooling capacity reported when piping losses are modeled (i.e., when piping losses are  $< 1$ ).

#### **1.33.1.2.24 VRF Heat Pump Terminal Unit Heating Load Rate [W]**

This output field is the sum of the terminal unit heating coil loads in Watts for the current time step being reported. This value is derived directly from the heating coils and represents the total heating load on the VRF system after piping losses have been accounted for. The total heating load will be less than the variable refrigerant flow total heating capacity reported when piping losses are modeled (i.e., when piping losses are  $< 1$ ).

#### **1.33.1.2.25 VRF Heat Pump Crankcase Heater Electricity Rate [W]**

This output field is the average electricity consumption rate of the heat pump's crankcase heaters in Watts for the time step being reported.

#### **1.33.1.2.26 VRF Heat Pump Crankcase Heater Electricity Energy [J]**

This output field is the electricity consumption rate of the heat pump's crankcase heaters in Joules for the time step being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

#### **1.33.1.2.27 VRF Heat Pump Evaporative Condenser Water Use Volume [m3]**

This output is the amount of water used to evaporatively cool the condenser coil inlet air, in cubic meters. This output is also added to a meter with Resource Type = Water, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

#### **1.33.1.2.28 VRF Heat Pump Evaporative Condenser Pump Electricity Rate [W]**

This is the average electricity consumption rate of the evaporative condenser water pump in Watts for the time step being reported.

#### **1.33.1.2.29 VRF Heat Pump Evaporative Condenser Pump Electricity Energy [J]**

This is the electricity consumption rate of the evaporative condenser water pump in Joules for the time step being reported. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Output:Meter objects).

#### **1.33.1.2.30 VRF Heat Pump Basin Heater Electricity Rate [W]**

This output is the electric consumption rate of the heat pump's basin heater (for evaporatively-cooled condenser type) in Watts. This basin heater only operates when the variable refrigerant flow heat pump's compressor(s) is off and therefore is reported as 0 anytime the compressor operates. If the compressor is cycling (see VRF Heat Pump Cycling Ratio output variable above), the basin heater electric power is proportional to one minus the cycling ratio of the compressor (i.e., the basin heater is on when the compressor is off).

#### **1.33.1.2.31 VRF Heat Pump Basin Heater Electricity Energy [J]**

This output is the electric consumption of the heat pump's basin heater (for evaporatively-cooled condenser type) in Joules. This output is also added to a meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Output:Meter objects).

**1.33.1.2.32 VRF Heat Pump Heat Recovery Status Change Multiplier []**

This output applies only when heat recovery is used and represents the multiplier used to derate the capacity of the system when transitioning from cooling or heating mode to heat recovery mode. This value is 1 when derating does not apply (i.e., the system has not recently changed modes to provide heat recovery). Derating during a transition period is applied according to the inputs for Heat Recovery Fraction and Heat Recovery Time Constant. To turn transition derating off, set Heat Recovery Fraction to 1. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

**1.33.1.2.33 VRF Heat Pump Simultaneous Cooling and Heating Efficiency[Btu/h/W]**

The ratio of the total capacity of the system (heating and cooling capacity) to the effective power when operating in the heat recovery mode. This value is specific to overall system performance, is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

**1.33.2 AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl****1.33.2.1 Inputs****1.33.2.1.1 VRF Heat Pump Heat Recovery Rate [W]**

The rate of heat recovered by the system in watts. This value represents the amount of heat recovered at the terminal units while in heat recovery operating mode. If the VRF system is in cooling mode and recovers heat then that amount of heat was recovered from terminal units in zone(s) requiring heating. If the VRF system is in heating mode and recovers heat then that amount of heat was recovered from terminal units in zone(s) requiring cooling. The results are averaged for the time step being reported. Reports at the detailed time frequency should match the corresponding coil total cooling/heating rate since piping losses are not included.

**1.33.2.1.2 VRF Heat Pump Heat Recovery Energy [J]**

The rate of heat recovered by the system in joules. This value represents the amount of heat energy recovered at the terminal units while in heat recovery operating mode. If the VRF system is in cooling mode and recovers heat then that amount of heat was recovered from terminal units in zone(s) requiring heating. If the VRF system is in heating mode and recovers heat then that amount of heat was recovered from terminal units in zone(s) requiring cooling. The results are summed for the time step being reported. Reports at the detailed time frequency should match the corresponding coil total cooling/heating energy since piping losses are not included.

**1.33.2.1.3 Field: Heat Pump Name**

This alpha field defines a unique user-assigned name for an instance of a variable refrigerant flow heat pump. Any reference to this heat pump will use this name. Since this object is not listed in an AirloopHVAC object, the most likely use of this name would be for reporting purposes.

**1.33.2.1.4 Field: Availability Schedule Name**

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value other than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (and all of its terminal units) as required. If this field is blank, the unit is enabled the entire simulation.

#### 1.33.2.1.5 Field: Zone Terminal Unit List Name

This alpha field defines the name of the zone terminal unit list. The name specified here should match the name of a valid `ZoneTerminalUnitList` object. In addition, each name specified in this list should match the name of a valid `ZoneHVAC:TerminalUnit:VariableRefrigerantFlow` object. All terminal units connected to this heat pump must be listed in this `ZoneTerminalUnitList` object.

#### 1.33.2.1.6 Field: Refrigerant Type

This alpha field defines the name of the refrigerant used in the VRF system. The name specified here should match the name of a valid `FluidProperties:Name` object.

#### 1.33.2.1.7 Field: Rated Evaporative Capacity

This numeric field defines the total evaporative capacity in watts at rated conditions. This is the capacity corresponding to the max compressor speed at rated conditions. The actual evaporative capacity is obtained by multiplying the rated capacity with the modification factor calculated by Evaporative Capacity Multiplier Function of Temperature Curve. The value must be greater than 0. This field is autosizable.

#### 1.33.2.1.8 Field: Rated Compressor Power Per Unit of Rated Evaporative Capacity

This numeric field defines the rated compressor power per Watt of rated evaporative capacity. Rated compressor power corresponds to the max compressor speed at rated conditions. The actual compressor power is obtained by multiplying the rated power with the modification factor calculated by Compressor Power Multiplier Function of Temperature Curve. The value must be greater than 0. If this field is left blank, a default value of 0.35 W/W is assumed.

#### 1.33.2.1.9 Field: Minimum Outdoor Air Temperature in Cooling Mode

This numeric field defines the minimum outdoor temperature allowed for cooling operations. Below this temperature, cooling is disabled. If this field is left blank, the default value is -6°C. If this field is left blank, the default value is -20°C.

#### 1.33.2.1.10 Field: Maximum Outdoor Air Temperature in Cooling Mode

This numeric field defines the maximum outdoor temperature allowed for cooling operations. Above this temperature, heating is disabled. If this field is left blank, the default value is 16°C.

#### 1.33.2.1.11 Field: Minimum Outdoor Air Temperature in Heating Mode

This numeric field defines the minimum outdoor temperature allowed for heating operation. Below this temperature, heating is disabled. If this field is left blank, the default value is -20°C.

#### 1.33.2.1.12 Field: Maximum Outdoor Air Temperature in Heating Mode

This numeric field defines the maximum outdoor temperature allowed for heating operation. Above this temperature, heating is disabled. If this field is left blank, the default value is 16°C.

#### 1.33.2.1.13 Field: Outdoor Unit Reference Superheating

This numeric field defines the reference superheating degrees of the outdoor unit. If this field is blank, the default value of 3.0°C is used.

**1.33.2.1.14 Field: Outdoor Unit Reference Subcooling**

This numeric field defines the reference subcooling degrees of the outdoor unit. If this field is blank, the default value of 3.0°C is used.

**1.33.2.1.15 Field: Refrigerant Temperature Control Algorithm for Indoor Unit**

This alpha field specifies the algorithm for the refrigerant temperature control. Two choices are available: ConstantTemp or VariableTemp. The indoor unit evaporating temperature at cooling mode or condensing temperature at heating are fixed in the ConstantTemp algorithm, while in VariableTemp algorithm they can be varied.

**1.33.2.1.16 Field: Reference Evaporating Temperature for Indoor Unit**

This numeric field defines the reference evaporating temperature for the indoor unit when VRF runs at cooling mode. This field is required if Refrigerant Temperature Control Algorithm is ConstantTemp. If this field is blank, the default value of 6.0°C is used.

**1.33.2.1.17 Field: Reference Condensing Temperature for Indoor Unit**

This numeric field defines the reference condensing temperature for the indoor unit when VRF runs at heating mode. This field is required if Refrigerant Temperature Control Algorithm is ConstantTemp. If this field is blank, the default value of 44.0°C is used.

**1.33.2.1.18 Field: Variable Evaporating Temperature Minimum for Indoor Unit**

This numeric field defines the minimum evaporating temperature for the indoor unit when VRF runs at cooling mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 4.0°C is used.

**1.33.2.1.19 Field: Variable Evaporating Temperature Maximum for Indoor Unit**

This numeric field defines the maximum evaporating temperature for the indoor unit when VRF runs at cooling mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 13.0°C is used.

**1.33.2.1.20 Field: Variable Condensing Temperature Minimum for Indoor Unit**

This numeric field defines the minimum condensing temperature for the indoor unit when VRF runs at heating mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 42.0°C is used.

**1.33.2.1.21 Field: Variable Condensing Temperature Maximum for Indoor Unit**

This numeric field defines the maximum condensing temperature for the indoor unit when VRF runs at heating mode. This field is required if Refrigerant Temperature Control Algorithm is VariableTemp. If this field is blank, the default value of 46.0°C is used.

**1.33.2.1.22 Field: Outdoor Unit Fan Power Per Unit of Rated Evaporative Capacity**

This numeric field defines the outdoor unit fan power per watt of rated evaporative capacity. If this field is blank, the default value of 4.25E-3 W/W is used.

**1.33.2.1.23 Field: Outdoor Unit Fan Flow Rate Per Unit of Rated Evaporative Capacity**

This numeric field defines the outdoor unit fan volumetric flow rate per watt of rated evaporative capacity. If this field is blank, the default value of  $7.50\text{E-}5 \text{ m}^3/\text{s-W}$  is used.

**1.33.2.1.24 Field: Outdoor Unit Evaporating Temperature Function of Superheating Curve Name**

This alpha field defines the name of a quadratic performance curve that parameterizes the variation of outdoor unit evaporating temperature as a function of superheating degrees. The output of this curve is the temperature difference between the coil surface air temperature and the evaporating temperature.

**1.33.2.1.25 Field: Outdoor Unit Condensing Temperature Function of Subcooling Curve Name**

This alpha field defines the name of a quadratic performance curve that parameterizes the variation of outdoor unit condensing temperature as a function of subcooling degrees. The output of this curve is the temperature difference between the condensing temperature and the coil surface air temperature.

**1.33.2.1.26 Field: Diameter of Main Pipe Connecting Outdoor Unit to the First Branch Joint**

This numeric field defines the diameter of main pipe connecting the outdoor unit to the first branch joint. This value is used to calculate the piping loss of the refrigerant when going through the main pipe, including the heat loss and pressure drop. If this field is blank, the default value of 0.0254m is used.

**1.33.2.1.27 Field: Length of Main Pipe Connecting Outdoor Unit to the First Branch Joint**

This numeric field defines the length of main pipe connecting the outdoor unit to the first branch joint. This value is used to calculate the heat loss of the refrigerant when going through the main pipe. The value should be greater than 0. If this field is blank, the default value of 30m is used.

**1.33.2.1.28 Field: Equivalent Length of Main Pipe Connecting Outdoor Unit to the First Branch Joint**

This numeric field defines the equivalent length of main pipe connecting the outdoor unit to the first branch joint. This value is used to calculate the pressure drop of the refrigerant when going through the main pipe. The value should be greater than the real pipe length specified in the above field. If this field is blank, the default value of 36m is used.

**1.33.2.1.29 Field: Height Difference Between Outdoor Unit and Indoor Units**

This numeric field defines the height difference between the outdoor unit node and indoor unit node of the main pipe. This value is used to calculate the piping loss of the refrigerant when going through the main pipe. The value can be positive, zero, or negative. Positive means outdoor unit is higher than indoor unit, while negative means outdoor unit is lower than indoor unit.

**1.33.2.1.30 Field: Main Pipe Insulation Thickness**

This numeric field defines the insulation thickness of the main pipe. This value is used to calculate the heat loss of the refrigerant when going through the main pipe. The value should be greater than 0. If this field is blank, the default value of 0.02m is used.

**1.33.2.1.31 Field: Main Pipe Insulation Thermal Conductivity**

This numeric field defines the thermal conductivity of the main pipe insulation material. This value is used to calculate the heat loss of the refrigerant when going through the main pipe. The value should be greater than 0. If this field is blank, the default value of 0.032 W/m-K is used.

**1.33.2.1.32 Field: Crankcase Heater Power per Compressor**

This numeric field defines the electrical power consumed by the crankcase heater in watts for each compressor. This crankcase heater power is consumed to warm the refrigerant and oil when the compressor is off when the outdoor temperature is below the maximum outdoor dry-bulb temperature for crankcase heater operation. The minimum value for this field is 0. If this field is left blank, the default value is 33 watts. Crankcase heater electrical consumption is applied only when the compressor is off or is applied during the off cycle when the compressor is cycling below the Minimum Heat Pump Part-Load Ratio. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.2.1.33 Field: Number of Compressors**

This numeric field defines the number of compressors in the heat pump condensing unit and is used exclusively to determine the operating characteristics of the crankcase heater. For example, if the number of compressors is 3, one crankcase heater will operate when the heat pump condensing unit's part-load ratio is less than or equal to 0.67 (when the ratio of compressor size to total compressor capacity input is 0.33) and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. Similarly, two crankcase heaters will operate when the heat pump condensing unit's PLR is less than or equal to 0.33 and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. If the heat pump condensing unit is off, all 3 crankcase heaters will operate if the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. The minimum value for this field is 1. If this field is left blank, the default value is 2. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.2.1.34 Field: Ratio of Compressor Size to Total Compressor Capacity**

This numeric field defines the size of the first stage compressor to the total compressor capacity and is used exclusively for calculating crankcase heater energy. If this field and the previous field are left blank, the default value is 0.5. If this field is left blank and the previous field is not blank, the compressors are assumed to be equally sized. When the number of compressors is greater than 2, the 2<sup>nd</sup> stage compressor and all additional compressors are assumed to be equally sized. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.2.1.35 Field: Maximum Outdoor Dry-bulb Temperature for Crankcase Heater**

This numeric field defines the maximum outdoor temperature, in degrees Celsius, below which the crankcase heater will operate. If this field is left blank, the default value is 5°C. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

**1.33.2.1.36 Field: Defrost Strategy**

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle. Defrost can be disabled by entering a resistive defrost strategy using a timed defrost control, a 0 defrost time period fraction and a 0 resistive defrost heater capacity in the following inputs fields. This method is used when the Maximum Outdoor Dry-Bulb

Temperature for Defrost Operation field value is greater than the expected minimum outdoor dry-bulb temperature simulated in the weather file.

#### **1.33.2.1.37 Field: Defrost Control**
